**Background:** Renal cell carcinoma (RCC) may increase the risk for venous thromboembolism. However, only a few reports have described the clinical features and risk factors for thromboembolism.

**Aims:** This study aimed to elucidate the clinical features of thromboembolic events and to identify prognosis in patients who experienced thromboembolism events.

**Methods:** We retrospectively reviewed medical records of patients who underwent nephrectomy at our institution between February 1998 and August 2015. We evaluated the data including pathologic stage, gender, age, smoking history, uncontrolled disease, preoperative laboratory findings and survival outcomes.

**Results:** A total of 3099 patients were included in the study. Among them, 208 thromboembolic events (6.7%) were identified in pathologic and image studies during median follow-up duration of 40 months. Patients who have increased preoperative platelet levels (>400x10^3/µL), neutrophil lymphocyte ratio (NLR) >1(86) and c-reactive protein (CRP) >1.2mg/dL experienced significantly more thromboembolic events than those with lower value according to multivariable analysis (hazard ratio [HR], 2.22 [95% CI, 1.01–4.85], P=0.047 for platelet levels; HR, 3.39 [95% CI, 1.67–6.90], P=0.001 for NLR; HR, 3.38 [95% CI, 1.67–6.80], P=0.001 for CRP). Moreover, patients who experienced thromboembolism showed poor overall survival (OS 195 vs 67 months HR 1.95, P=0.007).

**Summary/Conclusions:** Preoperative inflammation markers including NLR, CRP and platelet count can be the risk factors for venous thromboembolism in RCC patients who experienced nephrectomy. Thromboembolism also has a significant role on the prognosis of RCC patients.

**Background:** Essential thrombocythaemia (ET) and polycythaemia vera (PV) are MPN characterized by a high rate of thrombotic complications. We previously demonstrated increased plasma levels of procoagulant MP in ET (Marcetti et al. A.J.H. 2013).

**Aims:** Aim of this study was to extend the analysis of MP to PV patients and to characterize the cellular origin of plasma MP in both ET and PV patients. The influence of somatic mutations [i.e. JAK2V617F, calreticulin (CalR), thrombopoietin (MPL)] and concomitant cytoreductive or antiplatelet therapies was also evaluated.

**Methods:** Thirty-seven ET (19 JAK2V617F, 9 CalR and 2 MPL mutation carriers), 35 PV patients (all JAK2V617F carriers) and 36 healthy control subjects were included into the study. Flow cytometry was performed to characterize MP phenotype in platelet free plasma samples. To define MP cellular origin, anti-CD31 (endothelial cell marker), anti-CD41 (platelet marker), anti-CD11b (leucocyte marker), and anti-CD235 (erythrocyte marker) monoclonal antibodies were used. Annexin V (AnnV) staining was used to evaluate the expression of procoagulant phosphatidylserine on their surface. In healthy con-

Values expressed as Mean±standard deviation, in brackets maximum and minimum values. B12: serum vitamin B12; SF: Serum folate; RCF: Red cell folate; HCY: Homocysteine.

**Summary/Conclusions:** In the GAIT2 study, genetic and environmental factors were related to B12, SF, RCF and HCY. Moreover, a relationship was observed between B12 and VTE. In the GWAS analysis some signals were previously reported (FUT2 and B12 or MTHFR with SF and HCY). New signals were found that need to be clarified, especially their possible relationship with susceptibility to thrombosis.

trols, 71% of MP was positive for platelet (P-MP), 24% for erythrocyte (E-MP), 4% for endothelial cell (EC-MP) and 1% for leukocyte (L-MP) specific markers. In ET and PV patients, the percentage of P-MP was significantly higher (80%; p<0.05), while E-MP level was significantly lower (15%; p<0.05) than controls. L-MP and EC-MP values were comparable between patients and controls. The absolute counts of P-MP and L-MP were higher in both ET and PV versus controls. Overall, no significant correlations were found between the levels of MP derived from platelet, leukocytes or erythrocytes and the corresponding cell counts. The analysis according to patient mutations, revealed significantly higher levels (p<0.05) of both P-MP and E-MP concentration in patients carrying JAK2V617F mutation as compared to JAK2V617F negative patients. In addition, ET patients positive for GaM mutation displayed lower levels (p<0.05) of P-MP compared to JAK2V617F carriers. No influence of concomitant therapies on MP levels or composition was observed.

Summary/Conclusions: Our data confirm the presence of high levels of circulating MP in MPN, which support the role in the known hypercoagulable state of these patients. The MP cellular origin has a different distribution profile according to patient’s presenting different mutations. Importantly, the lack of correlation found between the total and subtype-specific MP counts with the corresponding cell of origin counts suggests an active stimulation of MP formation.

P767 ARE WE TESTING APPROPRIATELY FOR THE LUPUS ANTICOAGULANT? J. Shardel1,*, C. Humphrey1, I. Earnshaw1, J. Thaci1
1Haematology, Central Manchester University Hospitals, Manchester, United Kingdom

Background: The diagnosis of antiphospholipid syndrome (APS) requires the presence of thrombosis or defined pregnancy morbidity in addition to the presence of antiphospholipid antibodies on at least 2 occasions. Patients should be tested for antiphospholipid antibodies if they fulfill the required clinical criteria. Lupus anticoagulant may also be tested for when investigating a prolonged activated partial thromboplastin time which does not correct on mixing studies.

Aims: The aim of our study was to examine retrospectively the frequency of lupus anticoagulant (LA) testing in our institution, which we suspected to be high, and the incidence of positive results leading to a diagnosis of APS.

Methods: A total of 914 requests for LA were received over a 5 month period between 1st of May and 30th of September 2014. We examined which departments were requesting the tests and the clinical indications for testing.

Results: Over 90% (829) of LA tests were negative. Nine percent (85) of tests demonstrated a positive LA. 33 patients had experienced arterial (11) or venous (22) thrombosis. There were 3 patients who fulfilled the clinical criteria for pregnancy morbidity in APS. A total of 6 patients experienced miscarriage before 10 weeks gestation; however none of these patients had the defined 3 miscarriages. There was one preterm delivery at 25 weeks due to pre-eclampsia. A further 3 patients had a still birth, one of which had an identifiable cause. In total, of the 85 positive results, 12 patients had a confirmed diagnosis of APS; a further 26 patients had the clinical manifestations fitting the clinical criteria for APS. Forty eight patients had a positive LA but did not fit the clinical criteria for a diagnosis of APS. The clinical specialties requesting the majority of tests were obstetrics and gynaecology (231), rheumatology (179) and clinical haematology (118). Of these, clinical haematology had the highest yield of positive results (16%) compared to 3% in obstetrics and gynaecology.

Summary/Conclusions: Our results highlight a high frequency of LA testing in our institution with a low yield of positive results (9%), resulting in a total of 1% of patients being diagnosed with APS. Our results demonstrate that the majority of tests for LA are not of clinical significance and often requested in patients not fitting the clinical criteria for APS. Further education for all practitioners would help to ensure only appropriate patients are tested. Indeed if a patient fits the clinical criteria for APS they should be tested for all antiphospholipid antibodies namely anti-cardiolipin and anti-B2-glycoprotein I as well as the lupus anticoagulant.

P768 RESULTS OF USING BRIDGING THERAPY WITH SODIUM BEMIPARIN AT THERAPEUTIC-DOSE M.A. García Ruiz1,*, E. Morente Constantin1, P. Romero Garcia2, M. Gómez Morales1, M. Jurado Chacón1
1Servicio de Hematología y Hemoterapia, Complejo Hospitalario Universitario de Granada, Granada, 2Unidad de Cuidados Intensivos,Complejo Asistencial de Soria, Soria, Spain

Background: Bridging therapy consists of the administration of a fast-acting anticoagulant such as the low-molecular-weight heparin (LMWH) during the period of cessation of oral anticoagulant therapy. The decision to continue with anticoagulant therapy or to discontinue the treatment with the establishment of the Bridging therapy have been carried out carefully and on an individual basis. While taking this decision, we have taken into account three factors: the urgency of surgery or invasive process, the risk of bleeding and thrombotic risk for the patient. In recent decades, there have been multiple studies supporting the LMWH treatment, at least as safe and effective and more cost-effective than unfractionated heparin (UFH) in the 4 to 6 days of venous thromboembolism (VTE), including deep vein thrombosis (DVT) and pulmonary embolism (PE). Therefore, the LMWH is considered as the drugs of choice in the prevention of venous thromboembolism. There are several types of commercialized LMWH, with different pharmacological properties, such as molecular weight, anti-Xa/IIa ratio and average life. The sodium bemiparin is the LMWH with greater anti-Xa/IIa ratio, which implies a lower risk of bleeding. In addition, it has shown a low incidence of VTE and bleeding in actual clinical practice.

Aims: There are few published data from bridging therapy at therapeutic doses in patients treated with oral anticoagulants (AVK) and perioperative management. It is intended to assess the efficacy (recurrence of thrombosis) and safe use of sodium bemiparin at anticoagulant doses on the bridging therapy and possible thrombotic and/or hemorrhagic complications (major and minor bleeding) resulting from this use.

Methods: We have analyzed 975 bridging therapies at full dose in our clinic in the last year. They were made to a total of 650 patients (315 men and 335 women) with CHADS/VASC >2, aged between 15 and 92, with an average age of 69 years old. The reasons of anticoagulation in our patients were atrial fibrillation, mechanical prostheses, DVT, pulmonary embolism and recurrent thrombosis in patients with thrombophilia. In 70% of the cases, there were comorbidities, such as heart failure, chronic obstructive pulmonary disease, anemia, kidney failure, liver disease and long-term aftereffects of stroke. The bridging therapy has consisted of suspending the oral anticoagulant (warfarin) before the procedure, and replacing it by sodium bemiparin at full doses <50 kg: 5.000 IU/24h, 50 to 70 kg: 7.500 IU/24 h, 70-100 kg: 10.000 IU/24 h and >100 kg: 12.500 IU/24 h, and administration of a prophylactic dose of 3.500 IU, 12 hours before the procedure, and another dose 6-12 hours after the procedure, depending on the risk of bleeding of the intervention and the thrombotic risk of the patient’s disease. The bridging therapy has been performed in 225 cases of major surgery (orthopedic surgery, ophthalmological procedures, valvar replacements etc), 340 cases of minor surgery (removal of nevus, complex dental extractions, dental implants), 295 cases of invasive procedures (colonoscopies, endoscopies...), 50 cases of bleeding caused by AVK (epistaxis, petechiae and bruises, hemoptysis, menorrhagia and gastro-intestinal bleeding), 30 cases of hospitalization with INR decompensation with associated co-morbidities. In our study, sodium bemiparin has shown to be safe and effective with minimal bleeding complications. Treatment should not be administered on an individual basis according to each patient and factors related to surgery. Further studies will confirm our results.
Targeted therapies in relapsed in chronic lymphocytic leukemia

S769

IBRUTINIB IN PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA: UPDATED EFFICACY AND SAFETY OF THE RESONATE STUDY WITH UP TO FOUR YEARS OF FOLLOW-UP

Background: Ibrutinib is a first-in-class, once-daily oral inhibitor of Bruton’s tyrosine kinase. Ibrutinib as a single agent is indicated by the EMEA and US FDA for the treatment of adult patients with CLL and allows for treatment without chemotherapy. The phase 3 RESONATE trial in patients with relapsed CLL showed superior efficacy of ibrutinib compared with ofatumumab (Byrd NEJM 2014).

Aims: We report updated safety and efficacy results of the RESONATE trial with up to 4 years of follow-up.

Methods: Eligibility criteria included ≥1 prior therapy, ineligibility for treatment with a purine analog, and ECOG performance status 0-1. Informed consent was obtained from all patients prior to study initiation. Patients received oral ibrutinib (420 mg once daily) until disease progression or unacceptable toxicity or intravenous ofatumumab (300 mg week 1; 2000 mg weekly for 7 weeks and then every 4 weeks for 16 weeks) for up to 24 weeks. At the interim analysis (median follow-up of 9 months), the data monitoring committee declared superiority of ibrutinib vs ofatumumab for progression-free survival (PFS) and overall survival (OS), and access to ibrutinib was recommended for all patients in ofatumumab arm who had disease progression. Long-term follow-up of efficacy endpoints are ongoing. Analysis presented at this ASH is updated to 31.1 months with a median follow-up of 4 years. Summary/Conclusions: 1) Observed across baseline subgroups. In the ibrutinib arm, PFS for the del11q group was longer for ibrutinib vs ofatumumab (median NR vs median NR; P=0.0089). 2) Duration of response (DOR) observed in the ibrutinib arm for del17p and del11q patients was longer for ibrutinib vs ofatumumab (median NR vs 8 months; [HR 0.33; P<0.0001]). 3) The 3-year PFS was 59% for ibrutinib vs 3% for ofatumumab. A significant PFS benefit was observed across baseline subgroups.

Results: Of the 498 patients randomized to receive ibrutinib (n=195) or ofatumumab (n=196). The median age was 67 years, with 40% age ≥70 years, and Rai stage III/IV in 57% of patients. At a median follow-up of 44 months (maximum 53 months) for the ibrutinib arm, 61% said they were very satisfied with ibrutinib and 93% said they would recommend it to other patients. The most common AEs with ibrutinib from the most common to least common: anemia (57%), neutropenia (29%), thrombocytopenia (27%), hypertension (11%), diarrhea (9%), nausea (6%). Key secondary endpoints are MRD eradication in the bone marrow after 6 months and 24 months of combined IBR and VEN as well as the safety of the combination. Importantly, no new safety signals were reported and the AE profile of ibrutinib was consistent with previous reports. The combination of ibrutinib with VEN is well tolerated in patients with relapsed/refractory CLL. Here we report for the first time the safety of the combination as well as early signs of potential synergy.

Methods: After 8 weeks of Ibr monotherapy (420mg/day), VEN was added at a dose of 10mg/day with weekly escalations to 20mg, 50mg, 100mg, 200mg to a final dose of 400mg/day. After the initial 3 patients when there was no sign of tumour lysis syndrome (TLS) the starting dose of VEN was amended to 20mg/day. The primary end-point of the trial is MRD eradication (defined as less than 1 CLL cell in 10,000) in the bone marrow after 12 months of Ibr+VEN. Key secondary end-points are MRD eradication from the bone marrow after 6 and 24 months of combined IBR and VEN as well as the safety of the combination.

Results: A total of 35 patients have been recruited between May 2016 and January 2017. To date 21 patients have completed the dose escalation period of IBR with VEN and are currently in combination with Ibr. To date there has been only a single case of laboratory TLS in a patient whose phosphate (1.21 to 1.48mmol/l) and creatinine (75 to 146 mmol/l) both increased when VEN was increased from 100mg to 200mg. Dosing of VEN was interrupted for 7 days (due to the logistics of clinic closure periods over the Christmas break) and IBR for 24 hours. The biochemical changes were resolved with appropriate management and all patients remained on therapy.

Key secondary endpoints are rapid reduction in the peripheral blood level of CLL with concomitant rapid nodal response with redistribution of CLL into the peripheral blood whereas the combination of IBR and VEN is well tolerated in patients with relapsed/refractory CLL. Here we report for the first time the safety of the combination as well as early signs of potential synergy.

Results: More than half of all patients with relapsed/refractory CLL to date have ibrutinib and venetoclax as part of their combination therapy. The combination of ibrutinib and venetoclax is well tolerated and shows evidence of early clinical benefit. The combination of ibrutinib with venetoclax is promising and suggests a potent synergy between the drugs. The initial bone marrow responses are expected after 6 months of combination therapy.
Background: Venetoclax monotherapy in patients (pts) with relapsed/refractory CLL harboring deletion 17p (del(17p)) resulted in an ORR of 79% with a CR rate of 7% as determined by an independent review committee at the initial analysis of the pivotal M13-982 trial (n=107). Subsequently, 51 additional pts were enrolled in a safety expansion cohort.

Aim: The objectives of the full trial, including minimal residual disease (MRD) status by both flow cytometry and next generation sequencing (NGS).

Methods: Pts received venetoclax 400 mg daily after initial standard ramp-up until PD or discontinuation due to other reasons. CT scan was mandatory at week 36, after which disease assessment was by clinical evaluation. MRD assessment was performed beginning with the first clinical assessment of CR or PR with nodes <2 cm and then every 12 weeks until MRD negativity (defined at 10−4 sensitivity). MRD was assessed by NGS and multicolor flow cytometry and the best response was reported. Data cutoff date was 10 June 2016.

Results: Pts (N=158) had a median age of 67 (range, 29–85) years; a median of 4 (range, 0–10) 32% were fludarabine refractory; 11% had previously received a B-cell receptor signaling inhibitor (BCR); 48% had nodes ≥5 cm; and 78% had unmutated IGHV. The median duration of venetoclax therapy was 16.7 (range 0–34.4) months. Primary reasons for discontinuation (50.6% of pts) were PD (31.0%), adverse events (AEs) (12.6%), withdrawal of consent (2.5%), and other (1.9%). For all 158 pts, the investigator-assessed ORR was 77% and CR rate was 18%. The 24-month estimates for progression-free survival (PFS) and overall survival (OS) were 52% and 72%, respectively. The safety expansion cohort included 5 pts with previously untreated del(17p) CLL. These pts had an ORR of 80%, CR rate of 40%, and all 5 were alive and progression-free 1 year after their first clinical assessment and 1 pt was positive by flow cytometry (0.008% vs 0.002%). Pts who achieved blood MRD-negative CR by flow cytometry (n=19) had a 24-month PFS estimate of 100%, compared with 78.5% pts who had blood MRD-negative status. These results were obtained when assessed retrospectively.

Conclusion: Venetoclax monotherapy resulted in a high response rate that was durable in this high-risk population, including among pts who previously received a B-cell inhibitor. MRD negativity by either flow cytometry or NGS correlated with outstanding outcomes.

S772 CHEMO-FREE TRIPLET COMBINATION OF TGR-1202, UBLITUXIMAB, AND IRBUTINIB IS WELL TOLERATED AND HIGHLY ACTIVE IN PATIENTS WITH ADVANCED CLL AND NHL

1MD Anderson Cancer Center, Houston, 2University of Nebraska Medical Center, Omaha, 3Clearview Cancer Institute, Huntsville, 4City of Hope National Medical Center, Duarte, 5Emory University/Wisconsin Cancer Institute, Atlanta, 6University of California Irvine Cancer Center, Orange, 7TG Therapeutics, Inc., New York, United States

Background: Novel targeted agents are emerging for B-cell malignancies, but few studies have safely combined these agents. Ublituximab (UTX) is a novel anti-CD20 mAb+PI3Kδ+BTK inhibitor (irbutinib) in pts with B-cell malignancies.

Aims: The primary aim of the study was to understand the safety and activity of cerdulatinib in B-cell malignancies.

Methods: This is the first known triplet combination of an anti-CD20 mAb+PI3Kδ+BTK inhibitor. The combination of UTX, TGR-1202, and irbutinib has been well tolerated with activity observed across heavily pre-treated and previously untreated B-cell malignancies. Expansion cohorts at the highest dose (800mg TGR-1202+full dose irbutinib) are underway. Future trials for the triplet are warranted.

53% of evaluable CLL pts had high-risk cytogenetics and 4/6 DLBCL pts were non-GCB. One CLL pt (17p/11q del) ref to PI3Kδ and irbutinib achieved a CR while on study (10-12 mos). Med DOR not reached (range 3-24 mos).

52/158 pts had high-risk cytogenetics and 4/6 DLBCL pts were non-GCB. One CLL pt (17p/11q del) ref to PI3Kδ and irbutinib achieved a CR while on study (10-12 mos). Med DOR not reached (range 3-24 mos).

This is the first known triplet combination of an anti-CD20 mAb+PI3Kδ+BTK inhibitor. The combination of UTX, TGR-1202, and irbutinib has been well tolerated with activity observed across heavily pre-treated and previously untreated B-cell malignancies. Expansion cohorts at the highest dose (800mg TGR-1202+full dose irbutinib) are underway. Future trials for the triplet are warranted.

SUMMARY/CONCLUSIONS: This is the first known triplet combination of an anti-CD20 mAb+PI3Kδ+BTK inhibitor. The combination of UTX, TGR-1202, and irbutinib has been well tolerated with activity observed across heavily pre-treated and previously untreated B-cell malignancies. Expansion cohorts at the highest dose (800mg TGR-1202+full dose irbutinib) are underway. Future trials for the triplet are warranted.

S773 THE DUAL SYK/JAK INHIBITOR CERDULATINIB DEMONSTRATES COMPLETE INHIBITION OF SYK AND JAK AND RAPID TUMOR RESPONSES IN A PHASE I STUDY IN PATIENTS WITH RELAPSED/REFRACTORY B CELL MALIGNANCIES

P. Hamlin1,2, C. Farber1, T. Fenske3, J. Khatcheressian4, C. Miller5, J. Munoz6, M. Patel7, S. Smith8, D. Stevens9, A. Pandey10, M. Birrell10, J. Leeds10, Y.L. Wang10, G. Coffey10, J. Cumalte10,11,12

1Memorial Sloan Kettering Cancer Center, New York, 2Carol G. Simon Cancer Center, Morristown, NJ, 3Division of Hematology & Oncology, Medical College of Wisconsin, Milwaukee, WI, 4Virginia Cancer Institute, Richmond, VA, 5St. Agnes Hospital Cancer Center, Baltimore, MD, 6Banner MD Anderson Cancer Center, Gilbert, AZ, 7Florida Cancer Specialists/Sarah Cannon Research Center, Sarasota, FL, 8University of Chicago, Chicago, IL, 9Norton Cancer Institute, Louisville, KY, 10Portola Pharmaceuticals, South San Francisco, 11Department of Pathology, University of Chicago, Chicago, IL, 12United States

Background: Subsets of B cell malignancies are addicted to B cell antigen receptor (BCR) signaling for survival. Co-stimulation of the BCR with IL-2 or IL-4 in normal B cells significantly enhances cellular activation relative to BCR or cytokine stimulation alone, and combining SYK selective and JAK selective inhibitors synergize to suppress this response (Coffey et al., 2013). Hence, BCR/SYK and cytokine JAK/STAT signals cooperate to control B cell activation.

This cooperation appears to be relevant to B cell malignancies as well. IL-4 promotes the survival of CLL cells in culture via up-regulation of MCL1 and BCLXL, protecting the tumor from death induced by fludarabine and chlorambucil (Steele et al., 2010) and by idelisib and irbutinib (Aguilar-Hernandez et al., 2015). This is an open-label study with 28-day cycles. Twice daily (BID) 30 mg BID was identified as the Phase 2 dose based on Phase 1 data and a PK/PD modeling study in patients with relapsed/refractory B cell malignancies.

ORR amongst 36 evaluable pts is shown in the following Table 1.
mg and 35 mg) dosing was evaluated. Pharmacokinetics (PK), pharmacodynamics (PD), and safety were monitored, as well as an assessment of efficacy. Clinical response was assessed by standard criteria. Potency and specificity for SYK and JAK pathway inhibition were measured in whole blood assays by monitoring signaling responses following ligation of the BCR and receptors for IL-4. Serum markers of inflammation, minimal residual disease (MRD) and apoptosis in CLL patients were also measured.

**Results:** A phase 2 study was initiated in May 2016 to enroll up to 40 patients in each of three cohorts; 1) relapsed/refractory CLL/SLL, 2) relapsed/refractory indolent NHL, and 3) relapsed DLBCL, MCL and transformed FL. As of March 1, 2017, 37 patients have been enrolled, 17 with CLL/SLL, 15 with indolent NHL (10 FL, 4 MZL, 1 WM), and 5 with aggressive NHL (3 DLBCL, 1 MCL, 1 IFL). Median patient age is 70 years (range, 51-93). The median number of prior therapies is 3 (range 1–7). 11 patients had prior BTK or PI3K inhibitor therapy. The safety profile has been similar to what was seen in the Phase 1 study. However, 3 patients at 35 mg BID achieved higher than expected drug concentrations and had SAEs (2 grade 5 infections, 1 grade 3 pancreatitis). The starting dose was reduced to 30 mg BID and a PK monitoring and dose reduction strategy has been implemented. To date, this has resulted in a better safety profile without PK outliers. The most common AEs of any grade have been diarrhea (27%), fatigue (27%) and nausea (24%). Grade 3+ AEs occurring in more than 1 patient are infection (5 patients), abdominal pain (3 patients) and hypertension (3 patients). As seen in phase 1, significant inhibition of SYK and JAK signaling pathways in peripheral blood is observed. Evidence for tumor cell mobilization to peripheral blood in CLL/SLL is consistently observed following one week of therapy. PRs have been seen in all 3 cohorts including 10 of 13 (77%) CLL/SLL and 3 of 6 (50%) FL patients evaluated. Of these 13 PRs, 12 are still on drug with 4 patients in response for greater than 6 months. In addition, PRs have been seen in patients who relapsed onibrutinib (FL patient, 8+ months) and venetoclax (SLL patient, 7+ months) therapy. As demonstrated preclinically, we have seen evidence of apoptosis (Annexin V+ B-cells) in 6 CLL patients. 5 of these patients had a PR at the end of the 2nd cycle (Figure 1).

**Figure 1.**

**Summary/Conclusions:** Cerdulatinib demonstrates clinical activity in heavily pretreated patients with CLL/B-cell NHL and is generally well tolerated. Consistent activity is seen in patients with CLL and FL. Accrual is proceeding; update presented in 2017. As demonstrated preclinically, we have seen evidence of apoptosis (Annexin V+ B-cells) in 6 CLL patients. 5 of these patients had a PR at the end of the 2nd cycle (Figure 1).

| 2.5-yr PFS from EOI was 87.6% (95% CI 83.5–90.8) for PET-CR pts compared with 70.9% (95% CI 61.3–78.6) for PET non-CR pts; corresponding OS was 96.6% (95% CI 94.1–98.1) vs 90.9% (95% CI 84.7–94.6) (Figure 1).

**Summary/Conclusions:** This large prospective analysis confirms EOI PET as an early predictor of PFS and OS in FL with good concordance between INV and PET-CR.
and IRC PET evaluation. Comparison of PFS based on CT-response and re-analysis of PET scans applying the now recommended 5-point scale for PET response assessment will be presented. Pooled analyses of these and data from other studies with longer follow-up may determine PET response as a reliable early surrogate for PFS and OS, providing a platform for study of response-adapted therapy.

Figure 1.

S775
IMMUNOCHEMOTHERAPY WITH OBINUTUZUMAB OR RITUXIMAB IN PREVIOUSLY UNTREATED FOLLICULAR LYMPHOMA IN THE RANDOMIZED PHASE III GALLIUM STUDY: ANALYSIS BY CHEMOTHERAPY REGIMEN

1Department of Medicine III, Ludwig-Maximilians-University Munich, Munich, Germany, 2Department of Hematology, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, 3Department of Medicine, Hospital Universitario la Paz, Madrid, Spain, 4Haematology Department, Fiona Stanley Hospital, Murdoch, Australia, 5Department of Clinical Haematology, Oxford Cancer and Haematology Centre, Churchill Hospital, Oxford, United Kingdom, 6Medical Faculty (Haematology), Universitätsklinikum Essen, Essen, Germany, 7Oncology Center, HELIOS-Klinikum Erfurt, Erfurt, Germany, 8Department of Haematology, Prince of Wales Hospital, Sydney, Australia, 9First Faculty of Medicine, Charles University General Hospital and Institute of Pathological Physiology, Charles University, Prague, Czech Republic, 10Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 11The University of Manchester and The Christie NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, 12Department of Haematology, National Cancer Center Hospital, Tokyo, Japan, 13Pharma Development Safety and Risk Management, 14Pharma Development Biometrics Biostatistics, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 15Department of Haematology, Kings College Hospital, London, United Kingdom

Background: The Phase III GALLIUM study (NCT01332968) showed that obinutuzumab (GA101; G) significantly prolonged PFS in previously untreated FL pts relative to rituximab (R) when combined with chemotherapy (chemo; CHOP, CVP or bendamustine [B]). Grade 3–5 and serious AEs were more common with G-chemo.

Aims: To explore outcomes by immunochemotherapy regimen.

Methods: Pts were aged ≥18 yrs with documented, previously untreated FL (grades 1–3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7cm), ECOG PS 0–2, and requiring treatment according to GELF criteria. Pts were randomized 1:1 (stratified by chemo, FLIPI-1 group and geographic region) to R 375mg/m2 on day (D) 1 of each cycle (C) or G 1000mg on D1, 8 and 15 of C1 and D1 of C2–8, for 6 or 8 cycles depending on chemo. Pts with CR or PR at EOI (per Cheson 2007) continued to receive R or G every 2 months for 2 yrs or until progression. The cut-off date for this analysis was September 10 2016. All pts gave informed consent.

Results: 1202 FL pts were randomized. Baseline characteristics were generally similar across chemo groups, although B and CVP pts had relatively more comorbidities, e.g. GI and vascular disorders, than CHOP pts. After 41.1 months’ median follow-up, investigator (INV)-assessed PFS remained superior for G-chemo relative to R-chemo (HR, 0.68; 95% CI 0.54–0.87; p=0.0016) with consistent HRs across chemo groups (Figure 1). HRs for secondary time-to-event endpoints were supportive of the primary analysis. Difference in frequency of grade 3–5 AEs between arms was highest with CHOP and CVP (Table 1). Rates of second neoplasms and grade 3–5 infections were similar in G and R arms for CHOP and CVP but not for B. In all chemo groups, SAEs were more frequent with G than R, and AEs causing treatment discontinuation and fatal AEs were similar. Reductions in T-cell counts were more pronounced and prolonged in the B group than CHOP or CVP groups.

Table 1. Safety summary (number (%) of FL pts* with ≥1 AE).

Summary/Conclusions: In treatment-naive FL pts, PFS was superior with G-chemo relative to R-chemo with consistent effects across chemo regimens. Some differences were seen in safety profiles between chemo regimens, but comparisons may be confounded by the lack of randomization.

S776
EFFICACY AND SAFETY OF COPANLISIB IN PATIENTS WITH RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA: A SUBSET ANALYSIS OF THE CHRONOS-1 STUDY

1Department of Hematology, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, 2Department of Haematology, Hospital Universitario la Paz, Madrid, Spain, 3Department of Clinical Haematology, Oxford Cancer and Haematology Centre, Churchill Hospital, Oxford, United Kingdom, 4Department of Haematology, University College London Hospitals NHS Foundation Trust, London, United Kingdom, 5Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 14Pharma Development Safety and Risk Management, 15Pharma Development Biometrics Biostatistics, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 16Pharma Development Safety and Risk Management, 17Pharma Development Biometrics Biostatistics, F. Hoffmann-La Roche Ltd, Basel, Switzerland

Background: The Phase II CHRONOS-1 study showed that copanlisib (Selinexor; SEL) led to a partial response (PR) in 9/21 (43%) patients (pts) with relapsed / refractory follicular lymphoma (FL).

Methods: This subset analysis focuses on pts with relapsed / refractory follicular lymphoma. Pts must have received ≥2 prior chemotherapies. Pts must have had at least one disease site measurable by CT at baseline. Pts must have received SEL 14 mg/m2 on days 1, 4, 8, 11 on a 21-day cycle for 4 cycles. The co-primary endpoints were safety and PR rate. NEAEs were defined as those occurring at ≥Grade 3. PR rate was calculated as the proportion of pts achieving a PR or better, as defined by the IWCLL criteria.

Results: 26 pts were enrolled in the study from 12 centers. The safety population was 26 pts (mean age 64 years; 54% female; 46% ≥70 years; 77% stage IV; 81% Flips 1/2; 65% with ≥3 prior chemo regimens; 77% with ≥5 prior chemo regimens). 17 pts had received ≥1 prior anti-CD20 antibody therapy. 5 pts had received ≥1 prior allogeneic stem cell transplant, 10 pts had received ≥1 prior autologous stem cell transplant, and 8 pts had received ≥1 prior radioimmunotherapy. 23 pts had ≥1 measurable disease site and 21 pts had ≥1 measurable and ≥1 non-measurable disease site. 22 pts had CT scans every 4 weeks for ≥4 weeks, 21 pts had ≥1 bleeding event, 4 pts had ≥1 pulmonary embolism, 2 pts had ≥1 cerebrovascular accident, 7 pts had ≥1 cardiac arrest, 5 pts had ≥1 myocardial infarction, 5 pts had ≥1 deep vein thrombosis, 5 pts had ≥1 pulmonary embolisms, 7 pts had ≥1 non-COVID-19 pneumonia, and 3 pts had ≥1 limb amputation. 21 pts (81%) had ≥1 treatment-related adverse event (TRAE) of any grade, 19 (73%) had ≥1 TRAE of ≥Grade 3, and 15 (58%) had ≥1 TRAE of ≥Grade 4. Grade 4 TRAEs included atrial fibrillation (2), atrial flutter (1), cerebrovascular accident (1), deep vein thrombosis (1), dyspnea (3), pneumonitis (1), pneumonia (1), peripheral edema (1), pulmonary hemorrhage (1), pulmonary embolism (1), secondary thrombosis (1), and transient ischemic attack (1). 20 pts (77%) had ≥1 non-treatment related adverse event (NTRAE) of any grade, 17 (65%) had ≥1 NTRAE of ≥Grade 3, and 12 (46%) had ≥1 NTRAE of ≥Grade 4. Grade 4 NTRAEs included atrial fibrillation (1), atrial flutter (1), deep vein thrombosis (1), peripheral edema (1), and pulmonary embolism (1). A total of 4 pts (15%) had ≥1 TRAE of ≥Grade 3 causing treatment discontinuation, and 1 pt died of a TRAE (ventricular tachycardia). A total of 3 pts (11%) had ≥1 NTRAE of ≥Grade 3 causing treatment discontinuation, and 1 pt died of a NTRAE (cancer progression).

Summary/Conclusions: The results of this subset analysis of the CHRONOS-1 study demonstrate that SEL led to PR in 9/26 (35%) patients with relapsed / refractory follicular lymphoma and had a manageable safety profile in this patient population.
Background: Follicular lymphoma (FL) is the most common indolent non-Hodgkin lymphoma (NHL) subtype, yet treatment options in the relapsed/refractory setting are limited. Copanlisib is a potent and selective pan-class I PI3K inhibitor with predominant activity against the δ- and α-isozymes.

Aims: We report results from the FL subset of a large phase II study in NHL patients (NCT01660451, part B).

Methods: Patients with histologically confirmed indolent indolent FL (grade 1-3a) relapsed/refractory to ≥2 prior lines of treatment were treated with copanlisib (60 mg IV infusion) administered on days 1, 8 and 15 of a 28-day cycle until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) as assessed by independent radiology review according to the response criteria for lymphoma (Cheson et al, JCO 20:579, 2007).

Secondary endpoints included progression-free survival (PFS) and duration of response (DoR), safety and tolerability.

Results: A total of 141 patients with iNHL were treated in the phase II study, including 104 patients with FL. The FL subset was characterized as: 52% male, 83% white, median age 62 years, 62% ECOG 0, 63% refractory to last therapy, median time from most recent progression 8 wks (range 1-73) and median prior lines of therapy 3 (range 2-8). At the time of primary analysis the ORR was 58%, comprising 15 patients (14.4%) with complete response and 46 (44.2%) with partial response. Stable disease was observed in 35 (33.7%) patients and progression of disease as best response in 2 patients. The median duration of response was 370 days (range 0-687), with 43 responders censored at data cut-off. Median duration of treatment was 22 wks (range 1-105); 33 (32%) patients remained on treatment. Per investigator assessment, 87 of 96 evaluable patients (91%) had some degree of tumor shrinkage as best response, and 58/96 (60%) had >50% tumor shrinkage (Figure 1). For all patients in the phase II study, the most common treatment-emergent AEs occurring in >25% of patients included (all grade/grade 3+): diarrhea (34%/6%), reduced neutrophil count (30%/24%), fatigue (30%/3%), and fever (25%/4%). Hyperglycemia (50%/41%) and hypertension (30%/24%) were transient. The incidence of pneumonitis (8%/14%), hepatic enzypmatathy (AST 28%/1%/ALT 23%/1%), opportunistic infection (1.4%) and colitis (0.7%) were low. Six deaths were observed, 3 of which were attributed to copanlisib: one lung infection, one respiratory failure, and one thromboembolic event.

Summary/Conclusions: Copanlisib was highly active as a single agent in heavily pretreated relapsed/refractory FL patients and resulted in responses in the majority of patients with a median duration of response of 370 days. Toxicities were manageable, with a low incidence of severe AEs associated with other PI3K inhibitors, especially hepatic enzypmatathy, opportunistic infections, and colitis.
Background: Between March 2000 and May 2005 a multicenter randomized trial comparing frontline use of CHOP-R vs R-HDS with autograft has been performed on 134 Follicular Lymphoma (FL) patients, selected for age less than 60 yrs. and poor prognostic features according to age-adjusted IPI (2-3) and IIL-score (3 or greater). Results at 4-yr follow-up were previously published (Ladetto M et al, Blood 2008), showing superior disease control with R-HDS without any survival advantage.

Aims: We have recently performed a long term update and the results at a median follow-up of 13 yrs are here presented.

Methods: The long-term outcome has been updated for 119 out of the original 134 randomized patients (56 CHOP-R and 63 R-HDS arms). Main features of the updated patients included: median age 51 yrs. (22-60), M/F ratio 68/51, aaIPI 2-3 90%, high LDH 43%, bulky disease 60%, B-symptoms 46%, BM involvement 86%; no significant differences were observed in clinical presentation between the two arms, as previously reported. Treatment schedule consisted of: i. CHOP-R arm: 6 courses of cyclophosphamide/doxorubicin/vincristine/prednisone followed by 4-weekly rituximab courses; ii. experimental R-HDS arm: rituximab with high-dose sequential chemotherapy followed by autografting. The analysis was intention to treat with event-free survival as the primary endpoint. Minimal residual disease (MRD) was evaluated post treatment in 56 patients with a bcl-2/IgH MBR or mcr translocation confirmed at diagnosis by nested PCR. The trial was registered at www.clinicaltrials.gov, no. NCT00435955. The long-term outcome has been updated in January 2017 by 27 out of 30 participating Centers, on 119 patients (88% of the whole series).

Results: Complete remission (CR) was achieved by 86 (72%) patients, including 32 (57%) with CHOP-R and 54 (85%) with R-HDS (p <.001); Molecular Remission (MR) was achieved in 37 out of 56 (66%) evaluable patients. At a median follow-up of 13 yrs., 74 patients (63%) are alive. Overall, 22 patients died for lymphoma progression (13 CHOP-R, 9 R-HDS), 12 died for secondary malignancy (3 in the CHOP-R, 9 in the R-HDS arms), 11 patients died for other causes, including four early toxic deaths. The overall survival (OS) for the whole series is 63% at 13 yrs, as shown in Figure 1A. No significant differences in the long-term OS were observed between the two arms, with 13-yr survival of 65% and 61% for CHOP-R and R-HDS, respectively (p=0.51). At 13 years, the event free survival is 35%, whereas the disease-free survival (DFS) is of 53%, as shown in Figure 1B. Response to induction therapy had a major impact on the OS, with 13 yr survival of 75% for patients achieving CR vs 33% for those with less than CR (p <.001). Similarly, Molecular Remission (MR) achievement was associated with prolonged OS, with 13 yr survival of 81% for patients in MR on BM cells, and of 47% for those with positive MRD (p=.02) (Figure 1C).

Summary/Conclusions: i. poor risk FL may have a prolonged survival, with 63% of patients alive at 13 yrs.; ii. no survival differences between CHOP-R and R-HDS can be detected even at 13 yrs of follow-up; iii. achieving CR is still crucial for the long-term survival; iv. the MRD analysis has a prognostic impact not only on progression-free but also on OS; v. lymphoma progression remains the major cause of death, while secondary neoplasms represent the second cause of treatment failure; vi. a subgroup of advanced-stage FL may experience a prolonged DFS lasting at least 13 yrs: this raises the issue of the potential curability of FL.
Changing the strategy of therapy in multiple myeloma

S779

PHASE II TRIAL OF COMBINATION OF ELOTUZUMAB, LENALIDOMIDE, AND DEXAMETHASONE IN HIGH-RISK SMOLDERING MULTIPLE MYELOMA

I. Ogbuozor1, A. Cadil1, P. Henrick1, A. Savell1, J. Cappuccio1, B. Rivolta1, K. Reyes1, C. Papa-Prada1, R. Schlossman1, J. Laubach1, P. Richardson1, K. Noonan1, N. Munshi1, C.-J. Liu1, M. Caola1, P. Henrick1, A. Savell2, J. Cappuccio1, B. Rivotto1, 1Multiple Myeloma, Dana-Farber Cancer Institute, 2Blood Cancer Research Partnership, Boston, 3Multiple Myeloma, University of Maryland Greenebaum Cancer Center, Baltimore, 4Multiple Myeloma, Colorado Blood Cancer Institute, Denver, 5Multiple Myeloma, Beth Israel Deaconess Medical Center, 6Multiple Myeloma, Massachusetts General Hospital, Boston, 7Multiple Myeloma, Eastern Maine Medical Center, Bangor, 8Multiple Myeloma, Levine Cancer Institute, Charlotte, 9Multiple Myeloma, St. Francis Hospital, Hartford, 10Multiple Myeloma, Newton-Wellesley Hospital, Newton, 11Multiple Myeloma, Barbara Ann Karmanos Cancer Institute, Detroit, 12Multiple Myeloma, University of Chicago Medical Center, Chicago, United States

Background: This study aimed to determine the benefit of early therapeutic intervention with the combination of elotuzumab, lenalidomide, and dexamethasone in patients with high-risk smoldering multiple myeloma (SMSMM). The phase II study investigated the addition of a proteasome inhibitor to a doublet backbone therapy in newly diagnosed multiple myeloma (NDMM) patients (San Miguel et al, N Engl J Med 2008, Durie et al, Lancet 2017). Data from two phase 1/2 studies indicate that the combination of ixazomib plus lenalidomide-dexamethasone (IRD) is feasible and active in patients with NDMM, with weekly and twice-weekly ixazomib dosing having been investigated (Kumar et al, Lancet Oncol 2014). Aims: This phase 1/2 study (NCT01383928) evaluated twice-weekly ixazomib plus Rd as induction therapy, followed by maintenance therapy with single-agent ixazomib. We report long-term efficacy and safety data in patients who did not withdraw from the study in order to receive SCT.

Methods: Patients with NDMM (SCT-eligible or ineligible) received twice-weekly oral ixazomib (3.0 or 3.7 mg on days 1, 4, 8, and 11) plus lenalidomide (25 mg on days 1–14) and dexamethasone (20 mg [10 mg in cycles 9–16] on days 1, 2, 4, 5, 8, 9, 11, and 12) for up to sixteen 21-day cycles, followed by maintenance therapy with single-agent twice-weekly ixazomib. Patients were followed until disease progression or death, with the time to progression to ST as the primary endpoint. Maintenance therapy with single-agent twice-weekly ixazomib did not receive further ixazomib therapy. Response/progression was assessed per IMWG criteria after cycles 1, 2, 3, 4, and then every 2 cycles during induction and maintenance.

Results: Of the 64 enrolled patients, 40 continued on study treatment without withdrawal for SCT during follow-up; data for all 40 patients is reported here. The median age of patients was 66 years (range 34–82), and 45%/38%/18% of patients had ISS disease stage III/II/I. At a median follow-up of 47.0 months, the overall response rate (ORR; partial response [PR] or better) was 94%, the complete remission (CR)+very good partial response (VGPR) rate was 89%, and the CR rate was 87%. Median time to first response was approximately 1 cycle (0.72 months). Median time to a best response (CR+VGPR) was 4.2 months. Patients received a median (range) of 14 (1–75) treatment cycles. Median progression-free survival (PFS) for patients not proceeding to SCT was 24.9 months. Median overall survival (OS) was not estimable; the 2-year Kaplan-Meier estimate for OS was 92%. A total of 78% of patients had grade ≥3 treatment-related adverse events (AEs); the most common treatment-related grade ≥3 AEs and serious AEs are shown in the Table 1. After completing induction therapy with IRd, 18 patients went on to receive maintenance with single-agent ixazomib on a twice-weekly dosing schedule. Patients who went on to maintenance received a median (range) of 31.5 (17–75) treatment cycles. Among the patients who received maintenance therapy, the ORR (PR%) was 94%, the CR+VGPR rate was 89%, and the CR rate was 44%. Two (11%) patients improved their responses during maintenance therapy; 1 VGRPR to stringent VGPR and 1 VGPR to near-CR. The 2 patients who received maintenance therapy had an onset of a grade 3 treatment-related adverse event (AE) in cycle 17 or beyond. Rash (aggregate term) was infrequent with single-agent ixazomib during maintenance (1 patient, 6%).

Table 1.

S780

TWICE-WEEKLY IZAXOZIMIIB PLUS LENALIDOMIDE-DEXAMETHASONE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP DATA FOR PATIENTS WHO DID NOT UNDERGO STEM CELL TRANSPLANTATION

P. Richardson1,*, C. Hofmeister2, C. Rosenbaum3, M. Hutt1, D. Vesole1

1Dana-Farber Cancer Institute, Boston, 2Ohio State University, Columbus, 3University of Chicago Medicine, Chicago, 4Hematology and Stem Cell Transplant, City of Hope National Medical Center, Duarte, 5John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, 6Sarah Cannon Research Institute, Nashville, 7Stanford Congenetic and Regenerative Center, Stanford, 8Mount Sinai School of Medicine Rittenberg Treatment Center, New York, 9Fred Hutchinson Cancer Research Center, University of Washington, Seattle, 10University of Michigan Cancer Center, Ann Arbor, 11Massachusetts General Hospital, Boston, 12Milennium Pharmaceuticals Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 13H. Lee Moffitt Cancer Center & Research Institute, Tampa, United States

Background: An addition of a proteasome inhibitor to a doublet backbone therapy has been shown to improve efficacy in newly diagnosed multiple myeloma (NDMM) patients (San Miguel et al, N Engl J Med 2008, Durie et al, Lancet 2017). In total, 50 patients were enrolled on this study from January 2015 to date, with the participation of eight sites. The median age of patients enrolled was 62 years (range 29 to 79) with 18 males (36%) and 32 females (64%). Interphase fluorescence in situ hybridization (iFISH) detected high risk cytogenetics in 20 patients. The median number of cycles completed is 31.5 (17–75) treatment cycles. Among the patients who received maintenance therapy had an onset of a grade ≥3 treatment-related adverse event. Correlation with genomic studies can help define patients who benefit the most from this early therapeutic intervention.

Methods: Patients enrolled on study met eligibility for high-risk SMM based on the newly defined criteria proposed by Rajkumar et al, Blood 2014. Patients with high-risk SMM (SCT-eligible or ineligible) received twice-weekly oral ixazomib (3.0 or 3.7 mg on days 1, 4, 8, and 11) plus lenalidomide (25 mg on days 1–14) and dexamethasone (40 mg) was given on days 1, 8, and 15 for 40 of the 50 patients enrolled. After 8 cycles or best response, patients were given the option to mobilize with either cyclophosphamide or plerixafor and collect stem cells for transplantation. Patients were then allowed to continue on maintenance therapy where they were administered elotuzumab (20 mg/kg) on day 1, in combination with lenalidomide days 1-21 of a 28 day cycle. Bone marrow samples of 33 patients were obtained before starting therapy for baseline assessment and whole exome sequencing (WES) of plasma cells. Results: In total, 50 patients were enrolled on this study from January 2015 to date, with the participation of eight sites. The median age of patients enrolled was 62 years (range 29 to 79) with 18 males (36%) and 32 females (64%). Interphase fluorescence in situ hybridization (iFISH) detected high risk cytogenetics in 20 patients. The median number of cycles completed is 12 (range 1 to 24). Therapy related grade 3 toxicities included hypophosphatemia (30%), neutropenia (14%), infection (12%), anemia (2%), pulmonary embolism (2%), rash (4%), and diarrhea (2%). Therapy related grade 4 toxicities included (2%), neutropenia (2%) and one instance of cholecystitis (2%). Stem cell collection was successful in all patients collected to date. Of the 31 evaluable patients that completed the first 8 cycles of therapy, the overall response rate was 84%, including 2 complete responses (7%), 11 very good partial responses (36%) and 13 partial responses (42%), and a clinical benefit rate of 100%. None of the patients showed progression to symptomatic myeloma (MM). Furthermore, the study examined whether genomic studies can help in determining patients who would benefit the most from this early therapeutic intervention.

Results: Among the patients who received maintenance therapy had an onset of a grade ≥3 treatment-related adverse event. Correlation with genomic studies can help define patients who benefit the most from this early therapeutic intervention.

Summary/Conclusions: The combination of elotuzumab, lenalidomide, and dexamethasone is well tolerated and demonstrates a high response rates with no progression to overt MM to date. Correlation with genomic studies can help define patients who benefit the most from this early therapeutic intervention.

Table 1.

haematologica | 2017; 102(s2) | 317

Madrid, Spain – June 22 - 25, 2017
COMPARISON OF DENOSUMAB WITH ZOLEDRONIC ACID FOR THE TREATMENT OF BONE DISEASE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA; AN INTERNATIONAL, RANDOMIZED, DOUBLE BLIND TRIAL

1Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, 2Indiana University Simon Cancer Center, Indianapolis, United States, 3Medical University of Innsbruck, Innsbruck, Austria, 4National Hospital Organization Higashi Nagoya National Hospital, Nagoya, Japan, 5Hospital Universitario de Salamanca, Salamanca, Spain, 6Cedars-Sinai Medical Center, Los Angeles, 7Amgen Inc., Thousand Oaks, 8Massachusetts General Hospital Cancer Center, Boston, United States

Background: Multiple myeloma is characterized by osteolytic bone disease, with up to 80% of pts presenting with detectable lesions. Myeloma bone disease is mediated by osteoclast activating factors such as RANKL, increasing the risk of skeletal-related events (SREs) and impacting morbidity and mortality. DMB, a human monoclonal antibody that targets and binds to RANKL, can be administered subcutaneously (SC) to pts regardless of renal function.

Aims: This study evaluates the efficacy and safety of DMB compared with ZA in newly diagnosed myeloma pts.

Methods: Adult pts were randomized 1:1 to DMB 120mg SC Q4W or ZA-4mg IV (adjusted) Q4W along with anti-myeloma therapy. Key stratification factors included type of first-line therapy (novel or non-novel) and previous SRE. Pts with renal insufficiency were excluded if baseline creatinine clearance (CrCl)<30mL/min. The primary endpoint was non-inferiority of DMB to ZA with respect to time to first on-study SRE. Secondary endpoints included superiority of DMB for time to first on-study SRE and first-and-subsequent on-study SRE, and overall survival (OS). Progression-free survival (PFS) was an exploratory endpoint. Safety was also assessed.

Results: A total of 1718 pts were randomized, 859 to each arm. Baseline demographic and disease characteristics were balanced, with 66.0% of DMB and 67.2% of ZA pts reporting prior SRE history; CrCl<30mL/min was reported in 67.2% of ZA pts and 59.0% of DMB pts. DMB was non-inferior to ZA in delaying time to first on-study SRE (HR[95%CI]=0.82[0.68,0.99], P=0.039) (Figure 1) between DMB and ZA, OS was similar between DMB and ZA (HR[95%CI]=0.90[0.70,1.16],P=0.41), with fewer deaths with DMB (121[14.1%]) than ZA (129[15.0%]). PFS yielded a similar between DMB and ZA (HR[95%CI]=0.90[0.70,1.16],P=0.41), with fewer deaths with DMB (121[14.1%]) than ZA (129[15.0%]). PFS yielded a HR(95%CI)=0.80[0.68,0.99], descriptive P=0.038, with median times of 46.0m (95%CI:34.3,37.8) for DMB and 35.3m (95%CI:30.1,39.8) for ZA. The most common AE was ONJ, were consistent with the known DMB safety profile. The results of the landmark analysis and possible prolongation of PFS with DMB therapy is promising.

Figure 1.
Background: Pembrolizumab (pembro) is a humanized, highly selective, high-affinity IgG4κ antibody that blocks the interaction between programmed death 1 (PD-1) and its ligands PD-L1 and PD-L2, activating antitumor immunity. Pembro plus lenalidomide (len) and low-dose dexamethasone (dex) may provide synergistic antitumor activity in relapsed/refractory multiple myeloma (RRMM). Biomarkers indicative of response, pharmacodynamic activity, and/or mechanism of action to combination therapies are also needed.

Aims: To determine the maximum tolerated dose (MTD) and safety and tolerability of pembro plus len and low-dose dex in patients with RRMM. Additionally PD-L1 and PD-L2 expression in bone marrow (BM), immune profiles in circulating lymphocytes, and gene expression in blood were evaluated.

Methods: This open-label, phase 1 KEYNOTE-023 (NCT02038502) study of pembro plus len and low-dose dex enrolled patients with RRMM previously treated with ≥2 prior therapies, including both a proteasome inhibitor and an immunomodulatory drug. Patients received pembro 200 mg IV every 2 weeks (Q2W), len 25 mg orally on days 1-21, and dex 40 mg orally weekly on each 28-day cycle. Primary end points were safety and determination of the MTD. ORR was assessed by IMWG 2006. Exploratory biomarker analyses included analysis of PD-L1 and PD-L2 expression in bone marrow (BM), immune profiles in circulating lymphocytes, and gene expression in blood were evaluated. Analysis of PD-L1 and PD-L2 on CD38+CD138+ cells in BM aspirate samples obtained at screening, or before the first dose of study drug. Absolute and/or relative numbers of circulating lymphocytes (by flow cytometry [FC]) and gene expression profile (GEP) (by Nanostring) were evaluated in predose; cycle 1, day 1 (C1D1); and cycle 2, day 1 (C2D1) blood samples.

Results: MTD was determined as pembro 200 mg IV Q2W plus len 25 mg and dex 40 mg. Median (range) age was 61 years (46-77); median (range) number of prior lines of therapy was 4 (1-10); 38 (75%) patients were len-refractory, and 27 (53%) were double refractory. Most common grade ≥3 treatment-related AEs (TRAEs) were neutropenia (33%), thrombocytopenia (18%), and anemia (12%). 2 patients (4%) died because of TRAEs (hepatic failure, ischemic stroke). Immune-related AEs occurred in 5 (10%) patients. No pneumonitis was reported. ORR in the efficacy population was 20/40 (50%) (1 scR, 5 VGPR, 14 PR, 3 nPR) for len and double-refractory patients, respectively. The disease control rate (sCR+CR+VGPR+PR+SD) was 39/40 (98%) in the efficacy population and 28/29 (97%) in the len-refractory population. 35/40 (88%) patients had a reduction in M protein or free light chains. In 16/32 patients with FC-evaluable BM aspirate samples, ≥100 CD38+CD138+ cells, all were PD-L1+, while PD-L2 expression was variable. At C2D1, proportion of circulating HLA-DR+, central (CD45RO+CCR7+), and effector memory (CD45RO+CCR7−) CD8+ T cells significantly increased and naïve (CD45RA+)CD8+ T cells significantly decreased; all with multiplicity adjusted P values ≤0.01.

Summary/Conclusions: The combination of pembro, len, and low-dose dex has an acceptable safety profile and antitumor activity in patients with heavily pretreated RRMM, including len-refractory and double-refractory patients. PD-L1 was expressed in all patients evaluated by FC, whereas PD-L2 expression was variable. Pembro plus len and low-dose dex induced immune activation in the periphery and a phenotypic shift in effector CD8+ T cells among the circulating T-cell pool in blood.

RUXOLITINIB FOR THE TREATMENT OF INADEQUATELY CONTROLLED POLYCYTHEMIA VERA WITHOUT SPLENOMEGALY: 80-WEEK FOLLOW-UP FROM THE RESPONSE-2 TRIAL

Aims: To determine the durability of efficacy and safety of RUX vs BAT, after all pts reached 80 wk into the study or discontinued the study.

Methods: Pts were randomized 1:1 to RUX 10 mg twice daily or BAT. Primary end point was the proportion of pts who achieved HCT control at wk 28 (absence of PB T eligbility [HCT ≥45%, ie, ≥3 percentage points from baseline, or HCT ≥48% from wk 8 to 28, with ≤1 PB T eligibility from wk 0 to 8). Key secondary end point was the proportion of pts who achieved complete hematocrit remission at wk 28 (CHR: HCT <45%, WBC <10 x 10⁹/L, platelet count <450 x 10⁹/L, and no organomegaly). Patient-reported outcomes (PMN-SAF TSS) and change in JAK2V617F allele burden over time. BAT pts could cross over to RUX from wk 28.

Results: Baseline demographics were comparable among RUX (N=74) and BAT (N=79) arms. At wk 0, 20% of pts were still receiving RUX vs BAT arm. Of those who achieved a HCT response at wk 28, 33/38 (87%) in the BAT arm vs 28.4 wk in the BAT arm. At wk 80, durable HCT control was achieved in 35 pts (47%) in RUX vs 2 pts (3%) in BAT arm. Total number of PBT was higher in the BAT arm vs RUX arm (14/76 pts in the BAT arm). Of those who achieved a HCT response at wk 28, Kaplan-Meier estimate of maintaining response up to wk 80 was 78.7% in the RUX arm. Durable CHR was achieved in 18 pts (24%) in RUX vs 2 pts (3%) in the BAT arm. Total number of PBT was higher in the BAT arm vs RUX arm (Figure 1). At wk 80, 45% of pts randomized to RUX continued to achieve ≥50% of reduction in the PMN-SAF TSS. At wk 80, mean percentage change from baseline in JAK2V617F allele burden was −9.7% in the RUX (n=65) vs +0.3% in the BAT arm (n=3). AE’s observed were consistent with those generally reported with RUX (primarily grade 1-2). Most common AEs (all G, exposure-adjusted rate per 100 pt-years) were anemia (14.3%), weight increase (10.6%), arthralgia (9.1%), and pruritus (9.1) in the RUX arm vs pruritus (37.5%), headache (16.9), and thrombocytopenia (15.0) in the BAT arm. Rate of thromboembolic events (Standardized MedDRA Query, exposure-adjusted) was RUX (1.5) vs BAT arm (1.9). No pts in the RUX arm had disease progression. 2 pts in the BAT arm. No deaths were reported in the RUX arm vs 3 pts in the BAT arm (septic shock/disease progression/study indication 1 pt, each).

Summary/Conclusions: RUX provided durable HCT control, durable CHR, reduction in PBT requirement, improved symptom burden, and was generally well tolerated with ≥90% of pts still receiving Tx at wk 80. No new safety signals were observed. No new safety signals were observed. Results from both RESPONSE-2 studies suggest that RUX should be considered as a standard of care for sec-online Tx in this inadequately controlled pt population with PV.
Background: Momelotinib (MMB), an investigational oral JAK inhibitor, has been shown in early trials to reduce spleen volume, improve disease associated symptoms and improve red blood cell (RBC) transfusion requirements in patients with myelofibrosis (MF).

Aims: To test the non-inferiority of MMB vs ruxolitinib (RUX) in splenic volume reduction and symptom amelioration, and superiority in transfusion response, in JAKI naive patients with primary myelofibrosis, and post-polycythemia vera or post-essential thrombocythemia myelofibrosis.

Methods: Eligibility included primary myelofibrosis or post-polycythemia vera/esential thrombocytoblasitc myelofibrosis; International Prognostic Scoring System (IPSS) high risk, intermediate-2 risk, or intermediate-1 risk associated with symptomatic splenomegaly; palpable spleen ≥5cm; platelets ≥50 K/μl; no history of peripheral neuropathy. Informed consent was obtained. Stratification was by transfusion dependence and baseline TSS (modified MPN-SAF Total Symptom Score) <18 or ≥18. Patients were randomized 2:1 to 24 weeks of open-label MMB 200 mg QD or best available therapy (BAT). Assessments included spleen volume by MRI, and patient-reported symptoms using a daily eDiary for TSS. Primary endpoint was spleen response rate (SRR) or ≥35% reduction in volume from baseline). RBC transfusion response, RBC transfusion independence (TI), and RBC transfusion dependence (TD).

Results: 73 of 104 (70%) and 40 of 52 (77%) patients receiving MMB or BAT, respectively, completed the 24 week randomized treatment phase. BAT for MMB included ruxolitinib, and 27% of patients were on ruxolitinib in combination with other drugs. Efficacy results are in Table 1. The most common treatment-emergent adverse events in MMB patients were diarrhea (33%), asthenia (19%), nausea (19%), and cough (17%), and in BAT patients, asthenia (21%), fatigue (19%), anemia (15%), diarrhea (15%), and abdominal pain (15%); the most common Grade ≥3 adverse events in MMB patients were anemia (13%) and thrombocytopenia (7%), and in BAT patients, anemia (13%), thrombocytopenia (6%) and abdominal pain (6%). Treatment emergent peripheral neuropathy occurred in 11 (11%) of MMB (1 Grade 3) and in no BAT patients; MMB was discontinued in 3 patients due to neuropathy.

Summary: Conclusions: In patients with JAKI naive myelofibrosis, 24 weeks of momelotinib is non-inferior to ruxolitinib for spleen response but not for symptom response. Momelotinib treatment is associated with a reduced transfusion requirement. NCT01969838

S786

PHASE 3 RANDOMIZED TRIAL OF MOMELOTINIB VERSUS BEST AVAILABLE THERAPY IN PATIENTS WITH MYELOFIBROSIS PREVIOUSLY TREATED WITH RUXOLITINIB: RESULTS OF THE SIMPLIFY-2 STUDY

1University of Texas MD Anderson Cancer Center, Houston, United States, 2University of Florence, Florence, Italy, 3Medizinische Fakultät Carl Gustav Carus, Technische Universität, Dresden, Germany, 4Hospital Clinico, University of Barcelona, Barcelona, Spain, 5Princess Margaret Cancer Centre, University of Toronto, Toronto, Canada, 6Hadasah-Hebrew University Medical Center, Jerusalem, Israel, 7University of Insubria, Varese, Italy, 8Emory University School of Medicine, Atlanta, 9Gilead Sciences, Inc., Foster City, United States, 10Saint-Louis Hospital (APHP) and Paris Diderot University, Paris, France, 11Guy’s and St. Thomas’ NHS Foundation Trust, London, United Kingdom
Summary/Conclusions: In previously ruxolitinib-treated patients with myelofibrosis, 24 weeks of momelotinib was not superior to best available therapy for splenic response, but significantly better in improving disease related symptoms and transfusion independence. NCT02101268.

S787
MOLECULAR RESPONSE TO HYDROXYUREA AND ROPEGINTERFERON ALFA-2B IN THE PROUD-PV RANDOMIZED PHASE 3 TRIAL
J.-J. Klidjian1,2,3,4, B. Cassinat2,4, J. Soret-Duply1, E. Verger1, L. Roy5, J. Rey6, N. Maslah4, B. Grohmann-Izay7, C. Klade7, H. Gisslinger8, O. Hermine6, F. Awan7, E. Hexner8, M. Mauro9, J. Schwaab1, M. Jawhar1, J. Rey6, N. Maslah4, B. Grohmann-Izay7, C. Klade7, H. Gisslinger8

Background: Interferon alfa (IFNa) has been successfully used to treat myeloproliferative neoplasms (MPN) for many years and several phase 2 studies have independently shown high rates of hematological and molecular responses assessed by the quantification of mutant JAK2 allele burden (%JAK2V617F) in peripheral blood. However, direct in vivo studies investigating the impact of IFNa treatment on proliferation of bone marrow (BM) normal and malignant hematopoietic progenitors are lacking.

Aims: We took advantage of a randomized controlled phase III trial (PROUD-PV) comparing the novel, long-acting Rogepinterferon alfa-2b (AOP2014) with hydroxyurea (HU) in polycythemia vera (PV) patients (pts) to assess correlation between evolution of %JAK2V617F in peripheral blood and the impact of therapy on malignant clones by functional assays testing mutant BM hematopoietic progenitors in the French study population.

Methods: Randomized, controlled, multicenter phase 3 trial comparing efficacy, safety and tolerability of hydroxyurea and Rogepinterferon Alfa-2b in PV pts (NCT01949805). The primary endpoint was non-inferiority of AOP2014 vs HU at 12 months (mos) of therapy in terms of complete hematological response (CHR) according to ELN criteria and normal spleen size. As an important secondary endpoint the effect of treatment on %JAK2V617F was assessed as rate of complete and partial molecular response (C/PMR) according to modified ELN criteria. In the group of pts enrolled in France, we could study BM progenitors clonogenic potential by cultures with or without Erythropoietin (EPO) at baseline and after 12 months of therapy. The presence of colonies without EPO, namely Endogenous Erythroid Colonies (EECs) is a hallmark of PV. After 14 days, erythroid colonies were enumerated and picked for molecular analyses.

Results: A total of 257 pts were randomized in 13 European countries including 13 pts in France. Non-inferiority of AOP2014 versus HU regarding CHR could be demonstrated in the whole study population (43.1% vs 45.6%). In the subgroup of French pts (54% males, mean age 55 years) CHR at 12 mos was 40% in pts receiving AOP2014 (n=5) and 50%, in those receiving HU (n=8). %JAK2V617F at baseline in the AOP2014 and HU arms were 39.4% and 46.5% respectively, reduced to 29.1% and 25.8% after 6 mos, and 13.8% and 13.2% at 12 mos. No complete MR was achieved at 12 mos, but PMR was 46.5%, respectively, reduced to 29.1% and 25.8% after 6 mos, and 13.8% and 13.2% at 12 mos. Complete MR was achieved at 12 mos, but PMR was observed in 40% and 5% of pts in AOP2014 and HU arms (p>ns), respectively. BM progenitors could be studied in 10/13 French pts, 3 treated with AOP2014 and 7 with HU. AOP2014 treatment induced an important decrease of the proportion of EECs at baseline by 64% between samples collected at baseline and after 12 months of therapy compared to HU (median decrease 25%). In addition, clonal architecture studies showed that the % of JAK2V617F mutant colonies before and after treatment profoundly decreased in all AOP2014-treated pts (mean decrease at baseline to 46% at 12 mos. Among HU-treated pts, only 1 experienced a decrease in the % of mutated colonies while mean ratio of mutant vs wild type JAK2 colonies didn’t significantly decrease (from 87% at baseline to 79% after 12 mos).

Summary/Conclusions: In this phase 3 trial comparing Rogepinterferon alfa-2b versus HU, we found a different impact of both drugs on hematopoietic cells. Although both treatment induced a decrease of JAK2 mutant allele burden at 12 mos in peripheral blood, BM clonogenic assays suggest that AOP2014 is able to specifically target JAK2 mutant progenitors, an effect not seen in HU treated pts. Such targeted impact of AOP2014 may account for the strikingly different kinetics in allele burden reduction and suggests that sustained long-term molecular response may only be achieved with IFNa based treatment.

Background: Adv/SM (ie, aggressive SM [ASM], SM with an associated hematologic neoplasm [SM-AHN], and mast cell leukemia [MCL]) comprises rare hematologic neoplasms with a poor prognosis. KIT D816V mutations occur in a majority of patients with adv/SM. Midostaurin is a multitargeted kinase inhibitor that blocks wild-type and D816V-mutated KIT. Two single-arm phase 2 studies (D2201+A2213) evaluated the safety and efficacy of midostaurin in a pool of 544 patients from the midostaurin randomized, controlled phase 3 study. Over all, 60% and 69% of patients in D2201 and A2213, respectively, achieved the primary endpoint of complete or partial normalization of SM-related organ damage.

Aims: We compared pooled data from these studies with data from a patient registry to determine the effects of midostaurin on overall survival (OS).

Methods: Data from the midostaurin studies, in which patients received midostaurin 100 mg twice daily until progression or toxicity, were pooled. Historical control data were obtained from a contemporary patient registry based at University Medical Centre Mannheim, Germany. Although the primary analysis did not include matching for patient subgroup, analyses were performed to assess whether baseline patient characteristics affected OS and estimated HR. Propensity scoring was used for supportive analyses to match the patients in the registry. Patients were evaluated for OS based on time from diagnosis to death; patients in the pooled analysis with known dates of diagnosis were included in the primary analysis. A sensitivity analysis to compensate for potential bias of patient selection was conducted using the start date of last treatment to death.

Results: The primary analysis of OS in patients with adv/SM included 89 patients from the midostaurin pooled analysis for which the date of diagnosis was available (77% of the entire pooled cohort) and all 46 patients from the German registry who had not been treated with midostaurin. SM subtypes among patients from the pooled analysis and registry were similar; 66% of patients in the pooled cohort and 63% in the registry had an AHN (Table 1). KIT D816 mutations were present in 82% of patients in the pooled analysis and 96% in the registry. More patients in the registry (67%) vs the pooled analysis (42%) were aged >65 y. Median follow-up (time from diagnosis to data cutoff for the analyses) was similar for the 2 patient groups: registry, 54.9 (range, 1.9-150.4) mo and midostaurin, 53.6 (range, 31.6-215) mo. Patients in the midostaurin pooled analysis had a clinically relevant improvement in OS vs historical controls (HR=0.62 [95% CI, 0.39-0.98]; P=0.0204; Figure 1). Median OS was 42.8 (95% CI, 31.0-53.9) mo in the pooled analysis vs 24.0 (95% CI, 13.0-39.5) mo in the registry. Multivariate Cox regression analysis after adjusting for covariates was consistent with the primary analysis: HR=0.51 (95% CI, 0.30-0.88); P=0.0147. Data using propensity score for matched pairs (n=44) were also consistent (HR=0.38 [95% CI, 0.16-0.96]; P=0.101). Subgroup analyses of OS showed HR in favor of midostaurin for all subgroups analyzed (adv/SM subtypes >65 y, KIT D816V status, number of prior therapies [≥1 vs <1], and SM subtype) except MCL. Subgroup analysis data should be interpreted with caution due to the small patient numbers in the German registry. Sensitivity analysis of OS from date last treatment received (pooled analysis, n=115; registry, n=42) was consistent with the main analyses (HR from the multivariate analysis=0.38 [95% CI, 0.22-0.65]; P=0.0004).

Table 1.

---

haematologica | 2017; 102(s2) | 321.

Madrid, Spain, June 22 – 25, 2017
Summary/Conclusions: Midostaurin was associated with a 38% lower risk of death vs historical controls. Benefit was generally consistent across key subgroups.

Background: Approximately 10% of the children with Down syndrome are diagnosed with transient myeloproliferative disorder (TMD) within the first days of life. Previous studies have shown that TMD patients face an around 20% risk of early death and a 20% to 30% risk to develop myeloid leukemia during the first 4 years of life (ML-DS).

Aims: The aim of the AML-BFM TMD Prevention 2007 trial was to analyze the outcome of patients diagnosed with TMD and to evaluate whether the application of a low-dose cytarabine treatment can prevent the progression to ML-DS.

Methods: The AML-BFM TMD Prevention 2007 trial is a multi-center, non-randomized, historically controlled study. Patients with TMD were prospectively enrolled. They received a low-dose cytarabine treatment (1.5 mg/kg i.v./s.c. daily for one week respectively if they met the following criteria: TMD-related symptoms for one week), or qPCR≥10-4 eight weeks after diagnosis. Patients received cytarabine-treatment up to three weeks in case of failure to respond to the cytarabine-treatment (morphologic detection of blasts between week four and eight after diagnosis and/or MRD-positivity after treatment in week ten after diagnosis).

Results: Here we report a cohort of 108 patients (male: 60, female: 48) diagnosed with TMD. The median age at diagnosis was 4 days. As common in children with Down syndrome, many of the patients presented with comorbidities (cardiac defects: 68%, other malformations: 15%); 36% were delivered preterm. 45 patients received low-dose cytarabine treatment, 57 patients did not receive this treatment. Overall, patients in this trial do not show a significantly better event-free survival (EFS; 72±4% vs 63±4%, p=0.15) and overall survival (OS; 91±3% vs 85±3%, p=0.15) than the historic control group (n=146). The cumulative incidence (CI) of death was lower, (8±3% vs 15±3%) albeit not significantly (p=0.09). The CI of ML-DS was also similar (19±4% vs 22±4%, p=0.88).

Patients that presented with TMD-related clinical symptoms (n=43; symptoms: hyperleucocytosis [WBC>100,000], hepatopathy, ascites, hydrops fetalis) had a tendency for a better EFS (59±8% vs 44±8%, p=0.097), OS (80±6% vs 67±7% p=0.10) and CI of death (20±7% vs 33±7%, p=0.10) than patients with those symptoms in the historic control group (n=45). For the progression to ML-DS there is no significant difference between the two groups (21±7% vs 23±7%, p=0.91). For patients that do not show any of the TMD-related symptoms (n=59), no significant differences were observed regarding EFS (81±5% vs 71±5%, p=0.27), OS (98% vs 93±3%, p=0.16) and CI of ML-DS (19±8% vs 22±4%, p=0.95) compared to patients without these symptoms in the historic control (n=101).

Summary/Conclusions: The consequent treatment with low-dose cytarabine of symptomatic patients results in a trend towards reduced CI of death as compared to the historic control. However, progression to ML-DS remained unchanged suggesting that the treatment with low-dose chemotherapy does not seem to prevent the development of subsequent leukemia in TMD-patients. Therefore, a general preventive chemotherapeutic treatment of children diagnosed with TMD cannot be recommended. However, children with TMD-related symptoms should receive low-dose cytarabine to reduce disease-related mortality.
Background: AML is a heterogeneous disease based on genetic characteristics with impact on prognosis. So, it becomes necessary to treat patients according to risk-adapted therapies.

Aims: To analyze the results of intensive induction and post-remission treatment in 868 patients with the new AML enrolled into the CETLAM-03 trial between 2003 and 2012 with a prolonged follow-up (results reported at 10 years).

Methods: Patients were randomized to 1 or 2 induction chemotherapy courses of IDICE-G (idarubicin, intermediate cytarabine (IDC), VP-16 and priming with G-CSF) followed by mitoxantrone and IDC as consolidation therapy. Further treatment was assigned according to the CETLAM risk groups as follows: Favorable risk (FR) defined as favorable cytogenetics according to MRC: autologous stem cell transplantation (ASCT) if leukocyte index [leukocytes (BM blasts/1000) ≤20 or high dose cytarabine (HDAC) (one course) if LIC >20. Intermediate risk (IR), defined as patients in CR after a single induction course, ≤50/105/9/white blood cells at diagnosis, normal karyotype and absence of FLT3-ITD internal tandem duplication (FlT3-ITDwt) and no MLL rearrangement: ASCT. Adverse risk (AR), patients randomized in FR or IR or ASCT or alloSCT with reduced disease burden. Post-SCT lenalidomide (allo-SCT) depending on donor availability (HLA-identical sibling or unrelated donor if high risk of relapse).

Results: There were enrolled 868 patients. Median age was 53 years old (16-70). According to MRC cytogenetics, available in 802 patients, 99 belonged to the favorable (12%), 581 (73%) to the intermediate and 12% (15%) to the adverse groups. 66 patients with no metaphases. FLT3-ITD was present in 128 patients with normal karyotype (36%). Four patients died before treatment and 864 patients received induction therapy. 77% of patients achieved a CR (88% with a single course, 11% were refractory and 12% died during induction. CR rate was achieved in 89% of patients in NPM1 mutation without FLT3-ITD, 77% in intermediate cytogenetic and no mutations, 74% if FLT3-ITD, 70% in adverse cytogenetics and 62% if monosomal karyotype was present (p<0.001). The multivariate analysis showed that mutational status (adverse cytogenetics, FLT3-ITD and absence of NPM1 mutation) had an adverse impact on CR achievement. The median OS for patients with FLT3-ITD and no MLL rearrangement failed and most of them received HDAC. Forty-nine patients received an ASCT and 21 relapsed, 9 of them were rescued with an allo-SCT.

Summary/Conclusions: The FLT3-ITD mutation did not increase overall survival (OS) (1 year OS AZA 43% vs 41% p=0.32) as previously reported (Blood 2016 Abstract No 1065). The mean number of mutations per patient in the 250 genotyped patients was 3.4. The prevalence of mutations in CDKN2A (p=0.0001), IDH1 (p=0.004) and TP53 (p=0.003) was neither correlated with survival nor with treatment. No adverse effect of the mutation was observed for the incidence adjusted for all clinical variables mutations in CDKN2A, IDH1 and TP53 remained predictive of decreased OS. No mutations were associated with improved OS. The presence of ASXL1 (p=0.035) and ET3V (p=0.033) mutations were found to be associated with a reduced duration of response. ABA based therapy had no significant impact on LSC numbers in patients who failed to achieve a CR. LSC numbers were reduced but not eradicated in patients achieving a CR and observed to expand at relapse.

S792 SORAFENIB MAINTENANCE IN FLT3-ITD MUTATED ACUTE MYELOID LEUKEMIA AFTER ALLOGENEIC STEM CELL TRANSPLANT
S. Ahmed1, R. Saibila1, G. Rondon1, A. Alousi1, Q. Bashiri2, S. Ciurea3, K. Atrash1, K. Patel1, A. Olson1, D. Marin1, K. Rezvani1, P. Kebria1, U. Popat1, A. Shah1, R. Camplin1, B. Oran1,1Stem cell transplant and cellular therapy, 2Hematopathology, University of Texas, MD Anderson Cancer Center, Houston, United States

Background: The fms-like tyrosine kinase 3 internal tandem duplication (FLT3-ITD) mutation is a genetic alteration found in approximately 30% of patients with acute myeloid leukemia (AML). Although allogeneic hematopoietic stem cell transplantation (HCT) is the gold standard for patients with FLT3-ITD AML and achieves remission rates similar to those with FLT3 wildtype status with induction chemotherapy regimens; patients with FLT3-ITD have significantly shorter remission durations and increased rates of relapse. Even though allogeneic SCT improves outcomes, patients still have higher rates of relapse compared with patients with FAB prognosis AML. Sorafenib (SFB) is a TKI with activity against RAF, VEGF and FLT3-ITD and its use as maintenance therapy after allogeneic SCT has been shown as a promising approach to decrease relapse. Several studies report that SFB maintenance post SCT provides durable complete responses; however, there are also descriptions of sorafenib post SCT triggering acute GVHD, cytopenia, rash and other adverse events.

Aims: To assess the outcomes, including progression free survival (PFS) and overall survival (OS), in patients with FLT3-ITD mutated AML who receive SFB maintenance after allogeneic SCT.

Methods: We analyzed adult patients (age≥18) with a diagnosis of FLT3-ITD mutated AML leukemia in an AML registry. Although there were no AML to achieve remission rates similar to those with FLT3 wildtype status with induction chemotherapy regimens; patients with FLT3-ITD have significantly shorter remission durations and increased rates of relapse. Even though allogeneic SCT improves outcomes, patients still have higher rates of relapse compared with patients with FAB prognosis AML. Sorafenib (SFB) is a TKI with activity against RAF, VEGF and FLT3-ITD and its use as maintenance therapy after allogeneic SCT has been shown as a promising approach to decrease relapse. Several studies report that SFB maintenance post SCT provides durable complete responses; however, there are also descriptions of sorafenib post SCT triggering acute GVHD, cytopenia, rash and other adverse events.

Aims: To assess the outcomes, including progression free survival (PFS) and overall survival (OS), in patients with FLT3-ITD mutated AML who receive SFB maintenance after allogeneic SCT.

Methods: We analyzed adult patients (age≥18) with a diagnosis of FLT3-ITD mutated AML leukemia in an AML registry. Although there were no AML to achieve remission rates similar to those with FLT3 wildtype status with induction chemotherapy regimens; patients with FLT3-ITD have significantly shorter remission durations and increased rates of relapse. Even though allogeneic SCT improves outcomes, patients still have higher rates of relapse compared with patients with FAB prognosis AML. Sorafenib (SFB) is a TKI with activity against RAF, VEGF and FLT3-ITD and its use as maintenance therapy after allogeneic SCT.
characteristics were comparable between groups as presented in Figure 1. Patients were classified by the European Leukemia Net (ELN) classification and 23% in both groups were categorized as adverse risk while 77% were intermediate risk. All patients received myeloablative conditioning and diseases status at SCT was first/second complete remission (CR1/2) with or without count recovery (CRp). In 69% was active disease in 31%. PFS at 24 months post SCT was 82% in the maintenance and 45% in control group. HSCT: 0.3; 95% CI (0.1-1.3) p=0.1. Overall survival at 24 months was also higher in SFB cases as 100% compared with 60% in control group p=0.035. Only, 2 patients relapsed post SCT on SFB maintenance, one with new TP53 mutation at relapse, and other received only <30 days of SFB. However, more than half the patients had disease progression within the control period. The most commonly administered dose was 400 mg daily (5 patients) for 28 days cycle; only 2 patients tolerated higher doses and 6 patients received SFB as 300mg daily or less. There were delays in subsequent cycles in 10 of 12 patients, and the most common reasons for delays included cytopenias, liver function test abnormalities, and fatigue.

**Figure 1.**

**Summary/Conclusions:** Sorafenib maintenance is safe and can produce long term durable remissions after allogeneic stem cell transplant in a high risk population with FLT3-ITD mutated AML.

**S793**

**A PHASE 1B STUDY OF THE COMBINATION OF VADASTUXIMAB TALIRINE AND 7+3 INDUCTION THERAPY FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA**

1Baylor University Medical Center, Dallas, TX, 2Gehr Family Center for Leukemia Research - City of Hope, Duarte, CA, 3Ohio State University Comprehensive Cancer Center, Columbus, OH, 4Colorado Blood Cancer Institute, Denver, CO, 5Cleveland Clinic, Cleveland, OH, 6Massachusetts General Hospital, Boston, MA, 7John Theurer Cancer Center, Hackensack, NJ, 8Fred Hutchinson Cancer Research Center, Seattle, WA, 9Loyola University Medical Center, Maywood, IL, 10Karmanos Cancer Institute, Detroit, MI, 11Sarah Cannon Research Institute, Nashville, TN, 12University of Washington Medical Center, Seattle, WA, 13MD Anderson Cancer Center, Houston, TX, 14Seattle Genetics, Inc., Bothell, WA, 15University of Alabama-Birmingham, Birmingham, AL, United States

**Background:** For patients <65 yrs with newly diagnosed AML, standard induction treatment is continuous infusion of cytarabine for 7 days and an anthracycline for 3 days (7+3). Although a high percentage of patients achieve a CR by morphologic criteria, some requiring a 2nd induction, many are resistant to treatment or achieve a morphologic CR with evidence of minimal residual disease (MRD). Vadastuximab talirine (SGN-CD33A; 33A) is a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine dimer. Combining 33A with 7+3 could result in enhanced and deeper (MRD negative) remissions, resulting in reduced relapse rates and improved OS.

**Aims:** This phase 1b study (NCT02326584) evaluated the safety and antileukemic activity of escalating doses of 33A on 2 schedules: split dose (D1 and 4) or single dose (D1) with 7+3 induction therapy (cytarabine 100 mg/m2 and daunorubicin 60 mg/m2).

**Methods:** AML patients must be eligible for induction therapy. Response assessments occur on D15 and 28. Second induction and post-remission therapies were per investigator choice and did not include additional 33A. MRD was assessed centrally by bone marrow exam by a multiparametric flow at D15 and D28.

**Results:** Split-dose cohort: 42 patients (median age 45.5 yrs [range, 18-65]) were treated with 33A on D1 and D4 (10 [n=4] or 20 [n=38] mcg/kg) with 7+3. Most patients had intermediate (50%) or adverse (36%) cytogenetic risk. 19% had secondary AML. 2 patients had hematologic DLTs (lack of recovery of platelets [25K] and/or ANC [500] by D42) and 20+10 mcg/kg was determined to be MTD. The median count recovery from D1 of therapy in patients who achieved CR/CRi was 4.9 wks for ANC (≥1K) and 5.1 wks for platelets (≥100K). No non-hematologic TEAEs ≥G3 were reported in >10% of patients; non-hematologic TEAEs of any grade occurring in ≥25% of patients were nau-sea (62%), diarrhea, and constipation (38% each). Of the 42 efficacy evaluable (EE) patients, best responses included 25 CR (60%), 7 CRi (17%), and 5 morphologic leukemia-free state (mLFS; 12%) with a CR+CRi (CRc) rate of 76%; 23 of 25 (94%) responses were achieved in the 1st cycle. Of the patients with blast clearance (CR+CRi+mLFS), 73% (27/37) achieved MRD negative status. Single-dose cohort: To date, 25 patients (median age 58 yrs [range, 38-65]) were treated with 33A on D1 only (30 [n=14] or 40 [n=11] mcg/kg) with 7+3. Patients had intermediate (48%) or adverse (36%) cytogenetic risk. 16% had secondary AML. The median time to count recovery from D1 of therapy was 4.1 wks for ANC (≥1K) and 5.9 wks for platelets (≥100K) in patients who achieved CR/CRi. Four patients had hematologic DLTs, 1 at 30 and 3 at 40 mcg/kg. Non-hematologic TEAEs were consistent with those seen in the D1 and 4 schedule. Of the 24 EE patients, best responses included 12 CR (50%), 6 CRi (25%), and 3 mLFS (13%) with a CRc rate of 75%, achieved in 1st cycle. Of the evaluable patients with blast clearance, 89% (17/19) achieved MRD negative status. The CRc rate at the 40 mcg/kg dose level was 91% (10/11); all 11 patients had blast clearance and 90% (9/10) of evaluable patients achieved MRD negative status. Across schedules (N=67), the CRc rate was 76%; 79% (44/56) of evaluable patients with blast clearance achieved MRD negativity. The 30- and 60-day mortality rates were 1% and 7%, respectively. Median OS is not reached for either schedule and 52 patients (78%) were alive at the time of analysis.

**Summary/Conclusions:** 33A can be safely combined with 7+3 with acceptable count recovery in this population at the doses and schedules studied. Extramedullary AEIs, including hepatotoxicity, and induction mortality rates were similar to reported rates for 7+3 alone in this AML population. A high remission rate with the 1st induction cycle was observed, the majority of which were MRD negative.

**21-COLOR FLOW CYTOMETRY REVEALS IMMUNOPHENOTYPES ASSOCIATED WITH RESPONSE IN ACUTE GRAFT-VERSUS-HOST DISEASE PATIENTS TREATED WITH THE JANUS KINASE INHIBITOR INCB039110**

K. Staser1,2, J. Choi1, J. Khoury2, M. Jagasia3, H. Alf4, G. Schiller5, M. Arbushites6, P. Delaite7, Y. Yan8, K. Rhein9, Y-B. Chen9, M.-A. Perales10, L. Gehrs1, J. Ritchey1, J. DiPersio1, M. Schroeder1

1Washington University in Saint Louis, Saint Louis, 2Emory University School of Medicine, Atlanta, 3Vanderbilt-Ingram Cancer Center, Nashville, 4City of Hope, Duarte, 5David Geffen School of Medicine at UCLA, Los Angeles, 6Incyte Corporation, Wilmington, 7Massachusetts General Hospital, Boston, 8Memorial Sloan Kettering Cancer Center, New York City, United States

**Background:** Although ~50% aGVHD patients respond to steroids, no consensus second-line treatment exists. Recent preclinical models, retrospective studies, and this prospective trial have demonstrated safety and efficacy of JAK inhibitors (e.g. ruxolitinib, INCB039110) in steroid-refractory aGVHD.

**Aims:** Here, we present 21-marker FACS analysis of blood from patients enrolled in a prospective, randomized, parallel-cohort, open-label phase 1 trial of the potent and selective JAK1 inhibitor INCB039110 for aGVHD (NCT02614612). Preliminary results were previously presented at ASH 2016 (Schroeder et al).

**Methods:** Patients (n=30) were >18 years old undergoing first alloSCT from any source with steroid-refractory or treatment-naive grades IIb-IVa aGVHD, randomized 1:1 to 200 or 300 mg oral daily INCB039110 combined with corticosteroids. Peripheral blood, obtained at treatment days 7, 14, 28, 56, 100, and 180, was analyzed by 21-color FACS quantifying >30 cell types, including B, CD4+ and CD8+ T, memory T, regulatory (Treg), Th1, Th2, Th17, T follicular helper (Thf), Th1, Th17, T follicular helper (Thf), Th9, Th22, ThYM-CSF cells, granulocytes, monocytes, myeloid-derived suppressor cells (MDSCs), natural killer (NKs), and monocytes and plasmacytoid dendritic cells (DCs). Patients were stratified by treatment response (e.g. complete response (CR), partial response (PR), mixed response (MR)).

**Results:** During INCB039110 treatment, overall B, T, and myeloid proportions did not correlate with response. However, the CR group increased native NCs (CD3-CD20-CD24-HLADR-CD56+), mDCs (CD3-CD20-CD14-HLADR+CD11c+), and memory CD4+ T cells (CD3+CD4+CD45RA-RA). Among CD4+ memory cells, the CR group showed significant or trend-toward-significant increases in Tfh (CCR10-CXCR5+), Th1 (CXCR5-CXCR6-CXCR10- CXCR3+), Th2, Th17 (CXCR5-CXCR6+CXCR4+CXCR3-CXCR10-), ThGM-CSF (CXCR5-CXCR6-CXCR10-CXCR3+), and Th22 (CXCR5-CXCR6+CXCR4+CXCR3 CXCR10+). Tregs (CD4+CD25+CD127-) trended toward a ~2-fold increase in the CR group. Within the monocyte subgroup (CD3-CD20-CD14+), the CR group skewed toward classical monocytes (HLADR+CD16+) (84.7% vs 38.0%, CR vs PR/MR, p=0.0078) and away from MDSCs (HLADR-CD16+) (30.0% vs 58.4%, CR vs PR/MR, p=0.0139) during treatment. Interestingly, the NK-to-MDSC ratio was a sensitive and specific predictor of CR vs KR (95% CI, 19-39%) than in non-colonized patients (14%, 95% CI, 7-23%) (p=0.04). Moreover, MRD-GNB colonized patients had significantly more gas- tric GVHD (GI) GVHD CI as opposed to non-colonized patients (28% (95% CI, 20-41%) vs 14% (95% CI, 7-23%), p=0.02) and more acute GVHD-related mortality (16% (95% CI, 9-26%) vs 7% (95% CI, 3-15%), p=0.10). A substantial and independent role of gut colonization with MDR-GNB on the development of GI GVHD was confirmed by multivariate analysis using time-dependent covariate functions for high risk disease, myeloablative conditioning, peripheral blood stem cells, unrelated donor (hazard ratio 2.14; 95% CI, 0.99-4.68, P=0.05), older age (hazard ratio 2.15; 95% CI, 1.04-4.59, P=0.04) and MDR-GNB gut colonization (hazard ratio 2.26;95% CI, 1.05-4.83, P=0.03).

**Summary/Conclusions:** In summary, this report shows a significant role of MDR-GNB in the pathogenesis of severe acute GVHD. To our knowledge, we are the first to show that gut colonization with MDR-GNB represents an independent risk factor for GI GVHD. With growing resistance and lack of efficient antibiotics, decolonization strategies as fecal microbiota transplantation become an attractive strategy for restoration of healthy gut flora and prevention of severe acute GVHD.

**GUT COLONIZATION BY MULTI-DRUG RESISTANT BACTERIA IS AN INDEPENDENT RISK FACTOR FOR DEVELOPMENT OF INTESTINAL ACUTE GRAFT-VERSUS-HOST DISEASE**

Z. Perc1,2, N. Durakovic-1,2, L. Desnica1, V. Rezo Vranjes1, I. Marekovic1, R. Serventi-Serventi1, J. Blinski2, G. Basak2, R. Vhowan1, R. Varaldo1, S. Bregante1, C. Di Grazia1, S. Aquino1, A. Ibatici1, F. Gualandi1, M.T. Van Lint1, T. Lamparelli1, A. Risitano3, A. Bacigalupo4, E. Angelucci1

1Hematology, University Hospital Centre Zagreb, 2School of Medicine, University of Zagreb, 3Department of Microbiology, University Hospital Centre Zagreb, Zagreb, Croatia, 4Hematology, Medical University of Warsaw, Warsaw, Poland

**Background:** Research has recently highlighted the importance of healthy gut microbiota in the prevention of graft-versus-host disease (GVHD). Gut decontamination and the use of broad-spectrum antibiotics have led to the loss of natural microbiota diversity and the overgrowth of opportunistic pathogens with emerging antimicrobial resistance. However, the role of multi-drug resistant by MRSA in the development of acute GVHD is not well established.

**Aims:** Our aim was to evaluate the impact of gut colonization with MDR bacteria on the acute GVHD and related outcome.

**Methods:** Retrospectively we evaluated 145 adult patients who consecutively underwent allogeneic stem cell transplantation (allo-SCT) in our institution between 2011 and 2014. All patients were weekly screened by cultivating stool specimens for gut colonization by the following MDR bacteria: vancomycin-resistant Enterococcus (VRE), methicillin-resistant Staphylococcus aureus (MRSA) and multidrug-resistant Gram-negative bacilli (MDR-GNB). Univariate and multivariable proportional hazards models using the Fine and Gray model were considered to evaluate the variables for acute GVHD, treating death as competing event.

**Results:** Our study population included 88 male and 57 female patients who underwent allo-SCT at a median age of 46 years (range 18-64). Among them, most patients were treated for myeloid malignancies (70%), while the rest had lymphoproliferative disorders and one patient had aplastic anemia. The donors were unrelated in 74 cases, related in 67 patients and haploidentical in 4 patients. Most of the patients (70%) received peripheral blood stem cells after a reduced-intensity conditioning regimen (56%). At the time of allo-SCT 37% patients were colonized with MDR bacteria, while another 19% became colonized in the early posttransplantation period. Among colonized patients, 12% patients were colonized by VRE, 1% by MRSA, 43% by extended-spectrum β-lactamase (ESBL)-producing Enterobacteriaceae, 27% by carbapenem-resistant Enterobacteriaceae (CRE), 9% by MDR Acinetobacter baumannii and 50% by MDR-GNB. Univariate analysis of GI GVHD was confirmed by multivariate analysis using time-dependent covariate functions for high risk disease, myeloablative conditioning, peripheral blood stem cells, unrelated donor (hazard ratio 2.14; 95% CI, 0.99-4.68, P=0.05), older age (hazard ratio 2.15; 95% CI, 1.04-4.59, P=0.04) and MDR-GNB gut colonization (hazard ratio 2.26;95% CI, 1.05-4.83, P=0.03).

**Summary/Conclusions:** In our study, the first to show that gut colonization with MDR-GNB represents an independent risk factor for GI GVHD. With growing resistance and lack of efficient antibiotics, decolonization strategies as fecal microbiota transplantation become an attractive strategy for restoration of healthy gut flora and prevention of severe acute GVHD.
Aims: The goal of this study was to retrospectively compare the outcome of allogeneic SCT using CyTBI or VepTBI as conditioning.

Methods: Adult patients with Ph-negative ALL (n=1498) treated with alloHCT from either HLA-identical sibling (n=696) or unrelated donor (n=802), in CR1 (n=1186) or CR2 (n=312), between year 2000 – 2015, were included in the analysis. Peripheral blood was used as a source of stem cells in 62% of the cases. Conditioning was myeloablative in all cases (the median TBI dose was 12 Gy); 1346 patients were treated with CyTBI while 152 patients with VepTBI. Patients in the VepTBI group were younger (median 28 y. vs 30 y., p<0.04) treated in more recent median year of HCT (2007 vs 2009, p<0.009) and treated more frequently in CR1 (87% vs 78%, p<0.01).

Results: In a univariate analysis, as compared to CyTBI, the use of VepTBI was associated with significantly reduced incidence of relapse (17% vs 30% at 5 years, p=0.007), increased leukemia-free survival (LFS, 60% vs 50%, p=0.04) as well as improved “GVHD and relapse-free survival” (GRFS, 43% vs 33%, respectively). A significant effect could be observed in terms of the incidence of non-relapse mortality, acute or chronic GVHD. In a multivariate model the use of VepTBI was associated with reduced risk of relapse (HR=0.62, p=0.04) while the effect on other study end-points was no longer significant. Among other factors, recipient age (HR=1.17 per every 10 years, p=0.0001), year of alloHCT (HR=0.97 per every year, p=0.001) and disease stage (HR=2.14 for CR2, p<0.0001) had significant influence on the risk of treatment failure, either relapse or non-relapse mortality. The risk of relapse was additionally increased for sibiling vs unrelated donor transplants (HR=1.47, p=0.01) and donor/recipient gender combination other than female/male (HR=1.6, p=0.04).

Summary/Conclusions: Conditioning regimen based on etoposide combined with TBI appears more effective than the cyclophosphamide TBI combination for adult patients with Ph-negative ALL treated with alloHCT. Further, prospective studies are needed to confirm our observation and potentially discriminate subgroup of patients who are most likely to benefit from the use of etoposide.

S797 CYCLOPHOSPHAMIDE VERSUS ETOPOSIDE IN COMBINATION WITH TOTAL BODY IRRADIATION AS CONDITIONING FOR ADULTS WITH PH(-) ALLO UNDERGOING ALLO-HCT. A STUDY FROM THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

S. Giebel1, M. Labopin2,3, G. Socie4, J. Pavlu5, L. Volin6, P. Remenyi7, S. Giebel1,*, M. Labopin 2,3, G. Socie 4, J. Pavlu 5, L. Volin 6, P. Remenyi7, LEUKEMIA WORKING PARTY OF THE EBMT

Total body irradiation (TBI)-based over chemotherapy-based regimens. TBI is most frequently administered in combination with either cyclophosphamide (CyTBI) or etoposide (VepTBI).

Methods: All haploplants performed in two Italian institutions from August 2010 to July 2016 (n = 318) were included. All patients received a myeloablative regimen (MA) followed by unmanipulated bone marrow and high dose post-transplant cyclophosphamide (PT-CY), combined with cyclophosphamide and melphalan. Donors and recipients were typed, until 2015, using DNA method (SSO and SBT) for HLA A, B, C, DRB1, DQ and DBP at a high resolution level, as defined by EFL standards and by NGS at allelic level in 2016 for the same loci. When applicable (72.3% of patients) members of the immediate family who typed to definitively establish HLA genotype and haplotype identity. Differences in Cy/TBI vs Vep/TBI were calculated in terms of HLA incompatibility (±4) and myelodysplastic syndrome (33%). 144 patients (45%) were transplanted in advanced phase of disease. With a median follow up of 562 days (range 6-2241 days), 2-year OS was 55.7%. Concerning the proportion of “true” haploidential D/R pairs, 231 out of 318 (72%) couples showed 4/8 mismatches at HLA-A, B, C, DRB1 and HLA DRB1 loci. Neither OS nor NRM showed significant correlation with the degree of overall mismatches at 2 years (0:2-mm:54.2%, vs 3-4-mm:58.8%, p=0.58 and 0-2-mm:18.2% vs 3-4-mm:19.1%, p=0.93, respectively). Considering only GVH directed mismatches, no difference was highlighted between low or high HLA mismatch burden in cumulative incidence of aGVHD (12.6% vs 14.8%, p=0.13), cGVHD at 1 year (12.2% vs 14.8%, p=0.84) and relapse (33.3% vs 24%, p=0.26). In this series, graft rejection rate was 6.6%; no correlation was observed with the amount of HLA mismatch in the HSVG direction.

Summary/Conclusions: In this series, about one third of haploidential donor/recipient pairs differ for less than 4 /8 HLA antigens. Furthermore, in the setting of a MA conditioning with PT-CY the real degree of HLA mismatch observed had no impact on OS, NRM, CI of Relapse and acute and chronic GVHD.

Background: High-risk acute meydloid leukemia (AML) is mainly defined by the presence of determined poor-risk cytogenetic abnormalities and is a standard indication for allogeneic stem cell transplantation (SCT). Nevertheless, high-risk AML is a very heterogeneous group including several subtypes with different levels of prognostic impact. Deletion 5q or monosomy 5 (5q-) has been part of the high-risk group of AML for many years. SCT seems to improve their outcomes but the additive effects of other high-risk cytogenetic features on survival have never been thoroughly studied.

Aims: To evaluate the role of SCT in 5q- AML with additional cytogenetic abnormalities such as complex karyotype (CK), monosomal karyotype (MK), monosomy 7 (-7), or 17p abnormalities (abn(17p)).

Patients, who included adults and children, with 5q- reported to the EBMT registry as having their first SCT between 2000 and 2015.

Results: Five hundred and one pts, 21% of them with secondary AML, have been included. Median age at SCT was 55 year-old (range, 18-75) and median follow-up was 21 months (range, 2-173). At time of SCT, 338 pts (67%) were in first remission (CR1), 21 pts (6%) were in subsequent remission and 142 pts (28%) had active disease. Two hundred seventy-seven pts (55%) were transplanted from an unrelated donor (UD) and 224 from a sibling donor. A myeloablative conditioning (MAC) was administered in 45% of the pts and a reduced-intensity conditioning (RIC) in 55% of them. The 2-year probabilities of treatment failure, either relapse or non-relapse mortality was 20%. The cumulative incidence of grade II-IV acute graft-versus-host disease (GVHD) was 29% and the 2-year cumulative incidence of chronic GVHD was 50%.
Summary/Conclusions: SCT in -5q/-5q-AML provides a durable response for approximately 20% of pts. Active disease at time of transplantation was the most powerful predictor of an inferior outcome. The presence of -5q/-5q- without CK, MK or abn(17p) was associated with a significant better survival and the addition of MK or abn(17p) translated into worse outcomes. We confirmed the deleterious effect of the combination of -5q/-5q- and abn(17p) on SCT outcome. Future efforts should be focused on this subgroup in order to improve the deleterious effect of the combination of -5q/-5q- and abn(17p) on SCT outcome. Future efforts should be focused on this subgroup in order to improve the deleterious effect of the combination of -5q/-5q- and abn(17p) on SCT outcome.

Future efforts should be focused on this subgroup in order to improve the deleterious effect of the combination of -5q/-5q- and abn(17p) on SCT outcome. Future efforts should be focused on this subgroup in order to improve the deleterious effect of the combination of -5q/-5q- and abn(17p) on SCT outcome. Future efforts should be focused on this subgroup in order to improve the deleterious effect of the combination of -5q/-5q- and abn(17p) on SCT outcome. Future efforts should be focused on this subgroup in order to improve the deleterious effect of the combination of -5q/-5q- and abn(17p) on SCT outcome. Future efforts should be focused on this subgroup in order to improve the deleterious effect of the combination of -5q/-5q- and abn(17p) on SCT outcome.
high PU.1 expression without fusions showed extremely poor prognosis, suggesting the prognostic value of aberrant PU.1 expression in pediatric T-ALL. Although it remains unclear, why cases with PU.1 fusions/high PU.1 expression have a poor prognosis, our results indicate that these cases are genetically distinct subgroup from other pediatric T-ALL.

S801
MULTICENTER VALIDATION OF STANDARDIZED NGS ASSAYS FOR REARRANGED IG/TR MARKER DETECTION IN ACUTE LYMPHOCYTIC LEUKEMIA – A REPORT OF THE EUROCLONALITY-NGS CONSORTIUM
M. Brüggemann1, H. Knecht1, M. Kotrova2,1, J. Bartram3, V. Bystrý1, N. Darzentas1, F. Daví1, G. Fazio1, E. Frondova1,2, R. García-Sanz1, M. Giraud1, A. Grioni6, P. J. Groenen9, J. Hancock10, D. Herrmann1, M. Hummel11, A. Lauretti1, A. Guarini1, S. Chiaretti1,*, R. Foà1
1Hematology, Department of Cellular Biotechnology and Hematology, Sapienza University, 2GIMEMA Data Center, Rome, Italy
328 | haematologica | 2017; 102(s2)

Background: The outcome of Ph+ acute lymphoblastic leukemia (Ph+ ALL) has drastically improved since the introduction of tyrosine kinase inhibitors (TKI). At present however, well-defined prognostic markers, beyond the monitoring of minimal residual disease (MRD) during follow-up and to a lesser extent IKZF1 deletions, are lacking.

Aims: To identify genomic lesions of prognostic value, we evaluated copy number aberrations (CNA) by SNP arrays, confirmed them by multiplex ligation-dependent probe amplification (MLPA) and we set up a droplet digital PCR (ddPCR) assays for additional lesions. Furthermore, we correlated the lesions identified with MRD monitoring, outcome and biological features, such as type of fusion protein (p190 or p210). Finally, in a subset of patients gene expression profiling (GEP) was carried out.

Methods: Genomic DNA of 116 newly diagnosed adult Ph+ ALL patients enrolled in 4 consecutive GIMEMA trials, namely 021B1, 0904, 1205 and 1509, was evaluated. All the trials were based on an induction with steroids and TKI, the first 2 with imatinib and the remaining with dasatinib. For CNA, the Cytoscan HD Arrays (Affymetrix, Santa Clara, CA) were used. The lesions were confirmed by MLPA on all samples using the Salsa MLPA P335-A3 ALL-IKZF1 kit (MRC-Holland, Amsterdam, The Netherlands). ddPCR was used to validate lesions targeting MEF2C. In 42 cases, GEP experiments were performed using the HGU133 Plus 2.0 gene chips (Affymetrix, Santa Clara, CA).

Results: We found a similar load and type of lesions across the 4 trials, one of which included elderly. The majority of lesions targeted IKZF1 (84%), PAX5 (36%) and CDKN2A/B (32%). In our cohort, IKZF1 deletions alone did not affect complete MRD monitoring (CMR) achievement, whereas BM-complete MRD-free-survival (MRD-FS) was significantly better for patients harboring CDKN2A/B and PAX5 deletions had a significant inferior outcome (p=0.004, p=0.003 respectively). In line with this, a worse DFS was observed for the so-called "IKZF1 plus" cases, i.e. concomitant deletions of IKZF1 and CDKN2A/B and/or PAX5 (46% vs 24% at 36 months, p=0.005). MLPA confirmed the incidence of these deletions and allowed the study of IKZF1 isoforms. Among IKZF1 deleted cases, patients carrying the Δ4-7 isoform (25%) had a worse DFS (p=0.02) than patients harboring other IKZF1 isoforms. Importantly, SNP arrays highlighted novel genomic lesions targeting MEF2C in 13% of cases, which were associated to the achievement of a CMR (p=0.05) and had a significant impact on DFS (62% vs 32% at 36 months, p=0.02). The association with CMR was not affected by the trial (p=0.76) or the TKI used (p=0.57). This result was confirmed by ddPCR. Unsupervised hierarchical clustering of GEP experiments identified 3 subgroups: the first comprised mainly patients who reached a CMR, the second the one patients who had IKZF1 alone, and the last one comprised "IKZF1 plus" patients. This analysis allowed an overexpression of genes involved in cell communication and protein modification process in PAX5 deleted cases, suggesting that these genes could be contributing factors in BCR/ABL1 driven leukemogenesis.

Summary/Conclusions: In adult Ph+ ALL, IKZF1 deletions have a prognostic impact which is similar to other lesions. Among IKZF1 deletions, only the Δ4-7 deletion has a deleterious effect. MEF2C lesions carry prognostic implications, being significantly associated with a better prognosis. This study paves the way to design a prognostic model for adult Ph+ ALL that includes these findings and more conventional features, in order to better stratify patients at diagnosis and to further optimize treatment.

POST-INDUCTION MRD PREDICTS HIGH RELAPSE RISK FOLLOWING REDUCED INTENSITY CONDITIONED ALLOGENIC STEM CELL TRANSPLANTATION: A RETROSPECTIVE STUDY OF ADULT ALL (UKALL14.ISRCTN 66541317)
1) Cancer Institute, UCL, London, United Kingdom, 2)Cancer Centre, University Hospital of Alexandria, Egypt, 3)Cancer Trial Centre, Barts Cancer Institute, QMUL, London, 4)Royal Hallamshire Hospital, Sheffield, 5)University Hospitals Bristol NHS Trust, Bristol, 6)Department of Haematology, Cancer Institute, UCL, London, United Kingdom

Background: Amplification-based next generation sequencing (NGS) of immunoglobulin (IG) and T-cell receptor (TR) gene rearrangements can be used to identify suitable markers for subsequent quantification of minimal residual disease (MRD) in acute lymphoblastic leukemia (ALL). Within the EuroClonality-NGS Consortium we established and validated a standardized quality controlled amplicon-based NGS application to detect clonally rearranged IG, IGK, TRB, TRG and TRD genes in lymphoid disorders. As a proof of principle we used EuroClonality-NGS to assess MRD within an international multi-laboratory pilot for their suitability to identify clonal markers in ALL at diagnosis, and to compare these NGS results with conventional Sanger sequenc-
Background: Reduced intensity conditioned allogeneic haematopoietic stem cell transplant (RICalloHCT) enables HCT to be performed in older patients. The UK NCRI UKALL14 study of adult acute lymphoblastic leukaemia (ALL) considers patients ≥41 years “high risk” and recommends a RICalloHCT where there are high quality donors. Other “high risk” factors are high WBC at presentation, t(9;22), t(4,11), hypodiploidy/near triploidy, complex karyotype and positive minimal residual disease (MRD) after completing induction therapy. The presence of MRD at this time-point predicts poor outcome after conventional chemotherapy. There is evidence that myeloablation alloHCT can overcome this risk, but the benefit of RICalloHCT is uncertain.

Aims: To determine whether RICalloHCT mitigates the high relapse risk predicted by MRD positivity after induction therapy.

Methods: Protocol treatment: patients receive a steroid pre-phase before 2 cycles of induction chemotherapy. At the end of induction, patients are assigned subsequent therapy on the basis of risk. All patients over 41 years are allocated RICalloHCT, conditioned with fludarabine, melphalan and alemtuzumab. Post HCT, escalating doses of donor lymphocyte infusions were given for T-cell mixed chimerism +/- MRD persistence or relapse. MRD assessment: BCR/ABL1 or Ig/TCR MRD was assessed and analysed per EuroMRD guidelines. MRD is negative (undetectable with an assay quantitative range of 1x10^-6 or less), positive (1x10^-6-1), positive outside quantitative range (POQR)<1x10^-4 or indeterminate (undetectable but assay quantitative range ≥5x10^-4). Patients with indeterminate MRD were excluded from this analysis.

Results: There are 736 patients randomised to date, of whom 184 received a RICalloHCT, of these, 115 had analysable MRD. The following Table 1 shows patient characteristics.

</table>

At 2 years post transplant, overall survival (OS) was 63.1% in the 115 patients with evaluable MRD and 62.7% in the 184 patients receiving RICalloHCT; event free survival (EFS) was 55.2% and 58.9% respectively. By contrast, in the 38 of 115 patients with positive MRD after induction, OS and EFS were 40.6% and 28.4% respectively. Twenty eight of the 115 patients relapsed, with a 2 year actuarial relapse risk of 31.5% (22.2-43.5). We assessed the association of the following factors: age, sex, immunophenotype, presenting WBC, BCR/ABL1, other cytogenetics, post-induction MRD and donor type with the risk of relapse. Among this population of high risk patients, post-induction MRD was the only independent prognostic factor for relapse (univariable HR: 3.82 (1.59-9.16), p = 0.001 (see Figure 1) and multivariable HR: 4.14 (1.61-10.65), p = 0.003). The relapse rate of the MRD+ patients was 57.2% at 2 years post HCT.

Summary/Conclusions: The 2-year OS of 62.5% in UKALL14 participants over 41 yrs would not be expected with chemotherapy alone. However, MRD positivity after induction is associated with significantly lower OS, EFS and a higher risk of relapse, which is not abrogated by RICalloHCT.
Summary/Conclusions: We showed that Blin responders have significantly higher TRB repertoire diversity at scr compared to persisters and that the repertoire expansion during Blin treatment is sharper in responders. Other repertoire characteristics did not differ significantly between groups. Further studies on larger patient cohorts are necessary in order to elucidate whether the response to treatment can be predicted by repertoire diversity at scr.

Amplicon NGS is a useful tool for monitoring of T-cell repertoire. Development, standardization, and validation of TRB primer sets is in progress within EuroClonality-NGS Consortium.

Background: In neutropenic patients with unexplained fever the classical approach is maintaining the empirical antibacterial therapy (EAT) until neutrophil recovery. This strategy may result in unnecessarily prolonged EAT favoring bacterial resistance, organ toxicity and damage to microbiota. Nevertheless, the available scientific evidence supporting the alternative approach of stopping EAT before neutrophile recovery is moderate.

Aims: To investigate if a clinical approach (based on apyrexia and clinical recovery) is better than and as safe as the standard criteria (recovery from neutropenia) to decide the discontinuation of EAT.

Methods: After local Ethical Committee approval, a randomized, controlled, multicenter, open-labeled phase IV clinical trial was performed (EudraCT: 2011-005152-34). Study period: May-2012 to May-2016. Inclusion criteria: a) Adult patients (≥18 years); b) Hematologic malignancy or autologous or allogeneic hematopoietic stem cell transplantation (SCT) recipients; c) High risk febrile neutropenia (FN) d) Informed consent signed. Exclusion criteria: etiological diagnosis of FN. Patients were randomized 72 hours after fever onset to: 1. Experimental group (EG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h (independently of neutrophil count) or 2. Control group (CG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h, plus c) >0.5x106/L neutrophils. Follow-up: 28 days from EAT. Primary (efficacy) end-point was number of EAT-free days. Secondary (safety) end-points were total days of fever and crude mortality.

Results: One hundred and fifty seven patients were included (EG 78 and CG 79). There were no differences in baseline characteristics or clinical presentation between groups. The most frequent underlying conditions were induction/re-induction chemotherapy for acute leukemia (n=42, 26,7%), autologous SCT (n=42, 45,8%), and allogeneic hematopoietic stem cell transplantation (SCT) recipients; c) High risk febrile neutropenia (FN) d) Informed consent signed. Exclusion criteria: etiological diagnosis of FN. Patients were randomized 72 hours after fever onset to: 1. Experimental group (EG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h (independently of neutrophil count) or 2. Control group (CG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h, plus c) >0.5x106/L neutrophils. Follow-up: 28 days from EAT. Primary (efficacy) end-point was number of EAT-free days. Secondary (safety) end-points were total days of fever and crude mortality.

*ITT: Intention to treat; EAT: empirical antibacterial therapy; EG: experimental group; CG: control group; IQ range: interquartile range; *EAT: EAT-free days of follow-up (28) - days of EAT.

In Table 1. Initial fever frequency was 14,3% (EG) and 17,9% (CG) (p=ns) and crude mortality was 1,3% (EG) and 3,8% (CG) (p=ns).
Summary/Conclusions: In hematological patients with febrile neutropenia of unknown origin the discontinuation of empirical antibacterial therapy after 72 hours of apyrexia and clinical recovery regardless of neutrophils count is safe and reduces unnecessary exposure to antibiotics.

S805
CONJUGATED PNEUMOCOCCAL VACCINE TRIGGERS A BETTER IMMUNE RESPONSE THAN POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA A RANDOMIZED STUDY BY THE SWEDISH CLL GROUP

1Section of Heamatology, Institution of Medical Sciences, Uppsala, 2Department of Medical Sciences, Orebro University Hospital, Orebro, 3Falun Hospital, Falun, 4Institute of Clinical Sciences, Faculty of Medicine, Lund University Hospital, Lund, 5Hematology and Coagulation Section, Sahlgrenska University Hospital, Göteborg, 6Eskilstuna University, Eskilstuna, 7Karlstad Hospital, Karlstad, 8Section of Haematology, Institute of Medical Sciences, Uppsala, 9Department of Medicine, Unit of Hematology, Karolinska Institute and University Hospital, Huddinge, Sweden

Background: Patients with CLL have an increased risk for infection and Streptococcus pneumoniae is one of the most common pathogens with high morbidity. Patients with CLL are known to respond poorly to the traditionally used polysaccharide vaccines. Conjugation of polysaccharide to protein carriers renders a thymus-dependent, memory-inducing and more immunogenic vaccine. In patients with CLL, there is no consensus on a recommendation for pneumococcal vaccination, due to a lack of comparative studies.

Aims: To determine if patients with untreated chronic lymphocytic leukemia (CLL) benefit from vaccination with a 13-valent conjugated pneumococcal vaccine (PCV13), Prevenar13®, compared with a 23-valent capsular polysaccharide (PPSV23), Pneumovax®, in terms of immune response.

Methods: 128 treatment naïve CLL patients from eight hematology clinics in Sweden were randomized to vaccination with PCV13 (n=63) or PPSV23 (n=65) after stratification by IgG levels and CLL clinical stage (Rai). Blood samples for evaluation of immune response were obtained at baseline, at one and at six months after vaccination. Analyses for each of the 12 pneumococcal serotypes common for PCV13 and PPSV23 were performed by opsonophagocytic assay (OPA) and enzyme-linked immunosorbent assay (ELISA).

Results: PCV13 elicited a superior immune response than PPSV23 in 10/12 serotypes one month after vaccination and in 5/12 serotypes six months after vaccination, measured as OPA geometric mean titers (GMTs). Geometric mean concentrations of serotype-specific IgG antibodies elicited by PCV13 as measured by ELISA, were higher than those elicited by PPSV23 in half of the common serotypes, both after one and six months. The proportion of patients with good response (defined as response in 8 of 12 common serotypes according to predefined response criteria) was higher in PCV13 recipients than in PPSV23 recipients after one month (40% vs 22%, p=0.034) as well as after six months (33% vs 17%, p=0.041). Never did PPSV23 trigger a better immune response for any of the serotypes, than PCV13, regardless of analysis. For two of the serotypes, OPA GMTs were lower with the six months than at the one-month follow up. Negative predictive factors for vaccination response were hypogammaglobulinemia and long disease duration. Both vaccines were well tolerated.

Summary/Conclusions: In patients with previously untreated CLL, the efficacy and immune response is superior to PPSV23 for many serotypes common for the two vaccines. PCV13 should be considered as a part in vaccination programs against Streptococcus pneumoniae for these patients and administered as possible during the course of the disease.

Figure 1.

Summary/Conclusions: This new clinic-biological score based on age, CMV serostatus and levels of IgA and IgM, may contribute to the prompt identification of patients at higher risk of fatal infections prior to allo-HSCT, thus promoting post-transplant personalized intensive active surveillance strategies and immune-intervention approaches to improve the overall outcome of transplant. A multicentric Italian study in currently on the way for the external validation of these results.

S807
LETTERMOVIR FOR PREVENTION OF CYTOMEGALOVIRUS INFECTION IN ADULT CMV-EROSITIVE RECIPIENTS OF ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

1BMT Programme & Myeloid Leukemia Division, Hospital Universitario Puerta de Hierro, Madrid, Spain, 2Division of Infectious Diseases, Department of Internal Medicine at the University of Pennsylvania, Philadelphia, United States, 3Hematology, Karolinska University Hospital, Stockholm, Sweden, 4Department of Infectious Diseases, Infectious Control & Employee Health, UT MD Anderson Cancer Center, Houston, United States, 5Hematology, Universitaire Ziekenhuizen , Leuven, Belgium, 6Medicine, The Seattle Cancer Center, Seattle, Washington, United States, 7School of Medicine at the University of Pennsylvania, Philadelphia, United States, 8Internal Medicine, Universitätssklinikum Würzburg, Wuerzburg, Germany, 9Vaccine and Infectious Diseases Division, Fred Hutchinson Cancer Research Center, Seattle, 10Late Development Statistics, 11Global Clinical Development - Infectious Disease, Merck & Co., Inc., Kenilworth, United States

Background: CMV remains a common complication of HCT, yet no antiviral drug suitable for prophylaxis is available in HCT. LET is a first-in-class drug
that inhibits the CMV terminase complex. A dose-escalation phase 2 trial showed that LET prophylaxis for up to 12 weeks post-HCT was effective with a safety profile similar to placebo.

**Aims:** To compare LET prophylaxis to placebo for the prevention of clinically significant CMV infection (CS-CMV), defined as CMV disease or CMV viremia leading to preemptive treatment (PET) in a Phase III randomized, double-blind, placebo-controlled trial.

**Methods:** CMV seropositive HCT recipients 18 years or older who had undetectable plasma CMV DNA within 5 days of randomization were eligible (full eligibility at clinicaltrials.gov, NCT02137772). Subjects had to start treatment by Day+28 post-HCT. Subjects were randomized 2:1 to receive LET or placebo P0C, 9%, through Week 14 (Day +100) post-HCT, stratified by study site and high or low CMV disease risk. LET was dosed at 480 mg/d (or 240 mg/d if on cyclosporine due to drug-drug interaction). Subjects were assessed weekly through Week 14, biseweekly through Week 24, and every other month through Week 48 after HCT. Plasma obtained at each visit was assayed for CMV DNA in a central laboratory. Subjects who developed CS-CMV discontinued study drug and received anti-CMV treatment. Local CMV assay results could be used to start PET. The primary endpoint was the stratum-adjusted proportion of subjects with CS-CMV through Week 24 post-HCT among subjects with undetectable CMV DNA at randomization; subjects who discontinued the study for any reason or with missing data at Week 24 were considered failures. All adverse events (AEs) were analyzed through 14 days after the last dose of study drug.

**Results:** From June 2014 to March 2016, 565 randomized subjects received study treatment; 31% were at high CMV disease risk. 50% subjects received myeloablative conditioning, 35% received ATG. Donors included 14% mismatched unrelated, 13% haploidentical and 4% cord blood. Study arms were balanced. Subjects began study drug a median of 9 days post-HCT, 37% had engrafted prior to start. Of 495 treated subjects with undetectable CMV DNA at randomization, fewer subjects developed CS-CMV or were considered failures in the LET arm (122/325, 38%) compared to placebo (103/170, 61%; p<0.0001) by Week 24 post-HCT. Figure 1 shows the time to CS-CMV analysis. The most common AEs (LET, placebo) were GVHD (39%, 39%), diarrhea (26%, 25%), and nausea (27%, 23%). More frequent vomiting (19%, 14%), edema (15%, 9%), atrial arrhythmias (10%, 5%), and ALT levels >5xULN (4%, 2%) was noted in LET-treated subjects; no increased myelotoxicity or nephrotoxicity was observed. The Week 24 all-cause mortality was 10% for LET recipients and 15% for placebo recipients.

**Figure 1.**

**Summary/Conclusions:** Letermovir prophylaxis was effective in reducing clinically significant CMV infection, was overall well tolerated, and provides a new approach to CMV prevention after HCT.

**S808**

EFFICACY AND SAFETY OF DEFIBROTIDE TO TREAT HEPATIC VENO-OCCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME POST-CHEMOTHERAPY: A POST HOC ANALYSIS OF FINAL DATA OF AN EXPANDED-ACCESS PROTOCOL

N. Kernan1, P. Richardson2,*, S. Grupp3, J. Antin4, Y. Messinger5, W. Liang6, R. Ryan7, R. Humel8, W. Tappe4, R. Soiffer9

1Pediatric Bone Marrow Transplantation Service, Memorial Sloan Kettering Cancer Center, New York, 2Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 3Pediatric Oncology, The Children’s Hospital of Philadelphia, Philadelphia, 4Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, 5Children’s Hospitals and Clinics of Minnesota, Minneapolis, 6Jazz Pharmaceuticals, Inc., Palo Alto, 7Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

**Background:** Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT), and VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States. However, VOD/SOS can occur after chemotherapy without HSCT.

**Aims:** To perform a post hoc analysis of final data on safety and response to defibrotide in patients developing VOD/SOS after primary chemotherapy without HSCT.

**Methods:** In an expanded-access protocol for patients with VOD/SOS post-HCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25 mg/kg/d (4 divided doses of 6.25 mg/kg) was given a recommended ≥21 days after patients provided informed consent. Post-chemotherapy subgroup survival was analyzed post hoc from the day defibrotide was started (days 0–30 after start of chemotherapy) for 70 days (because follow-up data were collected for 100 days post-chemotherapy).

**Results:** Of 1154 VOD/SOS patients receiving defibrotide, 137 (12%) developed VOD/SOS post-chemotherapy without HSCT. Among the 82 patients (38 with MOD) treated with DF by day 30 after start of chemotherapy, median age was 7.5 years (range, 0–68 years) and 66 (81%) were pediatric patients ≤16 years of age. Among pediatric patients, 15% were age 0-23 months, 74% were 2-11 years and 11% were 12-16 years. Most common primary diseases were acute lymphocytic leukemia (51%), acute myeloid leukemia (13%), and neuroblastoma (6%). Kaplan-Meier estimated survival at Day +70 was 74% overall (95% CI, 63–82%); 86% (49–79%) in patients with MOD and 81% (66–90%) in patients without MOD. By age subgroup, Kaplan-Meier estimated survival at Day +70 was 80% (95% CI, 68–88%) in pediatric patients (Figure 1) and 50% (95% CI, 25–71%) in adults. Adverse events (AEs) were reported in 54/82 patients (66%). Hemorrhagic AEs (≥2%) were pulmonary (6%), epistaxis or mouth (4%), and hematocrit (2%). There were 22 (27%) patients with AEs assessed as being at least possibly related to defibrotide, the most common (≥2%) were pulmonary or mouth hemorrhage (4% each) and hematocrit, nausea, encephalopathy, epistaxis, or hypotension (2% each). Related AEs led to discontinuation in 6 patients and were associated with 1 death (pulmonary hemorrhage, hypotension).

**Figure 1.**

**Summary/Conclusions:** The 74% survival rate at Day +70 in patients with VOD/SOS receiving defibrotide within 30 days of starting chemotherapy (81% in patients ≤16 years) is clinically encouraging. Of note is the 66% survival rate in patients with MOD. The defibrotide safety profile was consistent with that previously reported in the overall population of this expanded-access protocol.

LACK OF THE FERROPTOSIS INHIBITOR GPX4 IN ERYTHROID CELLS CAUSES A BLOCK IN RETICULOCYTE MATURATION AND A HYPOXIC SIGNATURE WITH IMPAIRED HEPcidIN REGULATION

Background: GPX4 is a selenoprotein belonging to the family of the glutathione peroxidases, a class of enzymes involved in cellular defence against oxidative stress. This enzyme is essential for life since it is the only peroxidase able to use lipid peroxides as substrate. Mice constitutively lacking GPX4 die at embryonic day 6.5 (E6.5) due to a tissue-specific ablation in neurons and T-cells causing neurodegeneration and impaired immune response. Recent studies have identified GPX4 as the main regulator of ferroptosis, an iron-dependent ROS-mediated form of nonapoptotic cell death. Erythrocytes are highly specialized cells that utilize a large amount of iron to bind and deliver oxygen to all tissues. Being constantly exposed to oxygen, erythroid cells need to continuously fight against oxidative stress by expressing a variety of antioxidant enzymes, including GPX4. Iron availability for erythropoiesis depends on systemic iron levels which are regulated via the hepcidin/ferroportin regulatory system. Hepcidin binding to the iron exporter ferroportin reduces systemic iron export regulating body iron levels. In hypoxic conditions the erythroid hormone ErFe suppresses hepcidin synthesis to provide iron for the elevated erythropoietic demand.

Aims: The aim of this study is to identify how the lack of GPX4 in the hematological compartment affects iron homeostasis.

Methods: Lethally irradiated C57BL6 female mice were reconstituted with bone marrow cells from Gpx4fl/fl; Rosa26-CreERT2 or Gpx4wt/wt; Rosa26-CreERT2 and allowed to recover for 8 to 10 weeks. GPx4 deletion in the hematopoietic system was induced by feeding tamoxifen citrate for 3 weeks and blood and organs were drawn at 3 and 6 weeks after terminating the tamoxifen-containing diet. Erythroid cells have been analysed in FACS. Serum iron levels have been assessed using the SFBC and UIBC iron kits (Biolabo). Gene expression analysis has been performed using SYBR-green qRT-PCR. Circulating Hepcidin has been measured with a specific murine ELISA kit (Inniscient Lifesciences). Tissue iron levels have been measured with a colorimetric assay. All animal experiments were approved by and conducted in compliance with institutional guidelines.

Results: Compared to Gpx4wt/wt; CreERT2 controls, Gpx4fl/fl; CreERT2 transplanted mice lacking GPX4 in the haematological compartment show a decrease in the number of red blood cells, haemoglobin and haematocrit. Reticulocytes showed a strong increase in this population, suggesting that the erythropoiesis could be due to a block in the reticulocyte maturation. Reticulocyte FACS characterization revealed a shift towards a more immature population while electron microscopy analysis showed an accumulation of unphagocytosed vesicles containing remnants of mitochondria. Analysis of the spleen revealed extramedullary erythropoiesis. The anaemia and the erythropoiesis trigger a hypoxic signature hallmarking by an increase in circulating EPO and increased ErFe expression. However, both hepatic mRNA analysis and circulating protein measurement failed to show alteration in hepcidin production. Analysis of the liver showed an increase in non-heme iron content and in the lipid peroxidation causing an elevated mRNA and protein expression of heme oxygenase 1. Hepatic ferritin and ferroportin are also increased as a consequence of the increased iron content.

Summary/Conclusions: Our data show for the first time that the presence of GPX4 in the haematological compartment is essential for the proper hepcidin downregulation upon ErFe stimulation. This finding opens new insights in the mechanism that regulate hepcidin during hypoxia.
Aims: The main aim of our study is to assess the effects of RAP-011 on different cell types of MDAII. Methods: We measured circulating GDF11 levels in CD45 patients and healthy controls (HC) by western blot (WB). To assess the effectiveness of RAP-011 (provided by Cellegene Corporation), in vitro, we established two different cellular models of CD45: (i) K562 cells stably silenced for SEC23B by ShRNA carried in the psMD2G vector (ii) K562 cells stably overexpressing SEC23B-WT and the two variants, R14W and E109K. In vitro treatment has been performed at 0, 3, and 6 days of erythroid differentiation by hemin+GDF11 in presence or absence of RAP-011 in K562 cells stably silenced for SEC23B.

Results: WB and subsequent densitometric analysis showed an increase of GDF11 in SEC23B silenced cells from 1.00 to 0.70 (p=0.02). Stable silencing of SEC23B in K562 cellsed to the establishment of two different clones, Sh-70 and Sh-74, showing amarkedreduction of SEC23Bexpression compared to Sh-CTR (85%-90% and 60-65%, respectively). At 3 and 6 days of K562 erythroid differentiation by hemin, we observed an increase of GDF11 in psMD2G in GDF11-treated cells compared to non-treated ones; interestingly, a reduction of pSMAD2 in RAP-011+GDF11-treated cells was observed.

Summary/Conclusions: We firstly demonstrated the increased levels of GDF11 in CD45 patients. Thus, we used a combined treatment with hemin+GDF11 in SEC23B silenced K562 stable clones, in order to reproduce the pathologic phenotype of the disease, and to make K562 cells suitable for RAP-011 treatment, as attested by the increased expression of psMD2A in GDF11-treated cells. The reduced pSMAD2 in RAP-011+GDF11-treated cells suggests that RAP-011 treatment leads to repression of ActRIIA/B pathway, which is the most relevant transcriptional factor. This action should lead to an increased expression of GATA1-activated genes involved in erythroid development. The evaluation of GATA1 activation is ongoing, as well as the in vitro treatment of K562 stably overexpressing SEC23B-WT,SEC23B-R14W and -E109K.

INTRAVENOUS IRON VERSUS ORAL IRON VERSUS NO IRON WITH OR WITHOUT ERYTHROPOIESISSIMULATING AGENTS FOR CANCER PATIENTS WITH ANAEMIA: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

A. Weigl1,*, N. Köhler1, I. Monsef1, J. Bohlius2, I. Becker3, K. Kuhr3, N. Skoetz1

1Institute of Social and Preventive Medicine, University Hospital Cologne, Cologne, Germany, 2Institute of Social and Preventive Medicine, University Hospital Bern, Bern, Switzerland, 3Institute of Medical Statistics, Informatics and Epidemiology, University Hospital Cologne, Cologne, Germany

Background: A widely prevalent complication in patients suffering from cancer is the deficiency of haemoglobin-containing red blood cells, referred to as anaemia. While many patients develop anaemia due to an involvement of malignant bone marrow cells, others suffer from so-called chemotherapy/radiotherapy-induced anaemia. Erythropoiesis-stimulating agents (ESAs) stimulate the production of red blood cells within the bone marrow and have shown to increase Hb levels in anaemic patients. Uncertainties remain regarding the effect of iron supplementation on the fatal consequences of ESA-treatment.

Aims: The aims of this systematic review and network meta-analysis are to evaluate the effects of iron and ESAs and iron for the treatment of disease-related as well as therapy induced anaemia in cancer patients.

Methods: Based on an a-priori Cochrane protocol, we developed sensitive search strategies for Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, databases of ongoing trials and conference proceedings (search date 12/2016). We included only randomized controlled trials (RCTs) including anaemic patients of any age with solid and/or haematological malignancy undergoing chemotherapy, radiotherapy or no anti-cancer therapy. We included studies also including anaemic cancer-patients as a result of surgery or chemotherapy. Two authors independently assessed studies for eligibility, and a third author resolved further disputations.

Results: A total number of 105 eligible studies, including 25.722 patients were included in the network meta-analysis. Study mortality. Secondary outcomes included number of red blood cell transfusions and thromboembolic events. For binary outcomes, we used risk ratios (RRs) with corresponding 95% confidence intervals (CIs) to evaluate the treatment effects. We performed a random-effects meta-analysis for direct comparisons. In all secondary outcomes, heterogeneity was high (I² ≥ 50%) for the primary outcome. For this reason, for all secondary outcomes, we used the frequentist graph-theoretical approach. Treatment hierarchy was obtained giving P-scores on a scale from 0 (worst) to 1 (best).

Results: We identified a total number of 105 eligible studies, including 25,722 patients. The network analysis of the primary outcome, on-study mortality, including 22 RCTs and 8 indirect evidence networks. As the number of networks was not significant, we performed pairwise comparisons on the four subnetworks with 2 treatments each. Statistically significant treatment disadvantages were shown in the direct comparison of ESA plus iron supplementation (given if necessary) compared to placebo/no treatment plus iron supplementation (given if necessary) (RR 1.14 (95% CI 1.03-1.25), including 41 studies). Network meta-analyses on the need for red blood cell (RBC) transfusions showed the treatment of ESA plus iron supplementation to have the most positive effect compared to ESA alone (RR: 0.70 (95% CI 0.53-0.92) P-score: 0.87). No relevant heterogeneity was found within the analysed network of four treatments (I²=18.4%). No direct comparison could be not tested statistically as a closed loop was included. Thromboembolic events occurred most often in patients treated with ESAs, irrespective of iron supplementation (ESA plus iron vs no treatment/placebo plus no iron: RR 1.79 (95% CI 0.74-4.32) P-score: 0.22, ESA plus iron vs no treatment/placebo plus no iron: RR 1.90 (95% CI 0.96-3.75) P-score: 0.16). Subgroup analysis regarding type of iron, as well as route of administration will be presented at the EHA-congress (Figure 1).
Our findings have potential implications, on one side, for hemolytic diseases, where RBC hemolysis and elevated circulating heme might promote a detrimental chronic inflammatory state, and, on the other one, for infectious diseases, where free heme and iron, released upon cell damage, might boost inflammation and enhance resistance to infections. Conversely, accelerated RBC clearance, by suppressing macrophage pro-inflammatory response, is rather expected to promote infections in transfused individuals.

Background: Standard treatment for transfusion-dependent β-thalassemia (TDT) includes regular red blood cell (RBC) transfusions and management of iron overload. Successful allogeneic hematopoietic cell transplantation (HCT) can eliminate RBC transfusions and, eventually, chelation. However, due to transplant-related risks such as graft-versus-host disease (GVHD), as well as donor constraints, HCT is rarely an option for TDT patients. By transferring a functioning copy of the β-globin (HBB) gene into hematopoietic stem cells (CD34+ cells) and re-infusing the modified cells, gene therapy may be an alternative one-time treatment available to all patients with TDT, without risks of GVHD. LentiGlobin gene therapy is an investigational treatment consisting of autologous CD34+ cells transduced with the BB305 lentiviral vector. The Northstar (HGB-204) phase 1/2 clinical study of LentiGlobin gene therapy for TDT included 18 patients who received LentiGlobin DP in patients with non-β0/β0 genotypes and at least 12 months of follow-up stopped transfusions (median total hemoglobin [Hb] 11.2 [range 9.4–12.2] g/dL) and there was >60% reduction in transfusions in patients with a β0/β0 genotype. The safety profile was consistent with autologous HCT. In this initial study, the average number of therapeutic gene copies per CD34+ cell in the DP (i.e. DP vector copy number per diploid genome or DP VCN; median 0.7, range 0.3 to 1.5) correlated with peripheral HbA1c[β] (genetically engineered hemoglobin) expression at 6 months (ASH, 2016). In an effort to optimize the proportion of patients able to discontinue blood transfusions to achieve “transfusion independence” in all patients and increase unsupported Hb levels after treatment, the manufacturing process for LentiGlobin DP was modified to increase the DP VCN and the proportion of genetically modified cells. Northstar-2 (HGB-207) is a recently initiated phase 3 study using this new manufacturing process in patients with TDT and a non-β0/β0 genotype.

Aims: To evaluate safety and efficacy of autologous HCT with LentiGlobin DP in patients with TDT and a non-β0/β0 genotype.

Methods: After providing informed consent, patients 12 to 50 years of age (N=15) will have CD34+ cells collected via mobilization and apheresis. After individualized DP manufacture and satisfaction of release criteria, the patient will receive myeloablative conditioning with single-agent busulfan (starting dose 3.2 mg/kg/day for 4 days, with target AUC 4500 [range 4000–5000] µM*min) followed by infusion of LentiGlobin DP. Patients will be followed for engraftment, safety and efficacy endpoints for 2 years after infusion; patients will then have the option to enroll in a 13-year follow-up study. The primary endpoint is the proportion of patients who achieve transfusion independence after DP infusion, defined as total Hb ≥9 g/dL without RBC transfusions for a continuous period of ≥12 months. Secondary endpoints include time to neutrophil engraftment, adverse events, and biological parameters including VCN in peripheral blood and levels of HbA1c[β] over time.

Results: As of March 1, 2017, two 20-year-old females with β0/βE genotypes have been treated with LentiGlobin DP in the Northstar-2 trial. The DP VCN was 2.9 and 2.4 copies per diploid genome, respectively. Outcomes in all evaluable patients will be presented.

Summary/Conclusions: Results from the Northstar-2 study will provide data on safety and demonstrate the extent to which an increase in LentiGlobin DP VCN yields normalization of total Hb and consistently achieves transfusion independence in patients with TDT of non-β0/β0 genotypes. Optimizing DP VCN has the potential to improve outcomes across all TDT genotypes treated by investigational LentiGlobin gene therapy.
by the integration of signals from activating and inhibitory ligands and from cytokines such as IL-15.

Aims: We set out to identify the negative regulators of NK cell function in order to understand why immunogenic tumours and leukemia can evade or overcome NK cell detection and killing.

Methods: We used a multidisciplinary approach including RNAseq, Mass Spectrometry, structural biology, kinase enrichment and activity assays, NK cell in vitro analysis, biochemistry and de novo/experimental tumor/leukemia in vivo models.

Results: We identified cytokine-inducible SH2-containing protein (CIS, encoded by Cish) as a critical negative regulator of IL-15 signaling in NK cells. Cish was rapidly induced in NK cells in response to exogenous IL-15, and deletion of Cish rendered NK cells hypersensitive to IL-15, as evidenced by enhanced proliferation, survival, IFN-gamma production and cytotoxicity toward tumors. This was associated with increased JAK-STAT signaling in NK cells in which Cish was deleted. Correspondingly, CIS interacted with the tyrosine kinase JAK1, inhibiting its enzymatic activity and preventing JAK kinase-mediated degradation. Cish−/− mice are resistant to leukemia in vivo, and this was independent of MHC-I expression.

Summary/Conclusions: Our data uncover a potent intracellular checkpoint in NK cell-mediated tumor immunity and suggest possibilities for new cancer immunotherapies directed at blocking CIS function.

GENERATION OF MEMORY STEM T CELLS MODIFIED WITH A NOVEL OPTIMIZED CD30-SPECIFIC CHIMERIC ANTIGEN RECEPTOR FOR THE TREATMENT OF CD30+ T-CELL MALIGNANCIES

L. Escrb-a-Garcia,1,2 C. Alvarez-Fernndez,1 J. Wegner2, J. Rydzeck2, M. Tellez-Gabriel1, J. Sierra1, H. Einsele1, J. Briozzo3, M. Hutter1,1
1Hematolgy Service, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 2Universitatsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Würzburg, Germany

Background: Peripheral T-cell lymphomas (PTCL) represent the most aggressive form among non-Hodgkin lymphomas with a very poor prognosis (5-year survival of 30%), demanding innovative novel treatment strategies. Adoptive immunotherapy with chimeric antigen receptor (CAR) engineered T cells has demonstrated its therapeutic potential in advanced hematological malignancies. However, its application to PTCL remains a formidable challenge mainly due to a lack of truly tumor-specific antigens that are not expressed on normal T cells. Anaplastic large T-cell lymphomas (ALCL) and several other subtypes of PTCL express CD30, which is expressed by activated normal T cells but not other healthy tissues. Indeed, brentuximab vedotin, an anti-CD30 antibody-drug conjugate, has shown some clinical efficacy in PTCL and ALCL patients although duration of responses is short in the majority of cases. Here, we developed a refined CD30-CAR T-cell approach to target CD30+ PTCL as a novel novel therapeutic strategy. We selected a novel targeting domain that is unaffected by soluble CD30 protein to prevent blockade of the CD30-CAR in vivo. Moreover, we optimized the therapy by using memory stem T cells (TSCM) to promote engraftment and persistence of CD30-CAR T cells after transfer, and we have included an EGFR deletion marker as a safety feature.

Aims: We evaluated the antitumor effect of memory stem T cells (TSCM) genetically modified with a novel CD30-specific CAR that recognizes a membrane-proximal epitope in the CD30 molecule in a CD30+ T-cell lymphoma model.

Methods: A second-generation CD30-41BBZ-EFGR CAR was generated using a scFv that recognizes a tumor-cell membrane-proximal epitope of CD30 protein (Nagata S et al. Clin Cancer Res, 2002). Naive T cells from healthy donors were activated with anti-CD3/CD28 beads in presence of IL-7, IL-15 and IL-21 during 10 days to obtain a TSCM-enriched population (Alvarez G et al. J Transl Med, 2016); on day 2 of culture, cells were transduced with a third-generation lentiviral vector encoding the CD30-CAR. The anaplastic large T-cell lymphoma cell line Karpas 299 was used as tumor model. Cytotoxicity assay was performed at 4 hours at 10:1, 5:1, 1:1 and 1:5 effector/target (E/T) ratios, and the tumor cell death was determined by flow cytometry. Cytokines (IFN-γ and IL-2) were analysed at 24 hours in a 5:1 E/T ratio culture using Luminox technology.

Results: TSCMs were the most prevalent T-cell subset at day 10 of culture, representing 84 ± 3.1% of total cells, and the CD30-CAR expression in these cells was 76.9 ± 1.0% in CD4+TSCM and 77.3 ± 2.0% in CD8+TSCM. Although CD30 protein was detected in a fraction of activated T cells in culture (CD4+ T cells: 32.4 ± 2.1%; CD8+ T cells: 59.0 ± 4.3%), lentiviral transduction of TSCM with our novel CD30-CAR and confer potent antitumor efficacy against CD30+ PTCL in vitro. Our findings suggest the potential to improve outcome of patients with CD30+ PTCL through adoptive therapy with CD30-CAR modified T cells.

MESENCHYMAL STEM CELLS FOR THE TREATMENT OF STEROID-RESISTANT ACUTE GRAFT VERSUS HOST DISEASE: FACTORS INFLUENCING CLINICAL RESPONSES

1Division of Cancer Studies, King’s College London, 2Imperial College Health-care NHS Trust, 3Imperial College London, London, 4Central Manchester University Hospital, Manchester, 5University Hospitals Bristol, Bristol, 6University Hospital Southampton, Southampton, 7Birmingham Women’s and Children’s Hospitals, Birmingham, 8The Christie NHS Foundation Trust, Manchester, King’s College Hospital NHS Trust, London, 9Royal Hallamshire Hospital, 10Royal Victoria Infirmary, Newcastle upon Tyne, 11University of Liverpool, 12Heart of England NHS Foundation Trust, Birmingham, 13Plymouth Hospitals NHS Trust, Plymouth, 14King’s College London, London, United Kingdom

Background: The immunosuppressive activity of mesenchymal stromal cell (MSC) has been extensively tested for the treatment of steroid-resistant acute graft versus host disease (aGvHD). However, the factors affecting clinical responses are poorly understood.

Aims: We assessed the impact of MSC treatment on clinical outcomes and investigate factors influencing the response to MSC.

Methods: Data collected from a cohort of 60 patients treated with MSC between May 2008 and December 2014 in the UK were analysed. Clinical grade MSC were generated from bone marrow aspirates collected from the iliac crest of healthy donors and expanded using platelet lysate. All patients received MSC for the treatment of steroid-resistant aGvHD, defined as failure to respond to high-dose steroids (2mg/Kg methyl-prednisolone) after 6 days. Informed consent was obtained from all patients in accordance with the local ethics committee requirements. Clinical responses to MSC were assessed 1 week after MSC infusion. Patients were defined as: a) Responders if they had improvement of at least 50% in at least one organ affected by aGvHD was observed, or b) Non-Responders if they had stable or progressive disease.

Results: Patient characteristics are summarized in Table 1.

Table 1.

aGvHD was biopsy proven in 45 patients, while in the remaining patients the diagnosis was clinical and based on the exclusion of alternative causes. 10, 16 and 1 patients had skin, gut and liver involvement only, respectively. 16 patients exhibited gut and skin, 11 skin, gut and liver, 3 skin and liver and 3 gut and liver. 34 patients received a dose, while 19, 6 and 1 were treated with two, three and four doses, respectively. No side effects were observed. 36 patients (60%) responded to MSC. Amongst patients who received multiples doses (26), subsequent doses did not change the status after the first dose (24 responded, 1 did not respond), except from one patient who, although respond-
ing to the first dose, failed to respond to the second one. When we evaluated potential factors for response, organ involvement, age at transplant and the cumulative dose of MSC infused were found statistically significant. Response rate was 67% among patients with involvement of gut, skin or both, but only 22% among those with involvement of the liver (alone or in combination with skin and/or gut). Patients younger than 20 years fared better, with 88% of them responding. Conversely, only 30% and 42% of those aged 20-50 years or older than 50 responded, respectively. Lastly, higher cumulative MSC dose (>3.0x10^6/Kg) was associated with a response in 76%, while none of those receiving less than 1.5x10^6/Kg responded. All 3 factors remained significant in multivariate logistic regression analysis. Patient gender, pre-MSC therapy, interval from transplant or aGvHD diagnosis to MSC treatment and grade of aGvHD did not affect response. The impact of achieving a response 1 week after MSC had a profound impact on the overall survival at 18 months accounting for 59% in responders and 17% in non-responders (log-rank test, p<.001).

Summary/Conclusions: In our cohort of patients, MSC treatment was safe and well tolerated. We conclude that the presence of a response at one week highly impacted on the survival of patients with an otherwise very poor prognosis. Importantly, younger age at the transplant, absence of liver aGvHD involvement and use of higher MSC doses were strong predictors of a response.

CARD9 CONTROLS DECTIN-1-INDUCED T-CELL CYTOTOXICITY AND TUMOR GROWTH IN MICE
T. Haas1,*, S. Heidegger1, H. Poeck1, J. Ruland2
1Klinik und Poliklinik für Innere Medizin III, 2Institut für Klinische Chemie und Pathobiologie, Klinikum rechts der Isar, TU München, München, Germany

Background: Activation of the C-type lectin receptor Dectin-1 by beta-glucans triggers multiple signals within dendritic cells (DCs) that result in activation of innate immunity. While these mechanisms can potently prime CD8+ cytotoxic T cell (CTL) responses without additional adjuvants, the Dectin-1 effector pathways that control CTL induction remain unclear.

Aims: Aims of this study were: To define details of the intracellular signalling pathway responsible for cross-priming of a CTL response after activation of the C-type lectin receptor Dectin-1. To analyze whether identified signalling molecules were indispensable for antitumor immunity. To analyze whether NK cells played a role in antitumor immunity after Dectin-1-mediated CTL induction.

Methods: We used in vitro coculture between DCs (wildtype vs gene deficient) and CD8 T cells to define signalling components of Dectin-1 induced CTL cross-priming. We used WT and gene-deficient mice to define the signalling pathway of Dectin-1 induced CTL crosspriming in vivo and to test the role of this pathway for antitumor immunity by challenging mice with B16-Ova tumor cells intravenously, with or without depletion of CD8 T cells or NK cells, respectively.

Results: Here we demonstrate that Dectin-1-induced CTL cross-priming in mice does not require inflammasome activation but strictly depends on the adapter protein Card9 in vitro. In vivo, Dectin-1-mediated Card9 activation after vaccination drives both expansion and activation of antigen-specific CTLs, resulting in long-lasting CTL responses which are sufficient to protect mice from tumor challenge. This Dectin-1-induced antitumor immune response was independent of natural killer (NK) cell function and completely abrogated in Card9-deficient mice. Thus, our results demonstrate that Dectin-1-triggered Card9 signaling but not inflammasome activation can potently cross-prime antigen specific CTLs, suggesting that this pathway would be a candidate for immunotherapy and vaccine development (Figure 1).

Summary/Conclusions: We identify Card9 as central regulator of Dectin-1-induced cross-priming of cytotoxic T cells (CTLs) in mice. These antigen specific CTLs mediate potent antitumor immunity independent of inflammasome activity and NK cells. This pathway is a candidate for immunotherapy and vaccine development.
Acute lymphoblastic leukemia - Biology

PRECLINICAL COMBINATION OF A NOVEL IRE1 RNAE INHIBITOR MKC-8866 AND TYROSINE KINASE INHIBITION ACTS SYNERGISTIC IN ACUTE LYMPHOBLASTIC LEUKEMIA

M. Vieri1,2, A. Salmi1, J.B. Patterson2, A. Samal3, E. Cheve3, T.H. Brümmendorf1, I. Appelmann1, B. Kharabi1

1Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, University Hospital RWTH Aachen, Aachen, Germany, 2Klinikum Brandenburg, Valencia, United States, 3Department of Biochemistry, National University of Ireland, Galway, Ireland, 4Centre de lutte contre le cancer, Université Rennes 2, Rennes, France

Background: The role of the Unfolded Protein Response (UPR) in BCR-ABL+ ALL has extensively studied, proving the importance of BCR-ABL1 in pediatric acute lymphoblastic leukemia (pALL). In this study we aim to identify a potential synergistic effect of simultaneous pharmacological inhibition of IRE1 and BCR-ABL1 in pALL.

Aims: To introduce and test a high-throughput, high-resolution and comprehensive disease-relevant CNAs profiling approach applicable to all subtypes of pALL.

Methods: A new digitalMLPA (dMLPA) technique has been developed which combines the advantages of MLPA and next-generation sequencing (NGS), massively improving the number of simultaneously analyzable loci, limited to 55-60.

Aims: To introduce and test a high-throughput, high-resolution and comprehensive disease-relevant CNAs profiling approach applicable to all subtypes of pALL.

Results: CNAs directly indicating structural or whole chromosome aberrations or indirectly referring to gene fusions were detected in 93% of patients, in 44/48 pre-B ALL and 10/10 pre-T ALL cases. Among patients with CNAs, recurrent aberrations specifically affecting putative driver genes varied between 0 and 11. Interestingly, RUNX1 was among the most recurrently altered genes in pre-B and pre-T ALL, respectively, followed by CDKN2A/B, PAX5, RB1, VPREB1, MLLT3, CD200/BTLA, TBL1XR1, IKZF1, CASP8AP2, PTEN, RUNX1, BTF1, TP53, IKZF3, E2H2, NF1, NR3C2, RAG2 and the PAR region (in 5/10 cases respectively). To elucidate the role of CNAs within the pALL group, additional CNAs were detected genome-wide which was strongly facilitated by the inclusion of ~200 digital karyotyping probes covering each chromosome arm.

Summary/Conclusions: A novel NGS-based method has successfully been introduced for high-resolution profiling of CNAs in pALL. dMLPA is robust, fast and cost-effective technique; its input DNA requirement (20ng) is similar to those of other low-input NGS protocols and lower than the requirement for MLPA. Due to its targeted approach, data analysis is computationally less demanding as compared to most NGS methods. The number of genomic sites analyzed in dMLPA is much higher than with conventional MLPA. Due to its specific probe composition, dMLPA allows both high-resolution analysis of genomic driver regions and a genome-wide detection of aneuploidies and large CNAs.

E821
CRITICAL ROLE FOR NOTCH SIGNALING IN B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL) DRUG RESISTANCE

P. Takam Kamga1,2, G. Dal Collo1, M. Midolo1, A. Adamo1, A. Gatti1, R. Carusone1, M. Bonifacio1, M. Krampera1

1Medicine, University of Verona, Verona, Italy

Background: B-cell precursor acute lymphoblastic leukemia (B-ALL) is the leading cause of cancer-related death in children and young adults. There is still a need of more efficient therapies for the subset of refractory patients. Our group has previously shown that Notch-3 and Notch-4 promote human B-ALL cell survival in presence of stromal cell support. However, the contribution of Notch signaling to B-ALL pathogenesis in terms of prognosis, proliferation survival and drug response is poorly understood.

Aims: In this study we used B-ALL cell lines and samples from new diagnosed B-ALL patients to analyse the contribution of Notch signaling to B-ALL pathogenesis in terms of proliferation, survival and drug response in vitro and in mice xenograft models of B-ALL.

Methods: B-ALL cell lines were obtained from ATCC, while B-ALL primary cells were obtained from bone marrow or peripheral blood of 30 B-ALL patients. Flow cytometry and western immunoblotting were used to study the expression of Notch receptors and ligands. Drugs used were Cytarabine (ara-C), Dexamethasone (dexa) and Doxorubicin (doxo). To identify the mechanisms of drug resistance, the combination of the most active drugs with Notch modulators including anti-Notch blocking antibodies, gamma secretase inhibitors (GSIs), and Notch transcription factor inhibitor (SAHM1). Mouse xenograft model of B-ALL were obtained by injecting the B-ALL line RS4;11 in vivo.
NOD/Shi-scid/IL-2Rnull mice (NOG). Cell viability was evaluated by Annexin-V/PI and MTT assay; proliferation was assessed through CFSE dilution.

Results: Western blot and flow cytometric analysis showed that B-ALL cell lines as well as primary blasts cells displayed the same Notch expression pattern consisting in low expression levels of Notch2 and Jagged1, high expression levels of Notch1, Notch3, Notch4, Jagged2, DLL3 and DLL4. Notably, in primary blast cells deriving from patients, the expression of Notch3, Notch4, Jagged2, DLL3 and DLL4 was significantly higher in the cases refractory to treatment as compared to patients achieving complete remission, thus suggesting that Notch signalling could be involved in the response to chemotherapy. In line with this hypothesis, we found that the treatment in vitro of B-ALL cell lines with Ara-C or Dexa down regulates the expression of Notch receptors. This down regulation was also observed in human CD19+ blast cells isolated from bone marrow of recipient mice treated with Ara-C compared to cells isolated from not treated mice. In addition, Notch inhibitors significantly improved in vitro the cytotoxicity of Ara-C and Dexa towards B-ALL. Finally, we performed the administration to mice of a pan Notch inhibitor, i.e. the GSI XII, significantly lowered the CD19+ leukaemic burden in the bone marrow of recipient mice, potentiating anti-leukemic effect of Ara-C.

Summary/Conclusions: In this study we used both in vitro and in vivo assays to highlight the prognostic value of Notch expression in B-ALL, as well as its critical role in B-ALL cell survival and response to chemotherapy. We also demonstrated that Notch inhibitors were able to improve Ara-C-mediated reduction of blast cells in bone marrow, revealing that Notch signalling is a possible therapeutic strategy to eradicate minimal residual disease in B-ALL.

E822

REGULATION OF NOTCH AND WNT SIGNALING PATHWAYS BY NRARP IN T-CELL ACUTE LYMPHOBlastic LEUKEMIA

I. Pinto1, M. L. Oliveira1, J. T. Barata1, R. Fragoso1,*
1Barata Lab, Instituto de Medicina Molecular, Lisboa, Portugal

Background: T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive hematological malignancy. Although the outcome of T-ALL patients has improved over recent years, the poor prognosis of patients with resistant or relapsed disease is still a major concern. Even though NOTCH is a known driver in T-ALL, its inhibition cannot be efficiently achieved with the drugs currently available, due to their weak therapeutic effects and severe toxicity. We have shown previously that Notch inhibitors were able to improve Ara-C-mediated reduction of blast cells in bone marrow, revealing that Notch signalling is a possible therapeutic strategy to eradicate minimal residual disease in B-ALL.

Aims: To investigate the role of NRARP in human T-ALL cell growth and survival and its therapeutic potential in T-ALL.

Methods: mRNA and protein expression were determined by real-time-PCR and western blot analyses. In vitro functional evaluation of NRARP in T-ALL cell lines was performed by flow cytometry analysis of proliferation and viability upon NRARP overexpression using lentiviruses.

Results: We started by characterizing NRARP expression in human T-ALL cells and we observed that the expression of NRARP is human thymocytes. We found that NRARP protein levels are significantly increased in T-ALL cells. This result, although consistent with the fact that NRARP is a transcriptional target of NOTCH, suggests that NRARP is not sufficient to block NOTCH oncogenic signals. To test this hypothesis, we overexpressed NRARP in human T-ALL cell lines. Curiously, NRARP overexpression blocks the expansion of the T-ALL cell lines that display NOTCH1-activating mutations but promotes the expansion of the T-ALL cells without NOTCH1 mutations. Although in both cell types (WT and NOTCH1-mutated) NRARP overexpression blocks NOTCH1 signaling, in NOTCH1-WT T-ALL cells we observe an increase in c-Myc expression. Consistent with these results, NOTCH1-WT NRARP overexpressing cells are more sensitive to JQ1, a small-molecule bromodomain inhibitor that targets c-Myc. NRARP is known to positively regulate LEF1, a DNA binding transcription factor acting downstream of WNT. Thus we sought to investigate the impact of this novel interaction on the WNT signaling pathway. Very interestingly, our results show that in NOTCH1-mutant cell lines NRARP overexpression results in the down-regulation of the WNT signaling pathway while in NOTCH1-WT T-ALL cells results in its up-regulation.

Summary/Conclusions: Taken together our results suggest that NRARP may play a dual role in T-ALL pathogenesis, regulating both NOTCH and WNT pathways, with opposite functional effects on leukemia cells depending on NOTCH mutational status and signaling levels. This dual role may have important biological and therapeutic implications.

ETV6/RUNX1-LIKE ACUTE LYMPHOBlastic LEUKEMIA: A NOVEL B-CELL PRECURSOR LEUKEMIA SUBTYPE IDENTIFIED BY THE CD27/CD44 IMMUNOPHENOTYPE

M. Zaliova1,2,3, M. Kotrova1,2,3, S. Bresolin4, J. Stuchly1,3, J. Stary1,2, O. Hrusak1,2,3, G. te Kronnie5, J. Trka1,2,3, J. Zuna1,2,3, M. Vaskova1,3,*
1Department of Paediatric Haematology and Oncology, Second Faculty of Medicine, Charles University, 2University Hospital Motol, 3CLIP - Childhood Leukaemia Investigation Prague, Prague, Czech Republic, 4Department of Women’s and Children’s Health, University of Padova, Padova, Italy

Background: We have shown previously that ETV6/RUNX1-positive acute lymphoblastic leukemia (ALL) is distinguishable from other ALL subtypes by CD27pos/CD44low-immunophenotype. During diagnostic immunophenotypic analysis of 573 childhood B-cell precursor ALL (BCP-ALL), we identified eight cases with this immunophenotype among “B-other ALL” (BCP-ALL cases negative for hyperdiploidy, ETV6/RUNX1, TCF3/PBX1 and BCR/ABL1 fusion genes and KMT2A-rearrangements).

Aims: We aimed to characterize their genetic and biological background, to reveal to what extent they resemble ETV6/RUNX1-positive ALL and to elucidate whether they belong to the recently described ETV6/RUNX1-like ALL (Liljeblom et al., Nature Communications 2016).

Methods: We utilized microarrays to study the gene expression profile (GEP) and biological similarity of the B-ALL subtypes. Five ETV6/RUNX1-positive and five hyperdiploid ALL cases were analyzed using microarrays in parallel to seven CD27pos/CD44low-positive, BCR/ABL1-negative ALL, recently described as ETV6/RUNX1-like ALL. We identified multiple regions of acquired copy number aberrations (CNA) uniparental disomies (5 to 27 per case) and point mutations (10 to 41 per case) in all 7 cases and 3 in-frame fusions transcripts each in one patient. The most important findings are summarized in Figure 1. All 5 ETV6/RUNX1-like cases harbored a deletion of the ETV6 gene, resulting in an in-frame ETV6/BORC5 fusion in one of them. The deletion of ARPP21 was found in 3 cases, and the deletions of PAX5, ATP10A, BTG1 and the gain of RUNX1 were found in 2 cases each. The ARPP21 deletions displayed a strikingly uniform character and were highly enriched in ETV6/RUNX1-like ALL. Using WES and RNAseq, no recurrently mutated gene and no in-frame fusions were found, respectively, except for the ETV6/BORC5. Integrating data from all platforms, we identified IKZF1 as another recurrently affected gene; a deletion, a nonsense mutation and an IKZF1-invoking out-of-frame fusion were found in one case. The other cases with available material. Microarray data from all 17 B-ALL cases were combined with data from an independent Italian cohort of 291 B-ALL cases (including ETV6/RUNX1-positive, BCR/ABL1-negative, TCF3/PBX1-positive, KMT2A-rearranged, hyperdiploid and B-other ALL cases) whose specimens were analyzed using the same microarray. To study the genomic background, we performed comprehensive profiling using single nucleotide polymorphism (SNP) arrays and whole exome and whole transcriptome sequencing (WES and RNAseq).

Results: In the hierarchical clustering based on GEP all five ETV6/RUNX1-positive cases and 5 of 7 CD27pos/CD44low B-other cases clustered within the ETV6/RUNX1-positive cluster. These B-other cases were thus classified as ETV6/RUNX1-like ALL. We identified multiple regions of acquired copy number aberrations (CNA) uniparental disomies (5 to 27 per case) and point mutations (10 to 41 per case) in all 7 cases and 3 in-frame fusions transcripts each in one patient. The most important findings are summarized in Figure 1. All 5 ETV6/RUNX1-like cases harbored a deletion of the ETV6 gene, resulting in an in-frame ETV6/BORC5 fusion in one of them. The deletion of ARPP21 was found in 3 cases, and the deletions of PAX5, ATP10A, BTG1 and the gain of RUNX1 were found in 2 cases each. The ARPP21 deletions displayed a strikingly uniform character and were highly enriched in ETV6/RUNX1-like ALL. Using WES and RNAseq, no recurrently mutated gene and no in-frame fusions were found, respectively, except for the ETV6/BORC5. Integrating data from all platforms, we identified IKZF1 as another recurrently affected gene; a deletion, a nonsense mutation and an IKZF1-invoking out-of-frame fusion were found in one case. The other cases with available material. Microarray data from all 17 B-ALL cases were combined with data from an independent Italian cohort of 291 B-ALL cases (including ETV6/RUNX1-positive, BCR/ABL1-negative, TCF3/PBX1-positive, KMT2A-rearranged, hyperdiploid and B-other ALL cases) whose specimens were analyzed using the same microarray. To study the genomic background, we performed comprehensive profiling using single nucleotide polymorphism (SNP) arrays and whole exome and whole transcriptome sequencing (WES and RNAseq).

Figure 1.

Summary/Conclusions: We showed that similarly to ETV6/RUNX1-positive ALL, ETV6/RUNX1-like ALL is also associated with CD27pos/CD44low-immunophenotype. We identified deletion of ARPP21 to contribute to the specific genomic profile of ETV6/RUNX1-like ALL in addition to lesions of ETV6
and KZNF1. In conjunction with the single published study, our study establishes the ET6 lesion as the only common genetic aberration and thus the most likely key driver of ET6/RUNX1-like ALL.

GENETIC ALTERATIONS IN CHILDREN WITH T-CELL ACUTE LYMPHOBластIC LEUKEMIA IN TAIWAN
1Mackay Children’s Hospital and Mackay Medical College, Taipei, 2Chang Gung Memorial Hospital and Chang Gung University, 3Chang Gung Memorial Hospital, Taoyuan, Taiwan, Republic of China

Background: The leukaemogenesis of T-cell acute lymphoblastic leukemia (T-ALL) involves multistep processes of genetic alterations.

Aims: We aimed to determine the genetic alterations including common fusion transcripts, overexpression of T-cell transcription factor oncogenes and deletion or mutations of targeted genes in pediatric T-ALL in Taiwan as well as their impact on outcomes in those treated with TPOG-ALL-2002 protocol.

Methods: Between 1995 and 2015, bone marrow samples from 102 children (<18 years old) consecutively diagnosed with T-ALL were analysed. SIL-TAL1, MLL-ENL, and CALM-AF10 transcripts were detected by RT-PCR assays. RO PCR with TaqMan assays were used to measure the expression of HOX11, TAL1, and LYL1 oncogenes expressed as normalized copy number (NCN) to ABL internal control gene. TAL1 overexpression was defined as NCN > the lowest level of SIL-TAL1 positive patients. Overexpression of HOX11 and TAL1 was defined as NCN > the upper limits of the 50% normal bone marrow controls. Mutations of NOTCH1, FBXW7, PHF6, JAK1, JAK2, RUNX1, WT1, NRAS, and KRAS genes were analyzed by PCR-based assays followed by direct sequencing. P16 deletion was determined by RO-PCR or multiplex ligase probe amplification (MLPA), PTEN and PHF6 deletions, MYB duplication and NUP214-ABL1 fusion were detected by PCR and immunoblotting, respectively. Downregulation of PRDX1 was established as a novel pro-oxidative strategy in B-ALL treatment.

Results: The frequency of SIL-TAL1 fusion transcript was 16.2%, MLL-ENL rearranged 5.1%, CALM-AF10 1.0%, and no NUP214-ABL1. The frequency of NOTCH1 mutations was 46.9%, FBXW7 13.0%, RUNX1 5.2%, WT1 6.3%, NRAS 6.2%, KRAS 2.1%, and no JAK1 or JAK2 mutations. P16 deletion was present in 56.2%, PTEN in 11.1%, PHF6 deletion/mutation in 13.4%, and MYB duplication in 4.8%. Overexpression of TAL1 was present in 46.5%, 22% for LYL1, and 9% for HOX11. The correlation among the genetic alterations showed that LYL1 overexpression occurred more frequently in P16 wild-type compared with P16-deleted patients (P=0.003) and absence of SIL-TAL1 transcript was significantly associated with overexpression (P=0.018). A comparison of outcomes was made according to the status of each genetic abnormality. NOTCH1 mutations conferred a favorable overall survival (OS) (P=0.025), PHF6 deletion/mutation conferred an inferior OS (P=0.030), PTEN deletion was associated with shorter relapse-free survival (RFS) (P=0.001) and OS (P=0.001). Status of other gene mutations, deletion or duplication did not influence the RFS or OS. TAL1 overexpression predicted a higher risk of relapse (37% vs 21%, P=0.006), an inferior RFS (P=0.002) and OS (P=0.025) whereas HOX11 or LYL1 overexpression had no prognostic impact. Multivariate analysis, not including mutation status, showed each statistical significance for an independent predictor of OS (HR 0.167, P=0.112), PHF6 deletion/mutation was an independent unfavorable predictor for OS (HR 4.596, P=0.006), and PTEN deletion was also an independent predictor for both RFS (HR 35.943, P=0.007) and OS (HR 15.830, P=0.003). TAL1 overexpression was an independent risk factor for both RFS (HR 9.399, P=0.014) and OS (HR 2.701, P=0.047).

Summary/Conclusions: The present study showed that LYL1 overexpression was negatively associated with SIL-TAL1 or P16 deletion. PHF6 deletion/mutation, PTEN deletion, and TAL1 overexpression were the independent predictors of adverse outcomes. COMPUTATIONAL METHODS TO FIND NEW THERAPEUTIC TARGETS IN ALL, SYSTEMATICAL IDENTIFICATION OF ESSENTIAL GENES
L. Eldahl1,*, M. Pertesi1, A. Palm1, L. Järvästråt1, E. Jonsson1, U. Gullberg1, A.-K. Whibley1, B. Nilsson1
1Division of Hematology and Transfusion Medicine, Lund University, Lund, Sweden

Background: Deletion of chromosomal material is a hallmark of cancer genomes. While these lesions primarily target tumour suppressor genes, neighbour genes are frequently lost in parallel. Loss of one allele (haploinsufficiency) of a neighbouring gene that is essential for the survival of the cancer cells may constitute potential therapeutic targets in that the cancer cells may be selectively sensitive to further suppression of the function of that gene. Identifying such vulnerabilities is one of the current challenges in cancer genomics. We show that vulnerabilities in cancer cells can be identified by applying pattern recognition techniques to a copy-number dataset. This approach will identify genomic regions with potential essential genes. In these regions can be evaluated downstream by genome editing techniques to find novel targets for treatments. Using pattern recognition techniques to find essential genes is a straight-forward, easily applied and non-time-consuming method compared to genome wide experimental approaches.

Aims: Develop a computational framework to find regions with potential essential genes from copy-number data, with a primary focus on hematological malignancies and in particular ALL.

Methods: Our computational framework first selected regions of the tumour genome with heterozygous, but not homozygous, deletion. In sections flanking these regions we scanned for linear increases in homozygous deletion frequency. Genes near the start of these increases that have more than one case with homozygous deletion are discarded. Remaining genes were scored by calculating a line of best fit using the least square method towards the nearby peak in homozygous deletion. We sorted the results by settings cut-offs for the slope, amplitude and correlation coefficient of the linear regression line. Genes with the highest scores were then manually evaluated by comparing to known mean copy-number loss dependence score from other data-sets, by graphical manual evaluation and by investigating of their known function. The data set we analysed contains copy-numbers from tumour samples matched to normal blood samples or normal tissue from the same donor. To validate the essentiality of genes in the discovered regions we used pooled CRISPR/Cas9 editing in ALL cells with and without a deletion of the driving tumour suppressor.

Results: Our framework identified several regions with potential essential genes around well-known tumour suppressors. The strongest signals in the data set were located around the tumour suppressor CDKN2A. Downstream analysis with pooled CRISPR/Cas9 editing in ALL cells with and without a CDKN2A deletion provided evidence for the essentiality of several genes in the identified region, including one gene that was essential only in CDKN2A-deleted cells.

Summary/Conclusions: In conclusion, we explored a computational approach to identify regions with essential genes in copy-number datasets. Application of our approach to real data showed several regions with essential gene candidate around well-known tumour suppressors, indicating the framework works. Downstream genome-editing experiments in model cell-lines provided further evidence for the essentiality of some genes found in such identified regions. While we cannot yet draw conclusions on whether some of these genes are viable therapeutic targets it allows for informed guesses on limited sets of genes for further focused analysis in hematological model cell-lines.

Background: B-cell acute lymphoblastic leukemia (B-ALL) is a genetically heterogeneous disease characterized by abnormal expansion of B cell precursors and is mainly affecting children and adolescents. The backbone of the treatment is chemotherapy providing high cure rates in pediatric ALL (> 85%) but much worse treatment response observed in adolescents and adults (20%). Patients who relapse develop refractory, chemotherapy resistant disease and remain a clinical challenge. Growing body of evidence suggests that disturbance of redox homeostasis is a promising anticancer approach. Due to high metabolic demands and proliferation rate cancer cells elevate their antioxidative capacity to overcome excessive ROS production and depend on these antioxidative metabolic demands and proliferation rate cancer cells elevate their antioxidative capacity to overcome excessive ROS production and depend on these antioxidative metabolic demands and proliferation rate cancer cells elevate their antioxidative capacity to overcome excessive ROS production and depend on these antioxidant enzymes (PRDXs) that next to thioredoxins (TXNs) belong to the TXN-family and are the key components of TXN antioxidant system. PRDXs are enzymes involved in scavenging peroxides. TXNs are responsible for cysteine-thiol disulfide exchange in numerous protein substrates.

Aims: To investigate the potential of targeting the TXN antioxidant enzymes as a novel pro-oxidative strategy in B-ALL treatment.

Methods: We have used three different cell lines representing distinct cytogenetic subgroups of B-ALL: BV-173 (BCR-ABL), SEMK-2 (MLL-AF4) and NALM-6 (t(14;18)(q32;q21), involvement of PTEN deletion/mutation was an independent unfavorable predictor for OS (HR 4.596, P=0.006), and PTEN deletion was also an independent predictor for both RFS (HR 35.943, P=0.007) and OS (HR 15.830, P=0.003). TAL1 overexpression was an independent risk factor for both RFS (HR 9.399, P=0.014) and OS (HR 2.701, P=0.047).

Summary/Conclusions: The present study showed that LYL1 overexpression was negatively associated with SIL-TAL1 or P16 deletion. PHF6 deletion/mutation, PTEN deletion, and TAL1 overexpression were the independent predictors of adverse outcomes. (Grants support: CORPG3C0201, MHM-E-105-09, NSC-101-2314-B-195-004-MY2, and Terry Fox Foundation)
CRISPR v2 plasmid to produce lentiviral vectors encoding PRDX1-specific sgRNA and Cas-9 and used them to generate BV-173 cells with PRDX1 genom-
ic deletion. Proliferation rate was evaluated by trypan blue exclusion method. Cytostatic/cytotoxic effects of TXN-family enzymes inhibitors, such as adenano-
thin (ADE), auranofin (AUR) and SK053 were assessed by MTT viability assay and by detection of propidium iodide-positive cells in flow cytometry.

Figure 1.

Results: We have found that B-ALL cell lines exhibit significantly higher levels of ROS as compared to normal B cells isolated from human tonsils (Fig.1A). In accordance with this observation, our analysis of TXN antioxidant enzymes gene expression in B-ALL cell lines showed their upregulation (Fig.1B). Analysis of deposited data revealed that PRDX1 expression level is the highest in B-ALL among the other types of leukemia (Fig.1C). Moreover, we have observed elevated expression of PRDX1 in malignant lymphoblasts derived from pediatric patients at both RNA and protein levels. Genomic deletion of PRDX1 in BV-173 cells leads to suppression of their proliferation rate, comparing to parental cells and cells transduced with mammalian non-targeting sgRNA. These results allow us to suspect that PRDX1 may play growth-supporting role in these cells. Targeting TXN-family enzymes was also performed with the use of various small molecule inhibitors. Both B-ALL cell lines and primary cells are sensitive to PRDX and TXN inhibitors, which reduce cell viability in dose-dependent manner.

Summary/Conclusions: All the above results suggest that targeting TXN antioxidant system may exert desirable anticancer effects in the treatment of B-ALL. Inhibitors of TXN-family enzymes can be considered as putative agents to use in combination with classical drugs and improve existing therapeutic approaches. Further studies are underway.

RNA-BINDING PROTEIN IGF2BP1 PROMOTES SURVIVAL OF ET6V/
RUNX1 LEUKEMIA CELLS

M. Stoškus1,*, G. Valtkevičienė2, A. Eidukaitė3,4, L. Griskevičius1,5
1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskių Klinikos, 2Center for Pediatric Oncology and Hematology, Children’s Hospital, Affiliate of Vilnius University Hospital Santariskių Klinikos, 3Department of Laboratory Medicine, Children’s Hospital, Affiliate of Vilnius University Hospital Santariskių Klinikos, 4Department of Immunology, State Research Institute Centre for Innovative Medicine, 5Faculty of Medicine, Clinics of Internal, Family Medicine and Oncology, Vilnius University, Vilnius, Lithuania

Background: The IGF2 mRNA binding protein 1 (IGF2BP1, other aliases IMP-
1 (IMP1), CRD-BP (CRDBP), ZBP-1 (ZBP1), and VICKZ1) belongs to a family of regulatory RNA-binding proteins with an oncofetal expression pattern. IGF2BP1 has also been identified to be exclusively specific for ET6V/RUNX1-positive acute lymphoblastic leukemia (ALL) but biological significance of IGF2BP1 overexpression has not been thoroughly investigated to date (Anderson, Olofsson et al. 2005; Stoškus, Gineikiene et al. 2011). We have recently contributed by reporting that ET6V/RUNX1 transcript is a target of RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL, suggesting a role of IGF2BP1 in ET6V/RUNX1-mediated leukemogenic events (Stoskus, Valtkevi-
ciene et al. 2016).

Aims: To define the biological significance of IGF2BP1 overexpression in t(12;21)(p13;q22) ET6V/RUNX1-positive ALL.

Methods: In this study we have used stable sublines with downregulated IGF2BP1 from our previously published study (Stoskus, Valtkevičienė et al. 2016). Dynamics of viable cell population was assessed by flow cytometry using 7-AAD staining (BD Biosciences) following 72 hrs culture in complete medium. An Edu flow assay (Thermo Fisher Scientific, TFS) was used to assay DNA replication in proliferating cells. Spontaneous and doxorubicin (Doxo), staurosporine (STS), and STAT3 selective inhibitor S3I-201 (all from Santa Cruz Biotechnology) induced cell death rates were determined by Annexin V (TFS) and 7-AAD staining. All samples were analyzed on Accuri C6 cytometer (Accuri Cytometers) using CF0 Flow Plus and FCS Express software (De Novo Software). IGF2BP1, ET6V/RUNX1, and STAT3 RT-qPCR was performed previously and essential as reported by (Stoskus, Gineikiene et al. 2011). Statistical analyses performed using GraphPad Prism software (GraphPad Software).

Results: Downregulation of IGF2BP1 by 2-fold have rendered into approxi-
mately 2-fold lower population growth rate, increasing levels of spontaneous cell death in dynamics, and modest yet statistically significant attenuation of cell cycle progression (35.13% vs 40.40%, p<0.0001). Data from treatment with 50 nM of Doxo, 250 nM of STS suggest that IGF2BP1 downregulation has no effect on pharmacological effectiveness of these drugs. In contrast, IGF2BP1-downregulated cells are more sensitive to pharmacological inhibition of STAT3 even upon treatment with suboptimal 25 μM concentration of S3I-
201. Lastly, we have probed if STAT3 transcript levels could be sustained by IGF2BP1 protein as in agreement with previously reported (Stohr, Kohn et al. 2012) and our unpublished insights from anti-IGF2BP1 RNA immunoprecipita-
tion datasets. Correlation analysis of RT-qPCR data have confirmed these assumptions as downregulation of IGF2BP1 expression have resulted in a decrease of ET6V/RUNX1 mRNA (r2=0.8253, p<0.001, slope 0.9459) and also STAT3 transcript levels (r2=0.7709, p=0.002, slope 0.6436). These data sug-
gest that STAT3 transcript is also a potentially regulated by RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL model cells (Fig 1).

Figure 1.

Summary/Conclusions: We provide evidence that IGF2BP1 promotes survival of t(12;21)(p13;q22)-positive ALL model cells through cell cycle progression and preventing spontaneous cell death. Potentiation of ET6V/RUNX1®STAT3 signaling axis is one of the possible mechanisms responsible for this phenotype as IGF2BP1 maintains appropriate levels of primarily ET6V/RUNX1 and also STAT3 mRNAs. Further studies are clearly warranted to further delineate the role of IGF2BP1 in t(12;21)(p13;q22)-positive ALL (Stoskus, Eidukaite et al. 2016).

6-MERCAPTOPURINE PROMOTES ENERGETIC FAILURE IN LEUKEMIC
T-CELL LINE JURKAT

A. Fernández Ramos1,2,*, C. Marchetti-Laurent1,2, V. Poinessous1,2, S. Antonio2,3, P. Laurent-Puig1,2,4, S. Bortoli2,3, M.-A. Loriot1,2,4, N. Pallet1,2,4
1INSERM UMR-S-1147, 2Université Paris Descartes, 3INSERM UMR-S 1124, 4Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Paris, France

Background: 6-Mercaptopurine (6-MP) is a thiopurine drug with antiprolifera-
tive effects by blocking purine synthesis. 6-MP is largely prescribed for the treatment of childhood acute lymphoblastic leukemia (ALL). Recent evidence

haematologica | 2017; 102(s2) | 341
suggest that 6-MP inhibits the phosphatidylinositol 3 kinase (PI3K)/mammalian target of Rapamycin (mTOR) signaling pathway and modulates the transcriptional activity of hypoxia inducible factor 1α (HIF-1α). As mTOR and HIF-1α are key mediators of metabolic reprogramming in cancer and normal T cells we hypothesized that 6-MP can impact cellular metabolic remodeling through its action on nucleotide synthesis. Metabolic reprogramming fosters glycolysis, glutamine oxidation, and nucleotide synthesis after 24, 48 and 72 hours of treatment. In addition, 6-MP inhibits the expression of the metabolic checkpoints mTOR, HIF-1α and Myc after 24, 48 and 72 hours of treatment. 6-MP also decreases glucose and glutamine oxidation after 48 hours of treatment by 60% and 35%, respectively, suggesting that 6-MP inhibits TCA (tricarboxylic acid cycle) and OXPHOS (oxidative phosphorylation). The production of lactate, a marker of aerobic glycolysis, is significantly decreased by 30% after 6-MP treatment for 48 hours, meaning that aerobic glycolysis is also inhibited. However, 6-MP has no effect on glucose uptake or on glucose transporters (Glut1 or Glut3, SLC2A1 or SLC2A3) and so no significant expression suggesting that 6-MP metabolic effects are not linked to glucose uptake.

Summary/Conclusions: In conclusion, our findings offer new insights on the cellular effects of 6-MP treatment by promoting an early energetic stress that influence proliferation and raise apoptosis in leukemia T cells. Interestingly, the inhibition of the metabolic checkpoints (mTOR, HIF-1α, Myc) and the diminution of glycolytic and glutaminolytic fluxes by 6-MP treatment provide an original approach to better understand the cellular effects of 6-MP treatment.

Ribera1,2, 1Josep Carreras Leukemia Research Institute, 2Universitat Autònoma de Barcelona, 3Catàlana Institute of Oncology at Germans Trias i Pujol Hospital, Badalona, 4Catàlana Institute of Oncology at Josep Trueta Hospital, Girona, 5Catàlana Institute of Oncology at Duran i Reynals Hospital, Hospitalitat de Llobregat, 6Catàlana Institute of Oncology at Joan XXIII Hospital, Tarragona, 7Mutua de Terrassa, Terrassa, 8Doce de Octubre Hospital, Madrid, 9Clinic Hospital of Valencia, Valencia, 10Josep Carreras Leukemia Research Institute, 11Hospital Clinic, Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), 12University of Barcelona, 13Sant Pau Hospital, Barcelona, 14Reina Sofia University Hospital, Cordoba, Spain

Background: The survival rate of relapsed adult acute lymphoblastic leukemia (ALL) is around 10%. Aims: We looked for recurrent Copy Number Alterations (CNA) in relapsed adult B cell progenitor ALL (BCP-ALL) to shed light into the molecular mechanisms of relapse. Methods: BM or PB samples with at least 30% of blasts from 31 adult BCP-ALL patients at 1st relapse and, of them, 21 paired diagnosis and relapse samples were analysed by MLPA (MRC-Holland, The Netherlands). 19 out of these 21 paired samples were analysed by SNP array with CytoScan HD chips (Affymetrix, Santa Clara, California, USA). True CNA were considered when encompassed a minimum of 25 markers, and 25 markers and 320Mbp for CN-LOH.

Table 1.
Results: With a median follow up of 12.43 [2.4; 30.3] months, the median OS of the 31 patients at first relapse was 7.9 months. [2.4; 13.8]. The OS of patients at first relapse was significantly lower in those having more than 3 CNA by MLPA (median ≤3 CNA 9.7 months [0-20.7] vs median >3 CNA 4.2 months [0.6-7.8], p=0.042). CDKN2A/B deletion was the most common CNA observed at relapse (16/31, 52%) and most of these deletions were homozygous (12/16, 75%). Compared to patients with their deletions homozygous, homozygous tumors were more frequent at relapse (from 8 heterozygous CDKN2A/B deleted patients at diagnosis, 7 became homozygous at relapse, p=0.070). SNAP arrays detected 554 CNA (409 DEL, 125 DUP and 20 LOH) in 34 samples of 19 patients. At diagnosis (n=16 patients) the mean number of CNA was 12.3 (9.6 DEL, 2.3 DUP and 0.4 LOH), while at 24 and 48 hours (n=13 patients) was 17.8 CNA (12.6 DEL, 4.2 DUP and 1 LOH) and in second relapse (n=5 patients) was 21 CNA (14.6 DEL, 6.4 DUP and 0.4 LOH) (p=0.007). All matched diagnosis and first relapse samples (available for 10 patients) showed common CNA. In 6/10 cases some of CNA were retained from diagnosis while others were acquired or lost at relapse (suggesting that different leukemic clones exist both at diagnosis and at relapse). Finally, we compared those CNA retained at relapse between patients (median ≤3 CNA 9.7 months [0-20.7] vs greater than 3 CNA > 14.0 months [9.0-24.5]), and we found that patients with most retained acquired CNA at relapse in at least 4 out of 15 patients. Besides the high genetic heterogeneity observed, some recurrent CNA could be identified such as 9p, 1q, 12p, 22q and 7p deletions and 1q, 8q, 17q, 21+ and 22q duplications. In addition, we also detected tumor suppressor genes such as TP53, FOXO1, FOXO3 or RB1 were detected in 3 patients.

Summary/Conclusions: BCP-ALL has a high genetic heterogeneity at relapse, with most of the genetic alterations playing important roles for disease progression. This heterogeneity points out the need for search of personalized treatment, especially on their molecular targets. IGF1/IRS PHARMACOLOGICAL INHIBITION REDUCES CELL PROLIFERATION AND MIGRATION IN ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

A.P.N. Rodrigues Alves1,*, J. Machado-Neto1, R. Scopim-Ribeiro1, J.C. Fernandes1, B.A. Fenerich1, F.B. Da Silva1, P.S. Scheucher1, B.P. Simões1, E.M. Rego1, M. R. Mondejar1, M. Alonso1, C. Perez1, F. Burrows2, C. Scholz2, A. Gualberto2, J. Y.-H. Chao1,*, Y. Song1,2, X.-N. Cao1, Y.-Z. Qin1, Y.-Y. Lai1, H. Jiang1, Q. Jiang1, Y. Kong1, X.-J. Huang1,2

1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China.

Background: Relapse remains one of the major obstacles in Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ALL) even after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Relapse of Ph+ALL may result from the persistence of leukemic initiating cells (LPCs), which are defined by their ability to initiate human leukemia and self-renew in immunocompromised mice. In acute myeloid leukemia, higher LPCs frequencies and a gene expression profile typical of LPCs at diagnosis are predictive of unfavorable clinical outcome, however, the phenotype of LPCs in ALL is not well defined. We hypothesized that the CD34+CD38−CD58− fraction using a xenograft assay. Moreover, our cohort study indicate that the LPCs phenotype at diagnosis is an independent risk factor for relapse in Ph+ALL. However, little is known about the differential gene expression profiles between LPCs and the other cell fractions in de novo Ph+ALL patients.

Aims: To identify the potential molecular basis of LPCs-mediated relapse, the gene expression profiles of the sorted LPCs and other cell fractions from patients with de novo Ph+ALL were compared.

Methods: Twenty patients with de novo Ph+ALL were enrolled for this study at Peking University Institute of Hematology from 2015 to 2018. The LPCs (CD34+CD38−CD58−) and other cell fractions (including CD34+CD38−CD58− and CD34+CD38−CD58−) were sorted at the bone marrow mononuclear cells of de novo Ph+ALL patients (N=3) using a FACS Aria II. Differential expression analysis between LPCs and the other cell fractions were performed using RNA-sequencing (RNA-Seq) and the DESeq package (1.10.1), Gene Ontology (GO) enrichment analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis. RNA-Seq results were partially validated by a TaqMan-based real-time quantitative polymerase chain reaction (qRT-PCR) technique. Moreover, cell cycle status was compared between LPCs and other cell fractions in de novo Ph+ALL patients by flow cytometry.

Results: 1021 genes (301 up-regulated and 720 down-regulated), 1245 genes (354 up-regulated and 891 down-regulated) and 1228 genes (248 up-regulated and 980 down-regulated) were differentially expressed between LPCs and other cell fractions (patient No 1), and in second relapse (patient No 2), and LPCs and Other Cells (patient No 3), respectively. Most of differential expression of genes (DEGs) are related to the regulation of cell cycle and metabolism. GO analysis identified enriched terms of biological functions in DEGs including ATP binding process, ribonucleotide binding process, nucleoside binding process, DNA replication process, primary metabolic process, etc. KEGG analysis showed significantly enriched signaling pathways involved in DEGs including cell cycle, DNA replication, nucleotide metabolic pathways, biosynthesis of amino acids, glutathione metabolism, p53 signaling pathway, etc. Consistent with RNA-Seq results, mRNA levels of the cell cycle-related genes, such as CDK4 and CDK6, were significantly lower in LPCs fractions than those in other cell fractions. Moreover, the frequencies of quiescent cells in LPCs were significantly higher than those in other cell fractions.

Summary/Conclusions: Distinctive gene expression profiles and cluster, which are mostly related to the regulation of cell cycle and metabolism, were demonstrated between LPCs and the other cell fractions in de novo Ph+ALL. Therefore, our data indicate that it would be of value to develop LPCs biomarkers to contribute to personalized leukemia therapy and the need to identify therapeutic targets directed toward LPCs in Ph+ALL.
Acute lymphoblastic leukemia - Clinical

HOSPITALIZATION FOR PATIENTS IN THE U.S. AND EU TREATED WITH INOTUZUMAB OZOGAMICIN VS STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA IN A GLOBAL PHASE 3 TRIAL

Y. Su1,2, I. Van Costrum3, E. Vandendries1, V. Welch1, F.R. Loberiza1,2

1Pfizer Inc, New York, United States, 2Ingress-health Netherlands, Rotterdam, Netherlands

Background: Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, with its once a week one-hour infusion schedule, has demonstrated lower hospital utilization, in association with a clinically meaningful improvement in overall survival, high rate of complete remission, favorable patient-reported outcomes (PRO), and generally manageable safety profile versus standard of care (SOC, intensive chemotherapy) for relapsed/refractory acute lymphoblastic leukemia (R/R ALL) in the phase 3 INO-VATE trial.

Aims: This study aims to determine the regional-specific hospitalization days per patient in the INO-VATE trial.

Methods: Patients receiving study treatment (safety population) and recruited from the US and the EU were included in the analyses. The total number of days hospitalized for each patient was calculated. Hospital days prior to randomization and those after the end of study treatment were excluded. Due to different durations of treatment for InO and SOC (median 1 vs 3 cycles), calculations were reported for cycle 1 treatment period (randomization to end of cycle 1) and for the entire treatment period (all cycles - randomization to end of treatment).

Results: A total of 264 patients from the safety population of the phase 3 INO-VATE trial were available for the analyses. 149 were from the US, and 115 from 11 of the EU countries. The percentage of patients requiring hospitalization was lower for InO compared to SOC (Table). The median and mean hospitalization days were shorter for patients in the InO arm compared to the SOC arm across both regions. The difference between the two treatment arms appears to be greater in the US compared to the EU. Hospitalizations in the US appear to be shorter than in the EU, particularly for patients receiving InO.

Table 1. Hospitalizations in R/R ALL patients from the INO-VATE trial.

Summary/Conclusions: InO treatment in R/R ALL is associated with less hospitalization across both the US and EU compared to SOC, consistent with InO’s better efficacy, tolerability, PRO and dosing schedule. The finding that US has lower hospitalization than the EU might be explained by different patient care practices in the two regions. Given that hospitalization is the biggest cost driver in cancer care, the data suggest both EU and US could benefit from cost-savings of less hospitalization with InO treatment.

E836
NON-INTERRUPTIVE BUT NON-INTERRUPTIVE TREATMENT WITH FEWER ALLO-HSCT IS EFFECTIVE STRATEGY FOR ADULT PH-NEGATIVE B-CELL PRECURSOR (BCP-) ALL: OUTCOME OF THE RUSSIAN PROSPECTIVE MULTICENTER ALL-2009 STUDY

E. Parovichnikova1, V. Troitskaya2, A. Sokolov2, O. Gavrilina2, E. Gavrilina2, G. Baskhavae2, I. Piskunova3, O. Baranova4, Z. Akhmerzaeva2, G. Kliasova5, L. Kuzmina1, E. Gribanova2, S. Bondarenko3

1BMT department, 2Haematology department, National Research Center for Hematology, Moscow, 3BMT department, Raisa Gorbacheva Memorial Research Institute for Pediatric Oncology, Hematology and Transplantation, St. Petersburg, 4Haematology department, N.N. Blokhin Russian Cancer Research Center, 5Scientific clinical laboratory of clinical bacteriology, mycology and antibiotic therapy, 6Cytogenetics laboratory, 7Department of biostatistics, National Research Center for Hematology, Moscow, Russian Federation

Background: As Ph-negative-BCP-ALL in adults remains less favorable in prognosis than T-ALL, and by expert opinion needs intensive protocols with high proportion of allo-HSCT, the results of treatment based on the different approach to escalated but non-interruptive treatment with low numbers of allo-HSCT- may be of interest and can provide new insights to the common view.

Aims: To evaluate survival data and risk groups in Ph-neg-BCP-ALL pts in the RALL-study.
Methods: The ALL-2009 (NCT01193933) was initiated in Apr2009. The treatment plan was identical for all risk groups with allo-HSCT indicated only for MRD-positive patients. PC-MRD was performed in 64 patients (30/42 of PI-MRD-negative & 6/58 of PI-MRD-positive). PC-MRD was positive in 28% (18/64) (median, 0.23% (range, 0.002% to 6%) of PI-MRD-positive patients. PC-MRD was available in 64 patients (30/42 of PI-MRD-negative & 6/58 of PI-MRD-positive). PC-MRD was positive in 28% (18/64) (median, 0.2% range, 0.009% to 4%) of PI-MRD positivity. ETP-ALL was positive in 93% vs 53% (p=0.01). Median follow-up of all patients was 14 months (3-38 months). Patients were censored at death after alloHSCT. All-HSCT was performed in 13 (6 – matched related donors, 7 MUD) of 176 patients who survived induction (74%, 11% of them – in 1CR). Totally 59 pts (34.9%) had relapsed. All 7y OS for the whole cohort constituted – 54.3%, DFS – 56.5%, RP – 35.4%. In a multivariate analysis for BCP-ALL among common risk factors (age >30y, initial risk group, WBC >30, LDH>2N; immunophenotype, late CR >35d, CNS leukemia, cytogenetics) age, WBC, t(4;11) was statistically significant for OS, DFS and RP. We developed a new threshold for the most valuable risk factors. New risk groups stratification demonstrated 7y OS=79%, DFS=71%, RP=23% in the standard risk (SR) group (age <27y,WBC <75*10^9/l, no t(4;11)) & 64%,45%,47%, respectively, in the HR group (age >27y,WBC >75*10^9/l, t(4;11)).

Results: CR rate in 191 pts was 87.4% (n=167), induction death occurred in 8.9% (n=17), resistance was registered in 3.7% (n=9). Late responders constituted 13.6% (n=26). Death in CR on chemotherapy was 6.3% (n=12) and 1 death after alloHSCT. All-HSCT was performed in 13 (6 – matched related donor, 7 MUD) of 176 patients who survived induction (74%, 11% of them – in 1CR). Totally 59 pts (34.9%) had relapsed. All 7y OS for the whole cohort constituted – 54.3%, DFS – 56.5%, RP – 35.4%. In a multivariate analysis for BCP-ALL among common risk factors (age >30y, initial risk group, WBC >30, LDH>2N; immunophenotype, late CR >35d, CNS leukemia, cytogenetics) age, WBC, t(4;11) was statistically significant for OS, DFS and RP. We developed a new threshold for the most valuable risk factors. New risk groups stratification demonstrated 7y OS=79%, DFS=71%, RP=23% in the standard risk (SR) group (age <27y,WBC <75*10^9/l, no t(4;11)) & 64%,45%,47%, respectively, in the HR group (age >27y,WBC >75*10^9/l, t(4;11)).

Summary/Conclusions: Our data demonstrate that non-intensive but non-interruptive treatment with fewer allo-HSCTs is rather effective in adult BCP-ALL producing more than 50% OS at 7 years, though the RP is high. In our study among common risk factors only age, initial WBC and t(4;11) remained the most valuable markers of poorer prognosis, while immunophenotype, time to CR, CNS involvement, and other cytogenetic markers did not matter. So RALL protocol without intensive highly myelosuppressive consolidation courses and high portion of allogeneic HSCT, may become an alternative and reproducible approach for adult Ph-negative ALL.

POST-INDUCTION MINIMAL RESIDUAL DISEASE RESPONSE DETERMINED BY MULTICOLOR FLOW CYTOMETRY IS A POWERFUL INDICATOR OF EVENT-FREE-SURVIVAL IN THE CHILDHOOD T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

P. Subramanian1, G. Narula2, B. Arora2, N. Deshpande1, Y. Badrinath1, S. Gujral1, S. Banawali2, Subramanian1

1Department of Pediatrics and Adolescent Medicine, University Medical Center, Ljubljana, Slovenia; 2Department of Hematology, University Medical Center, Ljubljana, Slovenia

Background: Minimal residual disease (MRD) is a powerful predictor of event-free survival in acute leukemia including T-cell acute lymphoblastic leukemia (T-ALL). Due to lower incidence of T-ALL, MRD studies are limited, therefore restricted to a small cohort of patients. Moreover, flowcytometry based MRD (FC-MRD) studies in T-ALL are very few. AIEOP-BFM group showed that late (Day-78) MRD response determines overall risk-of-relapse and event-free-survival (EFS) using RQ-PCR. However, a larger study by COG (Brent Wood et al., 2017) showed that post-induction FC-MRD was more relevant in the pre-diction of EFS. This indicates that the best time for MRD evaluation for the risk stratification in T-ALL is still not clear and need more studies. We investigated the value of post-induction FC-MRD response in an assessment of EFS in childhood T-ALL. It is a first T-ALL MRD study from India.

Methods: We studied post-induction (Day-35) MRD (PI-MRD) & post-consolidation (Day-78) MRD (PC-MRD) in bone marrow samples from 100 patients of T-ALL treated under modified MOP-81 protocol between 2014 & 2016. In T-ALL with early-thymic-precursor (ETP) immunophenotype, patients received dexamethasone in place of prednisolone. MRD was performed using 10-color FC-MRD assay on Navios flow-cytometer (Beckman Coulter, BC) and MRD analysis was performed with Kaluza software v-1.3 (BC). Any detectable level of MRD (≥20 events) was defined as MRD-positive. Events included relapse & disease-related deaths. Statistical analysis was performed using SPSS v.16.

Results: The median age of patients was 11.5 years (range 2–16 y; M:F=4–6). Based on the immunophenotypic criteria, 13 patients were diagnosed as ETPALL & remaining 87 an as non-ETPALL type. PI-MRD was positive in 58/100 (58%) with the median level of 0.23% (range, 0.002% to 6%). PC-MRD was not performed in 71.4% (30/42) of PI-MRD-negative & 1.2% (6/58) PI-MRD-positive patients. PC-MRD was available in 64 patients (30/42 of PI-MRD-negative & 6/58 of PI-MRD-positive). PC-MRD was positive in 28% (18/64) (median, 0.2% range, 0.009% to 4%) of PI-MRD positivity. ETP-MRD positivity was significantly high in ETPALL as compared to non-ETPALL (93% vs 53%; p=0.01). Median follow-up of all patients was 14 months (3-38 months). Patients were censored at death after alloHSCT. All-HSCT was performed in 13 (6 – matched related donors, 7 MUD) of 176 patients who survived induction (74%, 11% of them – in 1CR). Totally 59 pts (34.9%) had relapsed. All 7y OS for the whole cohort constituted – 54.3%, DFS – 56.5%, RP – 35.4%. In a multivariate analysis for BCP-ALL among common risk factors (age >30y, initial risk group, WBC >30, LDH>2N; immunophenotype, late CR >35d, CNS leukemia, cytogenetics) age, WBC, t(4;11) was statistically significant for OS, DFS and RP. We developed a new threshold for the most valuable risk factors. New risk groups stratification demonstrated 7y OS=79%, DFS=71%, RP=23% in the standard risk (SR) group (age <27y,WBC <75*10^9/l, no t(4;11)) & 64%,45%,47%, respectively, in the HR group (age >27y,WBC >75*10^9/l, t(4;11)).

Summary/Conclusions: We concluded that 10-color FC-based post-induction MRD response is a powerful indicator of EFS in childhood T-ALL. The frequency of PI-MRD positivity was significantly high in ETPALL indicating a lower tumor clearance rate. There was no difference in the EFS based on the level of PI-MRD-positivity indicating even a low level (<0.01%) PI-MRD is important in risk-stratification of childhood-TALL.

E838

SMAC MIMETICS - A NOVEL THERAPEUTIC APPROACH IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M. Meyer1,*, J. Zinggrebe1, L.-H. Meyer1, K.-M. Debatin1

1Department of Pediatrics and Adolescent Medicine, University Medical Center, Ulm, Germany

Background: Pediatric acute lymphoblastic leukemia (ALL) is one of the most common malignancies in childhood. Survival rates have increased enormously over the past decades, but the prognosis for patients with relapsed ALL or ALL refractory to chemotherapy remains poor. Thus, novel therapeutic options are urgently required. The family of inhibitor of apoptosis proteins (IAPs) has been shown to play an important role in the prevention of cell death, and to mediate gene activation important for cell survival. Many of the cellular processes regulated by IAPs are deregulated in cancer. Thus, IAPs represent a promising target in anticancer therapy. IAP antagonists, also known as SMAC Mimetics (SMAs), were developed to counteract IAPs' function. SMAs have been shown to induce cell death in a number of different cancer entities, amongst them B cell precursor (BCP)-ALL. In BCP-ALL, SM-induced cell death was
showed to depend on autocrine TNF secretion. Of note, only a subset of BCP-ALL cell lines and primografts showed sensitivity to SM treatment. Little is known about the underlying molecular mechanisms conferring resistance to SM treatment.

Aims: Evaluation of the efficacy of different SMs in inducing cell death in BCP-ALL and T-ALL cell lines. Identification of the underlying molecular resistance mechanisms to SMs in BCP-ALL and T-ALL cell lines.

Methods: Cell death induced by SMs AT406 (Debiopharm Int.), LCL161 (Novartis), Binapantit (Medivir) and BV6 (Genentech) was evaluated by FSC/SSC in the BCP-ALL cell lines Nalm6, Reh, UoC86 and RS-114 and in the T-ALL cell lines ALL-SIL, CEM, Jurkat and Molt4. Expression of cellular inhibitor of apoptosis proteins (cIAPs) 1/2 and X-linked inhibitor of apoptosis protein (XIAP) in presence and absence of different SMs was assessed in the above-named cell lines by Western blot. The mode of cell death was assessed using inhibitors of Caspase activity (zVAD) and receptor-interacting protein 1 kinase (RIPK1) activity (Nec-1). Dependency of SM-induced cell death on TNF secretion was assessed by stimulation of Eanetrap, a TNF-R2-Fc fusion protein.

Results: BCP-ALL cell lines Reh and UoC86 and T-ALL cell lines ALL-SIL and CEM were identified to be sensitive to SM-induced cell death with half maximal inhibitory concentration (IC50) values below 1 micromolar. Interestingly, we found that the bivalent SMs Binapantit and BV6 are up to 100x more effective in killing BCP-ALL than their monovalent SMs AT406 and LCL161. SM treatment resulted in efficient and rapid degradation of cIAP1 and 2 in both, sensitive and resistant cell lines. Interestingly, all tested SMs were equally efficient in degrading cIAPs indicating that the resistance mechanisms are likely to be downstream of cIAPs. Next, we assessed the mode of SM-induced cell death in BCP-ALL cell lines by using zVAD or Nec-1 in order to block activity of Caspasases or RIPK1, respectively. These experiments showed that Reh and UoC86 cells die by apoptosis whilst CEM cells die by necroptosis upon stimulation with SMs. SM-induced cell death in ALL-SIL cells was neither blocked by zVAD nor Nec-1 nor the combination thereof. These results are substantiated by downregulation of Eanetrap, a TNF-R2-Fc fusion protein with the novel SMs BV6 and LCL161.

Summary/Conclusions: We identified a subset of both, BCP- and T-ALL cell lines to be sensitive to SM-induced cell death with IC50 values below 1 micromolar. Monovalent SMs are less effective than bivalent SMs in killing ALL cell lines. SMs induce differential modes of cell death with a variable dependency on autocrine TNF secretion in the sensitive ALL cell lines. In-depth molecular characterization of resistance mechanisms of ALL cells to SM-induced cell death is required to identify patients that will benefit from a SM-based treatment regimen.

SINGLE-AGENT MOR208 IN PATIENTS WITH RELAPSED/REFRACTORY (R/R) B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL): A SINGLE-ARM PHASE II STUDY

K. Klisovic1,*, M. Winderlich2, S. Ambarkhane2, E. Jabbour3

Methods: This is a single-arm phase II study of MOR208 in patients aged ≥16 years with histologically confirmed R/R B-ALL with progression after at least one prior therapy. Patients with Philadelphia-chromosome-positive (Ph+) B-ALL were excluded. Prior exposure to dose-limiting myelosuppressive and tyrosine kinase inhibitor. MOR208 was administered at 12mg/kg IV, weekly, over 2-28 day cycles, with a loading dose on day 4 of cycle 1. Patients with a partial response (PR) could receive a further 2 cycles of MOR208; patients with a complete response (CR) or CR with incomplete count recovery (CRi) after 2-4 cycles could receive an extended duration of up to 8 cycles. The primary endpoint was the overall response rate.

Results: 22 patients were enrolled; median age was 16 years (range 16-79). 12 (55%) patients were male. 6 (27%) patients had previously received an allogeneic stem cell transplant (SCT), the most common disease subtype was pre-B-ALL (15, 68%) and 2 (9%) patients had Ph+ B-ALL. 6 (27%) patients received ≥2 cycles of MOR208 and had a subsequent response assessment. Responses were seen in 2 patients; and included a CR and a CRi, giving an overall response rate of 9%. 2 patients received extended MOR208 treatment. A further 3 (14%) patients did not fulfill the criteria for PR but did not progress; 16 (73%) patients withdrew before completing cycle 2, in most cases due to progressive disease (PD). The patient in CR met the criteria for allo- genic SCT, but declined this at the time; response duration was 6 weeks, with subsequent PD. The patient with the CRi had a response duration of at least 4 weeks, but discontinued due to a treatment-emergent adverse event (TEAE), sclerosing cholangitis. For 12 out of 13 patients with available data, MOR208 treatment led to a rapid reduction in blast/B-cell counts in the peripheral blood; in most cases a reduction of >90% within 1 week of treatment initiation was seen. TEAEs were febrile neutropenia, thrombocytopenia, neutropenia, sepsis and hyperglycemia (each 5 [23%] patients). Infusion-related reactions were reported in 13 (59%) patients; all occurred on day 1 of cycle 1 and were mostly grade 1 or 2, with one grade 3 event; all patients recovered on the same day. Pharmacokinetic data were comparable with previous clinical studies and anti-MOR208 antibodies were not detected.

Summary/Conclusions: MOR208 showed signs of clinical efficacy with rapid reductions in peripheral blood blasts in most patients with R/R B-ALL, but the durability and frequency of achieving CRs was suboptimal, which was not unex- pected given the refractory disease setting. The median IC50 for MOR208 was consistent with previous studies and favorable, further development as a part of a combination treatment in R/R B-ALL remains a promising approach.

E840

UPDATED RESULTS FROM ZUMA-4: A PHASE 1/2 STUDY OF KTE-C19 CHIMERIC ANTIGEN RECEPTOR (CAR) T CELL THERAPY IN PEDIATRIC AND ADOLESCENT PATIENTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA

Methods: This is a phase 1/2 trial of KTE-C19 in pediatric and adolescent patients with relapsed/refractory acute lymphoblastic leukemia (ALL). Patients ≥2-21 y of age with relapsed/ refractory ALL and high disease burden with a median marrow lymphoblast content of 57% had high disease burden with a median marrow lymphoblast content of 57% and had undergone chemotherapy refractory to at least 1 prior therapy. Patients were treated with escalating doses of KTE-C19 at 1×10⁶ CAR T cells/kg, 2×10⁶ CAR T cells/kg and at 2×10⁶ CAR T cells/kg. As of 19 Jan 2017, 5 patients have enrolled and 4 have been treated with KTE-C19 at 2×10⁶ CAR T cells/kg. KTE-C19 was successfully manufactured in a centralized, streamlined 6-8 day process for all patients across a 4-week time frame. Baseline absolute lymphocyte counts (0.21–1.0x10⁹/L) except in 1 patient who had disease progression with white blood cells 150,000/µL at apheresis and <0.2% T cells in the apheresis collection. All 4 treated patients had high disease burden with a median marrow lymphoblast content of 57%
(range, 41–99%). All 4 patients received bridging chemotherapy during the manufacturing period before conditioning chemotherapy and KTE-C19. No patient experienced a dose-limiting toxicity. One patient had a grade 5 adverse event of disseminated mucormycosis which was not related to KTE-C19. Cytokine release syndrome was reported in all 4 patients (all ≤ grade 3); neurologic events were reported in 1 patient (grade 3). All cytokine release syndrome events resolved with tocilizumab, corticosteroids, and/or sulfasalazine plus other supportive care with a median duration of 8.5 days (range, 4-16 days). Minimal residual disease-negative remission was observed in all 4 patients. One patient received stem cell transplant post-remission, which is allowed per protocol at investigator discretion. Peak expansion of CAR T cells occurred 1-2 weeks post-KTE-C19 infusion. Updated data with additional patients, different dose of KTE-C19, earlier tocilizumab use, and biomarkers will be presented.

Summary/Conclusions: KTE-C19 after low-dose CyFlu has been tolerable and appears safe for further analysis in pediatric and adolescent patients with R/R ALL. No toxicities were observed with KTE-C19 at the 2×10^6 cells/kg dose in patients despite high leukemic burden. All patients receiving KTE-C19 achieved a minimal residual disease-negative remission. Based on these results, ZUMA-4 continues to enroll (NCT02625480).

Methods with strong sensitivity for OS prediction on D26 were RQ-PCR with 1.0×10^-4 cut-off (4-year OS: 76.6% vs 48.8%; median OS: not reached vs 39.1 months; p=0.012) and FCM (4-year OS: 78.3% vs 30.3%; median OS: not reached vs 27.4 months; p=0.016). The most sensitive method in W11 was RQ-PCR with every positive result considered MRD positive (4-year OS: 79.6% vs 53.1%; median OS: not reached vs 46.5 months; p=0.013). Flow cytometry and PCR with other cut-offs were not sufficiently sensitive. The sub-analysis of Ph-negative patients has shown the same results for RQ-PCR (p<0.01).

Summary/Conclusions: Our analysis has shown both RQ-PCR and FCM to be suitable methods for MRD assessment on D26 of induction in adult ALL patients receiving an intensive treatment. Furthermore it seems convenient to take any RQ-PCR positivity (even below 1.0×10^-4) into account in W11 and later stages of treatment. FCM can be used for MRD assessment on D26, but it is not sufficiently sensitive in later stages of treatment. We suggest using RQ-PCR as a method of choice for MRD assessment in adult ALL while reserving FCM as a backup method for patients without applicable RQ-PCR target or when faster MRD evaluation is needed.

Supported by MUNI/A/1106/2016 grant of Masaryk University, Czech Republic and the Czech Leukemia Study Group for Life.

**COMPARISON OF 8-COLOR FLOW CYTOMETRY AND PCR-BASED METHODS IN MEASUREMENT OF MINIMAL RESIDUAL DISEASE IN ADULT ACUTE LYMPHOCYTIC LEUKEMIA**

S. Hrabovsky1,2,*, F. Folber1,2, J. Horacek3,4, O. Stelhikova1, H. Jelinkova1, C. Salek1,6, M. Doubek1,2,7

1Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, 2Faculty of Medicine, Masaryk University, Brno, 34th Department of Internal Medicine – Hematology, University Hospital and Charles University, Faculty of Medicine Hradec Kralove, 4Department of Military Internal Medicine and Hygiene, University of Defence, Faculty of Military Health Sciences, Hradec Kralove, 5Institute of Hematology and Blood Transfusion, 6First Faculty of Medicine, Charles University, Prague, 7Central European Institute of Technology, Brno, Czech Republic

**Background:** The presence of minimal residual disease (MRD) is the most important prognostic factor in adult acute lymphoblastic leukemia (ALL). MRD monitoring is routinely performed by flow cytometry (FCM) and real-time quantitative polymerase chain reaction methods (RQ-PCR).

**Aims:** We conducted a retrospective analysis comparing these MRD measurement methods in ALL patients treated in three Czech hematology/oncology centers within the CELL group (Czech Leukemia Study Group for Life).

**Methods:** Adult patients (age 18-55) with both Ph-negative and positive ALL were enrolled in the study, all treated consecutively between 2008 and 2016 according to a pediatric-inspired CELL ALL protocol. Samples for MRD evaluation were acquired from bone marrow on day 26 of induction (D26) and in the 11th week of treatment before the first consolidation (W11). We divided RQ-PCR MRD positive and negative groups using three different cut-off values and analyzed them separately: 1) 1.0×10^-3, 2) 1.0×10^-4, 3) every RQ-PCR positive result considered MRD positive even below 1.0×10^-4. Cut-off value 1.0×10^-3 was used for FCM MRD. Results were statistically analyzed by the Kaplan-Meier method and log-rank (Cox-Mantel) test.

**Figure 1.** Results: total number of 103 patients was evaluated. Nine of them (8.7%) who did not reach a hematology remission on D26 were excluded from the study. The total response rate of the final cohort was 98.3% (N=73). RQ-PCR of immunoglobulin heavy chain (IgVH, N=62) or T-cell receptor (TCR, N=3) clonal rearrangements and BCR-ABL (N=24), MLL-AF4 (N=4) and E2A-PBX1 (N=1) fusion genes.

**QUALITY-ADJUSTED LIFE YEARS (QALY) FOR INOTUZUMAB OZOGAMICIN VS STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBlastic LEUKEMIA (R/R ALL)**

I. van Oostrum1,*, Y. Su1, B. Hoeij1, T. Wilke2, A. Smith3, F.R. Lobertza2

1Ingress-health Netherlands, Rotterdam, Netherlands, 2Pfizer Inc, New York, United States, 3Ingress-health Germany, Wismar, Germany, 4Pfizer, Ltd, Walton Oaks, United Kingdom

**Background:** Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, has demonstrated superior clinical activity versus standard of care (SOC; intensive chemotherapy), including clinically meaningful short- and long-term survival.

**Aims:** This study aimed to estimate mean overall survival adjusted for QoL (QALY) for patients treated with InO vs SOC.

**Methods:** A Markov model was developed with five health states - No CR, CR, post-HSCT, progression, and death. Lengths and transition probabilities between health states and mortality rates were based on the InO-VATE trial. These rates were extrapolated to a lifetime horizon using parametric survival curves fitted to available OS data, and published literature for survival beyond available data. Utilities (QoL valuations) for each health state were based on the patient-reported EQ-5D scores collected in the InO-VATE trial and a literature review for health states not captured in the trial. Disutilities from adverse events experienced during and after treatments, including adverse events as a result of subsequent HSCT such as veno-occlusive disease (VOD), were taken into account in overall QoL. Outcomes were discounted at 1.5% and half-cycle corrected.

**Results:** The estimated mean LY and QALY in each health state for InO and SOC and their differences are shown in Table. Most gains in LY and QALY for InO over SOC were from Post-HSCT. Additionally, a “tail-of-the-curve” survival gain Post-HSCT is observed in InO but not SOC. InO offers an average of nearly 2 more QALY compared to SOC in R/R ALL, based on higher CR and HSCT rates, “tail-of-the-curve” survival gains, and better QoL. This can help inform patients, physicians and payers in decision making.

**Summary/Conclusions:** This analysis taking into account both quantity and quality of life estimates shows that InO offers an average of nearly 2 years of QALY compared to SOC in R/R ALL, based on higher CR and HSCT rates, “tail-of-the-curve” survival gains, and better QoL. This can help inform patients, physicians and payers in decision making.

**A COST-EFFECTIVE, HIGH SENSITIVITY 10-COLOR SINGLE TUBE FLOW-CYTOMETRY BASED B-CELL PRECURSOR ACUTE LYMPHOCYTIC LEUKEMIA MINIMAL RESIDUAL DISEASE (MRD) ASSAY WITH STUDY OF ARTIFACTS AND MIMICS**

G. Chatterjee1,*, D. Dhaliwal1, S. Ghogale1, B. Yajamanam1, N. Deshpande1,

1Ingress-health Netherlands, Rotterdam, Netherlands, 2Pfizer Inc, New York, United States, 3Ingress-health Germany, Wismar, Germany, 4Pfizer, Ltd, Walton Oaks, United Kingdom

**Background:** MRD evaluation methods in ALL patients treated in three Czech hematology/oncology centers within the CELL group (Czech Leukemia Study Group for Life). The most sensitive method was RQ-PCR with every positive result considered MRD positive (4-year OS: 79.6% vs 53.1%; median OS: not reached vs 46.5 months; p=0.013). Flow cytometry and PCR with other cut-offs were not sufficiently sensitive. The sub-analysis of Ph-negative patients has shown the same results for RQ-PCR (p<0.01).

**Summary/Conclusions:** Our analysis has shown both RQ-PCR and FCM to be suitable methods for MRD assessment on D26 of induction in adult ALL patients receiving an intensive treatment. Furthermore it seems convenient to take any RQ-PCR positivity (even below 1.0×10^-4) into account in W11 and later stages of treatment. FCM can be used for MRD assessment on D26, but it is not sufficiently sensitive in later stages of treatment. We suggest using RQ-PCR as a method of choice for MRD assessment in adult ALL while reserving FCM as a backup method for patients without applicable RQ-PCR target or when faster MRD evaluation is needed.

Supported by MUNI/A/1106/2016 grant of Masaryk University, Czech Republic and the Czech Leukemia Study Group for Life.
Mineralization disease (MRD) has been proven to be the most important indicator of relapse in BCP ALL. Recently, flow-cytometry based MRD has been shown to achieve a sensitivity of <10^{-5} using a standardized panel with high number of event acquisition. However, high-sensitivity BMRD analysis is based on experience and acquisition of high number of events also includes other rare BM cellular elements and artifacts. We present a study of the cost-effective high-sensitivity 10-color single tube FC-MRD assay in BCP ALL along with description of rare BM cellular elements and artifacts causing interference in analysis.

Aims: 1. To study the applicability and sensitivity of a 10-color high event single tube FC-MRD assay for BCP ALL; 2. To document the rare BM cellular elements and artifacts causing interference in high-sensitivity FC-MRD assay for BCP ALL and describe their prevalence and immunophenotypic features.

Methods: We studied 230 BCP ALL MRD samples. FC-immunophenotyping was performed on Navios flow-cytometer using bulk-lysis-and-stain method and data was analyzed with Kaluza-software. MRD was monitored using 10-color single tube FC-MRD assay including CD45, CD10, CD19, CD20, CD34, CD38, CD58, CD98, CD123 and CD25/CD73 with an additional 4-color nuclear dye (SYTO13) tube. Samples with cluster of 2x0 and 2 leukemia associated phenotypes (LAIPs) were called MRD-positive. High number of events were acquired for MRD-assay (1.5 to 6 million). To evaluate the applicability of assay, number of LAIPs were determined in diagnostic and MRD samples. In addition, the frequency and antigen expression pattern of mimics and artifacts were studied.

Results: We studied 230 BCP ALL MRD samples. High number of events was acquired for MRD-assay with median events 3427000 (range, 1678000 to 6052800). We determined the limit of detection (LOD=10 events) and limit of quantitation (LOQ=30 events) by performing dilution assay. MRD was positive in 107 (46.5%) samples with median of 0.135% and range of 0.0003% to 48.3%. We categorized positive MRD results into samples with MRD <0.001%,<0.001-%<0.01%, <0.01%, <0.1%, <1.0% and >1% and they were respectively 1.74%, 10.43%, 13.48%, 5.65% and 10.00%. Furthermore, in 24 samples with MRD-positive <0.01% and >1.5 million acquired-events, the results were compared between time-gated initial 500000-events and all events acquired. Sixteen samples among these were found to be negative in initial 500000-events and eight in initial 1000000-events highlighting the importance of acquisition of >1.5 million cells. Further, we categorized rare cellular events and artifacts in the following way: 1) CD34+ mature B cells; 2) CD10+ mature B cells; 3) CD73+ mesenchymal stromal/stem cells and endothelial cells; 4) CD123+ CD19+ ?PDC precursors; 5) CD86+ CD58+ B cell precursors (BCP); 6) CD19+ NK cells (Table 1). We also described their immunophenotypic features highlighting the differential features from MRD and B cell precursors (Figure 1).
with b-blockers, as they could limit anthracycline toxicity by their heart rate-lowering activity and antioxidant effect. All the 8 patients subsequently improved in both GLS and LVEF values, despite the occurrence of one episode of mild hypotension in 2 patients.

**Summary/Conclusions:** All children, even if exposed to low doses of anthracycline, show early signs of LV impairment. Overt drop in LVEF, when present, mostly follow GES alterations. Alterations seem more frequent in HR pts, possibly due to the higher burden of both leukemia itself and HR treatment. Further studies on wider series are needed to confirm the relevance of the early diagnosis of LV preclinical dysfunction in pediatric ALL patients.

**NUDT15 VARIANT CAUSING HEMATOPOIETIC TOXICITY WITH LOW 6-TGN LEVEL IN KOREAN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA**

H. Hoe Koo1,*, E. Sang Yi2, Y. Bae Choi3, N. Hee Lee4, J. Won Lee1, K. Hee Yoo1, K. Woong Sung1, R. Choi2, S.-Y. Lee1

1Pediatrics, Sungkyunkwan Univ School of Medicine, Samsung Medical Center, 2Department of Pediatrics, Korea University Guro Hospital, Korea University College of Medicine, 3Department of Pediatrics, Chung-Ang University Hospital, Seoul, 4Department of Pediatrics, Cha Bundang Medical Centre, Cha University, Seongnam, 5Department of Laboratory Medicine and Genetics, Sungkyunkwan Univ School of Medicine, Samsung Medical Center, Seoul, Korea, Republic Of

**Background:** NUDT15 polymorphism has been recently identified as a determinant of thiopurine intolerance. 6-thioguanine nucleotides (6-TGN) is monitored to prevent hematopoietic toxicity in acute lymphoblastic leukemia (ALL).

**Aims:** This study intended to evaluate the impact of NUDT15 polymorphism on thiopurine intolerance and 6-TGN level in Korean children with ALL.

**Methods:** Genotyping of NUDT15 was performed in 258 children with ALL who were registered in Samsung Medical Center. According to NUDT15 diptotype, patients were classified into low risk (LR, wild-type), intermediate risk (IR, heterozygous) or high risk (HR, homozygous or compound heterogeneous variant). Total of 182 were finally included after 76 patients were excluded for TPMT variation or lack of information during maintenance therapy; LR (n=131), IR (n=46), and HR (n=5).

**Results:** The least 6-mercaptopyrine (6-MP) dose (mg/m²/day) were administered as per low risk 5.9 ± 3.0 (LR), 5.9 ± 3.1 (IR), 8.0 ± 3.8 (HR) by intent-to-treat, and the longest of days therapy of interruption (HR 167 vs IR 30 ± 15, p<0.01) and days of leukopenia (HR 131 vs IR 92 vs LR 59, p<0.01). The lowest WBC and platelet counts and hemoglobin level were observed in HR, 6-TGN level (mole/8x10⁸ RBC) divided by 6-MP dose (mgs/m²) was the lowest in HR group (4.4 ± 0.4 vs IR 13.3 ± HR 14.7, p<0.01).

**Summary/Conclusions:** Patients with NUDT15 variants encountered significant thiopurine intolerance even with low level of 6-TGN. This concurs with the existing hypothesis that NUDT15 protein may prevent incorporation of thiopurine active metabolites into DNA. Therefore 6-TGN monitoring is not useful to predict hematopoietic toxicity for patients with NUDT15 variant.

**USING NEXT GENERATION SEQUENCING TO DETECT CLONAL TRG AND TRB GENE REARRANGEMENTS**

P. Shah1,*, Y. Huang1, K. Hutt1, T. Stenzel1, J.E. Miller1

1Invivoscribe Technologies, Inc., San Diego, United States

**Background:** During early T-cell development, somatic rearrangements occur in T cell receptor beta (TRB) locus that bring together, sequentially, the joining of D and J gene segments, followed by joining of a V segment to the DJ (FR1, FR2, FR3) framework 1, 2, 3 (FR1, FR2, FR3); and joining regions (J) are the current gold standard for clonality testing in suspected B-cell malignancies. Recently, next-generation sequencing (NGS) based approaches for immune receptor genes have been developed that improve sensitivity and identify the specific V-(D-)J DNA sequences required to track clones in follow-up testing. We have developed comprehensive LymphoTrack® IGH and TRG (IGH1FR, 2FR, 3FR) Assays for both the Illumina® MiSeq and Thermofisher Scientific® Ion PGM® platforms, which detect the vast majority of rearrangements in a single NGS run. In this pilot study, we compared the performance of both LymphoTrack® IGH MiSeq and PGm Assays to the IGH PCR-CE assay by testing in 59 anonymized, blinded clinical samples.

**Aims:** To assess the clinical performance of LymphoTrack® IGH MiSeq and PGm Assays

**Methods:** LymphoTrack® IGH Assay has been developed for both the MiSeq and PGm platforms. Proprietary consensus primers targeting the V and J gene segments of IGH were designed to include both platform specific adapter sequences and individual barcodes so multiple independent PCR products could be combined and sequenced together on the MiSeq or PGm platforms. MiSeq IGH FR master mixes were individually manufactured with 24 indices to allow analysis of 22 samples with 2 controls. IGH PGm FR master mixes were manufactured with 12 indices to allow analysis of 10 samples with 2 controls. DNA was extracted from 21 PB, 37 FFPE and 1 BM clinical samples. Sample PCR amplification of 50 ng DNA input was followed by ampiclon purification. Equimolar amounts of purified amplicons were pooled and loaded onto the PGm or MiSeq instruments. The sequencing data was analyzed using LymphoTrack® software, which first sorted the sequences by both index and frame-specific sequences and individual barcodes so multiple independent PCR products could be combined and sequenced together on the MiSeq or PGm platforms. MiSeq IGH FR master mixes were individually manufactured with 24 indices to allow analysis of 22 samples with 2 controls. IGH PGm FR master mixes were manufactured with 12 indices to allow analysis of 10 samples with 2 controls. The on-target reads per sample were 100% (51/51).

**Summary/Conclusions:** This combo NGS assay provides a fast, simple, and accurate method to detect clonality. In combination with the LymphoTrack software, the TRG + TRB MiSeq assay can identify clonal TRB and TRG V-(D-)J rearrangements and the specific V-(D-)J region DNA sequences required to track clones in follow-up testing. Excellent concordance between clonality with specific rearrangements was demonstrated between LymphoTrack® MiSeq and PCR-CE method.

**DETECTION OF CLONALITY IN CLINICAL SPECIMENS FROM SUSPECTED B-CELL MALIGNANCIES USING COMPREHENSIVE IGH LYPHOTRACK® MISEQ® AND PGM® ASSAYS**

Y. Huang1,*, K. Hutt1, J. Panagian1, A. Jacobsen1, N. Wong1, D. Duong1, R. Bob1, S.A. Plen1, L. Bernard2, E. Gerbino3, T. Stenzel1, J.E. Miller1

1Invivoscribe Technologies, San Diego, United States, 2Institute for Pathodiagnosis Berlin, Germany, 3Haematopathology Unit at European Institute of Oncology, Milan, Italy

**Background:** PCR-based capillary electrophoresis (PCR-CE) methodstarget the heavy chain (IGH) framework 1, 2, 3 (FR1, FR2, FR3) andjoining regions (J) are the current gold standard for clonality testing in suspected B-cell malignancies. Recently, next-generation sequencing (NGS) based approaches for immune receptor genes have been developed that improve sensitivity and identify the specific V-(D-)J DNA sequences required to track clones in follow-up testing. We developed comprehensive LymphoTrack® IGH (FR1, FR2, & FR3) Assays for both the illumina® MiSeq and Thermofisher Scientific® ion PGM® platforms, which detect the vast majority of rearrangements in a single NGS run. In this pilot study, we compared the performance of both LymphoTrack® IGH MiSeq and PGm Assays to the IGH PCR-CE assay by testing in 59 anonymized, blinded clinical samples.

**Aims:** To assess the clinical performance of LymphoTrack® IGH MiSeq and PGm Assays

**Methods:** LymphoTrack® IGH Assay has been developed for both the MiSeq and PGm platforms. Proprietary consensus primers targeting the V and J gene segments of IGH were designed to include both platform specific adapter sequences and individual barcodes so multiple independent PCR products could be combined and sequenced together on the MiSeq or PGm platforms. MiSeq IGH FR master mixes were individually manufactured with 24 indices to allow analysis of 22 samples with 2 controls. IGH PGm FR master mixes were manufactured with 12 indices to allow analysis of 10 samples with 2 controls. DNA was extracted from 21 PB, 37 FFPE and 1 BM clinical samples. Single step PCR amplification of 50 ng DNA input was followed by ampiclon purification. Equimolar amounts of purified amplicons were pooled and loaded onto the MiSeq or PGM instruments. The sequencing data was analyzed using LymphoTrack® software, which first sorted the sequences by both index and framework region; then generated frequency distributions, V-J usage, identified specific sequences for top sequencing reads, and determined the somatic hypermutation rate of FR1 amplicons.

**Summary/Conclusions:** The analytical performance of the LymphoTrack® IGH Assay on both NGS platforms was evaluated using dilutions of contrived samples with known V-J rearrangements. Both NGS assays demonstrated excellent linearity (R²>0.90), sensitivity to detect 2.5% clonality, and reproducibility (<20% CV). The clinical performance of the LymphoTrack® IGH NGS assays was evaluated on 59 clinical samples that have also been tested using the PCR-CE IGH assay. Only samples that meet the specimen and data acceptance criteria for both methods were evaluated to determine concordance. Assessment of clonality using the LymphoTrack® IGH MiSeq and PGm Assays demonstrated excellent concordance. The assay was 100% sensitive when the results tested using the LymphoTrack® IGH PGm and PCR-CE assays. Concordance in clonality calls between the LymphoTrack® IGH MiSeq and PGm Assays was 100% (51/51).
Summary/Conclusions: Comprehensive IGH Assays have been developed for both MiSeq and PGM platforms. These assays identify clonal IGH V-J rearrangements and provide the clonal DNA sequences of the tumor-specific clonotypes required to perform follow up testing to detect residual disease. Combining FR1, FR2 and FR3 improved the overall clonality detection rate to 96%. Both NGS-based IGH assays have demonstrated excellent concordance in detecting clonality regardless of whether clonality was determined using a PCR-CE method or with assays formatted for the MiSeq and PGM platforms.

E848
CORRELATION BETWEEN A 10-COLOR FLOW CYTOMETRIC MINIMAL RESIDUAL DISEASE (MRD) ANALYSIS AND MOLECULAR MRD IN ADULT ACUTE LYMPHOPROLIFTIC LEUKEMIA
J. Singh1,*, M. Gorniak1, G. Grigoriadis1,2, D. Westerman3, M. McBean3, N. Venn4, R. Sutton4, M. Morgan1, S. Fleming2,1
1Laboratory Haematomolgy, Alfred Pathology, Alfred Health, 2Clinical Haematology, Monash Health, 3Pathology, Peter MacCallum Cancer Centre at the Victorian Comprehensive Cancer Centre, Melbourne, 4Children’s Cancer Institute, Lowy Cancer Research Centre, UNSW, Sydney, Australia

Background: Minimal residual disease (MRD) monitoring in Acute Lymphoblastic Leukemia (ALL) is an accepted standard of care in both adult and pediatric patients as one of the strongest predictive factors for disease outcome and as a stratification tool for treatment intensification and allogeneic stem cell transplant. The currently accepted standard of molecular monitoring with either immunoglobulin heavy or kappa chain (IG) or T-cell receptor (TCR) quantitative PCR (qPCR) in Philadelphia negative ALL allows for sensitive monitoring of MRD, but requires a high degree of expertise, and factors such as cost and turnaround time may limit generalized applicability of this technique. Flow cytometric MRD monitoring is utilized in many centers, with increased sensitivity seen with implementation of multi-parameter flow cytometry at 8-colours or more.

Aims: We sought to compare a 10-color flow cytometry assay for detecting MRD in B-ALL with standard molecular monitoring.

Methods: To facilitate rapid identification of MRD in patients with B-ALL, we developed a 10-colour single tube flow cytometry assay utilizing CD19, CD22, CD20, CD38, CD58, CD13/33, CD66c, CD10, CD45 and CD34 as markers. These markers were selected to provide at least two targets for identification of B-lineage cells, and to include the most frequently aberrant markers in pre-cursor B-lineage ALL. Samples were subject to bulk ammonium chloride lysis of B-lineage cells, and to include the most frequently aberrant markers in pre-cursor B-lineage ALL. Samples were subject to bulk ammonium chloride lysis to maximize cell yields with a target of 1 x 10^6 events. Once normal maturation patterns were established, patient samples were analyzed in parallel to standard of care molecular monitoring with either IG/TCR qPCR in Philadelphia negative (Ph-) disease and BCR-ABL qRT-PCR in Philadelphia positive (Ph+) disease. Statistical correlation was performed in Graphpad Prism version 7.0 for linear regression and calculation of correlation co-efficient.

Results: 33 samples at different time points from 13 patients were analyzed by flow cytometry. 9 samples from 9 patients were taken at diagnosis. Whilst an informative MRD phenotype was identified by flow cytometry in all 9 patients, a molecular assay was not able to be developed in one patient due to lack of an identifiable marker. 24 samples from 13 patients were tested for MRD by flow cytometry. The median lower limit of detection was 0.0078% (range 0.0016% to 0.028%) with a median lower limit of quantification of 0.018% (range 0.002% to 0.07%). A sensitivity of <0.01% was attained in 21 of 24 samples (88%). 20 samples from 11 patients were tested concurrently for MRD by both molecular and flow cytometry methods. 11 samples were in Ph- disease and 9 were in Ph+ disease. MRD was detected by both molecular and flow cytometry in 11 samples and not detected by both methods in 8 samples. In one sample, MRD was detected only by molecular at an unquantifiable level. There was a strong correlation co-efficient between molecular and flow cytometric MRD analysis (R^2=0.905, p<0.001). Correlation was strong with both IG/TCR based molecular analysis (R^2=0.949, p<0.001) and BCR-ABL based molecular assays (R^2=0.994, p<0.001).

Summary/Conclusions: 10-color flow cytometric minimal residual disease analysis with bulk lysis attains a high degree of sensitivity in minimal residual disease determination in precursor B-lineage Acute Lymphoblastic Leukemia. There was a strong correlation with molecular MRD monitoring for both quantification of MRD and determination of MRD negative status. Flow cytometric methods may also permit MRD monitoring in patients where a suitable molecular assay cannot be developed.

HYPOGLYCEMIC EVENTS DURING TREATMENT OF PEDIATRIC ACUTE LYMPHOPROLIFTIC LEUKEMIA: OBSERVATIONS FROM TRIAL AIEOP-BFM ALL 2009
D. Bleckmann1,*, J. Allen2, N. Bodmer2, E. Zapotocka3, D. Barbaric4, M. Schrappe1, S. Vieh1, M. Zimmermann5, A. Möricke1
1Department of Pediatrics, University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, Germany, 2Pediatric Oncology and Hematology, Universitäts-Kinderklinik Zürich, Zürich, Switzerland, 3Department of Pediatric Hematology and Oncology, Motol University Hospital, Prague, Czech Republic, 4Centre for Childhood Cancer and Blood Disorders, Sydney Children’s Hospital, Sydney, Australia, 5Pediatric Hematology/Oncology, Medical School Hannover, Hannover, Germany

Background: Hypoglycemia has been reported as a rare side effect in children and adolescents treated for acute lymphoblastic leukemia (ALL). It has been associated to purine nucleoside analogues (PNA), but potential relationship with asparaginase has also been described. Despite these reports, clinicians’ awareness of this risk seems to be limited.

Aims: Descriptive evaluation of symptomatic hypoglycemic events during ALL treatment.

Methods: Hypoglycemic events were analyzed among 3293 patients treated in the trial AIEOP-BFM ALL 2009 in four of the participating countries (Germany, Switzerland, Czech Republic, and Australia) between 06/2010 and 08/2016. PNA were administered during induction-consolidation, the second part of the intensification phase (reinduction-consolidation) and during maintenance (MT). Pegylated asparaginase (PEG-ASP) was given in induction-consolidation as well as high-risk blocks. Additionally, the benefit of intensified PEG-ASP was tested during induction-consolidation in the high-risk group, and during reinduction-consolidation/MT in the medium-risk group. Adverse events were generally captured in a targeted approach by means of defined events assessed as clinically relevant, not including hypoglycemia. Data collection of these events was based on proactive reporting by the investigators. For analysis, clinical severity of the events was retrospectively graded according to patients’ capacity of action and reaction.

Results: In total, 28 hypoglycemic events were reported in 26 of the 3293 patients. 25 events in 23 patients were described as symptomatic, to which further analysis was restricted (22 precursor B- and one T-ALL; 8 standard-risk, 12 medium-risk, and 3 high-risk). Age of patients ranged between 1.7 and 15.5 years at occurrence of symptomatic hypoglycemia. Balanced ratio between both sexes can be observed (13 male, 10 female), median age was essentially similar (male 3.2 y, female 4.1 y). Hypoglycemic events occurred in induction treatment (n=1), induction-consolidation (n=8), induction-consolidation in one standard (n=4; one in standard reinduction, 3 in reinduction with intensified PEG-ASP treatment), high-risk block (n=1), and in MT (n=11; 4 events during standard MT, 6 events during MT with intensified PEG-ASP treatment, and one event 4 weeks after last PEG-ASP during MT). Seven events were reported with mild symptoms, 6 patients showed moderate symptoms, and in 12 events patients showed severe symptoms (loss of consciousness, seizure-like).

Summary/Conclusions: In accordance with previous reports, hypoglycemic events accumulated in PNA containing treatment phases, but not exclusively. Considering that 324 patients of the total cohort were treated with intensified PEG-ASP in reinduction-consolidation/MT, an additive effect of PEG-ASP and PEG asparaginase (as the dominating part of the metabolic condition) may be assumed although a similar effect was not seen in induction-consolidation with intensified PEG-ASP. However, numbers are small and reporting bias of the present data is probable, as hypoglycemic events were not captured systematically. Investigators’ attention to adverse reactions and proactive reporting might be higher.
in experimental arms as well as in case of preceding hypoglycemic events in other patients of the respective trial center. Despite these analytical limitations, our data suggest that hypoglycemia during ALL treatment is a relevant and probably underestimated clinical problem. Further investigation including possible identification of predisposing metabolic conditions is required to avoid harm to patients by this preventable complication.

E850
NUDT15 VARIANT IN KOREAN CHILDREN WITH ACUTE LYMPHOPBLASTIC LEUKEMIA
1Pediatrics, Yeungnam University, College of Medicine, 2Pediatrics, Daegu Fati-
ma Hospital, 3Pediatrics, Keimyung University School of Medicine and Dongsan Medical Center, 4Laboratory Medicine, Yeungnam University, College of Medicine, Daegu, Korea, Republic Of

Background: Acute lymphoblastic leukemia (ALL) is the most prevalent pedi-
atric cancer with cure rates approaching 90% with current therapy. Patient with ALL require long-term maintenance therapy. The combination of weekly methotrexate and daily 6-mercaptopurine (6-MP) is well known to affect the 6-MP tolerance. However prevalence of non-function variant of TPMT is rare in Far East. Recently, a study has identified a variant of the NUDT15 gene associated with intolerance of 6-MP.

Aims: We examined the association between NUDT15 polymorphism and clinical data of Korean pediatric ALL.

Methods: NUDT15 genotyping and collection of clinical data was performed for 74 Korean pediatric ALL patients from two different hospital. For NUDT15 genotyping, DNA was extracted from whole blood/or bone marrow sample and Sanger sequencing was performed for exon 1 and 3 of NUDT15 gene. 6-MP dose intensity, defined as the ration of prescribed 6-MP dose over protocol planned dose.

Results: We found two kinds of variants, c.55_56insGAGTCG(rs869320766) in exon 1 from 8 patients and c.415C>T(rs116855232) in exon 3 from 14 patients. Of them, 7 patients had both variants and all variants were heterozygo-
te. Patients could be divided to four distinct groups according to combinations of genotype (Table 1). 6-MP dose intensity in wild type was higher than three other genotypes during maintenance therapy (p=0.003) (Fig 1). The number of genotype (Table 1). 6-MP dose intensity in wild type was higher than three other genotypes during maintenance therapy (p=0.003) (Fig 1). The number of hospitalization days in wild type is small compared to other three genotypes (p=0.017). Frequency of febrile neutropenia, hepatotoxicity, cumulative days of antibiotics use and overall survival did not significantly differ by NUDT15 genotype.

Table 1. Treatment outcome of children with acute lymphoblastic leukemia according to NUDT15 genotypes.

TREATMENT OUTCOME OF ACUTE LYMPHOCYTIC LEUKEMIA IN KOREAN ADOLESCENTS AND YOUNG ADULTS
1Center for Pediatric Oncology, 2National Cancer Control Institute, 3Hema-
ology Oncology Clinic, National Cancer Center, Goyang-si, Gyeonggi-do, Korea, Republic Of

Background: The outcome of acute lymphoblastic leukemia (ALL) has markedly improved for last centuries, but the improvement was mainly observed in children under 10 years older. In contrast, the treatment outcomes of ALL in ado-
lescents and young adults (AYA) still lag behind those of younger children.

Aims: We conducted this study to investigate the treatment outcome of AYA ALL in Korea, and to define any patterns of care related to the treatment out-
come of AYA ALL.

Methods: Clinical data of 10-29 years old ALL patients diagnosed between 2002 and 2010 were extracted from Korean national health insurance service. Data about patients' diagnosis, age, gender, mainly treated department (internal medicine vs pediatrics), usage data of medications (L-asparaginase, 6-mer-
captopurine, vincristine, prednisolone or dexamethasone), hematopoietic stem cell transplantation (HSCT), radiotherapy, survival, and follow-up duration were collected. Patients who were treated with steroid over 2 weeks, and L-asparaginase at least once in initial 2 months were considered to be treated as pediatric protocol, and who did not fulfill this criteria were considered to be treated as adult protocol.

Results: Total 1,223 ALL AYA patients were diagnosed between the 2002 and 2010, and excluding those who never treated, 1,208 patients underwent ALL treatment. Among them, 665 (55%) patients were treated with pediatric protocol, and the other 543 (45%) patients were treated with adult protocol. Radiotherapy was done in 278 (41.8%) and 186 (34.3%) in each group, and HSCT was done in 205 patients (30.8%) and 216 patients (39.8%) in each group, respectively. Pediatric protocol group showed significantly better overall survival compared to adult protocol group in total age (65% vs 43%, P<0.0001), 10-13 year old (76% vs 57%, P<0.0001), and 20-24 year old patients (51% vs 31%, P=0.0116). In unvariable analysis, patient age (younger), treatment protocol (pediatric), L- Asparaginase, 6-mercaptopurine, and steroid over 2weeks in initial 2 months were associated with better overall survival (P<0.0001 for each). Summary/Conclusions: The overall survival rates in Korean AYA ALL were comparable with previous studies done at other countries. Patients treated with pediatric protocol tended to result better overall survival rate when compared to patients treated with adult protocol. Radiotherapy and early HSCT were wide-
ly used in the 2000s, and further study is needed to follow up the recent trend of treatment, and outcome as a result.

AUTOLOGOUS TRANSPLANTATION AS TIME-DEPENDENT FACTOR FOR SURVIVAL OF PATIENTS WITH T-CELL ACUTE LYMPHOCYTIC LEUKEMIA: STUDY DATA AND SIMULATION MODEL
S. Kulikov1, M. Rusinov1, K. Kulikovskay1, E. Parvichnikova2
1Biostatistics, 2Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: The role of autologous hematopoietic stem cells transplantation (aHSCT) for patients with T-cell ALL is still being discussed. The recent Russia study of ALL shows the promising effect of aHSCT but there is a skepticism as the study was not randomized. The possible bias was referred to the “time selection” factor.

Aims: It’s need to prove that time selection can not explain the magnitude of the effect of aHSCT on patient’s survival.

Methods: We have developed SAS macros time-depend graphical and analytic procedures for time dependent factors: Land Mark (LM) methods, Mantel-Bay-
test, Cox regression model (CM) and also a base for simulation all end points and study events like remission, transplantation, relapse and death are well approximated by a mixture of exponent distributions. Non-constant (dropping) haz-
ard assumption as most possible source of biases was tested on our sim-
ulation model parameters. Russian ALL study group held a prospective multicenter trial RALL-2009 in the treatment of Ph-negative adult ALL patients based on non-intensive but non-interruptive treatment (NCT01193933). The therapy was unified for all Ph-negative ALL pts, but in T-
cell ALL/LBL autologous hematopoietic stem cell transplantation (auto-HSCT) after non-myeloblastic BEAM conditioning was scheduled as intensive condi-
tion (+3-4 mo of CR) followed by prolonged 2 years maintenance. From Jan 2009 till Jul 2016, 30 centers enrolled 107 T-ALL/LBL pts. Median age was 28 years (15-54 y), 34 f / 73 m; early T-cell (T/II) phenotype was verified in 56
(52.3%), mature (T-IV) - in 10 (0.4%), thymic (TIII, CD1a+) ALL - in 41 pts (38.3%). T-lymphoblastic lymphoma (T-IAL <25% b/m blasts) was diagnosed in 22 pts (20.5%). Autologous HSCT was performed in 35, allogeneic-in 7 pts. 

Results: The survival analysis of real data shows 4-fold dropping hazard rate. The effect of aHSCT was confirmed by LM analysis, Mantel-Bay test - PMB=.0004. Cox model output: 1/HR=15.9, P=0.008. (Fig.1). Simulation model for remission consists of 3 fractions: early (α=10%, τ=0.05 m, δ=0.2 m), normal (α=57%, τ=0.28 m, δ=1 m) and late remission (α=33%, τ=1.31 m, δ=2.2 m), for survival consists of 2 fractions: short life (α=59%, τ=22 m), long life (α=41%, τ=600 m). (Fig.2). The first simulation experiment was performed in preparation that transplantation has no effect (HR=1). To exclude the random effect the sample size was N=4000, Mantel-Bay and Cox model show significant (PMB=.50, PCM=.50, HR=.93) but LM plot demonstrates recognizable bias in transplanted patient group (Fig.3). The second experiment supposed that the existed effect of aHSCT (HR=0.5). N=500. Mantel-Bay and Cox model would show significance, but hazard ratio was underestimated (PMB=.03, PCM=.03, HR=.50). (0.5). (97%). Most experiments were done for repeated simulation, which demonstrated a very good agreement of Mantel-Bay and Cox methods and their robustness.

**Figure 1.**

**Summary/Conclusions:** The effect of autologous HSCT in T-cell ALL was confirmed by usual analysis and by simulation experiments. It was shown that potential bias caused by no constant hazard rate cannot explain the magnitude of HSCT effect demonstrated on real data. LM plot could express small bias. Mantel-Bay and Cox model analytical methods are robust against violation of constant hazard assumption and give very concordant output. Cox model underestimate the effect of time-depending factor in case of dropping hazard. Simulations model is a good instrument for testing tests in situations of deviation from theoretical assumptions.

**INDUCTION WITH TYROSINE KINASE INHIBITORS, CONSOLIDATION WITH FLUDARABINE, ARA-C AND DAUNOXOME FOLLOWED BY ALLOGENIC STEM CELL TRANSPLANT IS AN EFFECTIVE AND FEASIBLE STRATEGY FOR PH+ ALL PATIENTS**

N. Di Felice1,*, P. Minetto1, F. Guolo1, M. Clavio 1, M. Miglino1, R.M. Lemoli1, M. Gobbi1

1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa,
2Clinic of Internal Medicine III, Department of Internal Medicine (DIMI), University of Genova, IRCCS AOU San Martino-IST, Genova, Italy

**Background:** The prognosis of Philadelphia positive (Ph+) acute lymphoblastic leukemia (ALL) patients has improved since the introduction of tyrosine kinase inhibitors (TKI). Following TKIs treatment almost all patients rapidly achieve complete hematologic remission (CR). However, only a minority of patients obtain complete molecular response and mot of all will eventually relapse without further treatment. On the other hand, the concomitant combination of TKIs to conventional chemotherapy regimens greatly increases complete molecular responses, but at the price of significant toxicities and high rates of deaths due to toxicity.

**Aims:** We present here the preliminary results of a sequential therapeutic strategy starting with TKI (Dasatinib) as single agent induction until CR is achieved. Fludarabine (Flu), Cytarabine (Ara-C), Lymphosar Daunorubicine (DNX), FLAD regimen and Dasatinib were given as consolidation therapy, in order to maximize efficacy and reduce toxicity. Allogeneic stem cell transplantation (HSCT) was planned for all patients in MRD negative CR.

**Methods:** Dasatinib was given in association with steroids at the dosage of 140mg id until the achievement of CR. FLAD regimen consisted of a three-days administration of Flu 30mg/sqm followed by Ara-C 2000mg/sqm and DNX 100mg/sqm. Dasatinib was administered again from the end of chemotherapy and G-CSF was given to all patients starting from day 4 until complete hematological recovery. FLAD was administered for up to two cycles. Minimal residual disease (MRD) was evaluated in all patients after each FLAD either by multicolor flow cytometry (MFC), RQ-PCR for VDJ rearrangements, and RQ-PCR for BCR/ABL.

**Results:** From January 2008 to December 2016, 8 Ph+ ALL at diagnosis (medi-an age 52 years) have been enrolled in this protocol. The median follow-up was 27 months. All patients received 70 days induction with Dasatinib + Steroids and achieved CR with complete hematological recovery. In all patients but one, however, BCR/ABL was still positive both on day 33 and on day 70. Therefore we considered MFC MRD positive on day 33 (on day 70 also), whereas five patients achieved MFC MRD negativity on day 33. After the first FLAD course all patients achieved MFC MRD negativity, with four patients achieving also negativity for VDJ rearrangements and BCR/ABL transcript. FLAD was very well tolerated, with a median ANC and platelet recovery of 7.5 and 4 days, respectively. No patient experienced relapse so far and 8 patients proceeded to HSCT. Two patients are currently waiting for transplant. Overall, 6 patients are alive and in MRD negative CR at the time of analysis. One patient died at day +289 after SCT due to non-relapse mortality and one has died after the first FLAD in molecular CR because of an unrelated event.

**Summary/Conclusions:** This therapeutic strategy proved to be well tolerated and extremely effective for Ph+ ALL patients. Administering FLAD in patients who had already achieved complete hematological response with Dasatinib + steroids allowed us to reduce the period of neutropenia and thrombocytopenia compared to what is reported after combined TKI and chemotherapy treatment given at diagnosis. Most patients underwent HSCT in molecular CR.

**BONE MARROW MRD EVALUATION ON DAY 7 OF STERoidal TREATMENT OF MODIFIED STJUDE TOTAL X V THERAPY IN STANDARD/LOW RISK PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA**

S. Aytac1,*, M. cetin1, I. Yaman Bajin1, I. Altan1, S. unal1, B. kuskonmaz1, D. uckan1, F. gumruk1

Pediatric Hematology, Hacettepe University, Ankara, Turkey

**Background:** In the recent years it was clearly shown that levels of minimal residual disease (MRD) studied by flowcytometry during treatment reflect the overall response to the chemotherapy and give a chance to individualize treatment and improve outcome.

**Aims:** To determine the clinical significance of MRD on day 7 of initial steroid treatment in patients with childhood ALL we analyzed data from 173 patients treated with modified St Jude Total XV therapy between 1 January 2008 and 31 December 2015.

**Methods:** According to our previous successfull results with high dose m ethprednisolone (HDMPX) we add 7 days of HDMPX to the modified St Jude Total XV as an initial treatment and randomized patients at doses of 10mg/kg/d or 20mg/kg/d HDMPX: not exceeding at maximum 1000mg methylprednisolone. After the end of 7th day of steroid concomitant chemotherapy was given and the doses were tapered gradually to 5mg/kg/d and 10mg/kg/d in each group respectively. By the 3rd week of treatment steroid dose was tapered to 2mg/kg/d in both groups and continued with this dose till the end of 3rd week of induction phase. MRD levels were studied at the 15th, 22nd and 42nd days of induction according to the protocol. However, we also analyzed steroid response rate by the peripheral smear on day 7. Moreover, patients were asked to obtain simultaneously optional bone marrow aspiration after getting informed consents to show whether there will be any concordance with the steroid response and/or whether it can give any idea of the outcome.

**Results:** Steroid response rate on day 7 by peripheral smear was 91% (n=158) for the whole group. However simultaneously bone marrow MRD measurement was done in 22 of the 173 patients. There were 13 female and 9 male patient with a median initial WBC count of 8400/mm3 (1100-55300/mm3), all were Calla+ pre B cell ALL (17 low risk ALL, 6 standard risk and 1 high risk ALL), all were in complete remission and all exept one is alive at the time of the analy sis. There were 10 patients receiving 10mg/kg/d HDMPX and 12 patients were in the group of 20mg/kg/d HDMPX. MRD levels were not statistically different on day 7 between these two groups. Furthermore all patients except 2 (one in each group) were steroid responsive by means of peripheral absolute blast count <1000/mm3. Bone marrow MRD on day 15th and 42nd there were no statistically significant difference in each group (P>0.05). Although some of these patients in each group have high levels of MRD on day 7, interestingly they were all steroid responsive.

**Summary/Conclusions:** Our preliminary results suggest to think that MRD level on day 7 in a small group of low/standard ALL patients may not predict outcome.

**PONATINIB (PON) IN PHILADELPHIA CHROMOSOME-POSITIVE ACUTE LYMPHOBLASTIC LEUKEIA (ALL): PRELIMINARY REPORT OF THE OPAL OBSERVATORY.**

S. Tavilian1,*, E. Raffoux2, X. Thomas3, P. Chevallier1, M. Hunault4, T. Leguay6, K. Bilger7, S. Lepretre8, L. Legros9, I. Cano10, V. Lhermitte11, A. Virlogeux12, H. Dombret13, F. Huguet14

The OPAL Observatory.
and clinical outcomes of the patients were analyzed.

Methods: Pts were recruited if aged ≥18 years; with de novo Ph+ ALL or CML-LyBP treated by PON alone or in combination for at least 1 treatment day, for relapsed or refractory disease, between Apr 2012 and Dec 2014 (Expanded Access Program). Twenty-one pts were analyzed (16 men and 5 women; 17 de novo ALL and 4 LyBP-CML), with a median age of 60 years (22-73). Time from first ALL or CML-LyBP diagnosis was 6 months (1-123). At PON initiation, 1 pt had primary refractory ALL, 15 pts were in first salvage (1 in secondary complete remission [CR] after chemotherapy, 3 in molecular relapse only), 2 in second salvage, and 3 in third salvage or beyond. Numbers of patients who had previously received 1, 2, 3, or 4 other TKIs were 4, 15, 1, and 1, respectively (14 pts received 1 single agent for ≥2 years). Six pts had previously undergone hematopoietic stem cell transplantation (HSCT). Of the 18 pts screened for BCR-ABL mutations, 5 had none, 3 had T315I, 3 had other PON-sensitive mutations, while 5 had compound mutations (known to be resistant to all TKIs including PON) and 2 had E255V (of intermediate sensitivity to PON). PON was administered alone in 13 pts, combined to low-intensity chemotherapy in 3 pts, and to IFN-α in 2 pts. Dose at initiation was 45mg in 17 pts and 30mg in 4 pts.

Results: Median duration of PON therapy was 3 months (5 days-30 months+). Out of the 19 pts who received PON for ≥4 weeks, 5 pts failed to reach CR, while 14 (78%) reached or maintained it. Molecular response was not reported uniformly. During induction by PON, 5 grade 3-4 events occurred in 4 pts (1 pulmonary infection; 1 acute renal failure; 1 pancreatitis; 1 heparin-induced thrombocytopenia; no arterial occlusive event). Post-induction therapy consisted in PON-based therapy in most pts. HSCT was performed in 5 pts. Out of 10 pts in CR on PON, 1 pt died from CR from 6 months to 1 year after PON cessation, and 9 pts had a molecular relapse at 8 months, and 11 pts ultimately experienced bone marrow relapse, all of them within 6 months after PON initiation, except 2 who relapsed at 13 and 27 months after HSCT. Two patients are alive in CR at 14 and 30 months, 1 with ongoing molecular remission.

Summary/Conclusions: Our series of resistant pts is comparable to the PACE study population by initial characteristics and high frequency of BCR-ABL mutations. CR was achieved in most pts, suggesting the role of PON as a bridge-to-transplant with a favorable risk-benefit ratio. Effective post-induction combination of PON and IFN might be suggested for patients with failure to achieve CR on PON. Six pts had previously undergone hematopoietic stem cell transplantation (HSCT). Because global outcome of this very high-risk population remains poor, earlier introduction of PON in the course of the disease is warranted, as underlined by the excellent results of the hyperC-POD-VAD-PON combination in the first-line setting.
IMATINIB VS. DASATINIB FOR OUTCOMES AFTER ALLOGENEIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH PH+ ACUTE LYMPHOBLASTIC LEUKEMIA

A. Shigematsu1, A. Sokolov1, E. Parovichnikova1, V. Troitskaya1, I. Galtseva1, L. Kuzmina1
1Chemotherapy and BMT, 2Bone marrow transplantation, National Research Center for Hematology, Moscow, Russian Federation

Background: Philadelphia-positive acute lymphoblastic leukemia (Ph+ALL) who received allogeneic stem cell transplant (allo-HSCT) has improved over the development of tyrosine kinase inhibitors (TKIs). Currently, Imatinib (IMA) and Dasatinib (DAS) are widely used for the treatment for Ph+ALL. However, there has been no data comparing the outcomes between the patients who received allo-HSCT and the two distinctive TKIs respectively.

Aims: We conducted a retrospective analysis for comparing the two TKIs for the outcome after allo-HSCT.

Methods: Clinical data of patients were retrospectively collected from Hokkaido University Hospital and Sapporo Hokuway Hospital. The patients’ eligibility was as follows: diagnosis as Ph+ALL, aged more than 16 years, and received allo-HSCT between 1990 and 2016 and first time for SCT.

Results: Sixty-six patients were eligible for the study. Fifty-six out of the 66 were administered TKIs (TKI group) and the remaining ten who developed Ph+ALL in the early phase were treated without TKIs (non-TKI group). Overall survival was not different between the two groups. Of the 56 patients in the TKI group, 39 received IMA (IMA-pts), and the remaining 17 received DAS (DAS-pts). Compared with DAS-pts, IMA-pts received allo-HSCT in relatively older years of age, more frequent myeloablative conditioning regimen, and cyclosporine-containing, not tacrolimus-, regimen for GVHD prophylaxis more frequently. Overall OS was not different between the two groups. Incidences of Neutrophil engraftment and the number of days of neutrophil engraftment were similar between IMA-pts and DAS-pts. However, by multivariate analysis using Cox regression model for adjusting disease status, donor type, history of non-relapsed mortality, severe infections, and transplant-related mortality, IMA-pts had a superior OS of 64% (95% CI 54-74%) vs 43% (95% CI 31-57%) in DAS-pts (P=0.01). There was no significant difference in the cumulative incidence of chronic GVHD between IMA-pts and DAS-pts (P=0.3). In order to evaluate the impact of the two distinctive TKIs on clinical outcomes, a series of exploratory analyses were conducted. The results were consistent with the primary analysis. Our analysis suggests that overall survival may be superior for the Ph+ALL patients treated with allo-SCT and IMA compared with those with DAS. There are some limitations for our analysis due to retrospective nature and relatively small number of the patients analyzed. Therefore, prospective study comparing survival of the Ph+ALL patients treated with the two distinctive TKIs before HSCT is needed.
tyrosine kinase inhibitors (TKI) is the promising approach in treating Ph-positive ALL. Some other rearrangements like IKZF1 in Ph-like ALL, FLT3 and JAK2 in Ph-negative ALL are the potential targets to some TKIs.

**Aims:** To demonstrate effectiveness and toxicity profile of Blinatumomab+TKI treatment. To evaluate peripheral blood lymphocytes subpopulations kinetics during blinatumomab treatment.

**Results:** During this period, a total number of 353 patients with childhood ALL were treated in our Department, according to BFM protocols. Recurrence occurred in 86 patients (24.4%, 56 male - 30 female - median age: 4.83 years), within 3 to 184 months from initial diagnosis. Very very late recurrence was noted in 3.1% of our relapses (8 male - 3 female) at 53, 72, 83, 84, 87, 112, 116, 120 and 184 months from initial diagnosis. In 9 patients recurrence interventions were bone marrow, in 1 both bone marrow and central nervous system (CNS) and in 1 only the testicles. Two children had received allotransplant from a matched related donor in first complete remission (CR1) and they had a bone marrow relapse 4 and 5 years later, respectively. The mean WBC, Hb, Blasts and PLT values at diagnosis were 29260/mm3, 5.6g/dl, 21360/mm3 and 18000/mm3, respectively. All of them were B-cell ALL except for 1 who had CD33 and CD13 co-expression. Regarding the immunophenotypic profile of the disease at recurrence, it remained almost identical to the initial. Regarding cytogenetic characteristics of the patients at diagnosis, 3 of them had high hyperdiploidy, one del(6)(q12), one BCR-ABL fusion and one 47.XY,19(9), i(12)(p13.3); none del(12)(p13.3). In our ALL recurrences, the cytogenetic profile remained identical at recurrence, while in 1, trisomia 13 was not detected and another had heterozygous absence of iKZF1, PAIX, EBF1, CDKN2A and CDKN2B genes. On Day 8, nine of 11 patients were Prednisone Good Responders. On Day 15, nine children had bone marrow m1, one m2 and one m3, and on Day 33 only one had m2. Two patients were classified as low risk, 6 as intermediate risk and 3 as high risk. Second remission (CR2) was achieved in 9 children with very very late recurrence. The other 2 died from disease progression. Six of nine patients are still alive and well 6, 8, 10, 11 and 20 years after initial diagnosis. One patient died from very very late recurrence and the last 2 had a second allotransplant and died due to severe infection. 2 and 11 months following that BMT. Interestingly, 3 out of 5 patients who finally died, had the very very late recurrence (10, 10 and 15 years after initial diagnosis) and had been treated with adult type protocols.

**Summary/Conclusions:** The rate of very very late B-cell ALL recurrence was only 12.8% of all recurrences. The prognosis is worse in patients, older than 18 years, treated with adult type protocols.

**E863**

**NOVEL CRLF2 MUTATIONS AND CLINICAL SIGNIFICANCE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA**

Z. Ge1,2, Y. Gu1,3, Q. Han1,4, X.-L. Zhou2,3, B.-A. Chen1,2, J.-Y. Li3, C. Song2,4,5

1Pediatric Oncology Department, 2International Cooperative Leukemia Group and International Cooperative Laboratory of Hematology, Zhongda Hospital, South-east University Medical School, 3Hematology Department, The First Affiliated Hospital of Nanjing Medical University, 4Jiangsu Province Hospital, Nanjing, China, 5Pediatrics Department, Penn State University College of Medicine, Hershey, United States

**Background:** Cytokine receptor-like factor 2 (CRLF2) plays an important role in the development of normal B lymphocytes, which can mediate early B cell proliferation and survival. CRLF2 overexpression and rearrangement have been observed in acute lymphoblastic leukemia (ALL) and they are reported to contribute to oncogenesis and unfavorable outcome in ALL. We reported that CRLF2 overexpression in the patients without CRLF2 rearrangement, indicating the reason other than CRLF2 rearrangement is responsible to the CRLF2 overexpression. There is few reported CRLF2 mutations in adult ALL.

**Aims:** To study the mutations of CRLF2 and its clinical significance in adult ALL without CRLF2 rearrangement.

**Methods:** The 129 patients’ BM samples (95 B-ALL, 33 T-ALL and 17 B-T-ALL) were collected between April 2010 and Jan 2015 at the First Affiliated Hospital of Nanjing Medical University. The ALL diagnosis was made according to the cytogenetic, morphologic, Immunophenotypic and molecular FC diagnosis. The patients were collected continuously in all pts. T-helper, T cytotoxic, T-regulatory and NK cells were measured by flow cytometry in every week during all cycles of blinatumomab treatment.

**Results:** No one pt has neurological toxicity of any grade. All pts has significant decrease of normal IgG level and all of them received intravenous human normal immunoglobulin replacement. Palmar-plantar syndrome was observed in one pt on nilotinib completely resolved after temporarily TKI discontinuation. Diarrhea in 1 pt on dasatinib/nilotinib completely resolved on bosutinib. 8 pts achieved molecular remission (MolCR), one pt – cytogenetic remission and one pt with molecular relapse. 8 pts achieved complete remission (CR) on TKIs. 7 pts were treated with TKI Dasatinib, 1 pt with nilotinib and 1 pt with bosutinib. One pt of these patients received TKI discontinuation. Diarrhea occurred in 8 pts (7 – overt hemato-

1Pediatric Oncology Department, 2Hematology Lab, P.&A. Kyriakou, ATHENS, Greece

**Background:** Recurrence of acute lymphoblastic leukemia (ALL) during childhood usually occurs within the first 6 years after initial diagnosis.

**Aims:** The aim of this study is the identification of all relevant characteristics and outcomes in a group of patients with childhood ALL, who relapsed more than 6 years after initial diagnosis or more than 3 years after bone marrow transplantation (BMT).

**Methods:** All children diagnosed with a first relapse of ALL in our Department, from January 1992 till December 2010 were included in this study.

**Results:** From January 1992 till December 2010 were included in this study. Some other rearrangements like IKZF1 in Ph-like ALL, FLT3 and JAK2 in Ph-negative ALL are the potential targets to some TKIs.

Background: Recently, comprehensive genetic profiling of pediatric and adult core-binding factor (CBF) AML revealed a variety of cooperating events in a cohort of 85 t(8;21) AML patients (Fabre et al. Nat Genet 2016). These mutations comprised alterations in genes encoding for proteins in tyrosine kinase (TK) signaling, epigenetic regulation (ER), and in the cohesin complex (CC).

Aims: To validate and to further extend our recent findings by comprehensive characterization of the mutational landscape of t(8;21) positive AML using a high-throughput targeted sequencing (HTS) approach.

Methods: The HTS panel comprised the entire coding region of 244 genes that are involved in hematological malignancies. Pretreatment blood (n=23) or bone marrow specimens (n=72) of 95 additional adult t(8;21) positive AML patients (pts) (median age: 51 yrs, range 18-72 yrs) were analyzed. 92/95 pts were enrolled in one of seven prospective AMLSG treatment trials. Libraries (total probe size: 1.359 Mbp) were prepared using SureSelectXT custom solution (Agilent). Paired-end sequencing was carried out on a HiSeq 2000 (Illumina). The variant allele frequency (VAF) cutoff for reporting mutations was set at ≥0.05.

Results: The median coverage per pt was 900x. Mutations were detected with an average of 5.1 (SD: ±2.6) per pt with 99% of all pts harboring at least 1 mutation and 87% ≥ 3 mutations. Consistent with previous studies, mutations in TK signaling pathways were common events: KIT mutations were found in 22/95 pts (23%) followed by mutations affecting NRAS (16/95; 17%), FLT3 (11/95; 12%; point mutations only), and KRAS (4/95; 4%). A significant enrichment of mutations was also observed in genes involved in epigenetic regulation, ASXL1 (15/95; 16%), ASXL2 (12/95; 13%), KDM6A (11/95; 12%), CREBBP (8/95; 8%), SRCAP (8/95; 8%), EZH2 (7/95; 7%), SETD2 (5/95; 5%), TET2 (12/95; 13%) and DNMT3A (5/95; 5%), highlighting their contribution in altering the epigenetic state of this leukemia subtype. Moreover, mutations affecting members of the CC were found with a high frequency: RAD21 (13/95; 14%), SMC1A (5/95; 5%), STAG2 (3/95; 3%), and SMC3 (2/95; 2%). Of note, mutations in CC genes were almost mutually exclusive. We also identified additional mutations in previously detected cooperating genes such as mutations clustering in exon 2 of the ZBTB7A gene (15/95; 16%), encoding for a transcription factor involved in hematopoietic lineage fate. Recurrent mutations were also observed in CCN2 (9/95; 9%), that plays an important role in regulation of hematopoietic cell proliferation, as well as DDX15 (6/95; 6%) being involved in spliceosome function and ribosome biogenesis. With respect to the clonal architecture we found that the median VAF in genes belonging to ER and CC (0.30; range 0.03-0.91; 0.31, range 0.05-0.73, respectively) was higher than in genes associated with TK signaling (0.19, range 0.05-0.53). These data suggest that alterations affecting the epigenetic state and differentiation occur earlier than those in signaling during t(8;21) leukemogenesis.

Summary/Conclusions: Using a comprehensive, deep sequencing approach we could further characterize the mutational landscape of t(8;21) positive AML. Here, mutation clusters in genes involved in TK signaling, ER and CC were confirmed as well as novel CBF-associated gene mutations that play an essential role in regulation of hematopoietic cell proliferation and differentiation. Further analyses in terms of sample size extension as well as correlation of findings with clinical parameters are ongoing.
**Background:** Mixed Lineage Leukemia’s (MLL’s) are characterised cytogenetically by reciprocal translocations of the MLL gene and clinically by unfavourable outcomes. Evidence indicating that MLL leukemias are resistant to apoptosis encourages the identification of novel drug targets.

**Aims:** Using cord blood (CB) CD34+ cells (control) and CB CD34+ cells expressing MLL-AF9, we sought to determine the potential role of BTK in the development and progression of MLL+ leukemia. We further aimed to uncover possible downstream targets of BTK, improving the therapeutic efficacy of the drugs used.

**Methods:** Experiments were performed using control and MLL+ cells and leukemia blasts from 3 AML (MLL+) patients. Signalling events were evaluated by immuno blotting, p56 mediated BTK expression was determined by promoter assays. Cells were treated with specific inhibitors of BTK (Ibrutinib (IBR): 0.25, 0.5, 1.0 and 2µM) in combination with Daunorubicin (DAU 5nM) or RAC (NSC 23766 (NSC): 5, 10, 15 and 20µM) for 48 hrs and cell viability was assessed using Annexin V/ Sytox-Blue based flow cytometric analysis.

**Results:** In this study we characterized the influence of soluble factors secreted by AML cells in ex-vivo experiments. The influence of AML cell conditioned media (CM) on AMG 330 mediated cytotoxicity and T-cell proliferation was heterogeneous: the CM from AML patients in complete remission (CR) or from HD BM was used which did not negatively impact AMG 330 mediated cytotoxicity (mean% specific lysis FCS vs HD: 58.9 vs 78.3; % proliferation FCS vs HD: 58.9 vs 78.3; FCS vs PB: 32.2 vs 83.5). In transwell experiments we determined the influence of AML cell conditioned media on AMG 330 mediated cytotoxicity.

**Summary/Conclusions:** In summary, our study reveals a molecular basis for HSPO90 addiction of FLT3-ITD-driven AML and provides a rationale for treatment of this form of AML with HSPO90 inhibitors.
Summary/Conclusions: In summary we demonstrated that BM derived plasma from AML patients at primary diagnosis or relapse reduced T-cell proliferation and AMG 330 mediated cytotoxicity in half of the samples tested. The identified mutations were secreted by primary AML cells as judged by transwell experiments. Unraveling mechanisms of resistance to BiTE antibodies mediated cytotoxicity will allow the exploitation and usage of enhanced strategies to increase response rates.

MICROENVIRONMENT SECRETED PROTEINS MEDIATE RESISTANCE TO TARGETED THERAPY IN PRIMARY AML CELLS

A. Dokal1, J. Gribben2, P. Cutillas3
1Haematology-Oncology, Barts Cancer Institute, London, United Kingdom
2Department of Medicine and Comprehensive Cancer Research Center, University of Chicago, Chicago, IL, United States, 3Nationals Centrum für Hämatologie, Onkologie und Klinische Immunologie, Universitätsklinikum Hamburg, Hamburg, Germany

Background: The bone marrow stromal microenvironment (BMSM) plays an important role in the pathophysiology of acute myeloid leukemia (AML). This is demonstrated by primary AML blasts dependence on stromal conditioned media to survive long-term in culture although some of the components of the stromal secretome (the totality of secreted proteins by biological cells) that augment AML survival are known, the precise molecular mechanisms of the stromal-blast interactions are not fully defined.

Aims: i) Identify proteins secreted by bone marrow stromal AML cells that mediate AML survival (BMSM) in vitro; ii) Investigate global changes in signalling pathway activity induced by stromal factors in primary AML; iii) Validate the functional significance of these interactions through targeted inhibition of BMSM activated signalling pathways.

Methods: We used primary AML cells and established cell lines. Four different human AML lines were grown individually or in co-culture with a mouse bone marrow stromal line (MS-5). The resulting conditioned medium from these experiments (4 AML lines alone, 4 AML lines + MS-5, MS-5 alone) was purified to obtain the secretome (in triplicate). Proteins from these secretomes were quantified using Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS). Peptide sequence searches against both mouse and human protein databases allowed for discrimination between the mouse stromal and human AML proteins. Guava EasyCyte Flow Cytometry was used to measure the viability and proliferation of these cell populations, assessing the capabilities of the identified factors above on primary AML cells (n=6) as well as the effects of kinase inhibitors (BMSM1, Trametinib, S100-A11, connective tissue growth factor [CTGF] and bone morphogenic protein-1 [BMP-1]) based on their ability to effect growth and likely signalling capacity in AML cells. These six proteins were used in varying combinations to determine their effect on growth of primary AML cells from patients (n=6). We also analysed the phosphoproteomes of primary AML cells displaying the maximal effects on growth in response to the six factors above to determine the underlying biological mechanisms. These studies have shown that several different pathways are activated as a result of secretome treatment including mTOR and MAPK. Primary AML cells were sensitive to targeted inhibition of these pathways. However, the inclusion of stromal secreted factors to the same AML cell treatment induced sensitivity to another kinase inhibitor and insensitivity towards the previously effective inhibitor.

Summary/Conclusions: This proteoem approach has allowed identification of a panel of key proteins (including S100-A11, CTGF, BMP-1) secreted by the stromal cells that modulate cell signalling and cell fate in AML blasts. Using a proteoem approach to study global cellular effects we were able to dissect specificity of AML blast proteins. From these, six stromal proteins were selected (including BMSM1, Trametinib, S100-A11, connective tissue growth factor [CTGF] and bone morphogenic protein-1 [BMP-1]) and further examined for their ability to effect growth and likely signalling capacity in AML cells. The secretome of the six proteins was used in varying combinations to determine their effect on growth of primary AML cells from patients (n=6). We also analysed the phosphoproteomes of primary AML cells displaying the maximal effects on growth in response to the six factors above to determine the underlying biological mechanisms. These studies have shown that several different pathways are activated as a result of secretome treatment including mTOR and MAPK. Primary AML cells were sensitive to targeted inhibition of these pathways. However, the inclusion of stromal secreted factors to the same AML cell treatment induced sensitivity to another kinase inhibitor and insensitivity towards the previously effective inhibitor.

Summary/Conclusions: In summary we demonstrated that BM derived plasma from AML patients at primary diagnosis or relapse reduced T-cell proliferation and AMG 330 mediated cytotoxicity in half of the samples tested. The identified mutations were secreted by primary AML cells as judged by transwell experiments. Unraveling mechanisms of resistance to BiTE antibodies mediated cytotoxicity will allow the exploitation and usage of enhanced strategies to increase response rates.

CHARACTERIZATION OF FLT3 MUTATIONS AT DIAGNOSIS, REFRACTORY DISEASE OR RELAPSE IN AML PATIENTS TREATED WITH MIDOSTAURIN WITHIN THE CALGB 10603 (RATIFY) AND AMLSG 16-10 TRIALS

1Klinik für Innere Medizin III, Universitätsklinikum Ulm, Ulm, 2Medizinische Klinik und Poliklinik, Universitätsklinikum Hamburg, Hamburg, 3Klinik für Innere Medizin II, Universitätsklinikum Tübingen, Tübingen, 4Klinik für Hämatologie, Onkologie und Klinische Immunologie, Universitätsklinikum Düsseldorf, Düsseldorf, 5Klinik für Innere Medizin I, Universitätsklinikum Freiburg, Freiburg, 6Klinik für Hämatologie, Hämatoonkologie, Onkologie und Stammzelltransplantation, Medizinische Hochschule Hannover, Hannover, Germany, 7Department of Medicine and Comprehensive Cancer Research Center, University of Chicago, Chicago, IL, United States, 8Department of Medicine and Comprehensive Cancer Research Center, University of Chicago, Chicago, IL, United States, 9Nationals Centrum für Hämatologie, Onkologie und Klinische Immunologie, Universitätsklinikum Hamburg, Hamburg, Germany, 10Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States

Background: Internal tandem duplications (ITD) in the receptor tyrosine kinase FLT3 occur in about 22% of patients (pts) with acute myeloid leukemia (AML) and confer a poor prognosis depending on the mutational load. This is demonstrated by standard protocols. FLT3-ITD positive (FLT3-ITDpos) pts in combination with intensive chemotherapy [CALGB 10603 (RATIFY, NCT00651261) and AMLSG 16-10 TRIALS (NCT01477606) or CALGB 10603 (RATIFY, NCT00651261) trial in paired samples obtained at diagnosis (Dx), complete remission (CR) and relapse (Rel) by whole exome sequencing (WES). Methods: WES was performed in 17 FLT3-ITDpos pts using the Nextera Rapid Capture Exome kit (illumina) for library preparation followed by sequencing on an Illumina HiSeq2000. 6 pts were treated in the RATIFY trial receiving either midostaurin; 4 pts in the AMLSG16-10 (NCT01477606) or CALGB 10603 (RATIFY, NCT00651261) trial in paired samples obtained at diagnosis (Dx), complete remission (CR) and relapse (Rel) by whole exome sequencing (WES). Results: The median AR of FLT3-ITD was 0.51 (0.10-18.94) and 0.54 (0.07-26.31) at Dx and Rel, respectively. Loss of FLT3-ITD was observed in 5 pts; changes of the ITD clone at Rel occurred in 7 pts. Of those, 5 pts had a change of the breakpoint and 1 pt gained an additional ITD clone at Rel. 3 pts had a D835Y FLT3-ITD mutation that was lost at Rel. 6 pts had a NPM1mut that persisted at Rel in all pts. Using WES, 301 mut (226 missense, 24 nonsense, 41 indels, 6 splice sites, 4 unique) were identified. The average coverage was 125 (186-67) among all samples. 131 (43%) mut were present at both time points (Dx and Rel). 154 (47%) mut were found only at Dx, 44 (13%) mut were detected only at Rel and 14 (4%) mut with 14 (4%) mut with only 1 read at Dx. Besides FLT3-ITD, the average number of mut per sample (Dx or Rel) was 13. Mut were most frequently observed in genes related to signaling (23%), transcription (20%), DNA methylation (5%), chromatin remodeling (4%), components of the mitogen activated protein kinase signaling pathway (8%), SALL4 (3%) and ubiquitin-proteasome (4%). Pre-leukemic mut (DNMT3A, TET2, IDH1/2) were detectable in 10 pts at both time points and persisted at CR in 7 pts. Mut recurrent in transcription mediated changes occurred in 8 pts at Dx and Rel, with W71 mut being most frequent (n=7). Mut in signaling related genes present at both time points included NRAS (G12V/D) and NFT1 mut. At the time of Rel, gene mut frequently referred to signaling (34%) including a KRAS (G13D) and a KIT (D816V) mut, both in pts with loss of FLT3-ITD at Rel. Summary/Conclusions: Analyzing the clonal evolution of FLT3-ITDpos AML, known pre-leukemic mut were stably detectable at Dx and Rel in most pts, whereas the enriched gene mut were detectable at Dx and Rel in most pts. We speculate that the enriched gene mut are key drivers in vivo and mediate resistance to targeted therapies with a focus on TKI treatment, larger cohorts of pts are currently analyzed for the detection of recurrent mutational patterns. 41.8, n=7). In the remaining 7 primary AML samples, no immunosuppressive effect was observed on specific lymphocyte control vs AML 98.9 vs 98.2% proliferation control vs AML 82.8 vs 77.7, n=7).
University of Chicago, Chicago, IL, United States, 1Nationalle Centrum für Tumorerkranckungen, Universität Heidelberg, Heidelberg, Germany, 10Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States

Background: Internal tandem duplications (ITD) and mutations (mut) in the tyrosine kinase domain (TKD) of the receptor tyrosine kinase FLT3 occur in about 25% of acute myeloid leukaemia (AML) patients (pts). FLT3-ITD is associated with an unfavorable prognosis in particular in pts with a high allelic mutant to wildtype ratio (AR>0.5) as well as localization of the ITD in the beta1-sheet of the receptor. FLT3is targetable by tyrosine kinase inhibitors (TKI) and the combination of chemotherapy with the TKI midostaurin has been recently investigated within the CALGB 10603 RATIFY trial and is still under investigation within the AMLSG 16-10 trial.

Aims: To study the FLT3ITD status at the time of diagnosis (Dx), refractory disease (RD) and relapse (Rel) in AML pts treated within the CALGB 10603 (RATIFY) and AMLSG 16-10 (NCT01477606) trial with regard to AR of FLT3-ITD and FLT3-ITDmut, loss of FLT3-ITD and FLT3-ITDmut and change of ITD clones (ITD insertion site, length, number, clones).

Methods: FLT3-ITD and FLT3-ITDmut were detected using Genescan-based fragment-length analysis according to standard protocols. In the randomized phase-II RATIFY study, FLT3mut pts were treated with induction (daunorubicin/ cytarabine) and consolidation (high-dose cytarabine) and maintenance therapy in FLT3-ITD positive pts.

Results: In total, 83 pts were analyzed, of which 33 were treated in the RATIFY and 50 within the AMLSG 16-10 trial. 36 pts had RD and 47 pts had relapsed. FLT3-ITDwas present at diagnosis in all pts treated in the AMLSG 16-10 trial; one pt had an additional FLT3-ITDmut. Pts entering the trial had either a FLT3-ITD (n=22), a FLT3-ITDmut (n=8), or both (n=2). The median AR of FLT3-ITDmut at Dx was 0.82 (0.07-2.66) and the majority of pts showed loss of FLT3-ITDmut at RD or Rel (n=9/12; 75%). In relapsed pts, loss of FLT3-ITD occurred in 14 (36%) pts. There was no significant difference between the median FLT3-ITD AR at Dx [0.03 (0.10-18.94)] and Rel [0.65 (0.07-38.75); p=0.98]. A shift of the AR was observed in 14 (36%) pts at Rel, with switch of the ITD insertion site or length in 8 (21%) pts. 8/14 pts with change of the ITD clone at Rel had multiple ITD clones at Dx. For 35 FLT3-ITDPositive pts with refractory AML, FLT3-ITD loss was observed in 17 (49%) pts. The median AR of FLT3-ITD was significantly lower at the time of RD [0.09 (0.05-0.27)] compared to Dx [0.03 (0.05-0.91); p=0.02]. The ITD clone changed in 5 (14%) pts with RD. In pts with shift of the ITD clone at Dx (n=5) or Rel (n=14), no significant difference of the median ITD length was observed (p=0.84).

Summary/Conclusions: Comparing the FLT3-ITD status at Dx, at the time of RD or Rel, we found a lower median AR of FLT3-ITD in pts at RD compared to Dx, whereas no significant change of AR was observed at Rel. In addition, loss of FLT3-ITD was observed in 49% of pts at RD and in 36% of pts at Rel. These findings suggest that the FLT3-ITD clone can be targeted in a significant number of pts and other clones might mediate resistance to treatment. We also observed a switch of the ITD clone in about 20% of pts with Rel, indicating the presence of ITD clones that may be targets for novel targeted treatment. Despite the small number of TKD mutations in our study, it was remarkable that most of the TKDs (75%) were lost at the time of RD or Rel.

A NOVEL PML-RAR FUSION IN ACUTE PROMYELOCYTIC LEUKEMIA J.-S. Ha1,*, C.-S. Kim2, C. Lee3, D.-H. Kim1, Y.-R. Do1, W.-M. Lee1, N.-H. Ryoo1, H.-W. Kao1,*, R. Bera2, Y.-J. Huang2, J.-F. Fu2, D.-C. Liang3, L.-Y. Shih1 1Chang Gung Memorial Hospital and Chang Gung University, 2Chang Gung Memorial Hospital, Taoyuan, 3Mackay Medical Hospital, Taipei, Taiwan, Republic of China

Background: Our previous study showed that DNMT3A or RUNX1 mutations were frequently coexisted in the MLT-PTD AML patients (Oncotarget 2015). We aimed to investigate the role of coexisted DNMT3A or RUNX1 mutations in leukeogenesises of MLT-PTD AML.

Methods: After lentiviral-mediated over-expression of RUNX1 or DNMT3A mutants in MLT-PTD mouse bone marrow (BM) cells or human MLT-PTD+ AML cells, colony formation, cell proliferation, differentiation and apoptosis assays were carried out. Interaction of RUNX1, HIF-1α, and MLT-PTD were evaluated by co-immunoprecipitation assay. Differential genes and protein expression, histone modifying protein expression, and enrichment of histone 4 acetylation (H4Ac) were assessed by RT-qPCR, Western blot, and ChIP-qPCR, respectively. For BM transplantation assays in mice, MLT-PTD+ BM cells overexpressing DNMT3A-Wild type (WT) mutants and empty vector (EV) control were injected into C57BL/6 mice via tail vein.

Results: We observed that MLT-PTD mouse BM cells with RUNX1 mutants lacking C-terminal WVRKY sequence (H377LX and V453fsX576) had increased self-renewal, proliferation, increased HIF-1α and its downstream gene expression. In addition, the interaction of HIF-1α and MLT-PTD was disrupted in the cells transduced with C-terminal truncated RUNX1 mutants or RUNX1 shRNA. Compared with those expressing DNMT3A mutants, over-expression of DNMT3A-Wt reduced cell growth, colony formation and self-renewal activities of EOL-1 and MLT-PTD+ BM cells. All DNMT3A mutants impaired Na-butyrate-induced differentiation, but only R82H mutant impaired ATRA-induced differentiation in vitro. DNMT3A mutations were associated mostly with up-regulation of homepage B (HOXB) genes. The expressions of BCL2A1, AREG, PRKCA, and BCL2L1 were significantly increased in the DNMT3A-mutant cells compared to those of DNMT3A-Wt. Cells with DNMT3A mutants showed a reduction of H4Ac enrichment at the HOXB and HOXC12 promoter regions compared to the control cells or the cells with DNMT3A-Wt. DNA methylation microarray analysis identified both hypo- and hypermethylation features in different regions throughout the genome of DNMT3A-mutant-transduced EOL-1 cells. Up-regulated genes including HAX and HBOG were hypomethylated in the EOL-1 cells transduced with DNMT3A mutants. In vivo study showed that white blood cells including neutrophils, lymphocytes and monocytes increased significantly (P<0.03) in the DNMT3A-mutants mice compared to EV or WT mice at 10 months post-BM transplantation.

Summary/Conclusions: The present study showed that both RUNX1 and DNMT3A mutants dysregulated self-renewal, proliferation and apoptosis in the mouse MLT-PTD BM cells. Disruption of MLT-PTD-RUNX1-HIF-1α complex in the RUNX1-mutant and aberrant methylation in the DNMT3A-mutant cells might play an important role in AML pathogenesis. Our results showed that coexpressive RUNX1 or DNMT3A mutations had impact on leukeogenesises of MLT-PTD AML.

AML BLASTS INDUCE A SEQUENTIAL PHENOTYPE IN THE BM-MSC TRANSPLANTATION MODEL OF THE UPR REGULATION OF OCT4 E. Forde1,*, A. Abdul-Aziz1, T. Mehta2, F. Di Palma3, C. Ingham3, M. Lawes4, K. Bowles14, S. Rushworth1 1Norwich Medical School, University of East Anglia, 2Earlham Institute, 3Department of Trauma and Orthopaedic Surgery, NNUH, 4Department of Haematology, Norfolk and Norwich University Hospital NHS Trust, Norwich, United Kingdom

Background: Acute myeloid leukaemia (AML) is a heterogeneous clonal disorder that arises from the haematopoietic myeloid progenitor cells within the
Bone marrow microenvironment (BMM). Survival of patients with AML is presently poor, two-thirds of younger adults, and 90% of older adults die of their disease. Even in patients who achieve remission with chemotherapy, relapse is common and occurs from minimal residual disease sequestered in protective niches in the BMM. Reciprocal interactions between that of the AML and bone marrow mesenchymal stromal cells (BM-MSC) are central to the survival and proliferation of blasts themselves and the promotion of quiescence in malignant cells as well as the activation of anti-apoptotic and pro-survival pathways.

**Aims:** To investigate how BM-MSC are programmed by AML to generate a pro-tumoural environment.

**Methods:** Primary AML and BM-MSC were isolated from the pelvis of AML patients following informed consent and under approval from the UK National Research Ethics Service (LRECref07/H0310/146). Low input RNASeq of 10 AML BM-MSC and 10 healthy BM-MSC (taken from the pelvis of patients undergoing elective hip replacement surgery) was performed following CD271 MicroBead selection. AML blasts were co-cultured on confluent primary BM-MSC for 48 hours (h), 72h and 168h. Real-time PCR was used to verify the RNA sequencing data and Western Blot analysis to confirm protein expression. Lentivirus mediated knockdown was used to target gene expression in the BM-MSC. Senescence was assayed by β-Galactosidase staining. Results from the RNA sequencing carried out to compare 10 healthy and 10 AML BM-MSC show that 1125 genes were differentially expressed, with 924 down-regulated in AML derived BM-MSC and 201 up-regulated. From this analysis, we found that CDKN1A (p21) is up-regulated in BM-MSC from AML patients (7.406 logFC) compared to BM-MSC from patients with normal bone marrow. Expression of p21 mRNA and protein expression was confirmed using RT-qPCR and Western Blot in AML BM-MSC compared to normal BM-MSC. In-vitro experimentation showed that p21 mRNA and protein expression is increased in BM-MSC when co-cultured with primary AML. Furthermore, we show that AML increased senescence β-Galactosidase staining in BM-MSC and that p21 knockdown in BM-MSC reversed the senescent phenotype. Finally, primary AML cultured on p21 knockdown BM-MSC had reduced survival compared to control BM-MSC.

**Summary/Conclusions:** We have identified that AML induces a senescent BM-MSC niche via the p21 mediated pathway which in turn promotes survival and proliferation of AML. Silencing of p21 within the BM-MSC reduces AML survival. In identifying this novel microenvironment feedback loop in AML we highlight a potential new target for future AML therapies.

**Background:** Bone marrow vascular niches have been proposed to support acute myeloid leukemia (AML) growth. However, anti-angiogenic therapies do not improve patient outcome suggesting that a complex relationship between AML cells and the microenvironment influences the disease process.

**Aims:** To aim to study the complex vascular remodelling occurring during AML progression.

**Methods:** Using a murine model of AML we performed intravital microscopy to monitor endothelial cell behavior in the bone marrow.

**Results:** We show AML is an invasive species causing highly localized disruption of the endosteal stroma and outcompeting non-malignant cells. Particularly affected are endosteal microenvironments containing osteoblastic cells and type H endothelium, typically associated with hematopoietic stem cells (HSCs). In contrast, splenic endothelial cells expand, suggesting de novo niches in the spleen could potentially support extramedullary hematopoiesis in leukemia. Intravital microscopy further revealed that the endothelium in AML is more adhesive and permissive to transendothelial migration of hematopoietic cells. Pharmacological intervention known to induce type H endothelium preserved higher vascular density in endosteal areas.

**Summary/Conclusions:** Together, these data suggest that AML-induced vascular damage contributes to cell egress from the bone marrow, and that new therapeutic approaches aiming to normalize bone marrow vasculature may support normal hematopoiesis.

1Service d’hématologie pédiatrique, CHU Lille, 2UMR-S 1172, Inserm, 3Laboratoire d’hématologie, 4Service des Maladies du Sang, CHU Lille, Lille, France

**Background:** Acute myeloid leukaemia (AML) is the most common leukaemia in adults. Currently, despite intensive chemotherapy and bone marrow transplantation, outcome is still dismal. In particular, therapeutic stratification remains suboptimal, which is largely attributed to the clinical and molecular heterogeneity of AML.

**Aims:** To better characterize and study this heterogeneity, we developed an in vivo model of AML using patient derived xenografts (PDX) that allows us to study clonal evolution in the context of the patient.

**Methods:** We derived a patient-derived xenograft model from an acute myeloid leukaemia (AML) patient (AML2) in which leukaemia cells were intravenously injected into NOD-scid gamma (NSG) mice. Engraftment was surveyed by chimerism of CD45 (human versus murine) by flow cytometry. At sacrifice (peripheral blast count greater than 70% or clinical sign of illness), cells collected from bone marrow and spleen were used to perform targeted sequencing (AmpliSeq, Thermo Fisher Scientific) and gene expression analyses (HG-U133 Plus 2.0 microarray, Affymetrix®). Bone marrow cells were serially transplanted into secondary and tertiary animals. We then compared mutational and gene expression profiles of patient samples at diagnosis and corresponding PDX samples.

**Results:** From the retroanalysis of 45 injected samples (40%) successfully engrafted into mice with a median delay of 2.5 months (range: 26-154 days). Leukaemia infiltration into bone marrow was concordant with peripheral blood and spleen infiltration. Successful xenograft-engraftment was linked to younger age (50 vs 61 years, p=0.04) and elevated white blood cell counts at diagnosis (132 vs 35 G/L, p=0.001). No association was found between engraftment and karyotype or ELN classification. Relapse free survival (RFS) was worse for patients with successful PDX (0.3 vs 0.9 years, p=0.017). Despite previous reports suggesting better engraftment of AML harbouring FLT3-ITD mutations, we did not find
Background: The CD19/CD3 BiTE® antibody construct, blinatumomab, has been approved in Ph- relapsed/refractory B-cell precursor Acute Lymphoblastic Leukemia (ALL) patients, reasons for resistance have not been determined. In contrast to classical T-cell activation, BiTE® antibody construct mediated T-cell activation relies solely on binding to the CD3ε chain of the T-cell receptor (TCR) complex. Recent evidence has suggested that the phosphorylation pattern of membrane mediated T-cell activation is a prerequisite for our understanding of mechanisms of resistance.

Aims: In the present study we characterized the role of intracellular signalling in CD33/CD3 BiTE® antibody construct (AMG 330)-mediated T-cell activation.

Methods: We generated a murine cell line stably expressing human CD33 and deprivation of human costimulatory molecules (B33). In in vitro cocultures, cytotoxicity against B33 cells and the AML cell line MOLM-13 was evaluated by flow cytometry. Activation of downstream signalling pathways was assessed by a phospho-flow cytometry protocol for T-cell recruiting antibodies. Results: Coculture of B33 cells with CD3+ healthy donor T cells (n=4) resulted in AMG 330 mediated mean cytotoxicity of 58.3%. In contrast, MOLM-13 cells were completely lysed (% specific lysis relative to control B33 cells, no Akt phosphorylation was observed upon incubation with AMG 330, suggesting a highly target cell dependent T-cell activation (mean% pAkt with AMG 330 vs control B33: 65.1±19.7 vs 80.7±16.1, n=3). We next analysed intracellular Akt and Erk phosphorylation levels of T cells after stimulation with AMG 330 or a control BiTE® antibody construct (cBiTE®) and MOLM-13 cells. Anti-CD3/anti-CD28 antibodies served as positive control. In the presence of target cells, AMG 330 induced significantly lower Akt and Erk phosphorylation (mean% phosphorylated (p)Akt and pErk 7.9 and 7.6, n=3) compared to crosslinked CD3/CD28 antibodies (mean% pAkt and pErk 43.0 and 34.6). However, the combination of AMG 330 and CD28 increased the amount of phosphorylated proteins (mean% pAkt and pErk 11.6 and 11.1), but not to the level achieved by CD3/CD28 stimulation. In the absence of target cells, no Akt phosphorylation was observed upon incubation with AMG 330, suggesting a highly target cell dependent T-cell activation (mean% pAkt with vs without target cells: 0.8 vs 7.9).

Summary/Conclusions: Our data support the hypothesis that costimulation influences the susceptibility of target cells to lysis by T-cell recruiting antibody constructs. Currently, we are validating our results in a larger cohort using T cells from healthy donors and patients with AML. Furthermore, we will analyse the phosphorylation pattern within different T cell subsets and upon knock out of the cBiTE® constructs. Our results will contribute to the understanding of BiTE® mediated activation of T cells, which is a prerequisite for clinical responses.

E879
RAF KINASE INHIBITOR PROTEIN IS INVOLVED IN THE DEVELOPMENT OF MYELOID SARCOMA
V. Caraffini1,*, S. Schauer2, K. Kaschofer2, A. Wölfler1, G. Hoefler2, H. Sill1, A. Zebisch1
1Division of Hematology, 2Institute of Pathology, Medical University of Graz, Graz, Austria

Background: Myeloid sarcoma (MS) is a subgroup of acute myeloid leukemia (AML), where leukemia cells invade non-hematopoietic tissues and form solid tumors. It may occur as isolated event or simultaneously with leukemic infiltration of the bone marrow (BM). Loss of RAF kinase inhibitor protein (RKIP), a negative regulator of Ras signaling, has recently been described as a frequent event in AML and to be functionally involved in leukemogenesis. Although RKIP has been shown to inhibit the formation of metastases in solid tumors previously, its role in the development of MS is currently unknown.

In this study, we aimed to delineate the role of the metastasis-suppressor RKIP in the development of MS.

Methods: RKIP protein and mRNA expression was evaluated in formalin-fixed paraffin-embedded biopsies of MS and BM by immunohistochemistry and quantitative real-time PCR (qPCR). Sequence analysis of MS biopsies defined as RKIP+ was carried out by Next Generation Sequencing (NGS). For functional assays, both RKIP overexpression and knockdown was performed in THP-1 AML cells by lentiviral transduction of a FLAG-tagged RKIP expression construct and by RKIP shRNA, respectively. Subsequently, these cells were tested in migration and invasion assays using the transwell-methodology.

Results: This study comprised 14 patients with MS (MS-group) and 14 patients with AML without any evidence of extramedullary involvement (BM-AML group). Of the 14 cases within the MS-group, MS occurred as isolated event in three cases and concomitantly with systemic AML in eleven cases. Both groups were age- and sex-matched and clinical as well as laboratory values were comparable between them. Most importantly, however, when we measured the protein expression of RKIP in leukemic tissues of these patients (MS biopsies in the MS-group and leukemic BM biopsies in the BM-AML group), we observed a
significant increase of specimens exhibiting loss of RKIP expression in the MS-group (7/11 vs 1/14, P=0.0329). Interestingly, RKIP loss in MS specimens of cases with concomitant systemic AML was also present in the corresponding leukemic BM samples, thereby excluding a geographical clonal heterogeneity during MS formation in respect to RKIP expression. We then analyzed RKIP mRNA levels by qPCR and observed that RKIP loss correlated with decreased expression of miR-10a (P=0.041). To gain more insight into the molecular landscape of MS patients with and without RKIP loss, we performed NGS of 39 genes that are recurrently mutated in AML. Interestingly, five out of six (83%) MS patients with RKIP loss demonstrated mutation(s) affecting the Ras-pathway, suggesting a potential functional synergism between these events. Consequently, we performed in vitro overexpression and knockdown of RKIP in the Ras-mutated THP-1 AML cell line and subsequently studied these cells in functional migration and invasion assays. Importantly, RKIP knockdown increased both migration and invasion, thereby indicating a role of RKIP in the development of this condition.

INHIBITING MIR-10A OVERCOMES CYTARABINE-RESISTANCE IN ACUTE MYELOID LEUKAEMIA

T.T. Vu1,*, K. Wang1, F. Stözel2, G. Ehninger2, T. Molloy1, D. Ma1
1Haematology, St Vincent’s Hospital, Sydney, Australia, 2Medical Clinic and Polyclinic I, University Hospital ‘Carl Gustav Carus’, Dresden, Germany

Background: Chemoresistance is the principle cause of treatment failure in acute myeloid leukaemia (AML) despite a promising response to induction chemotherapy. Emerging evidence suggest the roles of autophagy, a self-eating process contributing to chemoresistance of leukaemia cells. We previously demonstrated that miR-10a, highly expressed in a subgroup of AML harboring Nucleophosmin1 mutations, promotes cell survival by inhibiting non-canonical cell death pathway, suggesting its function in autophagy and thus chemoresistance in AML.

Aims: We aim to demonstrate evidence that miR-10a, a regulator of autophagy, plays important roles in chemoresistance in acute myeloid leukaemia.

Methods: Apoptosis and proliferation in miR-10a inhibited and overexpressed leukaemia cells after cytarabine treatment was measured by Annexin V binding and MTT assay. Autophagy was measured by monitoring the levels of LC3/I/LC3II proteins, autophagy-related proteins via Western Blotting and monodansyl-cavarradine (MDC) staining (flow cytometry).

Results: First, we observed a decreased expression of miR-10a in the leukaemia cells after the exposure to stress induced by serum starvation. Overexpressing miR-10a in miR-10a low MV4-11 cells decreased apoptosis induced by nutrient starvation and resulted in the resistance to cytarabine. In contrast, its inhibition in OCI-AML3 cells, which express high miR-10a constitutively, resulted in the induction of apoptosis and increased chemosensitivity towards cytarabine. miR-10a was shown to directly downregulate key members of the p53-mediated tumour suppressor gene network, including the CDKN1A (p21) inhibitor Transcript Factor AP2-gamma (TFAP2C). The inhibition of either miR-10a itself or CDKN1A by siRNA treatment inhibited autophagy induced by serum starvation, treatment with autophagy inducer,mg132 or p53 stabiliser, Nutlin3a.

Summary/Conclusions: The data suggests miR-10a as an important regulator of autophagy in the modulation of the p53-p21 tumour suppressor signalling axis in subtypes of AML. It also emphasizes the significance of autophagy in chemoresistance in AML, supporting the targeting of the autophagy pathway as a potential therapeutic approach for AML.

BY AN MCL-1-DEPENDENT MECHANISM, ALVOCIDIB POTENTIATES THE ACTIVITY OF CYTARABINE AND MITOXANTRONE WHEN ADMINISTERED IN A TIME SEQUENTIAL REGIME IN AML

H. Haws1, M. Livingston1, W. Kim1, R. Mangelson1, A. Siddiqui-Jain1, P. Peterson1, C. Whatcott1, S. Weitman1, D. Bears1, S. Warner1

Background: Treatment with alvocidib has shown significant improvements in the complete remission rates in newly diagnosed acute myeloid leukemia (AML) patients when administered before cytarabine and mitoxantrone (ACM regimen) in a randomized Phase 2 study compared to 7+3. Although the mechanism of alvocidib action as a single agent is documented, the mechanism underlying synergy found in the ACM regimen is not fully understood. The ACM regimen was originally developed based on the perceived benefit of a time-sequential regimen starting with cell-cycle arrest (alvocidib), followed by release of the cells from arrest and inhibition of DNA replication (cytarabine/mitoxantrone) during S-phase. However, recent reports suggest that the transcriptional repression of key anti-apoptotic proteins (e.g., MCL-1) mediated by alvocidib’s CDK9 inhibition, may contribute to the activity in the ACM regimen.

Aims: We hypothesized that MCL-1 transcriptional repression constitutes the primary mechanism for the synergism observed with the ACM treatment regimen.

Methods: Following treatment, cell viability and caspase activation, an indicator of apoptosis, were assessed using CellTiter-Glo and Caspase-Glo assays, according to manufacturer protocol. mRNA levels were assessed using RT-PCR. Protein levels were assessed using standard immunoblotting technique.

Results: In this study, we demonstrate that treatment with alvocidib, followed by treatment with both cytarabine and mitoxantrone, synergized in vitro and correlated with the downregulation of MCL-1 protein and mRNA expression. Indeed, the ACM regimen resulted in a 2.4 or 3.4-fold increase in caspase activity relative to any single agent within the combination in MV4-11 or OCI-AML3 cells, respectively. As has been previously reported, we also observed that increased activity of cytarabine in alvocidib-treated cells corresponded with progression into the S-phase of the cell cycle, following the washout of alvocidib. However, this observation accounted for only a small portion of the inhibition of cell proliferation. This was further confirmed by the observation that CDK6/4 (cell cycle) specific inhibitors, such as palbociclib, did not show synergistic increases in caspase activity following treatment in the same setting. In various AML cell lines treated with MCL-1 siRNA, followed by cytarabine and mitoxantrone treatment, we also observed a synergistic increase in the inhibition of cell proliferation.

Summary/Conclusions: Considering our earlier work showing that MCL-1 dependence predicts AML patient response to the ACM regimen, we propose that MCL-1 repression is the primary mechanism of alvocidib’s clinical activity. As MCL-1 also confers resistance to cytarabine, the current study provides additional rationale for the inclusion of alvocidib in the treatment of AML, and in the AML regimen specifically. Taken together, this data suggests that the ACM regimen may be an effective regimen in treating patients with high-risk AML, because of alvocidib’s inhibition MCL-1.

DYREGULATION IN KEY REGULATOR GENES OF AUTOPHAGY AS A MECHANISM OF THERAPY RESISTANCE AND POOR PROGNOSIS IN ACUTE MYELOID LEUKAEMIA (AML): RESULTS FROM MICROARRAY ANALYSIS ON 148 PATIENTS

M.C. Fontana1,*, G. Marconi1, C. Papayannidis2, G. Simonetti2, A. Padella2, E. Ottaviani2, A. Ferrari2, E. Franchini2, N. Testoni2, C. Baldazzi2, S. Lo Mona- co2, S. Paolini2, M.C. Abbeneante2, J. Nanni2, L. Bertamini2, G. Martinelli2

Background: To date, there are no clear evidences if autophagy can lead to therapy resistance or favor apoptosis in cancer. Autophagy can function as a pro-apoptotic mechanism, or can improve stresses survival clearing damaged mitochondria and proteins accumulation. Levels and activity of pro-apoptotic and anti-apoptotic proteins, particularly BCL-2 and p53, high levels of CAMP, and a complex made by PINK/PARK could play as fulcrum of this yin and yang effect of autophagy.

Aims: Our study aims to define the role of PI3P pathways in AML, and to establish if autophagy could reduce the patients’ chance to respond to induction, and to worsen OS.

Methods: We analyzed 148 consecutively newly diagnosed non M3 AML patients treated with induction chemotherapy regimens containing at least one dose of anthracycline. We screened all patients for TP53, FLT3, NPM1 mutations. In all
patients, we perform Microarray-based High-Throughput Technology with Affymetrix SNP array 6.0 or Cytoscan HD. Survival data were collected prospectively from the time of diagnosis, with a median follow-up of 18 months. Survival analysis was performed with Kaplan Meyer method using log rank test. Univariable and multivariable regression and Cox Hazard Ratio (HR) model were performed. Correlation between variables was assessed with Fisher’s exact test. Results: Autophagy deficiency (gene group 1, n = 14) had 2 mutations each of ULK1 and CHCHD11: ULK1 Chr17; Becn1; Atg14; Amtbra1; Urvag; Atg9A; Atg9B; Pfk3c3; Pk3r4 (Fig. 2). These were related to elevated expression of IRS. Counting from these on the observed human cohort, all MSI samples were MSI+ with MSI criteria. Paired DNAs were separately screened on previously established MSI criteria, samples flagged in ≥20% of MSs. Outlier samples with elevated allele counts were flagged for each locus. Based on these observations, we indicated that none of the samples are MSI+. Comparison of alleles between the NGS and MSI PCR analysis system (Promega) was used on any pairs with significant allele count changes. DNA, using the 2xn version of Fisher’s exact test to determine significance. Results: One MS and one sample had elevated counts at 2 MSs. None of the samples had elevated counts for any of the MSs, 67 samples had elevated counts for one MS and one sample had elevated counts at 2 MSs. Because none of the samples met the criterion of ≥4 MS with elevated allele counts, these data indicate that none of the samples are MSI+. Comparison of alleles between the 86 paired AML and germline samples showed no differences in 78 pairs, and small but statistically significant differences in 8 pairs. However, subsequent assessment of these 8 pairs with the MS PCR analysis system proved that none of them were MSI+. Because MSI tumors have 10–100 times as many mutations as MS stable (MSI-negative) tumors, we examined the mutation counts in the 1,371 AML samples for the 80 genes on the target panel. Most results indicated that the 2 most highly mutated genes had only 9 mutations each. Since any putative MSI sample would harbor tens if not hundreds of mutations, these data support the absence of MSI in all samples. Finally, because it has been proposed that the AML might be more prone to MSI than de novo AML, we performed PCR-based MSI detection on an additional 23 AML cases, and found all were MS stable. Summary/Conclusions: The absence of even a single MSI case within this large cohort provides strong evidence that MSI is non-existent in AML.

E884

SY-1425, A POTENT AND SELECTIVE RARA AGONIST, REPROGRAMS AML CELLS FOR DIFFERENTIATION ALONG DISTINCT LINEAGES, UNCOVERING PD MARKERS FOR CLINICAL STUDIES

Background: SY-1425 (tambogrelate) is a potent and selective agonist of the retinoic acid receptor alpha (RARA) transcription factor (TF), currently in a bio- logical pharmacodynamics phase II clinical trial in AML and MDS (NCT02807558). A subset of AML and MDS has been found to have RARα pathway activation characterized by a large enhancer at the RARA locus (RARA-high) and/or upregulation of IRF8, a TF associated with RARα signaling, forming the basis of the SY-1414-sensitive tumor identification.

Aims: We sought to understand how SY-1425 agonism of RARα acts to promote maturation and halt proliferation of AML blasts locked into an immature cell state by the cancer circuitry. This characterization could further inform clinical pharmacodynamics markers.

Methods: We analyzed the epigenomic and transcriptional landscape of 66 non-APL AML patients and normal primary myeloid cells by RNA-seq and ChIP-seq for the enhancer marker H3K27ac. AML cell lines were profiled by RNA-seq, ChIP-seq for H3K27ac and RARA, and ATAC-seq with or without SY-1425 treatment. Cell surface marker changes were assessed by flow cytometry.

Results: A subgroup of the patient samples was defined by an SE driving RARα, which co-occurred with SEs driving FOS and JUNB, or IRF8, FOS and JUNB form the AP-1 heterodimeric TF known to promote an immature cell state and the interferon regulatory factor 8 (IRF8) pathway has been implicated in AML pathogenesis. Previously reported crosstalk between INF and retinoic acid signaling was supported by the strong induction of interferon gene sets by SY-1425 in IRF8-high AML models. We found that each AML cell line had distinct compositions of lineage factors consistent with cancer initiation from different stages of myeloid development. SY-1425 induced maturation features associated with monocytic, macrophagelike, dendritic, and granulocytic cell types. While AML has been characterized by downregulation of IRF8 and JUNB and upregulation of IRF8, a TF associated with RARα signaling, forming the basis of the SY-1414-sensitive tumor identification.

Aims: We sought to understand how SY-1425 agonism of RARα acts to promote maturation and halt proliferation of AML blasts locked into an immature cell state by the cancer circuitry. This characterization could further inform clinical pharmacodynamics markers.

MECHANISMS OF SYK-MEDIATED SUPPRESSION OF DIFFERENTIATION AND APOPTOSIS IN ACUTE MYELOID LEUKEMIA (AML)

A. Polak1, P. Kilišek1, T. Sewastianik1, M. Szydłowski1, E. Jabłonski1, E. Białopiotrowicz1, P. Gomia1, M. Nosszewska-Kania1, K. Piech1, J. Wozniak1, B. Krzymieniowski1, E. Lech-Mandara1, K. Warchoła1, P. Juszczynski1
1Department of Experimental Hematology, 2Department of Diagnostic Hematology, 3Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: Spleen tyrosine kinase (SYK) is a critical mediator of integrin b3 signaling in AML, leading to leukemia cell growth and disease initiation upon transplantation into healthy recipients. Genetic or pharmacologic inhibition of SYK leads to increased differentiation, reduced proliferation and apoptosis. However, the comprehensive description of mediators and effectors of SYK signaling in AML is lacking.

Aims: To identify key downstream mediators of SYK signaling in AML responsible for differentiation block, proliferation and leukemic stem cell (LSC) maintenance.

Methods: AML cell lines (KG1, MOLM14) or bone marrow primary AML blasts, were incubated 24h with R406 (1μM, 4 μM) or vehicle. Activity of SYK, ERK, STAT5 was assessed by western blot and/or intracellular phospho-flow. Proliferation was measured by BrdU, MTT staining and methylcellulose colony-forming assay. Differentiation was assessed by Giemsa-Wright staining, quantitative NBT, CD14/CD15 staining and qPCR.

Constitutively active form of MEK and STAT5A16 were retrovirally transduced to KG1. Activity toward LSC was assessed using leukemia cell line with stem cell properties, TX. ROS level, mitochondrial mass were assessed by DCF, MitoTracker Green FM staining. Expression of MYC, TFAM, NFR1, NFR2, EF-Tu were assessed by western blot and/or q-PCR.

Results: To identify downstream mediators of SYK in AML, we assessed the activity of key signal molecules in KG1 and MOLM14. AML cells exhibited basal expression of SYK, increased pERK and reduced phosphorylation of STAT5 and MYC. SYK inhibition increased expression of SYK targets, reduced proliferation, clonogenic potential, induced myeloid differentiation and apoptosis. Since ERK can block maturation, we assessed impact of this pathway on differentiation arrest downstream of SYK in KG1 transduced with MEKDD. R406 induced morphological evidence of differentiation and increased expression of myeloid differentiation markers in control cells, whereas in MEKDD transduced cells, R406 had no effect. Given the role of STAT5 in self-renewal of HSC we next assessed impact of this factor on clonogenic potential. R406 reduced clonogenic potential of control cells, while in cells expressing STAT5A16, clonogenic potential was maintained. Moreover, SYK inhibition in control cells showed clonogenic potential. SFK expression, namely SYK and LYN were increased in KG1, while expression of SYK, LYN and FGR in MOLM14. Importantly, we show increased expression of SYK, transcription factors associated with mitochondrial biogenesis (NRF1, TFAM, EF-Tu, NFR2), and lowered cellular mitochondrial mass. Conclusion: Taken together, we found that SYK inhibition obviates differentiation arrest imposed by ERK activity, and reduces clonogenic potential via decreased STAT5 activity. Moreover, we show that pSYK is associated with overexpression of MYC and increased expression of MYC and its targets that drive mitochondrial biogenesis is a characteristic feature of LSC, we hypothesized that R406 depletes LSC by reducing mitochondrial biogenesis/oxidative phosphorylation (OXPHOS). In TEK and primary CD34+ AML blasts, we found increased expression of MYC, transcription factors associated with mitochondrial biogenesis (NRF1, TFAM, EF-Tu, NFR2), and lowered cellular mitochondrial mass.

...
found 150 mutations in 31 genes, in 73 out of the 91 patients included (a median of 1 mutation per patient (range: 0-5) with a mean read depth of 1036Xs. Eighteen patients remained wild-type for all analyzed genes (Figure 1). Only one of this patients suffered relapse (5%). In the global series, no single mutation or functional category showed an association with clinical variables or prognostic impact in terms of overall survival or relapse free survival (RFS). There were no differences in the mean number of mutations per patient in each risk APL group (p=0.05). Patients who lack mutations belonged to the intermediate (13/48, 27%) and low risk (4/28, 14%) groups, except for only one patient (1/15, 6%) in high-risk group. FLT3 was the most frequently affected gene in high risk APL subgroup (10 out of 15): 8 patients carried an FLT3-ITD mutation and 2 patients had amino acid substitutions at codon 832. Seven patients assigned to intermediate-risk relapsed (7/38, 18%). All but one carried mutations that have been reported as unfavorable in AML (FLT3, PTEN, ASXL1, CUX1 and WT1). By contrast, patients who remain in complete remission in this group, lack mutations with a greater frequency (12/31, 39%). Finally, within the low-risk group 3 patients suffered relapse (3/27, 11.5%) and all of them presented missense mutations in the Ras domain of NRAS at diagnosis (p.Ser65Arg & p.Gln61Arg). Therefore, we could identify a small subgroup of patients at a very high risk of relapse (RFS at 5 years, 25% vs 100%, p<0.001).

Figure 1.

Table 1.

Summary/Conclusions: In summary, the present study shows that the mutation status of NRAS and FLT3 genes could be used as genetic markers for prognosis in APL, especially in the intermediate and low-risk groups, allowing a more accurate patient risk classification. Our data suggests the need to search for new mutations required for progression in APL, in order to benefit from a change in post-remission therapy.

Background: Programmed death ligand-1 (PD-L1) is regulated through miR-34α molecules in AML patients. Moreover, Cortez et al. for the first time identified novel, complete mechanism of PD-L1 regulation by p53 via miR-34a in non-small cell lung cancer (NSCLC).

Aims: In this study, our comprehensive analyses of PDCD1 (PD-1), CD274 (PD-L1), TP53 and miR-34a expression in AML patients shed new light on the complex regulation of PD-1/PD-L1 axis during development of this disease.

Methods: We performed analysis of TP53, CD274 and miR-34a expression in 197 AML patients available from The Cancer Genome Atlas (TCGA) database. Moreover, we assessed mRNA expression of PDCD1 in independent cohort of 54 AML, 62 MDS and 8 s-AML patients samples using qRT-PCR method. For miRNA analysis, CD3+ cells from 29 AML patients were isolated and miR-34a expression was analysed. We also characterized several SNP for PDCD1 that demonstrate relevant associations with a higher risk of developing autoimmune diseases: PD-1.1 (rs36084323), PD-1.3 (rs11568821), PD-1.5 (rs36084323), CD274 (UMO-2013/10/M/NZ5/00313).

Results: We observed significant differences in PDCD1 expression in groups of 54 AML, 62 MDS, 8 s-AML patients compared to HVs. TCGA data analysis showed that CD274 expression was elevated in group with TP53 mutations compared to unmutated TP53 group (p<0.001). We also found negative correlation of TP53 and miR-34a expression with CD274 expression (p=0.02 and p<0.005, respectively). The expression of miR-34a tended to be elevated in group with high expression of TP53 compared to group with low TP53 expression (p=0.17). We have not found any differences in CD274 expression between groups with or without following mutations: IDH1, TET2, RUNX1, NRAS, CEBPA, PTPN11, KIT, KRAS, FLT3, DNMT3, NPM1 and IDH2. Patients with more than 4 recurrent mutations were characterized with higher expression of CD274 compared to group of patients with 0-3 recurrent mutations. We also found that patients with >14 of all mutations had elevated expression of CD274 compared to group 0-13 mutations (p=0.06). We observed significant differences in PDCD1 expression level regarding to PD-1.1.5 polymorphism. Moreover, analysis of a PD-1.1.3 polymorphism in HVs and MDS groups revealed that genotype G/G was associated with nearly fivefold lower risk of disease (OR=4.93, p=0.009). We observed significant differences in OS in AML patients in case of presence of certain genotypes of PD-1.1.6. Genotype AA was significant associated with higher risk of shorter OS compared to the rest of the genotypes (58 vs 333 days, HR=3.5, p<0.001).

Summary/Conclusions: Our analyses indicate that p53 might specifically modulate the tumor immune response by regulating PD-L1 via miR-34a which directly binds to the PD-L1 3’ UTR and blocks its expression. Moreover, we found that high CD274 expression is associated with the higher numbers of recurrent and all mutations as well as poor cytogenetic and molecular risk groups of AML patients. We found significant differences in PDCD1 expression in AML patients compared to HVs that might indicate deregulation of a signal transduction through the PD-1/PD-L1 axis. While our SNP analysis in AML patients suggested a prognostic impact of CD-1.6 polymorphism, further studies are warranted to evaluate the impact of the PD-1/PD-L1 Axis in AML.

Background: Cancers kill primarily via disease recurrences after transient treatment responses. The emergence of therapy-resistant tumor escape variants is fueled by intra-tumor heterogeneity, underpinned by interference and Darwinian evolution across continuously developing sub-clones in the residual tumor. Several non-genetic factors add significant variation, on top of the diversification provided by the often complex landscape, resulting in intra-tumor genomic states that we wish to understand.

Aims: We aimed to understand how sub-lineage interference is regulated in AML, with the potential to inform the selection of sub-lineages and determine the functional impact of such differences.

Methods: We dissected the intra-tumor population dynamics of relapsing AML, beyond the genetic level, by performing single-cell lineage-tracing through cellular barcoding technology (lentivirus-integrated non-coding DNA-tags). We...
specifically evaluated the impact of in vitro exposure of a barcoded AML cell line (HEL) to chemotherapeutic regimen (doxycycline (DOX) and/or cytarabine (CYT)) and the hypomethylating agent decitabine (DCT) by comparing the barcode composition of the tumor population recurring after each therapy, versus non-treated (NT) controls. By comparing the barcode architectures between parallel replicate cultures for each therapy, we could further delineate whether AML relapse was driven by predetermination of recurrent barcodes found in multiple replicates or stochastically selected (if mainly diverse barcodes in each replicate) cells in response to each treatment regimen.

**Results:** Only treatment regimens containing DOX caused marked decreases in HEL cell numbers and barcode architectures diverging strongly from the nondrug-treated controls. Replicate AML cultures regrowing after treatment with DOX all converged to a very similar barcode architecture, reflecting that relapse following this mono-therapy was driven by predetermined single-cell lineages. Combination of DOX with CYT increased the degree of overall cell elimination by ~10-fold, while addition of DCT to either chemotherapy regimen had little impact (yielded similar cell number and re-growth kinetics). Interestingly, DCT additions nevertheless qualitatively changed which sub-lineages that regrew - specifically making replicates more divergent from each other, indicating a more stochastic selection of the cells emerging when DCT had been added to the respective chemotherapy regimen.

**Summary/Conclusions:** The development of curative treatment combinations requires deep understanding of how non-genetic factors synergize with cancer genetics to drive intra-tumor heterogeneity, which is key for tumor escape/disease recurrence. Our detailed analyses of the heterogenous dynamics among single-cell lineages in AML, following different treatment regimens with apparently similar global impact, represent an important step in dissecting kinship-dependent aspects that go beyond the genetic level. Critically, these studies directly provide the rationale for combining standard chemotherapy with administration of hypomethylating drugs to target AML. The mechanism is prevention of the development of chemotherapy resistance (mediated by selective release of a specific set of predetermined sub-lineages) - by partially randomizing which sub-lineages that emerge to drive relapse when DCT is added to the chemotherapy. Maintaining the chemosensitivity of relapsing AML would represent a paradigm shift, turning the currently often lethal recurrences into survivable/ repeatedly clinically manageable episodes of a type of chronic leukemic disease.

**MRD ANALYSIS BY NEXT-GENERATION SEQUENCING APPROACH FOR ACUTE MYELOID LEUKEMIA FOLLOW-UP**

E. Ochoa De La Fuente1,2, I. Rapado1,2, T. Cedena1,2, M. Llobos3, Y. Ruiz-Heredia1, J. A. García Vela4, J. Perez Oteyza5, A. Figueras3, F. J. Peñalver6, E. Barragán6, M. Gallardo1,2, J. Martínez-López1,2, R. Ayala1,2

1Hematologíapacinadores, Hospital 12 de Octubre, 2Haematological Malignancies Clinical Research Unit, CNIO, Madrid, 3Instituto de Investigación Sanitaria La Fe, Valencia, 4Hospital Universitari de Getafe, 5Hospital Universitario HM Sanchinarro, 6Hospital de la Princesa, 7Hospital Universitario Fundación Alcorcón, Madrid, 8Clinical Pathology Service, Hospital Universitario i Politécnic La Fe, Valencia, Spain

**Background:** Sensitive detection of molecular marker of minimal residual disease (MRD) in acute myeloid leukemia (AML) can improve prognostic of a possible relapse during the remission. Traditional methods for measuring minimal residual disease (MRD) in AML, such as quantitative time PCR and multiparametric flow cytometry (MFC) are associated with high technical complexity, low applicability and laborious standardization. However, some patients who achieve a negative MRD become to relapse and several MRD+ patients have a long survival, which indicates that the sensitivity and specificity of traditional techniques are not sufficient to detect MRD+ patients. Aims: To detect minimal residual disease in AML follow-up sample using high-throughput sequencing as a standard and accurate technique.

**Methods:** We studied 54 gonad bone marrow follow-up samples (27 after induction, 10 after first consolidation, 17 after second consolidation) from 30 AML patients treated according PETHEMA AML clinical protocols and with DNA sample at diagnosis. All patients had achieve CR at the moment of MRD assessment. We developed a custom-targeted sequencing panel of 32 genes (Ion Torrent Proton System-Thermo Fisher) for mutation (SNV and/or InDels) detection at diagnosis sample. From the 32 genes, we use specific primers to amplify the specific region of the four most frequent alterations at diagnosis (Samples at follow-up: FLT3/ITD n=2, NPM1n=46, IDH2 n=9 or IDH1 n=7). We analysed and detected at diagnosis and at follow-up (after induction, first consolidation or second consolidation), and sequenced with high-throughput approach. We achieve a technical sensibility around 10-4 for point mutations and 10-5 for Indels mutations according specific sensitivity calibration curves.

**Results:** We analyse the results of assessing MRD by NGS, and the presence or absence of MRD was established at a cut-off level of 0.0017 (between 10-4 and 10-5 technical sensitivity) by ROC curve with a sensitivity of 0.5 for DFS and 0.571 for OS, and a specificity of 0.92 for DFS and 0.897 for OS; thereby result above this level was considered as MRD positive. DFS (Disease Free Survival) and OS (Overall Survival) rates in this group were 29.9% and 24.1%, respectively; positive MRD sample was independent marker associated with shorter DFS (p=0.002, HR=0.33, 95% CI:1.60-33.51) and OS (p=0.002, HR=8.33, 95% CI:1.87-37.15) (see figure 1). These results support the usefulness of MRD evaluation in patients with AML by NGS in the context of molecular biology studies.

**Summary/Conclusions:** High-throughput NGS is a technique with the capacity to measure, identify and classified MRD levels. In fact, NGS MRD evaluation has a better DFS and OS prediction than other traditional methods. Implementation of NGS technique on MRD detection could help to anticipate to disease progression.

**THE ROLE OF MYELOID-DERIVED SUPPRESSOR CELLS-LIKE BLASTS WHICH SUPPRESS T CELL PROLIFERATION IN LEUKEMIC CELL GROWTH**

S. Y. Hyun1, J. I. Lee1, E. J. Na1, J.-W. Cheong2

1Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, 2Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of

**Background:** Myeloid-suppressor cells have an ability to suppress T cell function and have been known to facilitate tumor growth. We elucidated the immune suppressive function of leukemic blasts which resembled MDSC phenotype and their role in the growth of leukemic cells.

**Aims:** We elucidated the immune suppressive function of leukemic blasts which resembled MDSC phenotype and their role in the growth of leukemic cells.

**Methods:** CD11b+CD33+HLA-DR+ blast (MDSC like blast) were isolated using flow-cytometry from bone marrow mononuclear cells of primary acute myeloid leukemia (AML) patient samples. CD14, CD15, Arg1 and iNOS expression were checked by flow-cytometry to identify the phenotype of MDSC like blast. To evaluate the ability of MDSC like blasts to suppress T cell proliferation, CD8+ T cells from healthy donor and MDSC like blasts were co-cultured with the ratio of 1:1 without phytohemagglutinin-A10μg/mL. T-cell proliferation was measured by carboxyfluorescein diacetate succinimidyl ester dilution assay after 3 days of culture. Then, various leukemic cell lines were co-cultured with Jurkat T cells and/or MDSC like blasts at a leukemic cell line:Jurkat T cell: MDSC like blast ratio of 4:4:1. The effect of Jurkat T cells and MDSC like blasts on the proliferation of leukemic cells was assessed by the CCK-8 assay after 1 and 3 days of culture.

**Results:** MDSCs like blast can be divided into two subtypes, monocyte sub-subgroup expressing CD14 and granulocytic sub-subgroup expressing CD15, and CD14 expression was more frequent than CD15 (67.5% vs 39.3%). MDSC-like blasts showed higher expression of Arg1 (77.1% vs 38.5%, P<0.001) and iNOS (33.3% vs 1.1%, P=0.0001) compared to non-MDSC-like blasts. CD8+ T cell proliferation induced by PHA was significantly suppressed when co-cultured with MDSC-like blasts compared to those without. Among the various leukemic cell lines, the proliferation of NB4 cells were significantly suppressed when co-cultured with jurkat T cells on day 3 (NB4 23.49±6.26% of control, NB4+jurkat 12.62±3.92%, P<0.01). The decreased proliferation of NB4 cells was partially recovered after 3 days of co-culture with MDSC-like blasts (NB4+jurkat 12.62±3.92%, NB4+jurkat+MDSC like blast 18.71±6.19, P=0.022).

**Summary/Conclusions:** The role of leukemic cell line:Jurkat T cell: MDSC like blast ratio of 4:4:1. The effect of Jurkat T cells and MDSC like blasts on the proliferation of leukemic cells was assessed by the CCK-8 assay after 1 and 3 days of culture.

**Results:** MDSCs like blast can be divided into two subtypes, monocyte sub-subgroup expressing CD14 and granulocytic sub-subgroup expressing CD15, and CD14 expression was more frequent than CD15 (67.5% vs 39.3%). MDSC-like blasts showed higher expression of Arg1 (77.1% vs 38.5%, P<0.001) and iNOS (33.3% vs 1.1%, P=0.0001) compared to non-MDSC-like blasts. CD8+ T cell proliferation induced by PHA was significantly suppressed when co-cultured with MDSC-like blasts compared to those without. Among the various leukemic cell lines, the proliferation of NB4 cells were significantly suppressed when co-cultured with jurkat T cells on day 3 (NB4 23.49±6.26% of control, NB4+jurkat 12.62±3.92%, P<0.01). The decreased proliferation of NB4 cells was partially recovered after 3 days of co-culture with MDSC-like blasts (NB4+jurkat 12.62±3.92%, NB4+jurkat+MDSC like blast 18.71±6.19, P=0.022).
Summary/Conclusions: CD11b+CD33+HLA-DR+ MDSC-like blasts subpopulation which expressed the INOS and Arg1 existed in AML, and showed ability to suppress the T cell proliferation. MDSC-like blasts partially restored the suppressed leukemic cell growth of NB4 cells by jurkat cells. MDSC-like blasts might play a certain role in immune-escape mechanism of AML.

GENERATION OF NEW CELLULAR MODELS FOR THE STUDY OF PEDIATRIC NON DOWN SYNDROME ACUTE MEGAKARYOBLASTIC LEUKAEMIA BASED ON HUMAN PLURIPOTENT STEM CELLS
J. Domingo-Reinés1, F. González-Pozas1, L. Morales-Cacho1, M. Vogel-Gonzalez1, G. Rodríguez-Real1, J. Olmedo-Pelayo1, R. M. Montes1, V. Ayllón1, V. Ramos-Mejía1,1 Genyo, Granada, Spain

Background: Acute megakaryoblastic leukaemia (AMKL) is a rare and complex type of Acute Myeloid Leukaemia (AML) more frequent in children than in adults, characterized by the accumulation of immature megakaryoblasts and thrombocytopenia. Paediatric AMKLs are classified in Down Syndrome AMKL (DS-AMKL) with a good prognosis; and AMKL non-related to Down Syndrome (non-DS-AMKL), a more aggressive disease with a mortality rate close to 80%. There is a limited amount of research done on infant non-DS-AMKL, due to its low recurrency and early human hematopoietic stem cells (hPSCs) are cells that allow us to mimic human embryonic hematopoietic development. In this project, we aim to use human hPSCs expressing non-DS-AMKL-associated fusion oncoenes as cellular models for this leukaemia, to study the molecular and cellular pathways involved in the development of pediatric non-DS AMKL.

Methods: Generation of human models of non-DS AMKL using hPSCs: 1. Generation of hPSCs with the oncogenic fusion proteins RBM15-MKL1, CBF2AT3-GLIS2 and NUP98-JARID1 using transduction with lentiviral vectors. 2. Generation of hPSCs with the chromosomal translocations t(1;12) and t(11;12), that generate the fusion proteins RBM15-MKL1 and NUP98-JARID1 respectively, and the inversion of chromosome 16, that originates the fusion protein CBF2AT3-GLIS2.

Aims: It is essential to establish new human models to provide enough biological material for functional and molecular studies. As the genetic alterations that drive infant leukaemia occur in the developing fetus, we propose that human pluripotent stem cells (hPSCs) are ideal models to study non-DS AMKL, as these cells allow us to mimic human embryonic hematopoietic development. In this project, we aim to use human hPSCs expressing non-DS-AMKL-associated fusion oncogenes as cellular models for this leukaemia, to study the molecular and cellular pathways involved in the development of pediatric non-DS AMKL.

Summary/Conclusions: These models will serve as platforms to discover and understand the cellular and molecular alterations caused by these oncogenes, and their impact in the generation of hematopoietic cells during development. With this information we will have a better understanding of the origin and development of paediatric non-DS AMKL, so we will be able to design new therapeutical approaches for these children.

ASXL1 MUTATIONS IN AML ARE ASSOCIATED WITH SPECIFIC CLINICAL AND CYTOGENETIC CHARACTERISTICS
K. Kakosaiou1, F. Panitsas2, A. Ioannidou1, M. Pagoni2, P. Apostolou3, A. Daraki1, I. Vlachadami4, T. Marinakis5, C. Giatra2, D. Vasilatou6, C. Sambani1, V. Pappa6, K. Manolou1,1 Laboratory of Health Physics, Radiobiology & Cytogenetics, NCSR “Demokritos”, 2Hematology-Lymphoma Department - BMT Unit, Evangelismos Hospital, 3Laboratory of Molecular Diagnostics, NCSR “DEMOKRITOS”, 4Department of Pathophysiology, “Laiko” Hospital, 5Department of Hematology, “Georgios Gennimatas” General Hospital, 6Hematology Unit, University General Hospital “Attikon”, ATHENES, Greece

Background: Mutations of ASXL1 are considered early founder events in AML development. They are included in the definition of the “chromatin-splicing-some” genomic class of AML and among the high risk genetic prognosticators in the 2017 ELN recommendations.

Aims: We aimed to study the frequency of ASXL1 mutations in a cohort of newly diagnosed AML patients and to look for correlations with conventional cytogenetic findings and baseline characteristics.

Methods: Three hundred and sixty AML patients diagnosed between 2005 and 2014 were studied. Conventional cytogenetic analysis was performed on unstimulated bone marrow cells cultured for 24 and 48 hours. Molecular analysis of ASXL1 exon 12 mutations was performed by PCR and subsequent direct Sanger sequencing in diagnostic bone marrow or peripheral blood samples.

Results: Median age of the whole cohort was 63 years (11-95) and 56% of patients were male. Eighty two patients (22.8%) had secondary AML (sec-AML) with prior diseases being MDS (63), CMML (4), PV/ET (9), MF (2) and CML (2 and 4). Karyotypic analysis was successful in 352 (97.7%) AML samples of which 252 (71.6%) exhibited clonal karyotypic abnormalities. ASXL1 mutations were detected in 52 patients (14.4%). The most common mutation was c.1934 dupG in 44/52 (84.6%). ASXL1 mutated patients were significantly older with median age 72 vs 61.5 years in the unmutated (p=0.0001). Three of 61 patients (4.9%) aged ≤40, 10/97 aged 41-60 (10.3%) and 39/198 aged >60 (19.7%) were mutat-
ed. KS was 40% (71%) in patients with AML,36% (38%) in patients with MDS, 41% (50%) in CMML. Furthermore, we show multiple mutations in various AML-positive sample types, including mutations in CEBPα.

Conclusions: Our study demonstrates that amplify-based NGS enables comprehensive detection of multiple mutation types as well as gene expression levels relevant in hematologic malignancies. Importantly, NGS enables identification of novel gene fusions at nucleotide resolution, detection of ITDs and characterization of relative gene expression levels and CNAs.

CHARACTERIZATION OF HEMATOLOGIC MALIGNANCIES WITH ANCHORED MULTIPLEX PCR AND NEXT-GENERATION SEQUENCING
L. J. Anderlini1, M. Bautista1, A. Berlincourt1, J. Haines1, D. Fugger1,1, L. Griffin1, K. Trifo1, N. Manojlo1, H. Wang1, R. Ryan2, M. Hussain2, B. Kudlow1,1, 1Academic Division of Hematology, Cancer Center, Harvard Medical School, Boston, MA, 2Children’s Hospital Los Angeles, Los Angeles, CA, 3Department of Pediatrics, Emory University School of Medicine, Atlanta, GA, 4New York University School of Medicine, New York, NY, 5Case Western Reserve University, Cleveland, OH, 6University of Florida, Gainesville, FL, 7Children’s Hospital of Philadelphia, Philadelphia, PA, 8University of Texas at Southwestern Medical Center, Dallas, TX, 9Mount Sinai School of Medicine, New York, NY

Background: Hematologic malignancies can be driven by a diversity of mutation types, including single nucleotide variants, copy number variants, gene fusions, insertions and deletions and changes in gene expression profiles. However, comprehensive detection of these mutation types from a single clinical sample is challenging, as specific assays are required to detect each mutations type. Next-generation sequencing (NGS) enables comprehensive detection of all mutation types from whole genomes and transcriptomes. However, low detection sensitivity, high input requirements and high costs render these approaches impractical for routine detection of mutations from clinical sample types. Anchored Multiplex PCR (AMP™) is a target enrichment strategy for NGS that uses molecular barcoded (MBC) adapters and unidirectional gene-specific primers (GSPs) for amplification.

Aims: Our goal was to develop AMP-based NGS assays to simultaneously detect multiple mutation types from DNA and RNA, as well as relative gene expression levels and copy number aberrations (CNAs). In particular, we sought to develop methods to detect novel gene fusions, internal tandem duplications (ITDs) and mutations in CEBPα.

Methods: We developed AMP-based Archer® VariantPlex™ and FusionPlex™ assays to enable NGS-based detection of mutations from DNA and RNA, respectively. Open-ended amplification (OA) and target enrichment with novel gene fusions with FusionPlex and complex mutation types as ITDs with VariantPlex assays. MBC adapters ligated to RNA and DNA fragments prior to amplification enable relative gene expression and CNA analysis.

Results: We show instances of gene fusion detection from open-ended amplification, such as MLL, RUNX1 and RUNX1-T1, and novel gene fusions with缷ュンPlex FusionPlex and complex mutation types such as ITDs with VariantPlex assays. MBC adapters ligated to RNA and DNA fragments prior to amplification enable relative gene expression and CNA analysis.

Conclusions: Our study demonstrates that AMP-based NGS enables detection of multiple mutation types as well as gene expression levels relevant in hematologic malignancies. Importantly, AMP enables identification of native and novel gene fusions at nucleotide resolution, detection of ITDs and characterization of relative gene expression levels and CNAs.

haematologica 2017; 102(s2) | 367

Madrid, Spain, June 22 – 25, 2017
mutations. Moreover, ASXL1 mutations were detected in 3 of 12 patients with aberrations of 3q (25%), 2/9 (22%) with trisomy 13, 2/11 (18%) with t(9;22) and only 1 of 22 patients with t(15;17). Multivariate logistic regression suggested that independent predictors of the presence of ASXL1 mutations were older age (OR 1.43 per decade, 95% CI 1.13-1.79), chromosome 11 aberrations (OR 2.69, 95% CI 1.09-6.63), and sec-AML (OR 4.44, 95% CI 2.38-8.57), whereas a deleted 7q or -5/del5q predicted for lower frequency (OR 0.32, 95% CI 0.13-0.75).

Summary/Conclusions: Our results support the association of ASXL1 mutations in AML with advancing age and sec-AML. Association with trisomy 8 did not retain significance in multivariate analysis. Chromosome 11 aberrations emerged as an independent predictor. Despite the strong link with secondary AML (majority of cases post MDS), our data show inverse relationship with -7/del(7q) or -5/del5q. In addition, ASXL1 mutations were not positively associated with MDS-related cytogenetic abnormalities, complex or monosomal karyotypes.

A COMPREHENSIVE DNA TESTING FOR THE DETECTION OF TRANSLOCATIONS IN ACUTE LEUKEMIA
E. Van Den Berg-De Ruiter1,*, M.Z. Alimohamed1, L.F. Johansson1,4, E.N. de Boer2, E. Splinter3, P. Klous4, A.G. Bosgra1, M. van Min1,5, A.B. Mulder3, E.B. Slijper1, R.J. Sink1, R.H. Sijmons1, B. Sikkema-Raddatz1, E. Vellenga5, R.J. Sinke1, R.H. Sijmons1, B. Sikkema-Raddatz1
1Genetics, 2Genetic Coordination Center, UMCG, Groningen, 3Cergentis B.V., Utrecht, 4Laboratory Medicine, 5Hematology, UMCG, Groningen, Netherlands

Background: Patients with acute leukemias carry a wide range of chromosomal abnormalities, which affect their prognosis and treatment options. Currently, over 500 different translocations are reported to be involved in the disease progression. Traditional methods to detect chromosomal abnormalities involve a combination of techniques such as karyotyping, FISH, array and RT-PCR. However, these methods are laborious and at times inadequate. Targeted Locus Amplification (TLA), a new targeted next generation sequencing technology can overcome these shortcomings. It is based on proximity ligation (crosslinking) of DNA and outward oriented probes for enrichment and can therefore identify chromosomal translocation partners regardless of their identities.

Aims: Here we present a TLA multiplex panel in combination with next generation sequencing as a first tier screening tool in detecting translocations in acute leukemias.

Methods: A multiplex TLA panel was designed using primer sets covering known break-point regions of the 17 most frequently reported genes involved in acute leukemia’s. TLA was performed on five different cell lines carrying translocations detectable by our panel. t(12;21), t(11;14), t(11;19)(9;13), t(6;9), t(17;19). Various combinations of cell line mixtures in multiple dilution series were used to determine the specificity and sensitivity of the panel, and to set sample quality thresholds during analysis. Samples were processed using standard TLA protocol (de Vree et al, 2014). Targets were enriched by PCR amplification with the multiplex panel and subjected for sequencing on Illumina Nextseq 500. To facilitate an easy analysis workflow a semi-automated data analysis was developed. This includes a quality control step, labelling samples with no coverages at the anchor regions after filtering at more than half the expected of acute leukemia were taken for routine genetic diagnosis (Karyotyping, or RT-PCR, confirming the TLA findings. In fifteen samples no translocation was detected, concordant to (cyto)genetic findings. Three translocations were missed due to insufficient sequence reads on the partner chromosome. In addition, in one sample one translocation partner was also missed, located in the telomeric region of the chromosome and therefore resulting to nonspecific mapping of the sequence reads. An additional finding, involving a three way translocation t(9;12;11), missed by cytogenetics was detected by our panel.

Summary/Conclusions: Our TLA panel showed concordant results for 29 out of the 33 successful sequenced samples. No false positives were found, while an additional translocation was detected. Our panel is able to detect (cryptic) translocations with high confidence in combination with the fusion partner. Therefore, the TLA multiplex panel is suited as a first tier screening tool in acute leukemia. A prospective study, comparing the diagnostic yield of the TLA panel with current tests, can establish whether the TLA panel is applicable as a routine procedure.

ALTERATIONS IN NECROTOPSIS PATHWAY AFFECT PROGNOSIS OF PATIENTS WITH ACUTE MYELOID LEUKEMIA
S. Lo Monaco1,*, G. Marconi1, M.C. Fontana1, C. Papayannidis1, E. Ottaviani1, E. Franchini1, A. Ferrari1, A. Padella1, G. Simonetti1, S. Paolini1, G. Martinelli1
1University of Bologna, Bologna, Italy

Background: Necroptosis is a type of necrotic cell death involving several genes transcription and activation of molecular mechanisms as death receptors, interferon, toll-like receptors, intracellular RNA and DNA sensors. The process is leaded by the family of receptor-interacting protein kinase (RIPK3, RIPK2, RIPK1) and the MLKL substrate. Losses of RIPK3 or MLKL, as well as deficiency in apoptosis, could allow tumor cells to escape the immune-mediated cells death (ICD).

Aims: We want to investigate the role of necroptosis deficiency in correlation with chemotheraphy resistance and its impact as prognostic factor in AML.

Methods: We performed SNP Arrays (Cytoscan HD and SNP 6.0, Affymetrix) on a cohort of 300 non-M3 AML patients at diagnosis and we analyzed the Overall Survival (OS) of our patients with deficiency on necroptosis pathways. Survival was analyzed with Kaplan-Mayer method and Log-Rank test. We further analyze the relevance of different prognostic factors by the use of COX-Hazard Ratio statistical analysis.

Results: We found that 18 patients presented a loss of RIPK1 or MLKL (nobody presented losses in RIPK3-RIPK2) and 13/18 patients were older than 65 years old. The Overall Survival (OS) of patients with alterations in these genes is significantly lower than control group, with a median OS of 3 months respectively (p<0.001). With Fisher Exact Test we further demonstrate that copy number loss of RIPK1 or MLKL are associate to loss of TP53 or FANCA genes, complex karyotype and advanced age. COX-Hazard Ratio model with RIPK1 or MLKL loss, BRCA1 loss, TP53 mutation, FANCA loss, secondary disease and diagnosis karyotype considered as categorical variable show that necroptosis deficiency (HR 1.98, CI 95% 1.04-3.78) TP53 mutation, and secondary AML are independent negative prognostic factors in an optimal model.

Summary/Conclusions: Our study shows that losses in necroptosis pathways are an uncommon alteration in AML, prevalent in old population. Moreover, we hypothesize that the loss of genes involved in necroptosis could be a real mechanism of tumor immune-escape and could be a realistic to select patients that high probability to be resistant at chemotherapy promoting ICD mechanisn.

NGS ANALYSIS AND IMPACT OF VARIANT ALLELIC FREQUENCY AT RELAPSE AND REFRACTORY STATUS IN AML PATIENTS

E. Onecha De La Fuente1,2, I. Rapado1,2, M. Llops3, Y. Ruiz-Heredia1,2, T. Cedena1,2, E. Barragan3,4, M. Gallardo1,2, J. Martinez Lopez1,2, R. Ayalà1,2
1Hematología traslacional, Hospital 12 de Octubre, 2Haematological Malignancies Clinical Research Unit, CNIO, Madrid, 3Instituto de Investigación Sanitaria La Fe, 4Clinical Pathology Service, Hospital Universitari i Politècnic La Fe, Valencia, Spain

Background: A high number of patients with acute myeloid leukemia (AML) present resistance at treatment, which is associated with clonal persistence or evolution. The generation of high-depth sequencing data allowed to quantify variant allelic frequencies (VAF) and permitting estimation of the size of tumor clonal populations in each AML sample, and to perform an estimation of clonal evolution at relapse or refractory case according to diagnostic.

Aims: To evaluate the predictive impact of the fluctuation Variant Allelic Frequency in resistance to treatment cases in AML.

Methods: We performed a custom-targeted sequencing panel of 32 genes (all coding regions) implicated in leukemia prognosis, including ASXL1, CBL, DNMT3A, EPO, ETv6, EZH2, FLT3, HRAS, IDH1, IDH2, JAK2, KDM6A, KIT, KRAS, LNK, MLL, MRT, NRAS, PHF6, PRPF40B, PTEN, RUNX1, SF1, SF3A1, SF3B1, SRSF2, TET2, TP53, U2AF35, VHL, ZRSR2 and CALR, by Ion Torrent Proton System-Thermo Fisher. Primary tumor-refractory (n=8) and primary tumor-relapsed (n=17) samples pairs from 25 AML patients treated according PETHEMA AML clinical protocols were sequenced; in addition FLT3-ITD was detected by GENSCAN and NPM1 mutation was detected by PCR. We analyse the evolution of level of VAF, to measure the prevalence of somatic mutations between diagnosis and resistance status (relapse or refractory).

Results: Mutations in signalling pathway (EPOR, FLT3, JAK2, KIT, LNK or/and MPL) and GTPases pathway (KRAS, LNK, MLL, MRT, NRAS, PHF6, PRPF40B, PTEN, RUNX1, SF1, SF3A1, SF3B1, SRSF2, TET2, TP53, U2AF35, VHL, ZRSR2 and CALR) were found good results when combined with pazopanib in clinical trials for other kind of tumors, we expect similar results in AML.

Summary/Conclusions: These results show VAF increases of specific mutations as KIT correlates with relapse status. Furthermore, the variable frequency signalling pathway (EPOR, FLT3, JAK2, KIT, LNK or/and MPL) play a critical role in resistance status, increasing variant allelic frequencies of mutations in relapse and decreasing in refractoriness.

PRECLINICAL EVIDENCE THAT TRAMETINIB ENHANCES THE RESPONSE TO TYROSINE KINASE INHIBITORS IN ACUTE MYELOID LEUKEMIA

M.L. Morales1,2, M. Linareis1, A. Arenas1, I. Zagora2, R. Ayalà2, N. Castro1, I. Rapado1, M. Quintela-Fandino2, J. Martinez-Lopez1
1Servicio de Hematología, Hospital Universitario 12 de Octubre, 2Unidad de Proteómica, Centro Nacional de Investigaciones Oncológicas, Madrid, Spain

Background: Acute Myeloid Leukemia (AML) is the most common type of acute leukemia in adults and the second in children in whom overall survival is less than 35% and 60% respectively. Activating mutations of FLT3 are now recognized as the most common molecular abnormality in this disease, and the poor prognosis of patients harboring these mutations renders FLT3 an obvious therapeutic target. Although different tyrosine kinase inhibitors (TKI) have been used for this purpose, their ability to extend progression-free and overall survival is limited by drug resistance. This strategy could be improved by rationally combining TKIs with other agents. In this work, we have explored bone marrow samples from a FLT3-AML patient before and after TKI treatment by phosphoproteomics and observed enhanced activity of Ras-Raf-MEK-ERK1/2 pathway as a possible mechanism for TKI resistance.

Aims: To validate the role of ERK1/2 during TKI resistance in vitro and ex vivo and to search suitable combinations that allow overcome/avoid resistances in preclinical models of the disease.

Methods: Resistance mechanisms were studied in vitro in MOLM13 (FLT3WT/ITD) after generating resistance by two different methods: by subculturing with increasing doses of sorafenib or by treating them with high doses of sorafenib, and recollecting alive proliferative (resistant) cells after CFDA and Annexin labeling. Phosphoproteomic analyses were carried out by LC-MSMS after IMAC enrichment or by western blot techniques. Drug sensitivity assays with trametinib (MEK inhibitor) and three TKIs (sorafenib, pazopanib, midostaurin) were read after 48 hours or 72 hours of treatment in vitro or ex vivo respectively. The efficacy of the combinational treatments was characterized by cell viability assay using WST8, and analyzed with Graphpad Prism software. Synergy effects were measured with CalcuSoft software.

Figure 1. We performed a custom-targeted sequencing panel of 32 genes (all coding regions) implicated in leukemia prognosis, including ASXL1, CBL, DNMT3A, EPO, ETv6, EZH2, FLT3, HRAS, IDH1, IDH2, JAK2, KDM6A, KIT, KRAS, LNK, MLL, MRT, NRAS, PHF6, PRPF40B, PTEN, RUNX1, SF1, SF3A1, SF3B1, SRSF2, TET2, TP53, U2AF35, VHL, ZRSR2 and CALR, by Ion Torrent Proton System-Thermo Fisher. Primary tumor-refractory (n=8) and primary tumor-relapsed (n=17) samples pairs from 25 AML patients treated according PETHEMA AML clinical protocols were sequenced; in addition FLT3-ITD was detected by GENSCAN and NPM1 mutation was detected by PCR. We analyse the evolution of level of VAF, to measure the prevalence of somatic mutations between diagnosis and resistance status (relapse or refractory).

Results: Mutations in signalling pathway (EPOR, FLT3, JAK2, KIT, LNK or/and MPL) and GTPases pathway (KRAS, LNK, MLL, MRT, NRAS, PHF6, PRPF40B, PTEN, RUNX1, SF1, SF3A1, SF3B1, SRSF2, TET2, TP53, U2AF35, VHL, ZRSR2 and CALR) were found good results when combined with pazopanib in clinical trials for other kind of tumors, we expect similar results in AML.
IDENTIFICATION OF NOVEL THERAPEUTIC DRUGS IN DISTINCT PEDIATRIC AML SUBTYPES BY TARGETING EPIGENETIC REGULATORS

C. Wiggers 1,2, D. Lelièvre 3, D. Egan 4, M. Bartels 1, T. Gjertsen 5, S. Weitman 1, D. Bearss 1, S. Warner 1
1Centre for Cancer Biomarkers (CCBIO), University of Bergen, 2Department of Biomedical Laboratory Sciences and Chemical Engineering, Bergen University College, 3Department of Internal Medicine, Haematology Section, Haukeland University Hospital, 4Department of Clinical Science, Leukaemia Research Group, University of Bergen, Bergen, Norway

Background: The current treatment of pediatric AML is based on the “7+3” regimen combining cytarabine and daunorubicin. However, most patients (approximately 25% of newly diagnosed cases) do not achieve complete remission (CR) and achieve high-risk (<15% CBF) AML with a poor outcome. To improve clinical outcomes, new treatment strategies are needed.

Methods: We performed a high-throughput drug screen on three pediatric AML cell lines (THP-1, Kasumi-1 and MOLM-13) to identify new therapeutic agents.

Results: From the 80 epigenetic compounds tested in THP-1, Kasumi-1 and MCL-1 cells, we observed significant effects following treatment with the HDAC inhibitor Mifamostat, the p38 inhibitor Alvespimycin, the phosphatidylinositide 3-kinase (PI3K) inhibitor GDC-0941 and the CDK9 inhibitor Bromosporine. Dose-response curves showed differential cytotoxicity of the compounds and suggested Mifamostat as most effective. Cell proliferation was inhibited by Mifamostat at an IC50 of 0.1μM, 0.13μM and 0.425μM in Kasumi-1, CMK and THP-1, respectively. While inhibition by Mifamostat resulted in an immediate decrease of apoptosis, Bromosporine-treated cells retained viability and morphology. Interestingly, in the co-treatment of THP-1 and Kasumi-1 cells, we observed an increase in cell S-phase and G2/M. Among the differential effects of the compounds in the cell lines, we also observed differences in sensitivity. In line with previous studies, THP-1 cells were more resistant, illustrated by a 10-fold increase in concentration required for NC8352-induced apoptosis. Interestingly, upon treatment with Bromosporine, Kasumi-1 and CMK cells showed a similar response, while Kasumi-1 cells were significantly more sensitive to NC8352-induced effects. These data are currently validated in pediatric AML patient cells.

Summary/Conclusions: Treatment of three distinct pediatric AML cell lines with the epigenetic compounds LMK235, NC8352 and Bromosporine resulted in cell line-specific effects, including cell cycle regulation and induction of apoptosis. Our data suggest a potential role for epigenetic compounds, with specificity for molecular subtypes, in the treatment of clinically and biologically distinct pediatric AML subtypes.

**KEVETRIN: PRECLINICAL STUDY OF A NEW COMPOUND IN ACUTE MYELOID LEUKEMIA**

R. Napolioli1, S. De Matteis1,2, S. Carloni2, G. Simonetti2, G. Musuraca3, A. Lucchesi3, D. Calisti1, A. Cuneo4, K. Menon5, G. Martinelli2

1Bioscience Laboratory, IRCCS, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), Meldola, Italy, 2Department of Hematology and Oncological Sciences, University of Ferrara-Arcispedale Sant’Anna, Ferrara, Italy, 3Celleceutix Corporation, Beverly, United States

**Background:** Acute Myeloid Leukemia (AML) is a heterogeneous disorder defined by clonal expansion of immature myeloid cells that infiltrate bone marrow and other tissues. AML therapeutic strategies remain unchanged since 1970 and the majority of patients often eventually relapse and die due to disease progression. Tumor protein p53 transcription factor is a key regulator of several cellular pathways, such as cell cycle, apoptosis and angiogenesis. It is mutated in 8-14% of AML cases and its mutations are commonly associated with a complex karyotype. Kevetrin is a new molecule compound, proposed by Celleceutix, with the ability to target both wild type and mutant p53 tumors.

**Aims:** The aim of this project is to explore cellular and molecular alterations induced by Kevetrin, focusing on its role in the p53 pathway.

**Methods:** Kevetrin was kindly provided by Celleceutix, dissolved and stored at 4°C in sterile water in a 600 μg/ml stock solution, and diluted in medium immediately before use [concentration range in use 15-60μg/ml]. Cell lines, MOLM-13 and KASUMI-1, were cultured in RPMI 1640 supplemented with 20% heat inactivated fetal bovine serum, 2mM L-glutamine, 100 U/ml penicillin and 100 μg/ml streptomycin. After 24 and 48 h of treatment MTS, Annexin-V, TUNEL, JC-1 and Active Caspase-3 assays were performed according to manufacturer’s instructions. Proteins were separated by polyacrylamide gel electrophoresis and transferred to 0.2 μm polyvinylidene fluoride membranes. Quantitative analysis was performed with Quantity One software. Statistical analysis was carried out using the paired and unpaired two-tailed Student’s t tests. p values <0.05 were considered as significant.

**Results:** Our data indicate that Kevetrin exposure induces cell growth arrest, a great drop of mitochondrial membrane potential and a remarkable increment of Caspase-3 cleaved form, features that contribute to apoptotic cell death in the two cell lines. Cellular changes can be associated with a dose and time-dependent effect in the TP53 mutated cell line (KASUMI-1) but not in the wild type one (MOLM-13), in which we can observe an activity only after 48 h at the higher concentration. Regarding molecular alterations in KASUMI-1 we found a great p53 down-regulation, probably due to Hsp90 reduction, resulting in a less marked formation of the Hsp90-p53 oncogenic complex. We also found a down-regulated p53 active form (Ser15), a reduced expression of p53 targets, p21 and PUMA, and a down-regulation of SIRT-3, that cannot exert its inhibitory activity on p53. The MOLM-13 cell line showed a great p53 reduction, probably related to SIRT-3 up-regulation and Hsp90 down-regulation. Regarding p53 active form, we noticed slight variations in protein expression, suggesting a physiological response of the protein to cellular damage. In accordance with p53 activity, we observed a great increment of TP53, probably associated with a drug resistance mechanism; in contrast, PUMA protein was highly down-regulated, suggesting a p53-independent mechanism of action or a feedback regulation of the apoptotic process, after Caspase-3 activation (Figure 1). In order to better understand drug’s mechanism of action we are performing gene expression profiling after 48h of treatment with Kevetrin 60μg/ml.

**Figure 1.**

**Summary/Conclusions:** IFNα does not add beneficial effects to VPA treatment in the two in vivo orthotopic models tested, possibly due to immune constitution and tumor load.

**MONEY LEUKEMIA**

**CLEARANCE OF ‘DRIVER-COSMIC’ MUTATIONS POST CR1 WITH OPERATING RUNX1 L565 IS UNLIKELY TO CONTRIBUTE TOWARDS DISEASE PROGRESSION IN AML**

L. Rai1, T. Boneva2, D. Brazma2, R. Dunn2, C. Grace2, E. Nacheva2,3

1Onco-Cytogenomics, 2OncoGenomics, HSL Analytics LLP, 3Cancer Research Institute, UCL, LONDON, United Kingdom

**Background:** Clinical significance of gene variants in AML is well established (Papaemmanuil E, et al, NEJM 2016) and is increasingly being implemented into routine diagnostic algorithms. Although 80% of patients achieve morphological remission after induction chemotherapy, long-term relapse free survival is a meagre 50% (Walter RB et al, JCO 2010). Monitoring of disease kinetics, is therefore, very critical.

**Aims:** To study the kinetics of gene variants post-induction chemotherapy in AML patients.

**Methods:** 130 follow-up samples from 45 de novo AML patients [median age 60 yr & median FU period- 18.6 mo] were screened for gene variants using TruSight Myeloid panel (Illumina, CA, USA) covering 54 genes with relevance in myeloid diseases. Gene variants at Variant allele frequency (VAF) of ≥10% at diagnosis and VAF of ≥1% during follow-up; both with target coverage of ≥300 reads were considered. Bone marrow (BM) or peripheral blood (PB) was obtained at presentation (BM-44; PB:1) and follow-up (BM-130). Gene variants in 95 samples from 40 MDS patients were also evaluated for progression to secondary AML. Public databases-Catalogue of Somatic Mutations In Cancer (COSMIC), dbSNP and 1000 genome (≥2%) were used to classify gene variants as either Drivers (D), variants of unknown significance (VUS) and germline polymorphisms (SNP). P-value was generated with 2-tailed Fisher Exact (GraphPad Software, Inc, USA).

**Results:** Of 45 AML patients 19 achieved complete morphological remission (CR), 21 had a relapse and 5 had refractory disease with a median of 4 mutations/patient in each subgroup. Driver mutation was identified in 38 patients; 82% of who had persistence until clinical end-point. While 17 of 18 relapse patients retained a driver only 9 of 15 patients in remission retained it (Table 1). 8 of the 9 patients had a ‘driver with COSMIC and SNP’ (D-C/S) reference that persisted, while all ‘driver with COSMIC only’ (D-C) disappeared post-induction. This suggests that drivers with both COSMIC and SNP reference may not always contribute towards disease progression. We also found that D-C mutations persist in 85.7% of relapse patients compared to only 11% of patients in remission (P-value: 0.001). Additionally, D-C mutations were retained in all 13 relapse patients with intermediate risk cytogenetics while complete clearance was observed in all 6 patients who were in sustained remission (P-value: 0.001).

Further investigation of genes with D-C/S mutation in the remission cohort (8x) revealed that 4 patients had persistent DNM3A-25457242, 1 had DNM3A-25457243, 2 had RUNX1-36259324/L565 and 1 had CBL-119149011. As DNM3A mutations are considered to occur in pre-leukemic immunocompetent brown Norwegian myeloid leukemia (BNML) syngeneic rat model. VPA mono-treatment increased survival from a median of 34 days to 38 days in the MOLM-13 wild type mouse model, and from 21 days to 50 days in the BNML rat model. Additionally, the IFNo-Le (0.8x10⁶ IU/kg) and VPA (400mg/kg) combination treatment indicated a tendency to increased survival in the BNML model. However, IFNo-Le monotherapy (1x10⁶ IU/kg) decreased survival in the MOLM-13 wild type model.

**Figure 1.**

**Conclusion/Conclusions:** Our results suggest Kevetrin is a promising new drug in AML patients treatment, both in wild type and, even more, in TP53 mutated tumors, through different molecular mechanisms, giving more therapeutic alternatives in the treatment of this disease.
stem cells contributing to clonal haematopoiesis (Askush et al, Nature 2014; Genovese et al, NEJM 2014); this led us to study the distribution of RUNX1 gene variants in an additional 119 AML diagnostic samples. 34 patients (21%) harboured RUNX1 mutation, of which 5 had RUNX1_L56S that were often associated with D-C mutations (4 of 5 cases). Finally, we evaluated kinetics of D-C in 40 MDS cases of which 34 had chronic MDS and 6 had secondary AML (sAML). No significant difference was observed in the number of patients with persistent D-C mutation in the 2 subgroups (chronic MDS: 16 of 19 (84.2%); sAML: 5 of 5 (100%); P-value: 1.000).

Table 1.

Summary/Conclusions: Clearance of ‘Driver-COSMIC only’ mutations while RUNX1_L56S persists is unlikely to contribute towards disease progression in AML.

Acute myeloid leukemia - Clinical

E906

PROGNOSTIC SIGNIFICANCE OF FLT3 STATUS, CYTOGENETIC, ECOG AND 50% BLAST DECREASE IN PRIMARY REFRACTORY OR EARLY RELAPSED AML PATIENTS BEFORE SALVAGE THERAPY

P. Sesques 1, S. Bertoti 2, M. El-Hamm 3, S. Ducastelle 1, G. Salies 1, C. Recher 3, X. Thomas 1, E. Paubelle 1, 2

1hematology, Chu Lyon Sud, Pierre Benite, 2hematology, Oncopole Toulouse, Toulouse, France

Background: Prognosis of relapsed/refractory acute myeloid leukemia (R/R AML) is unfavorable with a long term overall survival around 10%. Thus, management of R/R AML represents one of the most difficult challenges. Because allogeneic-Hematopoietic Stem Cell Transplantation (allogeneic-HSCT) is considered as the best treatment for this category of patients, to determine which patient will benefit from this cumbersome strategy is a crucial issue. A better understanding of the mutational status, cytogenetic, histological and clinical findings of early R/R AML patients and their outcomes could help treatment decisions, particularly for those who allogeneic-HSCT is considered as the best therapeutic option.

Aims: The objective of this study is to determine prognostic factors and develop a prognostic score using usual mutational status, cytogenetic, histological and simple clinical variables in R/R AML patients before salvage treatments.

Methods: In this retrospective study in two hematological departments (Hospices Civils de Lyon and CHU of Toulouse), we evaluated clinical, biological, histological, cytogenetic and current mutational status of early R/R non APL AML patient between age from 18 to 70 years. Univariate and multivariate analysis were performed and we developed a prognostic score based on the independent prognostic parameters from Cox model.

Results: From January 2009 to May 2016, 58 patients presenting early relapse and/or primary refractory AML were analyzed. Overall Survival (OS) and Progression Free Survival (PFS) median were 9 and 2 months respectively. In univariate analysis, cytogenetic findings (unfavorable groups), unfavorable ECOG (>2), FLT3 positive status and <50% blast decrease (between induction and R/R assessment) independently predicted poor OS and were identified as significant prognostic parameters of OS (p=.037, p=.0084, p=.0452, p=.0071 respectively). In multivariate analysis, these last four criteria confirmed their worst prognostic impacts (p=.015, p=.017, p=.026, p=.015 respectively) and were used to create a five groups prognostic score. Better OS were statistically observed for patient with score 0 or 1 compared to 2, 3 or 4 (2-years OS 48% and 11% respectively, p=0.0104) using a log-rank regression. When data were censored to allogeneic HSCT, the scoring system revealed a relevant difference with favorable OS for those with a score 0-1 compared to score 2-3-4 (2-years OS 64% and Not Reached respectively, p=.001) (Figure 3).

Figure 1.

Summary/Conclusions: Our prognostic score based on simple and usual data: FLT3 status, cytogenetic, ECOG and percentage blast decrease found distinct groups with statistically different outcomes. Basically, the higher is the score, the worst is the OS. This new score is a valuable, simple and useful score for the therapeutic salvage management of AML patients presenting early relapse and primary refractory.
PRELIMINARY RESULTS FROM A PHASE 1 STUDY EXAMINING THE NOVEL BCL-2 INHIBITOR S55746/BCL201 AS SINGLE AGENT IN PATIENTS WITH ACUTE MYELOID LEUKEMIA OR HIGH RISK MYELODYSPLASTIC SYNDROME

A. Wei1∗, A. Bajel2, N. Boissel3, I. Kloos4, C. Delifer4, S. Banquet4, X. Thomas4, N. Vey5
1Department of Clinical Haematology, The Alfred Hospital and Monash University, 2Department of Haematology & Bone Marrow Transplantation, The Royal Melbourne Hospital, Melbourne, Australia, 3Department of Hematology, Hôpital Saint Louis, Paris, 4Servier, Suresnes, 5Department of Hematology, Centre Hospitalier Lyon Sud, Lyon, 6Department of Hematology, Institut Paoli-Calmettes, Marseille, France

Background: Novel and effective therapeutic options for patients (pts) with advanced acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) are limited. Targeting the prosurvival molecule BCL-2 is clinically efficacious in various hematological malignancies. S55746/BCL201 is a novel, selective and potent inhibitor of BCL-2, with demonstrated antileukemic activity in preclinical models.

Aims: To evaluate the safety, recommended phase 2 dose (RP2D), pharmacokinetic (PK), pharmacodynamic (PD) and preliminary activity of S55746/BCL201 in patients with AML (relapsed/refractory (R/R) or ≥65 years until for intensive chemotherapy (CI)), or MDS failing prior therapies.

Methods: A phase 1 study (EUDRACT 2014-002559-24, NCT02920541) is underway to investigate S55746/BCL201 as a single agent in 5 European and Australian centers. S55746/BCL201 was initially administered in fasting conditions, once daily (21-day cycles), until disease progression, unacceptable toxicity, or investigator’s or patient’s decision. Pts giving informed consent received S55746/BCL201 at escalating dose levels according to a modified continual reassessment method for dose allocation.

Results: As of 23 February 2017, 34 pts have received S55746/BCL201 at doses ranging from 100 to 1300mg/day (median time on treatment: 43 days, range 1 to ≥374), 28 pts were R/R AML, 2 pts were elderly AML unif for IC, and 4 pts had MDS failing prior therapies. Median age was 70 years (range 19-80), median number of prior therapies 2 (range 0-6), ECOG ≤2, and median WBC 3 G/L (range 0-30). Among the AML cohort, European LeukemiaNet risk (Döhner 2010) was adverse in 53%, intermediate-1 in 20%, and intermediate-II in 17%. Preliminary PK results in fasting pts showed that exposure increased linearly but with some inter-individual variability. Most common (≥20% of pts) non-hematological adverse events (AEs), all grades, included diarrhea (27%), hypokalemia (27%), nausea (21%), and vomiting (21%). The most frequent grade ≥3 AEs were hematological [anemia (35%), thrombocytopenia (32%), febrile neutropenia (21%), and neutropenia (18%)], hypokalemia (18%), and sepsis (15%). Of 12 pts (38%) with AEs possibly related to study drug, the most frequent were diarrhea (3 pts), muscle spasms, thrombocytopenia, and anemia (2 pts each). One 74-year-old pt had grade 5 cardiac failure considered drug-related after 5 cycles of treatment (900mg). Non-related fatal AEs were reported in 7 pts (including sepsis, hemorrhagic stroke, pneumonia, and disease progression). There were no reported episodes of clinical or laboratory TLS. No DLT was reported and MTD has not been reached. Of 26 AML pts evaluable for response (at least 1 cycle completed), one achieved a CR (complete remission with incomplete blood count recovery lasting 10 months) and one a PR (partial remission lasting 3 months before proceeding to allogeneic stem cell transplant). In MDS, 4 out of 4 pts had stable disease (lasting 1 to ≥7 months). Bone marrow blasts decreased in 50% of all evaluable pts, with the nadir reached (87%) within the first two cycles (Figure 1).

Summary/Conclusions: Initial findings suggest that S55746/BCL201 has acceptable tolerability and clinical activity in advanced AML and MDS. Based on non-compartmental pharmacokinetic food interaction results from another study, demonstrating that S55746/BCL201 Cmax and AUC increased about 6-fold with food, dose escalation has started in patients with drug intake during a meal.

E908
DISSECTING THE CLINICAL HETEROGENEITY OF NUCLEOPHOSMIN-1 (NPM1) MUTATED ADULT ACUTE MYELOID LEUKEMIA: THE CONTRIBUTION OF FLOW-CYTOMETRIC DETERMINATION OF MINIMAL RESIDUAL DISEASE

E. Buccisano1, A. M. Maurillo1, M. I. Del Principe1, A. Di Veroli1, E. De Bellis1, L. Cicioni1, M. Divona1, T. Ottone1, S. Lavorgna1, V. Rossi1, A. Zizzari1, M.A. Irno Consalvo1, D. Fraboni1, C. Conti1, G. Del Poeta1, M.T. Voso1, W. Arecesi1, F. Lo Coco1, A. Venditti1
1Biomedicine and Prevention, University For Vergata Rome, Rome, Italy

Background: Acute Myeloid Leukemia (AML) with mutations of the gene encoding Nucleophosmin-1 (NPM1) identifies a subgroup of patients with favorable prognosis according to the 2008 WHO classification. However, recent evidences (Papaemmanuel, NEJM 2016) suggest that the coexistence of additional gene mutations (e.g. DNM3A, IDH1, IDH2R1408fs, and TET2) may determine an inferior clinical outcome as compared to favorable risk AML and precludes a reliable outcome prediction. The presence of minimal residual disease (MRD), as determined by quantization of NPM1 mutated transcripts, provides powerful prognostic information independent of other risk factors (Ivey, N Engl J Med 2016).

Aims: The aim of our study was to investigate if detection of NPM1 transcripts by multiparametric flow cytometry (MFC) might represent an alternative tool to discriminate different prognosis within the NPM1 mutated AML group, in a setting where an extensive gene profiling at diagnosis or a quantitative determination of NPM1 transcripts in remission would not be available.

Methods: We analyzed a series of 69 AML patients with NPM1 mutations; all the patients were in complete remission (CR) after intensive induction cycle of EORTC-GIMEMA protocols. The frequency of NPM1 mutated cases was not different among patients below (48/142, 34%) or above (216/1, 34%) the age of 60 years, respectively. Twenty out of 65 patients (31%) carried a concomitant FLT3-ITD mutation; 51/66 (77%) NPM1 mutated cases had a normal diploid karyotype. Upon full hematological recovery after consolidation cycle, counting, by MFC, ≥3.5x10^4 (0.035%) residual leukemic cells (RLCs) in the bone marrow (BM) was regarded as a condition of MRD positivity.

Results: Among NPM1 mutated patients, the rate of MRD negative CR was significantly lower (5/69, 7%) as compared to NPM1 WT ones (39/134, 29%), respectively (p<0.001). Although there was not a statistically significant difference, probably due to the low numbers, MRD negative/NPM1mut patients had a lower Cumulative Incidence of Relapse (CIR) as compared to MRD positive/NPM1mut patients. The overall survival (OS) was significantly higher for patients submitted to ASCT (no=14) as compared to those (no=15) submitted to autologous (AuSCT) or allogeneic (ASCT) transplantation on the outcome of MRD positive/NPM1mut patients. The overall survival (OS) was significantly higher for patients submitted to ASCT (no=14) as compared to those (no=15) submitted to AuSCT (93% vs 33%, p=0.011). This was confirmed even after excluding from the analysis FLT3-ITDmut patients. When all the meaningful clinical variables were challenged in multivariate analysis (MRD, type of transplant, age >60 yrs, karyotype), the type of transplant (ASCT vs AuSCT) was the only variable that significantly influenced OS and DFS (p=0.001 and 0.033, respectively).

Summary/Conclusions: In conclusion, although quantitative RT-PCR represents the gold standard, MFC determination of MRD also confirms that the quality of remission is critical to discriminate patients with a different outcome among NPM1mut patients. In fact, these patients have a low chance to become MFC MRD negative and in a situation of MRD positivity, a very poor outcome can be substantially improved only by a timely use of an allogeneic procedure.

E909
EXPRESSION OF IMMUNE CHECKPOINT MOLECULES (PD-1, PD-L1, AND PD-L2) ON BONE MARROW T CELLS IN ACUTE MYELOID LEUKEMIA

1Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, 2Department of Pediatrics, Asan Medical Center Children’s Hospital, University of Ulsan College of Medicine, 3Department of Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: Immune checkpoints constitute a mechanism by which tumors escape from the host immune system and involve the programmed death-1 (PD-1) receptor and its ligands, PD-L1 and PD-L2. In a tumor microenvironment, PD-L1 expression of PD-1, an inhibitory receptor on the surface of T cells, can lead to dysfunction of antitumor effector cells. Recently, investigators have detected overexpression of PD-1 for patients with acute myeloid leukemia (AML) who experienced relapse following allogeneic stem cell transplantation

Figure 1.
Aims: The authors evaluated patients with AML to determine expression levels of checkpoint molecules (PD-1, PD-L1, and PD-L2) according to diagnosis and treatments (chemotherapy [CTx] and SCT). The purpose of this study was to identify optimal candidates for checkpoint blockade therapy for AML.

Methods: Bone marrow (BM) samples were obtained from 195 AML patients in different stages of the disease. Samples were stratified by at time of diagnosis (n=69) and treatment response (complete remission [CR] after CTx, n=30; persistence after CTx, n=29; relapse after CTx, n=7; normocellular marrow with trilineage regeneration [NMTR] after SCT, n=19; persistence after SCT, n=18; and relapse after SCT, n=23). BM samples also were collected from 23 patients with no evidence of hematologic malignancies (control group). Flow cytometric analysis of PD-1 expression on T cells and PD-L1/PD-L2 expression on leukemic cells was performed by means of a FACSCanto II system (Becton-Dickinson, Sunnyvale, CA, USA).

Results: There were no differences in levels of PD-1 expression on CD8+ and CD4+ T cells at time of AML diagnosis, compared with controls. However, PD-1 expression levels on CD4+ T cells were significantly correlated with time since diagnosis. For patients at time of diagnosis, PD-1 expression on CD8+ and CD4+ T cells was significantly different compared with patients who experienced relapse after SCT (P=0.025 and P<0.0001), and NMTR after SCT (P<0.0001 and P<0.0001). In contrast, no difference in PD-1 expression was observed between patients at time of diagnosis and patients after CTx (Figure 1). For CD4+ T cells, a significant difference was found between SCT and CTx groups, and PD-1 expression levels of groups that experienced relapse (P<0.0001) or persistence (P<0.0001) after SCT were significantly higher than those of patients in the CTx groups. PD-L1 and PD-L2 expression on leukemic cells at time of diagnosis was higher in secondary AML transformed from myelodysplastic syndrome than in de novo AML (P=0.0001 and P=0.039). Although PD-L1 and PD-L2 expression levels for patients at time of AML diagnosis did not differ from groups that experienced relapse or persistence after SCT, PD-L1 and PD-L2 levels for diagnosed patients did differ from those of patients who experienced persistence after CTx (P=0.038 and P=0.023).

Summary/Conclusions: Our study shows that HIV status has no prognostic impact on AL patient’s outcome. HIV patient with acute leukemia should thus be included in clinical trials to improve and standardize their therapeutic management.
with SOC at the end of induction, after completion of the 1st cycle of consolidation, and before maintenance or proceeding to allogeneic stem cell transplantation induction and consolidation would be well tolerated without adding significant toxicity and may improve clinical outcomes of patients (pts) with newly diagnosed acute myeloid leukemia (AML).

**Aims:**
To investigate the efficacy and safety of the 10-day decitabine regimen in older fit AML prospectively.

**Methods:** Twenty-one older patients (>60 years old) with newly diagnosed intermediate- or adverse cytogenetic risk group AML, considered fit for intensive chemotherapy, were enrolled in a prospective clinical trial. These patients refused to take intensive chemotherapy. All patients were treated with at least one course of 10-day decitabine regimen. The patients achieved less than 5% bone marrow blasts were subsequently treated with 5-day decitabine courses as maintenance therapy. Median age was 64 (range 60-74) years. There are 5 patients with (23.8%), 10 (47.6%), 6 (28.6%) in favorable, intermediate and, poor-risk group, respectively, based on the NCCN guideline. All patients had an Eastern Cooperative Oncology Group performance status of 1.

**Results:** 1The primary objective of the phase 1 portion of the trial is to characterize the A. Emadi1,2,3, N. G. Holtzman1,2, M. Imran1, F. El Chaar1, M. Koka4, Z. Singh1, A. Shahlaee1, E. A. **INDOXIMOD IN COMBINATION WITH IDARUBICIN AND CYTARABINE FOR UPFRONT TREATMENT OF PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML): PHASE 1 REPORT**

A. Emadi1,2,3, N. G. Holtzman1,2, M. Imran1, F. El Chaar1, M. Koka4, Z. Singh1, A. Shahlaee1, E. A. Sausville1,2,3, J. Law1,2, S. T. Lee1,2, A. Banerjee1,2, A. Rapoport1,2, M. R. Baer1,2, V. H. Duong1,2, D. H. Munns1, M. Loken1, E. Kennedy1, N. Vahanian1, C. Link1

1University of Maryland Greenebaum Comprehensive Cancer Center, 2Medicine, 3Pharmacology, Pathology, University of Maryland, Baltimore, 4Institute for Cancer Care and Department of Pediatrics, Medical College of Georgia, Augusta, 5Hematologics Inc., Seattle, 6NewLink Genetics Co., Ames, United States

**Background:** AML cells can acquire immune evasion and tolerance through overexpression of IDO, which ectopically overexpress immunomodulatory effects through tryptophan (Trp) catabolism and kynurenine production. By degrading Trp, IDO shifts the balance from a Trp-rich environment, which encourages T-cell proliferation and activation, to a Trp-poor environment, where the immune response is suppressed. We hypothesized that incorporation of indoximod, an inhibitor of the IDO pathway, into conventional remission induction and consolidation would be well tolerated without adding significant toxicity and may improve clinical outcomes of patients (pts) with newly diagnosed AML.

**Aims:**
1The primary objective of the phase 1 portion of the trial is to characterize the A. Emadi1,2,3, N. G. Holtzman1,2, M. Imran1, F. El Chaar1, M. Koka4, Z. Singh1, A. Shahlaee1, E. A. **Methods:** Twenty-one older patients (>60 years old) with newly diagnosed intermediate- or adverse cytogenetic risk group AML, considered fit for intensive chemotherapy, were enrolled in a prospective clinical trial. These patients refused to take intensive chemotherapy. All patients were treated with at least one course of 10-day decitabine regimen. The patients achieved less than 5% bone marrow blasts were subsequently treated with 5-day decitabine courses as maintenance therapy. Median age was 64 (range 60-74) years. There are 5 patients with (23.8%), 10 (47.6%), 6 (28.6%) in favorable, intermediate and, poor-risk group, respectively, based on the NCCN guideline. All patients had an Eastern Cooperative Oncology Group performance status of 1.

**Results:** 1The primary objective of the phase 1 portion of the trial is to characterize the A. Emadi1,2,3, N. G. Holtzman1,2, M. Imran1, F. El Chaar1, M. Koka4, Z. Singh1, A. Shahlaee1, E. A. **PHASE III STUDY OF MEK INHIBITOR (MEK-162; BINimetinib) IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MYELOID MALIGNANCIES**

K. Naqvi1, T. Kadia1, G. Borthakur1, K. Takahashi1, P. Bose1, N. Daver1, Y. Alvarado1, M. Ohanian1, C. DiNardo1, E. Jabbour1, G. Garcia-Manero1, H. Kantarjian1, A. Patel1, F. Ravandi1

1Department of Leukemia, UTMD Anderson Cancer Center, Houston, United States

**Background:** Activation of the mitogen-activated protein kinase (MAPK) signaling (RAS/RAF/MEK/ERK pathway) promotes growth and inhibits apoptosis of hematopoietic cells. Inhibition of MEK/ MAPK pathway has shown antiproliferative effects in acute myeloid leukemia (AML) cells and AML blasts. MEK-162 is an oral, potent, selective allosteric, ATP-competitive inhibitor of MEK1 and 2.

**Aims:** To study the efficacy and safety of MEK-162 in patients with advanced myeloid malignancies.

**Methods:** Patients with relapsed/refractory AML, not candidates for intensive chemotherapy, and patients with high risk myelodysplastic syndrome (MDS) who were resistant/intolerant to standard treatment including stem cell transplant were treated with MEK-162 twice daily every 28 days. Patients in the expansion phase had to be RAS mutated. The primary endpoint was overall response rate (ORR=CR + CRi) after 1 cycle of therapy. Survival was estimated using the Kaplan-Meier method. Safety analysis included all patients who had received at least 1 dose of MEK-162. MEK-162 dose escalation followed a 3+3 design; phase 2 had built in futility/toxicity boundaries. 45mg twice daily is the first dose level for expansion phase.

**Results:** Sixteen patients were treated (escalation=7; expansion=9): 14 AML and 2 MDS. Median age was 62 years (31-85). 56% were male; 94% had a performance status of 1-2. Median number of prior therapies was 4 (1-6); 31/69 (19%) patients had complex karyotype. 11/16 (69%) patients were RAS mutated. ORR of 10%. The study is currently on-going. Additional studies involving combination of MEK-162 with RAF and PI3 kinase inhibitors are ongoing.

**HAPLOIDENTICAL TRANSPLANTATION IS SAFE AND EFFECTIVE FOR OLDER PATIENTS WITH AML/MDS**

S. Ciurea1, R. Saltib1, M. Shah1, S. Gaballa2, G. Rondon1, J. Chen1, A. Gulbis1, W. Wallis1, B. Oran1, A. Alousi1, G. Basharli1, S. Ahmed1, D. Mann1, K. Rezvani1, W. Wallis1, B. Oran1, A. Alousi1, Q. Bashir1, S. Ahmed1, D. Marin1, K. Rezvani1, R. Champlin1

1Stem Cell Transplantation, The University of Texas MD Anderson Cancer Center, Houston, 2Thomas Jefferson University, Philadelphia, 3Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

**Background:** Acute myeloid leukemia (AML) is more common in the older population. Haploidentical stem cell transplantation (haploSCT) is a potentially curative therapy.
ative treatment option for patients with AML and allows transplantation for patients without an HLA matched donor. Recent trials have shown that the use of post-transplant cyclophosphamide-based (PTCy) GVHD prophylaxis has improved outcomes of haploSCT; however, outcomes of haploSCT in older patients remain unclear.

Aims: Here we evaluated outcomes of older patients with AML/MDS who underwent haploSCT.

Methods: We retrospectively analyzed outcomes of all 43 patients ≥55 years with AML/MDS who underwent a haploSCT at our institution after year 2009. All patients were treated with fludarabine-melphalan (FM)-based conditioning regimen (melphalan 100 or 140mg/m²) plus thiotepa 5mg/kg or 2GyTBI. Characteristics of these patients are presented in Table 1.

Results: Median age was 61 years (range 55-69), 22 patients (51%) were in CR1/2, 16 patients (37%) had poor-risk cytogenetics, and median HCT-CI was 2 (range 0-11). Reduced melphalan regimen (100mg/m²) was used in 29 pts (67%). Donors were children in 35 (81%) or siblings 10 (19%) patients. Median follow-up was 19 months (range 6-49). One patient died prior to engraftment. Forty-two patients engrafted the donor cells (100%). Median time to neutrophil and platelet engraftment was 19 (13-28) and 28 (15-117) days. Day 30 chimerism was 100% donor in 38 patients (88%). The cumulative incidence of grade 2-4 and 3-4 aGVHD at 6 months post-transplant was 35% and 5% while CI of cGVHD at 2 years post-transplant was only 9%. The 2-year overall survival (OS) and progression-free survival (PFS) was 42%, and relapse rate was 24%. Cumulative non-relapse mortality (NRM) was 21%, 30% and 34% at day 100, 1 year, and 2 years post-transplant. Patients in CR1/2 had 2-year NRM and relapse rate of 23% and 14%, and OS was 61%. The 2-year OS for patients in CR1/2 with intermediate/favorable-risk cytogenetics was 73%. In multivariate analysis, favorable predictors for OS were CR1/2 (HR:0.4, p=0.05), good/intermediate cytogenetics (HR:0.2, p=0.01), and donor age <73%. In multivariate analysis, favorable predictors for OS were CR1/2 (HR:0.4, p=0.05), good /intermediate cytogenetics (HR:0.2, p=0.01), and donor age <73%. In multivariate analysis, favorable predictors for OS were CR1/2 (HR:0.4, p=0.05), good /intermediate cytogenetics (HR:0.2, p=0.01), and donor age <73%. In multivariate analysis, favorable predictors for OS were CR1/2 (HR:0.4, p=0.05), good /intermediate cytogenetics (HR:0.2, p=0.01), and donor age <73%. In multivariate analysis, favorable predictors for OS were CR1/2 (HR:0.4, p=0.05), good /intermediate cytogenetics (HR:0.2, p=0.01), and donor age <73%. In multivariate analysis, favorable predictors for OS were CR1/2 (HR:0.4, p=0.05), good /intermediate cytogenetics (HR:0.2, p=0.01), and donor age <73%.

OS for patients in CR1/2 with intermediate/favorable-risk cytogenetics was 34% at day 100, 1 year, and 2 years post-transplant. Patients in CR1/2 had 2-year OS of 73%. In multivariate analysis, favorable predictors for OS were CR1/2 (HR:0.4, p=0.05), good /intermediate cytogenetics (HR:0.2, p=0.01), and donor age <73%.

Summary/Conclusions: HaploSCT with PTCy-based GVHD prophylaxis is safe and effective for older AML/MDS patients. Lack of an HLA matched donor is not a contraindication to proceeding to a haploidentical transplant in older AML/MDS patients. In addition to remission status and cytogenetics, we found that younger donor age was significantly associated with improved survival in older AML/MDS patients undergoing haploidentical transplantation.

Summary/Conclusions: Our data show that MRD assessment at different time-point reduction in older patients retains a strong prognostic impact. However, the evaluation of MFC-MRD at TP2 with 0.1% cut-off is the most useful for patients risk stratification. However, the evaluation of MFC-MRD at TP2 with 0.1% cut-off can early identify a group of patients with a significantly low risk of relapse. At the same time, MFC and WT1 MRD integration allows a better risk stratification. MFC MRD is accurate also in NPM1-mut patients; however, in this cohort NPM1-based MRD evaluation is the most accurate predictor of prognosis.

Summary/Conclusions: Our data show that MRD assessment at different time-point reduction in older patients retains a strong prognostic impact. However, the evaluation of MFC-MRD at TP2 with 0.1% cut-off is the most useful for patients risk stratification. However, the evaluation of MFC-MRD at TP2 with 0.1% cut-off can early identify a group of patients with a significantly low risk of relapse. At the same time, MFC and WT1 MRD integration allows a better risk stratification. MFC MRD is accurate also in NPM1-mut patients; however, in this cohort NPM1-based MRD evaluation is the most accurate predictor of prognosis.
Background: Hematopoietic recovery is considered to associated with the number of multipotent hematopoietic stem cells in the bone marrow, as observed in functional assays involving stem cell transplantation. However, there is little evidence related to hematopoietic recovery in non-transplantation settings, which is accomplished by endogenous hematopoietic cells. A recent study suggested that progenitors are the main contributors during this steady-state hematopoiesis, which differs from exogenous transplantation. And our previous data revealed that, CD34+CD38+CD117+HLA-DR+CD13+CD33+ (P cells), a kind of progenitor cell, is significantly decreased in patients with delayed neutrophil recovery after chemotherapy compared with that without delayed count recovery.

Aims: To further examine a potential impact of P cells percentage on hematopoietic recovery.

Methods: The data of 223 patients diagnosed with de novo AML was analyzed retrospectively. All these patients enrolled in our previously registered prospective randomized clinical trial AML 2010-01(201002024). We reviewed the data from bone marrow flowcytometry before the first and second course of consolidation therapy, in which the CD34+CD38+CD117+HLA-DR+CD13+CD33+ progenitor cell percentage on the bone marrow was analyzed. Platelet recovery time and time of neutropenia were counted for the evaluation of hematopoietic recovery ability after chemotherapy.

Results: We found that less P cell percentage was significantly associated with prolonged neutropenia recovery time after the first and second courses of consolidation chemotherapy (p=0.001; p=0.028, respectively). We also observed similar results regarding platelet recovery time after the first course of consolidation chemotherapy (p=0.001). Univariate analysis showed that P cell percentage, rather than gender, age, WHO classification and cytogenetic subgroup, were associated with neutrophil recovery after chemotherapy. Multivariate analysis showed that P cell percentage is an independent factor affecting neutrophil recovery capability for both first and second courses (p=0.015; p=0.036, respectively).

Summary/Conclusions: Our results indicate that CD34+CD38+CD117+HLA-DR+CD13+CD33+ cells before each course of chemotherapy is associated with chemotherapeutic hematopoietic reconstitution capacity independently. These findings may help better understand endogenous hematopoietic reconstitution and modify future chemotherapy regimens based on progenitor cell percentages.

E918 CYTOKINE RECEPTORS AND SOLUBLE ADHESION MOLECULE LEVELS ARE ASSOCIATED WITH PROGNOSIS OF NEWLY DIAGNOSED AML

T. Kupsa1,2, P. Zak2, L. Jebraivy1,2, J. M. Horacek1,2,*
1Department of Military Internal Medicine and Hygiene, Faculty of Military Health Sciences, 24th department of Internal Medicine - Hematology, University Hospital in Prague, Charles University, Faculty of Medicine, Hradec Kralove, Hradec Kralove, Czech Republic.

Background: The outcomes of acute myeloid leukemia (AML) treatment are beleaguered by the high resistance of malignant clones to therapy. Cytokines and adhesion molecules have been studied as markers for molecular-based therapy. Interestingly, miR-34a-5p was recurrently found upregulated in both AML and RL samples, suggesting a potential involvement in the mechanisms at the base of both onset and relapse in these subtypes of high-risk AML.

Methods:

Aims: The aim of this study is to evaluate baseline levels of selected cytokines, cytokine receptors and adhesion molecules and their relationship with prognosis in newly diagnosed AML patients.

Methods: A total of 75 AML patients, age 52.9±13.0 years, median 58.4 years, were studied in the period 2010-2015. Only patients with minimal follow-up of 1 year were included. All patients were induced with “3+7” induction chemotherapy consisting of Cytarabin 100mg/m2 per day for 7 consecutive days and Daunorubicin 90mg/m2 for the first 3 days of therapy in younger patients. Since the beginning of 2015, the induction dose of Daunorubicin used has been 60mg/m2 even in younger patients, according to recent evidence-based data modifications. Those who failed to achieve CR were given FIA-Glal salvage therapy by allogeneic stem cell transplantation in younger and fit patients. In CR, the patients were treated either with HIDAC consolidations alone, followed by allogeneic cell transplantation in older patients. In total, 39 patients underwent allogeneic stem cell transplantation. We evaluated serum levels of the following 29 analytes: interleukins (IL-1α, IL-1β, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-15), Erythropoietic Growth Factor, Granulocyte Macrophage Colony Stimulating Factor, Interferon-γ, Macrophage Inflammatory Protein-1α, Monocyte Chemoattractant Protein-1, Tumor Necrosis Factor-α (TNF-α), Vascular Endothelial Growth Factor, E-selectin (E-SEL), P-selectin (P-SEL), Intercellular Adhesion Molecule-1 (ICAM-1), Vascular Cell Adhesion Molecule-1 (VCAM-1), Matrix Metalloproteinase-9, soluble IL-2 receptor (s-IL-2Rα) and soluble receptors for IL-6 (s-IL-6R) and TNF-α type I and II receptors.

Results: Comparing all AML samples with HCs, we found 16 up- and 509 downregulated miRs, respectively. A trend towards downregulation, as well as in RL vs HCs analysis, in which we found 12 and 374 up- and downregulated miRs, respectively. RL vs ND comparison showed a total of 16 up- and 15 down-regulated miRs. In the attempt to identify a signature predictive of relapse at time of diagnosis, we compared all AML samples with ND and RL samples, revealing 301 miRs that maintained their deregulation in the 2 subgroups, while 113 and 85 were uniquely found in ND vs HCs and RL vs HCs, respectively. Remarkably, miR-34a-5p (P<0.0001) was the recurrent and most statistically significant upregulated miR in both ND and RL samples. Moreover, upregulated miR-10a-5p and miR-99a-5p (P<0.0001), and downregulated miR-5-5p (P<0.0001) were the most statistically significant miRs in the FLT3-ITD and MLL-rearranged sets respectively, underlying putative unique elements distinguishing the two clinical subsets.

Summary/Conclusions: Our results suggest the presence of different microRNA signatures in pediatric AML carrying FLT3-ITD and 11q23 translocations ([t(9;11) and (t(10;11)]. The identifications of new targets linked to this miRs would be useful for further studies focused on finding molecular-based therapies. Interestingly, miR-34a-5p was recurrently found upregulated in both ND and RL groups, but in the comparative analysis between ND vs RL, suggesting a potential involvement in the mechanisms at the base of both onset and relapse in these subtypes of high-risk AML.
MRD-DRIVEN CHOICE OF CONSOLIDATION AND MODULATION OF INDUCTION AND CONSOLIDATION INTENSITY RESULTED IN A SIGNIFICANTLY IMPROVED OUTCOME OF YOUNGER AML PATIENTS IN THE LAST THREE YEARS

M. Clavio1, F. Guolo1, P. Minietto1, M. Migino1, F. Ballerini1, D. Guardo1, E. Coviello1, R.M. Lemoli1, M. Gobbi1
1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa, IRCCS OAU San Martino-IST, Genova, Italy

Background: In the last decades no effective new drugs have been introduced and AML induction therapy is still based on an anthracycline and cytarabine. The MRD group has, however, reported a progressive increase of cure rates in younger patients. Our group has recently showed that the outcome can be improved by a fludarabine-containing induction (FLA15, with fludarabine administration in first course only), followed by a risk- adapted consolidation.

Aims: The aim of the present study was to evaluate if the disease free survival (DFS) and the overall survival (OS) of younger (<65 years) AML patient treated in our center had shown any modification in four consecutive periods of treatment (< 2008; 2008-2010; 2011-2013; 2014-2016) and to recognize factors possibly leading to this result.

Methods: We reviewed the outcome of 145 consecutive AML patients aged 65 or less and uniformly treated according to the above mentioned strategy. Minimal residual disease (MRD) evaluation was performed by flow cytometry (MFC), assessment of WT1 expression levels and, where applicable, evaluation of recurrent abnormalities such as NPM1 mutation.

E920
EFFECTIVENESS OF TREATMENT ACUTE MYELOID LEUKEMIA IN THE ELDERLY USING CLADRIBINE WITH LOW-DOSE ARAC

M. Wątek1,*, T. Gromek2, A. Pluta3, K. Budziszewska4, S. Gooßen1, A. Wierzboski3
1Department of Hematology, Holy Cross Oncology Center of Kielce, Kielce, 2Department of Hematooncology, Medical University of Lublin, Lublin, 3Department of Hematology, Medical University of Lodz, Lodz, 4Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 5Holy Cross Oncology Center of Kielce, Kielce, Poland

Background: Treatment of acute myeloid leukemia(AML) in the elderly, unfit patients is a challenge for clinical hematologists. Therapeutic management in this group of patients is different due to the introduction of prophylaxis with posaconazole. The lower rate of IFI may be associated with a reduced incidence of invasive fungal infections (IFI) and numerous complications including early deaths. A standard treatment of low dose cytarabine (LD-AraC) or using hypomethylating therapy is not satisfying enough. Polish Adult Leukemia Group’s (PALG) studies showed, that addition of cladribine to daunorubicine and cytarabine increases the complete remission rate and improves overall survival in younger patients with AML. We also proved effectiveness of cladribine combined with high dose AraC and mitoxantrone in relapsed and refractory AML (1, 2). Cladribine, enhances the concentration of Ara-CTP, an active metabolite of Ara-C in leukemic cells (3). Recent data indicate that cladribine has also hypomethylating properties.

Aims: The aim of our study was to evaluate the efficacy and toxicity of cladribine in combination with LD-AraC in older AML patients.

Methods: Patients with newly diagnosed AML (excluding APL), older than 60 years, unfit for standard induction chemotherapy, were enrolled to our study. The patients were given two cycles of cladribine 5mg/m^2 i.v on days 1-5 and low-dose cytarabine 40mg/m^2 s.c on days 1-10 every 28 days followed by two cycles of cladribine 5mg/m^2 i.v on days 1-2 with LD-AraC (40mg/m^2 s.c 1-10 days).

Results: Responding patients were treated with a prolonged maintenance consisting of LD-AraC (40mg/m^2 1-10 day). The treatment was continued until progression.

Summary/Conclusions: The combination of cladribine plus low dose AraC is effective and well tolerated regimen in elderly AML patients unfit for standard chemotherapy.

SMALL CUSTOMIZABLE NGS BASED TARGET CAPTURE PANELS DETECT VARIANTS IN CLINICAL SPECIMENS AT FREQUENCIES AS LOW AS 0.5%

L. Chamberlain1,*, A.R. Carson1, V. McClain1, B. Patay1, O. Kiya1, W. Huang1, D. Hubbard2, D. Cagoula2, Z. Xie1, J. Thennes2, T. Stenzel1, J.E. Miller1, D. Susmizalp, L. Osorio2, E. Deckter3, M. Inivosecibe, Inc., 2LabPMM, San Diego, United States

Background: The use of large scale hybridization panels in early stages of clinical trials for novel therapies elicits a plethora of information for targeted biomarkers. However, as therapeutic targets are further characterized large panels generate an overly broad set of data, compromising sensitivity in the selected biomarker subset. Therefore, once biomarker targets are identified, the use of smaller hybridization panels can facilitate specific variant detection by analyzing specific genomic regions of interest with greater sensitivity than larger gene panels and PCR-based assays. Modifications of laboratory methods for small scale panels allow for the maintenance of high analytic quality with finely targeted panels. Our small panels (~10kb) focused on 1-4 genes, allowing for high-multiplexing of samples on sequencers, and reduced costs/processing times without compromising accuracy.

Aims: To demonstrate the sensitivity, linearity, concordance with other assays, and clinical applications of small NGS target capture panels.

Methods: Two separate next generation sequencing-target capture assays were developed with bioinformatics software under ISO13485 design control. A high throughput panel contained 3 genes, including fms related tyrosine kinase 3 (FLT3); the second covers only CD274 (PD-L1). Libraries were made, hybridized with baits, and sequenced using the Illumina MiSeqDx. Validation was carried out by spiking in fixed amounts of mutant DNA into wild type DNA to establish the linearity and sensitivity of the assays. Sequencing libraries were generated by concomitantly hybridized with baits from either both panels. Sequencing data was analyzed using proprietary software developed by Inivosecibe. Eight AML clinical samples were cross validated for FLT3 mutations by this small panel, amplicon based NGS assay, and capillary electrophoresis (CE) assay.
Results: DNA from 24 cell lines was assessed using both panels, confirming variants previously detected using other methods. A validation was run on the 3-gene panel using a series of convoluted samples generated from cell lines containing between 0.5% and 25% variant allele frequencies for expected variants. Initial validation indicates that these small panel assays can detect mutations down to 0.5% variant allele frequencies. Assay linearity for FLT3/TKD detection from 0.25% to 12.5% or for FLT3/ITD detection from 0.5% to 25% is excellent (R² = 0.996 and 0.998, respectively). Average sequencing coverage was high, ranging from 5.26x to 7.68x. Comparison of FLT3 analysis of the small panel to amplicon based NGS assay and CE, FLT3-ITD showed complete concordance in clinical samples - and showed a strong linear relationship between validated VAFs, and detected VAF sizes. There was also complete concordance for FLT3/TKD mutations in clinical samples.

Summary/Conclusions: Small hybridization panels are cost effective in detecting low-frequency variants from smaller subsets of genes while using far less DNA than individual PCR-based biomarker assays would require. Additionally, preliminary data shows great accuracy on clinical samples. These smaller assays focus on the most pertinent genes for a targeted therapy, and have the potential to greatly assist in understanding the molecular backgrounds of responders, super-responders, and non-responders, information which can help improve patient outcomes. Developing these assays with bioinformatics using the international ISO13485 design control standards makes them suitable for regulatory approval worldwide.

MOLECULAR GENETIC TESTING PATTERNS FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML) ENROLLED IN THE CONNECT® MDS/AML DISEASE REGISTRY

1University of Colorado Cancer Center, Aurora, 2University of New Mexico, Albuquerque, 3University of Alabama at Birmingham, Birmingham, 4Aurora Research Institute, Aurora Health Care, Milwaukee, 5Weill Cornell College of Medicine, New York, 6Division of Florida Health Cancer Center–Orlando Health, Orlando, 7Swedish Cancer Institute, Seattle, 8New York Medical College, Valhalla, 9University of Florida, Gainesville, 10Celgene Corporation, Summit, United States

Background: Recurrent mutations in AML-associated genes have prognostic value and may help guide treatment decisions. Molecular genetic testing patterns for AML in clinical practice are largely unknown. Previous results of the CONNECT MDS/AML Disease Registry (George et al. ASH 2016; abstract 354b) showed suboptimal adherence to WHO 2008 recommendations for AML diagnostics in a cohort of patients with newly diagnosed AML in clinical practice.

Aims: To report a detailed analysis of patterns of molecular genetic testing in patients with newly diagnosed AML in community and academic settings.

Methods: The CONNECT MDS/AML Disease Registry (NCT01688801) is a longitudinal, observational cohort study of patients with newly diagnosed AML (≥25 years) or myelodysplastic syndrome (MDS). All clinical decisions are made by the treating clinicians. Data are collected, using an electronic data capture system, at screening, enrollment, and approximately quarterly throughout the duration of the patient’s participation in the registry. All patients provided informed consent. Enrollment is ongoing. The current analysis evaluated the percentage of patients with AML who had undergone molecular genetic testing recommended by NCCN guidelines (NPM1, FLT3-ITD, CEBPA, IDH1, IDH2, DNMT3A, and KIT). Chi-square tests evaluated effects of several variables on likelihood of molecular genetic testing.

Results: Between 22 Jan 2013 and 8 Dec 2016 (data cutoff), 259 patients with AML were enrolled at 86 sites. Molecular genetic testing was reported in 67% (173/259) of patients. Likelihood of testing varied, respectively, for academically vs community settings (76% [70/92] vs 62% [103/167], P = .018), normal vs acute myeloid leukemia (AML) (<70% [79/103] vs 59% [79/133], P = .006), age <65 vs ≥65 (83% [85/102] vs 50% [108/211], P = .0003), and lymphoma vs hematologic malignancy (<61% [83/137] vs 74% [90/122], P = .025). In patients who had undergone molecular genetic testing (n=173), the mutations tested varied substantially. All of the NCCN-recommended molecular genetic tests were reported in 9% (15/173) of patients, including 8% (6/173) with normal karyotype. Of the seven NCCN-recommended tests, NPM1 (77%) and FLT3-ITD (76%) were most often reported and DNMT3A least often (16%).

Summary/Conclusions: Early data from the CONNECT MDS/AML Disease Registry reflect that despite molecular testing reported in 67% of patients with newly diagnosed AML, a majority of patients did not receive guideline-recommended testing. This prospective registry is uniquely positioned to capture changes in testing patterns as guidelines are established.
course of AML treatment, a drug interaction study was performed to assess PK when Q is co-administered with CYP3A4 inhibitors.

**Aims:** The primary aim was to determine the effect of ketoconazole (K), a strong CYP3A4 inhibitor, and fluconazole (F), a moderate CYP3A4 inhibitor, on PK of Q and AC886. The secondary aim was to assess the tolerability and safety of Q co-administered with K or F.

**Methods:** This was an open-label, randomized, parallel-group study. Healthy subjects (HS) age 18–55 years (y) who provided informed consent were randomized 1:1 to receive K 200mg twice daily (BID), F 200mg BID, or placebo (P) BID on Days (D) 1-28. A single 30mg dose of Q was administered to all HS on D8. Plasma Q and AC886 conc were measured D8-28, using a validated liquid chromatography-tandem mass spectrometry method. PK parameters were determined using noncompartmental analysis. Steady-state (SS) drug conc, following repeated once daily dosing, were predicted using non-parametric superposition. An analysis of variance (ANOVA) was performed to assess the CYP3A4 inhibitory effect of K and F on the PK.

**Results:** 93 subjects were enrolled (31 per arm) and 88 received Q. 75% were male, median age 32 yr (18-53). Relative to Q+P, co-administration of Q+F or Q+K increased the geometric mean (GeoMean) C_max of Q by 17% and 11%, and GeoMean AUC0-24 by 94% and 20%, respectively (Table 1 below). The GeoMean C_max and AUC0-24 of AC886 were decreased by 60% and 15%, respectively, for Q+K, and were increased by 3% and 14%, respectively, for Q+F. Apparent clearance (CL/F) of Q was 50% lower and t_{1/2} of Q and AC886 were 46% and 96% longer, respectively in Q+K vs Q+F. CL/F of Q was 17% lower and t_{1/2} of Q and AC886 were 10% and 28% longer, respectively, in Q+F vs Q+P. AC886 is a minor component in circulation relative to Q (approximately 25%). An increase of 86% in simulated SS Q C_max and GeoMean AUC0-24 was predicted following repeat daily dosing of 30mg Q+K vs Q+F, while a modest decrease in AC886 exposure (<20%) was predicted. The most common (≥5%) adverse events were headache (7.5%) and diarrhea (5.4%), with the majority being Grade 1/2. There were no clinically significant hematology, clinical chemistry, QTc, or vital sign observations, and no deaths or serious adverse events.

**Summary/Conclusions:** Co-administration of Q with K or F was well tolerated and safe. Overall, there was an approximate 2-fold increase in Q exposure when Q was co-administered with K, which is considered clinically significant. The increase in Q exposure when Q was co-administered with F was within 20% and is not considered clinically relevant. Given the relationship between Q conc and QTc prolongation, these results support reducing Q doses by approximately one-half when taken concomitantly with a strong CYP3A4 inhibitor. No dose reduction is needed when Q is co-administered with a moderate or weak CYP3A4 inhibitor. This approach has been implemented in two ongoing Phase 3 trials of Q in FLT3-ITD mutated AML.

**E926**

**CLINICAL OUTCOMES OF CHILDHOOD ACUTE MEGAKARYOBLASTIC LEUKEMIA: THE CHILDREN CANCER HOSPITAL EGYPT 57357 EXPERIENCE**

N. Maarouf1,*, S. Mahmoud1,2, R. Abdelaziz1,2, L. Lehmann3, K. Shaaban4,5, S. Fahmy4,5, S. Ibrahim4,5, O. Hassanain7, N. Nader7, A. Elhaddad1,2

**Background:** Acute megakaryoblastic leukemia is a rare subtype of pediatric AML occurring in both Down and non-Down syndrome patients. Down syndrome patients with M7 subtype have an excellent prognosis while non-Down syndrome patients have poor outcomes. Heterogenous cytogenetic abnormalities have been described in M7 AML and the impact of different prognostic factors on outcomes is yet to be determined.

**Aims:** To evaluate the prognostic significance of various cytogenetic abnormalities and minimal residual disease (MRD) by flow cytometry after induction 1 and correlate their clinical outcomes of patients with acute megakaryoblastic leukemia.

**Methods:** We retrospectively analyzed the data of 80 non-Down syndrome patients diagnosed with M7 AML treated at CCHE between January 2007 through December 2016. Three treatment protocols were used.

**Results:** The median age at diagnosis was 1.7 years (range 0.2-15). The median time to diagnosis was 1 month. The overall (OS), event free survival (EFS) and cumulative incidence of relapse at 2 years were 53.4%, 42.9% and 28.4% respectively. Sixty one patients had abnormal cytogenetic abnormalities including Trisomy 19 (n=20), 13q (n=20), Trisomy 8 (n=12), Complex karyotype (n=28), t(1;22) (n=12), MLL gene rearrangement (n=9), Triomy 21 (n=24) but none of these had an impact on outcomes. Out of the 80 patients 56 were in complete remission post induction I. Two hundred patients had MDR=0.1% after induction I. In the univariate analysis patients with MRD <0.1% post induction I had a better OS and EFS with a lower cumulative incidence of relapse however these findings did not reach a statistical significance.

**Summary/Conclusions:** Acute megakaryoblastic leukemia in non-Down syndrome patients have poor outcomes irrespective of any cytogenetic abnormalities. Future direction to determining tumor biology based on molecular pathways in this disease is being considered.

**IDENTIFICATION OF RESISTANCE ASSOCIATED CPG METHYLATION CHANGES IN ACUTE MYELOID LEUKEMIA PATIENTS UNDERGOING INDUCTION CHEMOTHERAPY**

C. Niedwiesker1, C. Rohde1, H. Serve2, W. Beder3, G. Ethinger1, S. Göllner1, L. Müller1, C. Müller-Tidow1
Background: Acute myeloid leukemia (AML) is a heterogeneous disease associated with epigenetic alterations that can be targeted with demethylating agents to induce CR in a subgroup of patients. However, there are currently no predictive markers that reliably distinguish responder from non-responder patients.

In this analysis we assessed DNA methylation changes in a group of refractory patients with AML treated either with the hypomethylating agent azacytidine followed by intensive chemotherapy or with intensive chemotherapy alone in order to identify the alterations and genes involved.

Aims: The exploration of whole genome methylation changes of azacytidine and chemotherapy treatment in refractory patients with AML guides treatment refinement.

Methods: Patients from the AML-aza trial of the Study Alliance Leukemia were randomized to receive either azacytidine followed by chemotherapy or chemotherapy alone. Cells were harvested at baseline and 15 days after chemotherapy from 16 of the 105 patients receiving the combination and from four of the 109 patients randomized to receive chemotherapy only. Genome-wide DNA methylation was analysed using a 450k Illumina array (Illumina, San Diego, USA).

Results: Of the 41 patients who attained complete morphologic remission, 20 patients (26.3%) from the whole cohort received an allogeneic transplant (SCT) and 2 patients (4.9%) did not receive consolidation. Of those receiving IDAC+2 25 (86.2%) were intermediate cytogenetic risk and 3 (10.7%) having as poor risk. The event-free survival median is 314 days and overall response rate was 52 patients (68.4%). The event-free survival median is 314 days for azacytidine/chemotherapy patients. Differences were not statistically significant. The 3-year OS for patients receiving IDAC+2 25 (86.2%) was intermediate cytogenetic risk and 3 (10.7%) having as poor risk. The event-free survival median is 314 days and overall response rate was 52 patients (68.4%). The event-free survival median is 314 days and overall response rate was 52 patients (68.4%). The event-free survival median is 314 days and overall response rate was 52 patients (68.4%). The event-free survival median is 314 days and overall response rate was 52 patients (68.4%). The event-free survival median is 314 days and overall response rate was 52 patients (68.4%).

Summary/Conclusions: Methylation changes associated with azacytidine and chemotherapy treatment more hypomethylated loci were observed. This potentially indicates specific loci may be associated with therapy resistance. Hence, the methylation changes correlating with the percentage of blasts (p=0.14, exploratory regression among blast change and median methylation change day 0 to day 15 each), since these are likely to reflect the increased lymphocyte counts observed in unsorted samples used for analysis. Moths most strongly impacted by methylation changes were detected using the Homer software (Salk institute, San Diego, USA). Methylation changes were compared between the two groups to identify the changes associated with the use of azacytidine prior to chemotherapy.

Results: In the Azacytidine plus Chemotherapy treated group, a total of 389 differentially methylated regions (DMRs), most of which were single CpGs, were identified, 176 of which were hypermethylated and 213 hypomethylated. The most highly represented hypermethylated loci were INS1M (p=1e-17, 6.25% of 176 DMRs), KLF13 (p=1e-14, 7.95%), HIC2 (p=1e-11, 5.11%), while those that were hypomethylated were NR1I2 (p=1e-15, 2.82% of 213 DMR’s), MYB (p=1e-14, 3.76%) and STAT1 (p=1e-14, 1.88%). The chemotherapy alone group yielded 7181 DMRs, 5752 of which were hypermethylated and 1429 hypomethylated. The genes most commonly hypermethylated in these patients were HPFHETS (p=1e-226, 32.79% of 5752), CEBPE (p=1e-90, 10.34%), while Jun-A (p=1e-45, 6.10%), while those most commonly hypomethylated were RUNX1 (p=1e-24, 28.34% of 1429 DMRs), TCF4 (p=1e-21, 8.40%) and SMAD3 (p=1e-17, 1.05%). Median overall survival did not differ between the two treatment groups, with 153 days for chemotherapy and 143 days for chemotherapy patients.

Summary/Conclusions: Methylation changes associated with azacytidine and chemotherapy of refractory patients were particularly found in genes previously associated with cancer and AML. DNA hypomethylation was more common after chemotherapy alone. This finding suggests that DNA hypermethylation of specific loci may be associated with therapy resistance. Hence, the methylation levels were measured from the most resistant cells. Of note, upon Azacytidine treatment more hypomethylated loci were observed. This potentially indicates DNA hypomethylated in vivo.

Background: Acute myeloid leukemia (AML) is a fatal hematopoietic malignancy with poor clinical outcomes characterized by blasts infiltrated in tissues.

Methods: Relative quantitative real-time PCR analysis was employed for detecting levels of ZEB2-AS1. SYBR Green RT-PCR was performed, followed by obtaining relative threshold cycle normalized to reference GAPDH gene. Cell migration, invasion, proliferation and apoptosis tests were used to analyze biological phenotypes of AML cells after knocking down ZEB2-AS1 IncRNA by small interfering RNAs.

Results: Results showed that expression of ZEB2-AS1 IncRNA was prominently high and closely correlated with adverse clinical outcomes in AML patients, based on either modified MRC or ELN risk stratification system. Univariate analyses indicated that patients with higher expression of ZEB2-AS1 IncRNA had significant shorter 3-year overall survival (OS) (0% vs 68.2%, p=0.036) and disease-free survival (DFS) (25.0% vs 69.8%, p=0.039). In addition, Patients with higher expression of ZEB2-AS1 IncRNA had significant lower complete remission (CR) rate in response to induction chemotherapy (75.0% vs 27.3%, p=0.031). In patients with low levels of ZEB2-AS1 IncRNA, patients treated by allogeneic hematopoietic stem cell transplantation had significant longer OS (3-year OS, 75.8% vs 28.6%, p=0.037) and DFS (3-year DFS, 81.8% vs 28.6%, p=0.049) compared to that of chemotherapy.

Summary/Conclusions: Moreover, knockdown of ZEB2-AS1 IncRNA could effectively inhibit invasion and migration in AML cells, which was closely associated with down-regulation of ZEB2 and up-regulation of E-cadherin. Collectively, although independent prognostic value for survivals was not rigorously determined, ZEB2-AS1 IncRNA may serve as candidate to improve conventional risk stratification system and contribute to evaluating therapeutic responses. Furthermore, ZEB2-AS1 IncRNA could be a potential target for AML.

Background: Acute myeloid leukemia (AML) is a fatal hematopoietic malignancy with poor clinical outcomes characterized by blasts infiltrated in tissues.

Aims: To demonstrate the safety and tolerability and provide preliminary efficacy evidence for anthracycline intensification during induction and consolidation in older adults with Acute Myeloid Leukemia.

Methods: A retrospective pilot study was done on 76 consecutive patients above the age of 55 years with newly diagnosed AML between January 2010 to June 2016 at Alfred Hospital, Melbourne, Australia. All received the 7+3 induction regimen (AraC) during induction at dose of 100mg/m²/day on days 1 to 7, and idarubicin at a dose of 12mg/m²/day on days 1 to 3, with a planned consolidation course (AraC 100mg/m² twice daily Day 1, 3, 5, and idarubicin 12mg/m²/day Day 1-2). Outcomes were assessed according to the Cheson criteria with cytogenetic risk assessed by the refined Grimwade MRC criteria.

Results: 76 patients, with a median age of 62 years (range 55.4-70.6 years) received the 7+3 induction with a median overall survival of 590 (range 6-1996) days and overall response rate was 52 patients (68.4%). The event-free survival median is 109 days (range 6-1988) and the relapse-free survival median is 314 days (range 4-1947). There were 9 treatment-related deaths (11.8%) within 30 days following 7+3 induction. Of 41 patients who attained complete morphologic remission after induction, 29 patients (70.7%) received the planned IDAC+2 consolidation with 17 (41.5%) receiving two consolidation cycles. Of those not receiving IDAC+2, 10 patients (24.4%) received an alternative consolidation regimen and 2 patients (4.9%) did not receive consolidation. Of those receiving IDAC+2 25 (86.2%) were intermediate cytogenetic risk and 3 (10.7%) were poor risk. No treatment-related deaths occurred in consolidation with IDAC+2. 20 patients (26.3%) from the whole cohort received an allogeneic stem cell transplant (SCT), and 8 patients (27.6%) of those who received the IDAC+2 consolidation regimen proceeded to an allogeneic SCT. In all IDAC+2
consolidation cycles, the median days to neutrophil recovery was 26 days (range 18-72), platelet recovery 32 days (range 17-75), and the ICU admission rate was 12.8% (range 2-10 days). 18 patients (62.1%) receiving IDAC+2 consolidation suffered disease relapse. For patients receiving IDAC+2 consolidation the median OS was 727 days (range 113-1614 days) with an EFS of 388 days (range 109-1614 days). For patients aged 60-65 years the remission rate and median OS were similar to those published by Lowenberg et al.

Summary/Conclusions: Anthracycline intensification was well tolerated with low treatment related mortality and rates of ICU admission along with acceptable time to count recovery. In patients aged 60-65 outcomes were similar to published data with high-dose daunorubicin. Despite this intensive post-remission therapy approach rates of disease relapse were high highlighting the need for novel therapeutic approaches in this patient group. Aims: To evaluate the clinical efficacy and safety of decitabine (DAC) in combination with HAAG regimen [idarubicine (IDAC), cytarabine (Ara-C), doxorubicin (Acla) and recombinant human granulocyte colony stimulating factor (G-CSF)] for advanced patients with AML.

Methods: Thirty-six patients with advanced AML receiving DAC combined with HAAG chemotherapy in our center from December 2012 to August 2015 were enrolled in this study. Eighteen of them were refractory or relapsed AML, and another 18 patients were those who didn’t achieve CR after a course of induction chemotherapy. The therapeutic responses, side effects and long-time survival were retrospectively analyzed.

Results: After a course of treatment, the rate of CR and partial response (PR) was 58.3% (21/36) and 22.2% (8/36) respectively, while the overall response rate (ORR) was 80.6% (29/36) in the cohort. For the patients with refractory or relapse AML, CR was 61.0% (11/18), PR was 22.2% (4/18), and ORR was 83.3% (15/18). While for the other not getting CR after a course of induction chemotherapy, CR was 55.6% (10/18), PR was 22.2% (4/18), and ORR was 77.8% (14/18). Grade 4 hematological toxicities were observed in all patients, and 72.2% cases experienced infection. And all non hematological side effects were mild and well-tolerated. With a median follow-up of 7.5 (0.5-33.3) months, the 1-year overall survival (OS) rate was 43.3%, 24.2% for the refractory or relapsed AML patients, and 61.6% for those not achieving CR after a course of induction chemotherapy. The difference was significantly (P<0.01).

Summary/Conclusions: DAC combined with HAAG regimen is safe and effective salvage treatment for advanced stage AML patients.
markers. Results were given overall and stratified by age (<60/≥60 years) and sex. Kaplan Meier curves and Cox regression (Hazard ratios; HRs) was used to compare survival by cohabitation (living with someone, living alone) and marital status (married, divorced, widowed, unmarried).

Results: The study included 3243 AML patients. Patients living with someone (n=2056) were younger, more likely to be married, male, to be working, and to have a higher education than patients living alone. Comorbidity, white blood cell count, lactate dehydrogenase, and blast counts did not differ between groups, however patients living with someone tended to have better performance status at time of diagnosis. Patients living with someone were more likely to receive intensive chemotherapy than patients living alone when aged 60 years or older (41.2% vs 22.8%, adjusted OR 0.81 (CI=0.46-0.81)). In patients <60 years, never-married patients were less likely to receive intensive therapy (adjusted OR 0.43 (CI=0.19-0.99)) than married patients. In patients <70 years achieving CR, the chance of alloHSCT was reduced when living alone (11.8%, adjusted OR 0.47 (CI=0.28-0.78), versus 19.0% in patients living with someone). In divorced patients, the chance was also reduced (7.6% adjusted OR 0.38 (CI=0.20-0.74)) compared to married patients (19.3%). Crude survival by cohabitation is shown in Figure 1. Overall survival was inferior in patients ≥60 years living alone (adjusted HR 1.21 (CI=1.09-1.33)) and unmarried patients (never-married: adjusted HR 1.29 (CI=1.06-1.57), divorced/widowed: adjusted HR 1.11 (CI=1.00-1.23)) compared to married patients. In contrast, cohabitation and marital status did not affect treatment response (living with someone: CR 70.6%, living alone: CR 72.8%) or overall survival (adjusted HR 1.08 (CI=0.81-1.23)) in intensive therapy patients only.

Summary/Conclusions: Our study results indicate, that the effect of cohabitation and marital status on AML outcome, especially in patients ≥60 years, is explained by social support rather than by differences in income and occupation. Patients living alone do not present with more advanced disease or higher comorbidity burden than patients living with someone. Still, patients living alone and never-married patients are less likely to receive intensive chemotherapy affected overall survival. Increased focus on what drives treatment decisions in patients lacking social support is important to improve survival in these patients.

TREATMENT OF MOLECULAR RELAPSE IN ACUTE MYELOID LEUKEMIA WITH MUTATED NPM1 REDUCES TOXICITY OF SALVAGE TREATMENT AND IMPROVES DISEASE CLEARANCE

F. Guolo¹,*, P. Minetto¹, M. Clavio¹, D. Guardo¹, E. Covelli¹, N. Colombo¹, F. Ballerini², M. Migliori¹, R.M. Lemoli¹, M. Gobbi¹
¹Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCCS AO Ulisse San Martino-IST, Genova, Italy
²Clinic of Hematology, Department of Internal Medicine (DiMI), University of Milan, IRCCS AO S. Matteo, Pavia, Italy

Background: Acute Myeloid Leukemia with mutated NPM1 (NPM-AML) is characterized by a favorable prognosis. Most patients achieve hematological complete remission (CR) and are not considered eligible for an early allogeneic stem cell transplantation (HSCT). The importance of longitudinal NPM1 minimal residual disease (MRD) monitoring in NPM-AML is well recognized but no data are currently available on MRD-directed therapy in this AML subset. Since 2004 we have prospectively evaluated NPM1 MRD at precise time points to evaluate response to therapy and predict the risk of hematological relapse (HR).

Aim: The primary aim of this study was to set a standardized operational definition of molecular relapse and to evaluate the efficacy and feasibility of MRD-directed salvage therapy.

Methods: From January 2004 to January 2014, 36 consecutive younger intensively treated patients with NPM-AML achieving CR were included in the study. MRD assessment was performed on bone marrow (BM) samples after 1st and 2nd induction cycle, after each of the three consolidation cycles and then every three months for five years. If MRD positivity was found, a new analysis was devised to analyze a total of 15 days. NPM1 mutation was measured on BM samples using MutaQuant® kit Ipsogen® from Qiagen. All Real-Time PCR were performed on 7500 Fast Real-Time PCR System from Applied Biosystems.

Results: Among the 36 patients, 13 showed HR, after a median of 24 months (range 1-75) after the first course and after 2nd consolidation. Eight (62%) patients obtained hematological CR, and one patient died during therapy. Complete NPM-MRD clearance was achieved in HR received two cycles of MEC. Eight (62%) patients obtained hematological CR, and one patient died during therapy. Complete NPM-MRD clearance was achieved in HR received two cycles of MEC.

Summary/Conclusions: Despite the good overall prognosis, a significant proportion of NPM-AML patients will relapse. Our preliminary data strongly support the feasibility and efficacy of MRD-directed therapy in NPM-AML. This strategy reduces the toxicity related to re-induction and increases the proportion of patients achieving a MRD negative CR.

E934
MINIMAL RESIDUAL DISEASE AND LAIP CHANGES BY FLOW CYTOMETRY IN DE NOVO ACUTE MYELOID LEUKEMIA DURING CHEMOTHERAPY AND CLINICAL OUTCOMES

T. Lobanova¹,², I. Galtseva¹, Y. Davydova¹, N. Kapranov¹, V. Troitskaya¹, E. Parovichnikova¹
¹Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation
²Leukemia, MD Anderson Cancer Center, Houston, United States

Background: Minimal residual disease (MRD) detection by multicolor flow cytometry (MFC) in acute myeloid leukemia (AML) is widely explored by different researchers and it is an additional independent factor in clinical outcomes. The prognostic value of leukemia associated immunophenotype (LAIP) changes in not explored enough.

Aims: To investigate the amount and clearance of MRD reduction and LAIP changes in de novo AML during chemotherapy and compare the results with clinical outcomes.

Methods: In a clinical prospective study since March 2016 till February 2017 50 patients (pts) of de novo AML (f/m 32/18 m. age 44 (17-85) were included. 14 pts by this moment completed basic chemotherapy (ChT) courses: +3+2 induction and 2 consolidation. Among them favorable cytogenetics was in 4pts (t(16,21)-1, 16q22-1, t(8,21)-2), 16p13.1 (1 pts), intermediate-7 (6-with normal caryotype, 1-t(11,17)), poor-3 (complex karyotype-2, 11q23-1pt). Bone marrow samples were studied in standardized panel with most common antibodies by 6-color MFC (BD FACSCanto II, USA) before the treatment, after 1st and 2nd courses of induction and after 2nd consolidation. Any amount of MRD >0 was assumed as MRD positivity. Besides MRD status we also explored LAIP changes in patients with CR after 1st and 2nd courses of ChT.

Results: Leukemia associated immunophenotype (LAIP) was detected in all monitored patients at the diagnosis. Molecular markers were detected in 28.5% (2pts-with NPM1+FLT3+CEBPA+, 1-with FLT3+, 1-NPM1+), 2 pts had resistant AML after 2 courses (CR), 3 pts out of 7 with complete morphological remission (CMR) after 1st course had MRD positivity (0.03%, 1.61%, 8.3%), and these pts became MRD-negative after 2nd course. CMR was achieved after 2nd course in 5 more pts and MRD positivity was detected in 3 pts (0.033%, 0.523 and 3.9%) with intermediate cytogenetic risk. By the end of 4th course 11 pts stayed in CR and we diagnosed 1 morphological relapse (patient with MRD-negativity and CMR after 2nd ChT). Two early relapses were also traced: both with persistent MRD during all period of ChT and CMR after the second ChT. All pts with MRD-negative status after first course are alive and in CMR (8 months from diagnosis). While monitoring, LAIP changes were distinguished in 7 pts. One from two with resistant AML lost CD65, another one acquired CD11b. 5 pts were in CR after 2nd course and during ChT one of them gained CD56 and CD13, 2nd lost CD56 and CD11b, 3rd – gained CD65, 4th gained CD11b after 2nd ChT, the last one didn’t change LAIP. We detected relapse in 3 pts from this group and one – with increasing MRD after 4th course and cytopenic syndrome. We may suggest that LAIP changes during ChT reflect selection of more chemotherapy sensitive leukemia clone, followed by subsequent relapse.

Summary/Conclusions: 1. The most favorable group consisted of MRD negative pts after 1st course. 2. LAIP changes are common in pts with less favorable prognosis.

E935
LENALIDOMIDE MAINTENANCE IN PATIENTS WITH HIGH RISK ACUTE MYELOID LEUKEMIA

T. Kadia¹, J. Cortes¹, F. Ravandi¹, N. Daven¹, E. Jabbour¹, A. Ferrari¹, N. Pemmaraju¹, K. Naqvi¹, S. Pelletier¹, M. Brandt¹, Z. Estrov², H. Kantarjian¹
¹Leukemia, MD Anderson Cancer Center, Houston, United States
²Hematology, MD Anderson Cancer Center, Houston, United States
**Background:** New drug combinations and higher intensity therapy have led to significant improvements in complete remission (CR) rates for patients with acute myeloid leukemia (AML). However, relapsed disease remains a major source of failure. With the exception of allogeneic stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk patients. NK cells as part of the immune microenvironment are important mediators of immune surveillance in AML. Lenalidomide has demonstrated single-agent activity in AML and enhances NK cell activity and immune synapse formation in leukemia.

**Aims:** We designed a phase II clinical trial studying the efficacy of lenalidomide as maintenance therapy in AML patients with high-risk disease in remission, who were not being considered for SCT.

**Methods:** AML patients ≥18 years with a high-risk feature in 1st CR (CR1) or any patient in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Patients should be within 12 months of achieving CR, have PS ≤3, adequate kidney/liver function, ANC >0.5 and platelets ≥30. Patients were treated continuously with lenalidomide 10mg PO daily on D1-28 of a 28 day cycle up to 24 cycles. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. After cycle 1, stepwise dose escalations were allowed to 20mg daily in pts who were tolerating their dose and have presence of minimal residual or morphologically detectable disease.

**Results:** A total of 14 patients have been enrolled with a median age of 57.5 years (range, 23-67). All pts were in CR at the time of enrollment, with 12 pts (86%) in CR1 and 2 (14%) in CR2. Baseline pt characteristics are outlined in Table 1. AML-related mutations detected at start of therapy included: CEBOA (n=5), NPM1 (3), FLT3 (3), IDH2 (2), NRAS (2), DNMT3a (2), and 1 each of JAK2, TET2, and EZH2. High risk features at the time of enrollment were as follows (some are overlapping): 5 (36%) with history of prior myeloid neoplasm or therapy related AML, 4 (29%) persistent MRD, 4 (29%) adverse mutational profile, 2 (14%) adverse karyotype, 1 (7%) primary refractory disease, and 2 (14%) CR2 status. Patients have received a median of 9 cycles (1-24) cycles of therapy. With a median followup of 19+ months (8.5-39), the 6- and 12-month estimated RFS were 100% and 69%, respectively. The 6- and 12-month estimated OS were 100% and 89%, respectively (Figure 1). The regimen was well tolerated. Cytopenias were mild and managed with dose adjustments. The most common grade 3 (no grade 4 toxicity) non-heme toxicities were 1 each of nausea, vomiting, and anemia.

**Summary/Conclusions:** Lenalidomide is a safe and feasible maintenance strategy in high-risk AML patients who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of relapse-free survival of high-risk patients based on a historical cohort. Studies evaluating dynamics of MRD on study are ongoing.

**E936 POSTREMISSION THERAPY FOR AML WITH INTERMEDIATE RISK CYTOGENETICS IN FIRST COMPLETE REMISSION**

J. Vydra 1, C. Šálek2, J. Schwarz1, P. Cetkovský3, P. Žák2, J. Novák3, V. Pešelová4, J. Mayer5, Z. Račič6,

1Institute of Hematology and Blood Transfusion, Prague, 24th Department of Internal Medicine - hematology, Charles University, University Hospital Hradec Králové, Hradec Králové, 3Dept. of Hematology, Charles University, University Hospital Královské Vinohrady, Prague, 4Department of Internal Medicine/Haematology-Oncology, University Hospital Brno, Brno, Czech Republic

**Background:** Postremission therapy of AML with intermediate risk cytogenetics in first CR is based on chemotherapy with high dose cytarabine (HIDAC) or hematopoietic cell transplantation (HCT). Evidence from single trials with regards to optimal postremission therapy has been inconclusive, metaanalyses suggest a survival benefit of allogeneic HCT in first CR, except for patients with mutation of NPM1 without concomitant FLT3/ITD.

**Aims:** We analyzed retrospectively data from patients with AML with intermediate risk cytogenetics in CR1 with the aim to determine rates of completion of postremission therapy, rates and risk factors for early relapse and non relapse mortality (NRM), overall survival (OS) and relapse free survival (RFS) according to postremission treatment and describe causes of and risk factors for treatment failure.

**Methods:** Data on 304 patients in CR1 treated with curative intent between 2007 and 2016 in four centers participating in Czech Leukemia Study Group for Life were analyzed. All patients signed informed consent with data collection, analysis and publication. Cox regression was used to determine risk factors for OS and RFS, using time dependent covariates for postremission therapy. Age, WBC count, number of induction cycles, NPM1 mutation, FLT3/ITD, performance status, BMI, previous malignancy and extramedullary disease were included in models. Postremission therapy was completed after HCT or after three cycles of HIDAC. After completion of two cycles of intermediate dose cytarabine (IDAC) in patients >60 years. Competing risk cumulative incidence estimates were calculated for NRM and relapse. Early relapse and NRM were defined as relapse/NRM before completion of postremission therapy.

**Results:** Median age was 52 (18-74) years. Median follow up time was 481 (31-3364) days. Early relapse rate (RR) and NRM were 11.0% and 5.29%, respectively. Median OS after early relapse was 128 days. Presence of FLT3/ITD and NPM1 and high body mass index were associated with increased risk of early relapse on multivariate analysis (HR 14.48, 95%CI 3.24-68.43 and 2.34, 95%CI 1.3-4.2, respectively). Age increased risk of early NRM (HR 5.13, 95%CI 1.5-17.58 for age 55-35 years). 76% of patients completed therapy: 42% received allogeneic HCT in CR1, 21% completed three cycles of HIDAC and 13% completed two cycles of IDAC. 3-year OS and RFS of the whole cohort were 53.68% and 40.26%, respectively. OS was 67% in a group of patients who completed HIDAC, 34% in IDAC group and 64% in SCT group (p=0.2846). Cumulative incidence of NRM and RR 3 years after completion of therapy was 23% and 20% after HCT, 7.13% and 51% after HIDAC and 16.8% and 66.4% after IDAC, respectively, differences among groups were significant (p=0.00947 and p<0.00001). HCT reduced the risk of relapse in comparison to chemotherapy (HR 0.51, 95%CI 0.3-0.85). RFS was adversely influenced by concomitant FLT3/ITD/NPM1 mutation (HR 2.17, 95%CI 1.06-4.45). Increasing age had negative effect on OS (HR 1.65, 95%CI 1.13-2.42 for age 55-35 years). After HCT, HLA mismatch and TBI based myeloablative conditioning were associated with increased NRM (HR 6.32 (95%CI 1.89-21.14) and 6 (95%CI 1.86-19.2), respectively) in comparison to transplantation from HLA matched donors and busulphan based myeloablative conditioning.

**Summary/Conclusions:** The majority of patients within intermediate cytogenetic group in our analysis received allogeneic HCT. Patients who relapsed before completion of treatment had dismal outcome with very short OS. Allogeneic HCT decreased risk of relapse but led to increased NRM, reducing positive effect of HCT on OS. Risk of NRM was increased after TBI based myeloablative conditioning and after HCT in mismatched unrelated donors.

LONG TERM FOLLOW UP OF PATIENTS OVER 60 YEARS TREATED WITH INTENSIVE CHEMOTHERAPY FOR ACUTE MYELOID LEUKAEMIA AND MYELODYSPLASTIC SYNDROMES

Background: More and more data on patients over the age of 60 years treated with intensive chemotherapy are emerging, however, long term data with patient outcomes after those 2-5 years are lacking. In 2007, we published a single center study on patients over the age of 60 years, suffering from acute myeloid leukemia (AML) or high risk myelodysplastic syndrome (MDS), treated with intensive chemotherapy (Knip et al. Cancer 2007, 110:345-52). We now present long term follow up data of these patients, the first patient being treated in 1991, meaning 26 years ago.

Aims: To characterize the longterm outcome of elderly AML and high risk MDS patients treated with intensive chemotherapy after the usual 2-5 year follow up period.

Methods: We treated 160 patients aged 60 years or more suffering from high risk MDS and AML with intensive chemotherapy regimen between 1991 and 2004. None of the patients underwent allogeneic stem cell transplantation afterwards. We now performed a follow up of the surviving patients 10 years after publication of the initial study.

Results: In the initial study median survival from the start of induction therapy was 9.5 months (10 days to 157 months), with the median survival from diagnosis of 14 months (1 day to 157 months). At the publication of the study in the year 2007, 20 patients were still alive, 18 of them presented with a low risk karyotype. 13 of these patients were in complete remission and 7 patients had relapsed. Since then 13 of the 13 patients who were in CR relapsed and died of their leukemia. One patient died of other causes and only one patient is still alive and well, currently at the age of 84. This patient initially presented with a normal karyotype, too. As a result the rate of long term survivors 5 years after treatment is 5.6% only.

Summary/Conclusions: Long term follow up data of elderly patients treated for AML and MDS with intensive chemotherapy is scarce. Our data show, that induction chemotherapy not followed by allogeneic stem cell transplantation does not result in a meaningful improvement of outcome. In addition, morbidity and lack of quality of life has to be taken into account. More data and studies on this subject are urgently needed in an aging population. In our population of 160 treated patients, 158 died of their leukaemia, only one patient died of another cause and only one single patient is still alive and well over a decade later.

Figure 1.

Summary/Conclusions: FLAG-ida is an effective salvage regimen in patients with refractory or relapsed AML allowing the achievement of complete remission in the majority of cases. In this single-centre cohort, early relapse, within 12 months, from first line therapy was associated with an inferior survival following salvage therapy with FLAG-ida.

A SINGLE CENTRE 5-YEAR STUDY

Background: The treatment of relapsed/refractory Acute Myeloid Leukaemia (AML) remains a formidable challenge as the therapeutic options are limited. The regimen most commonly used in this setting, FLAG-ida (Fludarabine, Cytarabine, G-CSF and idarubicin) is considered more toxic than standard Daunorubicin plus Cytarabine (DA) regimen, often associated with prolonged periods of bone marrow suppression and predisposition to severe infections.

Aims: In this study, we present a single centre experience in the use of this regimen with a view to identifying predictive factors for survival following FLAG-ida chemotherapy. The secondary aim of this project was to assess its efficacy and safety profile in the routine clinical setting.

Methods: We conducted a retrospective chart review of patients treated with FLAG-ida chemotherapy regimen for relapsed or refractory acute myeloid leukaemia (including secondary AML) between 2011 and 2016 in a large tertiary hospital. Patients treated with FLAG-ida as first line therapy were excluded.

Results: Fifty-four patients met the criteria for inclusion in this study. The median age of the patients was 53 (10-69) years. Eighteen percent (18%) received FLAG-ida for primary refractory AML while the remainder were treated having relapsed after at least 1 previous regimen. The median time to relapse was 15 months. Complete remission was achieved in 70% of patients and 81% of these patients proceeded to have an allogeneic stem cell transplant. The median overall survival following FLAG-ida chemotherapy was 16 months with 1-year and 2-year survival rates of 59% and 46% respectively. Approximately 6% therapy-related mortality was observed. The median overall survival in patients with early relapse (<12 months) was significantly shorter than those with late relapse (>12 months): 6 months and 20 months respectively (log-rank test p value: 0.04) (Figure 1). Complete remission rates were similar between relapsed and primary refractory AML patients.
E940

DRUG-DRUG INTERACTION POTENTIAL OF GILTERITINIB IN HEALTHY SUBJECTS AND PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

Methods: The effects of CYP3A4 inhibitors (itraconazole [ITZ] and fluconazole [FLZ]), as well as a CYP3A4 inducer (rifampin [RIF]), on the gilteritinib pharmacokinetic (PK) profile were assessed in an open-label, parallel-group study conducted in 81 healthy subjects. Gilteritinib was administered as a single 20-mg dose on Day 1 and 200mg FLZ on Days 2–28, or in combination with once daily 10mg dose alone on Day 6, or in combination with 200mg ITZ administered twice daily on Day 1 and once daily on Days 2–28, or in combination with once daily 400mg FLZ on Day 1 and 200mg FLZ on Days 2–28. When given concomitantly with ITZ or FLZ, gilteritinib was administered on Day 6. In an additional cohort, RIF 600mg was administered on Days 1–21 and gilteritinib was administered on Day 6. In an additional cohort, RIF 600mg was administered on Days 1–21 and gilteritinib was administered as a single 20-mg dose on Day 8. Additionally, the potential inhibitory effects of gilteritinib on the PK profile of a CYP3A4 substrate (midazolam) was assessed in a cohort of patients with R/R AML (n=9) in the Phase 1/2 CHRYSTALIS study (NCT02014458). Patients received oral gilteritinib (300mg/d) and single oral midazolam (2mg) doses. Gilteritinib was administered on Cycle 1 Day 1 and continued once daily in 28-day cycles; midazolam was administered on Day -1 and Cycle 1 Day 15. Furthermore, in patients with R/R AML, gilteritinib trough concentration data for patients on strong (eg, voriconazole or posaconazole) or moderate (eg, FLZ) CYP3A4 inhibitors were compared with those for patients not using CYP3A4 inhibitors.

Results: In healthy subjects, gilteritinib exposure (expressed as C max and AUC 24) was higher (2.2-fold increase) in subjects who were coadministered gilteritinib with a strong CYP3A4 inhibitor (ITZ) than in subjects who were administered gilteritinib alone. Coadministration of gilteritinib with RIF, a strong CYP3A4 inducer, resulted in an approximate 70% decrease in gilteritinib exposure in healthy adult subjects (Figure 1). In patients with R/R AML, midazolam exposure was approximately 10% higher when administered with gilteritinib compared to midazolam alone as reflected by the geometric mean ratio and 90% confidence intervals of midazolam C max (111.64%; 69.54%–179.25%) and AUC 24 (109.46%; 49.82%–240.48%). Additionally, a 10% decrease in gilteritinib exposure was observed in patients who were taking concomitant medications that were moderate or strong CYP3A4 inhibitors relative to patients who did not use a CYP3A4 inhibitor. The increased exposure in these patients, however, did not translate to differences in the incidence of drug-related safety events when compared across groups.

Conclusion: These data suggest limiting concomitant use of strong CYP3A4 inhibitors, such as itraconazole, with gilteritinib. Furthermore, these data suggest coadministration of CYP3A substrates with gilteritinib is unrestricted. A comprehensive review of safety data in patients with R/R AML did not suggest that dose adjustment is warranted when gilteritinib is coadministered with strong CYP3A4 inhibitors. Although concomitant use of gilteritinib with strong CYP3A4 inhibitors (eg, ITZ or FLZ) may be permissible, precaution is warranted.

E941

A FLUDARABINE-BASED ACUTE MYELOID LEUKEMIA INDUCTION IS WELL TOLERATED UP TO 75y OF AGE ALLOWS EARLY CONSOLIDATION AND LONG TERM SURVIVAL. A SINGLE CENTRE EXPERIENCE OF 136 CONSECUTIVE PATIENTS

Methods: Patients were treated with the FLAIE or FLAI regimen followed by Idarubicin plus Aracytin as 2 step induction. Exclusion criteria for treatment were: acute promyelocytic leukemia, poor performance status and severe comorbidity. Post remission treatment included up to three cycles of high dose Aracytin, autologous (Auto) or allogeneic (Allo) stem cell transplantation according to cytogenetic and molecular risk stratification (CMR, Döhner Blood 2010 PMID 19880497) aiming for a curative strategy for all our AML patients.

Results: Median age at diagnosis was 55ys (18-75ys), median follow up was 18 months (range 3-172 months), 75% of patients (102/136) had de novo AML with strong (FLT3/ITD) had such as itraconazole, mostly from myelodisplastic syndrome, 19% of patients (26/136) had good CMR risk disease, 45% of patients (61/136) had intermediate risk and 36% of patients (50/136) had high risk disease. Complete remission (CR) rate was 68% and was comparable to the majority of pub-
lished trial data, considering the proportion of high CMR risk (36%) and leukemia of secondary origin (25%) and the relatively high median age: 36% of patients (49/136) were above the 60ys old age limit of most AML protocols. In multivariate analysis CR rate was significantly affected by age below 50ys: p=0.011; good/intermediate CMR risk: p=0.011 and de novo AML: p=0.008. The induction death rate was 4% in line or slightly lower than published results, showing that the treatment was well tolerated. The low CMR score, age below 60, and low toxicity incidence was 9.6% allowing to proceed to consolidation in more than 70% of CR patients. Overall 80/136 patients (59%) were beyond 50ys, intensive consolidation with Allo or Auto was done in 34/80 patients (43%) confirming the feasibility of this therapeutic strategy. The Kaplan-Meier median probability of overall survival (OS) of the whole cohort was 28 months and factors significantly affecting OS were age below 50 ys p<0.0001; de novo AML p<0.0003; good-intermediate CMR risk p<0.0002; intensive consolidation with Allo or Auto transplant p=0.0001 compared to chemotherapy alone. The mean probability of Leukemia free survival (LFS) was 88 months (median not reached). Patients above 50ys (median OS=29.3 months) showed no karyotype profiles and NPM1/FLT3 status. The median probability of OS and LFS were 16.4 and 23.4 months respectively, this compares favorably with many published results. Chen Medicine 2016 PMID: 27472687 reported a median OS of 10.3 months in a large cohort of patients of similar age treated with intensive induction. Moreover we did not find a significant difference between the 50-59ys and 60-75ys age groups: median OS was 20.8 and 14 months (p=0.12) and median LFS was 15.9 and 23.6 months (p=0.71) respectively.

Summary/Conclusions: In our real life experience the FLAIE/FLAI regimen combined with intensive consolidation demonstrated good long term results in both terms of OS and LFS in patients younger than 50ys, this regimen was also feasible and manageable in patients with intermediate-risk cytogenetics, (p=0.001 and p=0.05 respectively), or even in those with normal karyotype profile (p=0.022 and p=0.111, respectively). In multivariate analysis, high SOX4 expression was found to be an independent poor prognostic factor of OS (RR 1.924, 95% CI 1.020-3.628, P=0.043) irrespective of age, WBC count at diagnosis, karyotype profile and NPM1/FLT3-ITD status. Our results also reveal that SOX4 is an independent prognostic factor of AML. In conclusion, we reveal that BM SOX4 expression could serve as an informative new biomarker for the clinical prognosis of AML patients.

AN OPEN-LABEL, MULTICENTER, PROSPECTIVE, RANDOMIZED STUDY OF RECOMBINANT HUMAN THROMBOPOIETIN AS AN ADJUNCT AFTER INTENSIVE CONSOLIDATION CHEMOTHERAPY IN ACUTE MYELOID LEUKEMIA

X.-H. Sui1, Y. Li1, X. Wang2

1Hematology department of Shandong provincial hospital affiliated to Shandong University, 2Hematology department of Shandong provincial hospital affiliated to Shandong University, Shandong University school of medicine, Jinan, China

Background: Thrombocytopenia is a common problem in the management of patients with acute myeloid leukemia (AML) receiving induction and consolidation therapy. AML patients with platelet count of less than 20 × 10^9/L may have a high risk of bleeding complications and had to take dose modifications instead of intensive chemotherapy leading to increased disease-free survival and overall survival. Platelet transfusions have a short therapeutic effect and are associated with all types of transfusion reactions. Recombinant human thrombopoietin (rhTPO) has been shown to improve the megakaryocyte and platelet development in solid tumor patients and immune thrombocytopenia (ITP) patients refractory to conventional corticosteroids. We conducted this study to determine the availability of rhTPO in the platelet recovery after intensive consolidation chemotherapy with AML patients.

Aims: The aims of this study were to identify the effectiveness and safety of rhTPO in supportive care in patients with AML receiving consolidation chemotherapy.

Methods: Patients: Patients were eligible if they were 15-70 years of age who achieved complete remission after one course of IA induction therapy, and had platelet counts of less than 50 × 10^9/L after induction therapy, with an Eastern Cooperative Oncology Group (ECOG) performance status of 0-3. Patients with FAB M3 (acute promyelocytic leukemia) and FAB M7 (acute monocytic leukemia) were excluded from the study. All patients provided written informed consent according to protocol guidelines approved by the institutional review boards at their individual institutions.

Study design: Patients received consolidation chemotherapy with DA, MA and intermediate-dose arabinosylcytosine (ARA-C), et al. When the platelet count was less than or equal to 50 × 10^9/L, patients in study group received 15000u/day of rhTPO (trade name: TPIAO) administration subcutaneously and patients in control group not received rhTPO therapy. The administration of rhTPO continued until the platelet count was more than 100 × 10^9/L for the maximum of 21 days. Statistical analysis: The main characteristics of patients were analyzed using independent samples test and chi-square test. Other statistical data analyses were performed using the two-tailed Student’s t-test and were represented as means±SD of values. All differences were considered to be statistically significant when the P value was less than 0.05.

Results: The main difference was observed in the main characteristics between study group (n=49) and control group (n=36), including age, gender and other baseline characteristics. No patient withdrew. Platelet transfusion and time required for platelet recovery were shown in Table 1. Platelet transfusions: The median number and days of platelet transfusions for patients in each group were those in the table. The results showed that there were no significant differences of statistic status between the patients. Platelet recovery: 1. rhTPO might reduce the duration of platelet count less than or equal to 20 × 10^9/L and 30 × 10^9/L after chemotherapy. 2. rhTPO could increase the maxi-
mal and minimal platelet count after chemotherapy. 3. rhTPO might shorten the days of platelet count recover to at least 20×10⁹/l from its nadir. The incidence of side effects were similar in both groups of the study.

Summary/Conclusions: rhTPO, administered as dose of 15000u/day when platelet count less than or equal to 50×10⁹/l, might improve the recovery of thrombocytopenia of patients with acute myeloid leukemia in CR after consolidation chemotherapy. While there was no significant difference between study group and control group, there was a decreasing trend of platelet transfusion number and shorter time required for platelet transfusion for patients in study group.

E944

TREATMENT-ASSOCIATED SURVIVAL RATES IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): A SYSTEMATIC LITERATURE REVIEW

J. Bell1, A. Galaznik2, R. Huelin3, M. Stokes4, D. Faller5, R. Fram6
1Global Outcomes Research, 2Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 3Meta Research, Evidera Inc, Waltham, United States, 4Retrospective Observational Studies, Evidera Inc, Dorval, Quebec, Canada, 5Oncology Clinical Research, 6Takeda Oncology, Cambridge, United States

Background: AML patients ≥60 years old are more likely to experience complications following intensive induction chemotherapy and are at higher risk of unfavorable outcomes compared with younger patients. Information regarding optimal treatment approaches for older AML patients is limited.

Aims: Summarize outcomes associated with therapies among older AML patients, with a focus on treatment patterns and overall survival (OS) as reported in the literature.

Methods: Searches were conducted in Medline and Embase (Jan 2014–May 2016) and supplemented by conference abstracts (2015–2016). Eligibility included studies in English reporting on treatment regimens and outcomes associated with older AML patients or subgroups thereof, and conducted in the US, EU 5 (United Kingdom, Germany, France, Spain, Italy), or Japan. Only studies enrolling ≥50 patients were included.

Results: Twelve studies (19 publications) reporting on OS among older AML patients were included. Participants in most studies were newly diagnosed with AML; ages ranged from 60 to 93 years. Five non-comparative studies examining the effects of various treatment modalities were identified. Median OS in studies examining azacitidine (AZA) ranged from 10 to 12 months, whereas in studies examining induction chemotherapy or reduced intensity conditioning (HMA), and BSC. Patients appeared to have longer OS when receiving IC compared to LD-AraC (median OS: 12.4 vs 9.6 months; 3-year OS: 27% vs 12%; p=0.07), and those receiving LD-AraC compared to BSC had significantly improved OS (median: 9.6 vs 3.4 months, p<0.001). In this same study, while OS was longer with HMA than LD-AraC, this difference was not significant (median OS 16.1 vs 9.6 months; 3-year OS 22% vs 12%, respectively; p=0.1). Two studies assessed the efficacy of AZA vs moderate-IC, LD-AraC, or palliative therapy, alone or in combination. AZA had a significantly better survival rate vs LD-AraC in poor prognosis patients (p=0.015). Furthermore, 1-year survival was higher for AZA-treated patients (67.8%) compared to those not treated with AZA (36.9%) (p=0.004). The efficacy of AZA relative to other conventional care regimens (CCRs) including BSC, LD-AraC, or standard IC was also examined in a randomized clinical trial (n=488). Median OS at 1-year was significantly higher for AZA relative to CCR (10.4 vs 6.5 months). Results also showed that 1-year median OS was higher with AZA than CCR in all cytogenetic risk groups, normal risk (14.1 vs 10.0), intermediate risk (13.0 vs 10.1), and high risk (6.4 vs 3.2), respectively.

Summary/Conclusions: Among older AML patients, IC tended to be associated with improved OS compared with other CCRs. However, evidence from this review indicates that AZA could be an alternative treatment option for older AML patients, whether fit or unfit for IC.

E945

SYSTEMATIC REVIEW OF HEALTH STATE UTILITY VALUES FOR ECONOMIC EVALUATION OF ACUTE MYELOID LEUKEMIA

A. Forsythe1, V. Bal 2, M. Dolph 3, S. Patel 4, G. Tremblay5
1Purple Squirrel Economics, New York, 2Novartis Pharma, East Hanover, United States, 3Purple Squirrel Economics, Montreal, Canada, 4Novartis Pharmaceutica UK Limited, Surrey, United Kingdom, 5Purple Squirrel Economics, Quebec city, Canada

Background: Cost-utility analyses undertaken to inform decision making regarding acute myeloid leukemia (AML) require a set of health state utility values (HSUVs) so that the time AML patients spend in different health states can be aggregated into quality-adjusted life-years (QALY).

Aims: This study reviews AML-related HSUVs that could be used in economic evaluation and assesses their advantages and disadvantages with respect to valuation methods used and AML clinical pathways.

Methods: Embase, MEDLINE, Cochrane database, and conference abstracts (ASCO, ESMO and ASH) were systematically searched from Jan 2000 through Nov 2016 for relevant studies that reported quality of life (QOL) and HSUV in AML. Identified relevant EORTC Quality of Life Core Questionnaire QLQ-C30 values were mapped to HDUV using previously published algorithm by Crott, et al. 2010. HSUV for induction, consolidation, consolidation or relapse, stem cell transplantation (SCT) treatment, SCT recovery and CR post SCT were identified.

Results: Ten relevant studies were identified. Six were cost effectiveness analyses utilizing HSUVs for calculation of Quality Adjusted Life years (QALY), one effectiveness analysis (incremental QALY). Two QOL studies reporting specific AML utilities (either collected or mapped from QLQ-C30). An additional study reported QOL for patients undergoing SCT. Since no study reported HSUV for relapse, values from study of secondary AML patients who failed prior treatment for Myelodysplastic Syndrome, were used. Where multiple HSUVs were available, prioritized clinical trials were used. HSUVs were summarized, and QALYs were calculated, then cost effectiveness ratio (ECR) was calculated.

Summary/Conclusions: None of the HSUVs had sufficient levels of evidence to support economic decision making. Future research should focus on evaluating utility in older AML patients.
Summary/Conclusions: This interim analysis of the use of decitabine in real life showed a superimposable OS to controlled international clinical trials. Safety profile was acceptable considering setting of pts and incidence of important comorbidities. Despite a similar OS, the comparison between our data and Cashen study (56 vs 55 pts) showed in our cohort, a poorer rate of CR+CRi vs CR. This apparent impact of the use of second-line decitabine therapy, WBC >10000/µL as well as high cytogenetic risk. This apparent contradiction supports the idea that in elderly pts recovery of peripheral blood cells counts (PR+hematological improvement) is probably the most important factor influencing OS (Ferrara, Hemat 2016).

E947

ASPARAGINASE ERWINIA CHRYSANTHemiM EFFECTIVELY DEPLETES PLASMA GLUTAMINE, HAS CLINICAL ACTIVITY, AND IS WELL TOLERATED IN ADULT PATIENTS WITH RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMiA

A. Emidi1,2,3, E.T. Stroble1, R.G. Lapidus1,2, L.J. Jeng1,2,4, M. Lee1, M.G. Blitzer2, B.A. Carter-Cooper1, D. Sewell2, I. Van Der Merwe1, M. Imran1, S.L. Yu1, H. Li1, P.C. Amrein1, V.H. Duong1,2, E.A. Saussville1,2, A.T. Fathi1, Z. Singh1, M.R. Baer1, S.M. Bentzen1,2,3

1University of Maryland Greenebaum Comprehensive Cancer Center, 2Medicine, 3Pharmacology, 4Pediatrics, 5Pathology, University of Maryland, Baltimore, 6Massachusetts General Hospital Harvard Medical School, Boston, 7Epidemiology and Public Health, University of Maryland, Baltimore, United States

Background: Asparaginase-induced glutamine (Gln) depletion demonstrates anti-leukemic activity in preclinical studies of AML. We hypothesized that administration of asparaginase Erwinia chrysanthemi (Erwinaza) would lead to effective plasma Gln reduction and may be a feasible therapeutic approach for AML, because myeloblasts may be addicted to Gln.

Aims: The primary aim was to determine the dose of Erwinaza inducing plasma Gln levels ≤120μmol/L, with an acceptable safety profile, 48 hours (h) after the first intravenous (IV) dose and before each subsequent dose administered thrice weekly for 2 weeks in patients (pts) with relapsed or refractory (R/R) AML.

Methods: This was a phase 1, single-arm, pharmacokinetic investigator-initiated trial (NCT02283190, funded by Jazz Pharmaceuticals), with a 3+3+3 design with dose de-escalation/escalation rules that incorporate both safety and biochemical activity (nadir plasma Gln levels) of Erwinaza. There was no intrapatient dose adjustment. For safety, a 3rd cohort of three pts was to be added if 2 of 6 pts in the 1st and 2nd cohorts experience a dose limiting toxicity (DLT) at a certain dose level. If ≤3 of 9 patients experienced DLT, the trial was to be terminated. To evaluate Gln reduction ability of Erwinaza, the dose could be increased based on 48h trough plasma Gln in cohorts of 3, 6, or 9 pts per dose level. Correlative studies measured plasma Gln, glutamate (Glu) and asparagine (Asn) levels, plasma asparaginase activity and plasma and urine 2-hydroxylutarate (2-HG) levels.

Results: Five pts were enrolled on study. Enrolment was then halted due to Erwinaza supply manufacturing complexities. Median age was 69 (range 20-83) years, 4 were male, 2 had prior MDS or CMMML, 3 had high risk abnormal karyotype, 3 had isocitrate dehydrogenase (2 IDH1, 1 IDH2) mutations, and 3 had been treated with ≥2 lines of prior treatment. Erwinaza was administrated IV (25,000 IU/m2; dose level 0) for 6 doses MWF for 2 weeks to all pts. No DLT was observed. Anemia and electrolyte abnormalities were the most common adverse events. Plasma asparaginase activity ≥0.1 IU/mL was achieved in all pts at 48h trough, but in 3 pts it decreased to zero on day 8 (72h trough). Median trough plasma Gln, Asn and peak Glu levels (μmol/L) at 28 were 27.6 (range <12.5-227), 0 (range 0-0), and 704 (range 474-754), respectively. Asn remained undetectable for the entire 2 weeks. Gln levels increased significantly on day 8 (72h trough) compared to day 5, p<0.001. Four of 5 pts (80%, lower limit of 1-sided 95% CI: 34%) achieved at least one nadir Gln value ≤120 μmol/L. The fold reduction (FR) in Gln level in 3 days, relative to baseline, was 0.16 (p=0.031 for achieving partial remission (PR) and one achieved hematologic improvement (HI) after 6 doses of single agent Erwinaza. Both pts had plasma Gln levels <65 μmol/L on days 5, 10 and 12. Off study, after completion of Erwinaza, they have been treated with azacitidine. Both pts are still alive in complete remission (CR) and with complete count recovery (CR) 13.3 and 13.4 months after the on-study date. Plasma and urine 2-HG levels did not change significantly. The 3 pts with IDH mutations tended to have higher plasma 2-HG levels (p=0.10).
Summary/Conclusions: To the best of our knowledge, this is the first clinical report demonstrating that an asparaginase product is capable of not only decreasing plasma Gln level to ≤120μmol/L but also depleting it to undetectable (i.e. <12.5μmol/L) levels in pts with AML. Two of 5 patients with R/R AML had clinical responses and are alive in remission. Given clinical activity of asparaginase in AML, we are to investigate mechanically-designed asparaginase combination therapies.

E948

PROGNOSTIC SIGNIFICANCE OF SOX2, SOX3, SOX11, SOX14 AND SOX18 GENE EXPRESSION IN DE NOVO ACUTE MYELOID LEUKEMIA (AML) PATIENTS

N. Tosic1,*, M. Virijevic2, I. Petrovic3, N. Kovacevic Grujicic3, S. Davidovic3, N. Stuvacic Vukovic2, S. Pavlovic1, M. Stavrovic2
1Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, 2Clinic of Hematology Clinical Centre of Serbia, University of Belgrade Faculty of Medicine, 3Laboratory for Human Molecular Genetics, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, Belgrade, Serbia

Background: Members of the SOX (SRY-related high mobility group (HMG) box) gene family encode a group of transcriptional factors with important functions in embryonic development. Also, SOX genes are aberrantly expressed in different types of cancer. However, their role in hematological malignancies, especially in acute myeloid leukemia (AML), remains elusive.

Aims: The aim of this study was to investigate the expression level of SOX2, SOX3, SOX11, SOX14 and SOX18 genes in de novo AML patients, and to evaluate their potential as prognostic markers.

Methods: Fresh bone marrow (BM) samples were collected from 50 non-APL AML patients at diagnosis (27 male, 23 female, median age 52.5 years, range 22-73) and from 8 healthy donors. Relative quantification analysis of SOX genes expression level was performed by RQ-PCR methodology, with GAPDH gene as endogenous control, and using comparative ΔΔCt method with healthy controls as calibrator.

Results: The median expression level of SOX2, SOX3, SOX11, SOX14 and SOX18 in AML patients was 0.46 (0.01-226.13), 0.81 (0.01-1210.00), 0.35 (0.01-177.29), 0.98 (0.02-469.51) and 3.53 (0.18-332.00), respectively. This was not significantly different from the levels detected in healthy controls where the median expression levels were 1.00 (0.32-2.54), 1.00 (0.45-5.73), 1.00 (0.19-2.83), 1.04 (0.38-2.38) and 1.00 (0.48-12.29), respectively. As a cut-off value above which the patients were considered to be positive for SOX2/3/11/14/18 gene expression we used median expression level of each SOX gene in healthy controls + 2SD. The percentage of patients who were positive for the expression of the studied genes ranged from 14% (SOX2 and SOX11), 20% (SOX3 and SOX18) to 28% (SOX14*). A significant association with the presence of FLT3-ITD and NPM1 mutations was detected in all but SOX14* patients. The same result was found concerning association with higher leukocyte count. There were no significant associations with any other presenting clinical parameters. As for the impact that SOX expression positive status that any of the analyzed genes had on the prognosis and outcome of the disease, we detected higher relapse rate in SOX14+ patients (p=0.045). Significantly shorter disease-free-survival (DFS) was detected among SOX2*, SOX11* and SOX18* patients (p<0.001; p=0.001; p=0.017, respectively). Although all of the SOX* patients had shorter overall survival (OS) time compared to SOX- patients, the most prominent influence has been detected for the SOX2* patients (p=0.034).

Summary/Conclusions: This is the first study focused on examining the expression level of SOX2/3/11/14/18 in AML patients. We have found that these genes are overexpressed among patients in comparison with normal BM. However, in some patients, the expression of these genes is highly increased, and associated with a negative prognostic factors such as the presence of FLT3-ITD mutations and higher leukocyte count. Also, increased expression of these genes has been clearly associated with shorter DFS and OS. As for the exact function of these genes in the pathogenesis of AML is not yet known, our preliminary results show that their overexpression can have prominent prognostic significance in AML patients and therefore should be the subject of further investigation.

ACUTE ANTHRACYCLINE INDUCED CARDIOTOXICITY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

O. Pasvolsky1,*, O. morelli1, U. rozovskii1, M. vaturi1, I. amitai1, I. vaxman1, R. ratzon1, M. yeshurun1, Z. Iakobishvilli1, R. kornowski1, P. raanani1
1Beilinson Hospital, Petach Tikva, Israel

Background: Chemotherapeutic agents are associated with a wide range of cardiotoxic adverse effects. Anthracyclines and related drugs are some of the most implicated agents, with a well-recognized potential for the development of cardiomyopathy and heart failure. Chronic anthracycline induced cardiotoxicity can lead to cardiomyopathy, which may develop several years after treatment. Acute and subacute anthracycline induced cardiotoxicity is considered relatively uncommon, described mostly in patients treated for solid tumors or lymphomas. While anthracycline based regimens have been used to induce remission in newly diagnosed patients with acute myeloid leukemia (AML) for more than four decades, relatively little is known about the acute cardiotoxic effect of anthracyclines in AML setting. Since many of these patients were candidates for hematopoietic stem cell transplantation (HSCT), an intensive intervention usually reserved for fit patients, even transient decrease in cardiac function might render them ineligible for this intervention, or might increase their transplant related morbidity.

Aims: To study the short-term outcomes of anthracycline exposure on cardiac function in patients with AML who are candidates for allogeneic HSCT. Because current AML-induction regimens use anthracyclines (most commonly daunorubicin) at a relatively high dose between 45 and 90mg/m2/day for three consecutive days, we hypothesized that the incidence of post-induction cardiac injury in patients with AML might not be high.

Methods: The medical records of 55 consecutive patients who had received induction chemotherapy and had undergone HSCT in our medical center were reviewed. Patients included in the study were those with echocardiographic data both prior to and post induction therapy. Median age at diagnosis was 59 years (range: 19-73) and 49% were males. Approximately half of the patients had de novo AML (N=29, 53%). 26 patients (47%) had either therapy related AML or AML secondary to a previous hematological disorder. Induction treatment included 7 days of cytarabine at a dose of 100mg/m2/day and 3 days of daunorubicin at a dose of 45mg/m2/day (N=2, 3.6%), 60mg/m2/day (N=34, 61.8%), and 90mg/m2/day (N=15, 27.3%).

Results: Selected patient characteristics are summarized in Table1. Post-induction echocardiogram studies demonstrated a significant cardiac deterioration in left ventricular ejection fraction (EF) (defined as 10% or more absolute decrease from baseline EF) in 25.5% of the patients (N=14). Higher doses (90mg/m2/day) of anthracyclines were associated with a higher risk of cardiac function deterioration (odds ratio: 4.1, 95% confidence interval: 1.06 to 15.7). Patients with cardiovascular risk factors and male patients tended to develop cardiotoxicity at higher rates, whereas age, white blood cell counts at diagnosis and AML type (de novo vs. secondary) had no impact on cardiotoxicity. The decrease in cardiac function was temporary in 10.9% of the patients (N=6) with subsequent normalization of left ventricular EF in those patients.

Table 1.

Summary/Conclusions: The use of daunorubicin at a dose of 60mg/m2/day or less is associated with significantly lower rates of acute cardiotoxicity. Our findings should be taken into consideration when choosing the anthracycline dose, particularly in male patients with cardiovascular risk factors who are candidates for HSCT.
ASSESSMENT OF AMINO ACID DEPENDENCE OF ADULT T-CELL LEUKEMIA / LYMPHOMA (ATL) IN VITRO AND VIVO

AN INTEGER WEIGHTED GENOMIC MUTATION SCORING (IWGMS) USING THE TRUSIGHT MYELOID SEQUENCING PANEL SHOWS HIGHER MORPHOLOGY IN PATIENTS WITH INTERMEDIATE RISK ACUTE MYELOID LEUKAEMIA: A RETROSPECTIVE STUDY

1Internal Medicine, Houston Methodist Hospital, Weill Cornell Medical College, 2Laboratory and Genomic Medicine, Houston Methodist Hospital, 3Hematology, Houston Methodist Cancer Center, 4Baylor Miraca Genetics Laboratories, Baylor College of Medicine, Houston, United States

Background: AML is currently classified by European LeukemiaNet into favorable, unfavorable, and intermediate prognosis based on cytogenetic aberrations. Although favorable and unfavorable categories have good prognostic values, the intermediate category encompasses the majority of patients and offers unclear prognosis. The development of Cancer Genome Atlas (TCGA) opens new windows for the incorporation of next generation sequencing (NGS) into cytogenetics to enhance prognostic risk stratification. However, few studies explore the combination of cytogenetics and NGS in prognostic predictions.

Aims: Here we have developed a system of Integer Weights for the Genomic Mutation Score (IWGMS) for a quantifiable stratification of the prognostic risks associated with a combination of cytogenetic aberrations and genomic mutations. Our next step is validating the scoring system through its application to data obtained from other institutions.

Methods: Patient data at Houston Methodist Hospital was queried from Methodist Environment for Translational Enhancement and Outcomes Research (METEOR), a clinical data warehouse that integrates research databases and national registries. The diagnosis of AML was queried along with patient demographics, cytogenetics, NGS, and OS. The resultant patients were divided into three categories based on their MRC cytogenetic risks: favorable, intermediate, and poor. Using the TruSight Myeloid Sequencing Panel (ILLUMINA), mutations in 54 genes associated with myeloid disorders were tested in NGS. A set of scoring weights was developed that xenografted each of the nine TCGA mutation categories (Transcription- Factor Fusion, Nucleophosmin (NPM1), Tumor Suppressor Genes, DNA-Methylation related genes, Signaling Genes, Chromatin Modifying Genes, Myeloid Transcription Factor Genes, Cohesion complex Genes and Spliceosome-complex genes) a score between -2 (good risk) and +2 (poor risk). The IWGMS for each patient was calculated by the sum of the individual mutation scores. A IWGMS score greater than 3 was considered significant as a poor prognostic factor. Statistical analysis was done using Chi-Square, Mann Whitney U test and multivariate logistic regression analysis.

Results: A hundred of the 1200 AML patients met the criteria for having both cytogenetic and NGS data availability. The two-year mortality rates were 43%, 52%, and 51% respectively for the favorable, intermediate, and poor cytogenetic groups. In the intermediate cytogenetic group, high IWGMS score (>3) was associated with higher mortality when compared to low IWGMS score (80% vs 44%; p=0.045, Fig 1). A look at the gene mutation distribution in the intermediate risk cytogenetic group also showed a general correlation between known favorable gene mutations with low IWGMS scores and unfavorable ones with high IWGMS scores. We thus hypothesized the IWGMS scoring system can be utilized to divide intermediate cytogenetic and lower mortality subgroups based on a combination of cytogenetic and genetic mutations. We expect similar results with data from other institutions.

Figure 1.

Summary/Conclusions: Most studies in current literature focuses on the individual contributions of cytogenetic aberrations or genetic mutations to risk stratification and treatments risk stratification and treatment response. However, prognosis varies widely in the heterogeneous, intermediate cytogenetic class, where 60% of the AML patients belongs. We propose a systematic approach that correlates cytogenetics with genetic mutations in stratifying prognostic outcomes with a focus on the intermediate cytogenetics group. The ability to differentiate in this specific group opens great potentials for targeted therapies and improving outcomes.

E950

SUCCESSFUL IDENTIFICATION OF SPECIFIC AMINO ACID-DEPENDENCE IN ADULT T-CELL LEUKEMIA / LYMPHOMA (ATL) AND PRECLINICAL APPLICATION FOR NEW THERAPY

T. Ishigaki1,2,*, S. Yamazaki3, Y. Taya1, K. Uchimaru4, A. Tojo5, H. Nakamura6,1
1Division of Stem Cell Therapy, 2Department of Laboratory Medicine, Research Hospital, 3Department of Project Division of Advanced Regenerative Medicine, The Institute of Medical Science, The University of Tokyo, 4Laboratory of Tumor Cell Biology, The University of Tokyo, 5Department of Hematology and Oncology, Research Hospital, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan, 6Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, California, United States

Background: Adult T-cell leukemia / lymphoma (ATL) is highly aggressive malignancy caused by human T-cell leukemia virus type 1 (HTLV-1). As leukemia/lymphoma cells are often resistant to combination chemotherapy and recent antibody therapy, new strategies should be developed. Our laboratory recently found that proliferation and survival of hematopoietic stem cells are critically dependent on the amino acid valine (Science, 2016).

Aims: We here aimed to assess amino acid-dependence of lymphoma and leukemic stem cells, and tried to establish a novel therapy by utilizing the differences in amino acid-dependence between normal and leukemic stem cells.

Methods: First, primary ATL cells were sorted from samples of 7 typical acute-type ATL patients by 12-color flow cytometry, and serially passaged on stromal cells. Then passageable ATL cells from 3 patients were transduced with GFP-expressing lentivirus for tracking and counting by image cytometry. Using complete medium and twenty different culture media each lacking a single amino acid, we examined amino acid dependency of ATL cells. Amino acids vital for ATL cells were screened by co-culture with stromal cells. Effects of these media on normal lymphocytes of healthy volunteers were also examined. Finally, the effectiveness of amino acid restriction was evaluated in vivo by xenotransplantation of ATL cells into NOG mice. Mice were fed with different diets lacking specific amino acids at 6 weeks after transplantation, and sacrificed at 10 weeks for analysis of peripheral blood, organs, and lymphoma size.

Results: In vitro studies revealed that ATL cells have dependency on specific amino acids: cysteine, methionine, and valine. As 2-weeks restriction of the former two amino acids damaged stromal cells or normal lymphocytes, valine was picked up for further analysis. Proliferation of ATL cells was dramatically inhibited by valine restriction while the influence on normal cells was limited. Interestingly, valine restriction did not effect a significant change in the proportion of normal CD4+ populations, such as Treg, naive, central memory, effector memory, and effector T-cells. Moreover, 4-week restriction of valine succeeded in eradicating ATL cells in vitro and no recurrence was observed after refilling valine although 2-weeks restriction was insufficient for extermination. In-vivo model also showed that 4-weeks restriction of valine could dramatically reduce ATL tumor size. Valine-depleted diet did not significantly reduce hemoglobin or platelet count, and there were no significant organ damages as far as examined macroscopically.

Summary/Conclusions: We discovered that proliferation and survival of adult T-cell leukemia / lymphoma cells were dependent on valine. ATL cells could be eradicated by 4-weeks of valine in vitro. In-vivo model also showed that the growth of ATL cells was significantly inhibited by dietary restriction of valine. Massive lymphoma cells, which are known to be resistant to antibody therapy, were also vulnerable to the valine restriction. There were no severe complications such as anemia, thrombocytopenia, and organ damages which are often seen in chemotherapy recipients. These data demonstrate that valine restriction may potentially provide a new option for leukemia/lymphoma therapy.
Aims: Since the roles of these SNPs in clinical aspects, response to therapy and prognosis of DLBCL treated with R-CHOP- are still unknown, these were the aims of the present study.

Methods: Our analysis included 168 consecutive DLBCL patients at diagnosis seen at University Hospital from July 2009 to September 2014. Genotypes were identified in DNA of peripheral blood by real-time polymerase chain reaction, using a Taqman SNP Genotyping Assay. Replicates were performed in 10% of the reactions, achieving 100% of concordance. Chi-Square test, Fisher's Exact test, and multivariate analysis, using the logistic regression model, served to assess associations between genotypes and clinical aspects. Kaplan-Meier analysis was used to evaluate the effect of clinical features and genotypes on the cumulative risk of event-free survival of IS and overall survival (OS). EFS and OS were calculated from the date of diagnosis to the first event date (relapse, progression or death by disease) or last seen date and death by any cause or last seen date, respectively. The Cox proportional hazards regression model was used to evaluate the effects of clinical features and genotypes of the above mentioned SNPs on PFS and OS, and the results of analysis were presented as hazard ratios (HRs) with their corresponding 95% confidence intervals (CIs). First, these associations were examined using univariate Cox proportional hazards regression. In a second step, all variables with P<0.10 were included in a multivariate Cox regression. All reported P values were two-sided, and P<0.05 was considered to indicate statistical significance.

Results: Concerning clinical features, the frequency of the wild-type VEGF -1154G allele and VEGF-634G allele were more common in stage II or IV patients. The wild-type VEGFR2 -604TT genotype was more common in high intermediate and high international prognostic index (IPI) patients. Concerning response rate, patients with the wild-type VEGF 936CC genotype was associated with higher complete response (CR). These patients had 2.65 more chances of achieving CR to therapy than others. The median follow-up time of 168 DLBCL patients enrolled in the study was 43 months (range: 1-105). The estimated probabilities of 60-months EFS and OS were 58% and 66%, respectively. At 60 months of follow-up, patients with the variant VEGF 1154A and 936 T alleles had 1.52 and 1.52 more chances of presenting disease relapse or progression, and 1.47 and 1.60 more chances of evolving to death in univariate analysis, respectively. After correction with other classical prognostic factors in DLBCL (IPI and GCB subtype), only the VEGF 1154 G/A SNP was associated with PFS and OS: patients with the variant VEGF 1154 A allele had 1.88 and 1.83 more chances of having an event. Summary/Conclusions: Our data present, for the first time, preliminary evidence that inherited abnormalities in AG pathway, related to the VEGF -1154A/G, -634G4 and 936C/T, and VEGFR2 -604TT/CT, influence clinical features, response to R-CHOP and outcome of DLBCL patients.

THE PROGNOSTIC SIGNIFICANCE OF CD11b+CX3CR1+ MONOCYTES IN PATIENTS WITH NEWLY DIAGNOSED DIFFUSE LARGE B-CELL LYMPHOMA

J.Y. Kwak1, J.-A. Kim2, H.-Y. Yihim1, S.-H. Ko2, Y. Park3

1Internal Medicine, Chonbuk National University Hospital, Jeonju, 2Internal Medicine, Catholic University of Korea, Seoul, 3McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, Korea, Republic Of

Background: Interest in the role of myeloid-lineage cells, including monocytes and their precursors, has been increasing in prognosis of lymphoma. It has been shown that the circulating monocyte count at the time of diagnosis shows prognostic significance in diffuse large B-cell lymphoma (DLBCL), suggesting the role of specific subset of monocyte in prognosis of DLBCL. Recent studies suggest CD11b+ monocytes expressing CX3CR1 promote angiogenesis and suppress anti-tumor immunity through the interaction with fractalkine (CX3CL1), the only ligand for CX3CR1. However, limited data is available regarding the prognostic significance of CD11b+CX3CR1+ monocytes in DLBCL patients.

Aims: The study investigates the prognostic significance of peripheral blood (PB)- and bone marrow (BM)- CD11b+CX3CR1+ monocytes on progression-free survival (PFS) and overall survival (OS) in newly diagnosed DLBCL patients.

Methods: This is a retrospective multicenter study including patients older than 17 years, with a BM and a PET/CT performed simultaneously as part of the routine pre-therapy staging for newly diagnosed DLBCL. Patients had not received either chemotherapy or corticosteroids and no concomitant malignancy was known to be present at the time of both procedures. Only patients treated with R-CHOP as first line therapeutic strategy were included. Only variables that were significant in univariate analysis were included in the multivariate Cox regression for outcome predictors.

Results: A total of 271 DLBCL patients were initially identified; we excluded: 31 patients who received low intensity chemotherapy regimens (R-COP, Mini-CHOP-R, monotherapy with steroids) due to advanced age, comorbidities or detection of clinical signs and symptoms of relapse, 45 patients enrolled in clinical trials including standard regimens plus new agents (Bortezomib, Lenalidomide, Ibrutinib) or non-standard regimens (R-CHOP/14, Da-EPOCH-R, MACOP-B, Mega-CHOP, Hyper-CVAD). In the homogeneously treated (R-CHOP/21) 205 DLBCL patients subset, the median age at diagnosis was 61 y.o. (range 18-85), with a balanced gender distribution (61% females and 39% males). Twenty of these patients (21%) had BM on BMB, whereas 43 (21%) had BM according to PET/CT finding. Fifty-three patients (25.9%) had BM to either BM or PET/CT. Concordant BM by means of both techniques was present in 16 (7.8%) patients. With a median follow-up of 25 months (15-47 months, p25-p75), 50 patients (24.4%) progressed or relapsed and 41 (20%) died. The 3-year estimated progression-free survival (PFS) and overall survival (OS) were 70%, and 78%, respectively. By univariate analysis, factors associated with a shorter PFS, with a p<0.150, were: female gender, IPI3, abnormally elevated B2-microglobulin levels, PET/CT-BMI(+) and BMB-BMI(+). In multivariate analysis only two factors were identified (p<0.05): (1) BMI3 (HR: 3.65, 95CI 1.29-10.00; p=0.015) and (2) BMB-BMI(+) (HR: 2.65, 95CI 1.45-4.89; p=0.015). By univariate analysis, factors predictive of a shorter OS, with a p<0.050, included: female gender, IPI3, abnormally elevated B2-microglobulin levels, PET/CT-BMI(+) and BMB-BMI(+). In multivariate analysis only IPI3 (HR: 2.6, 95CI 1.13-5.14; p=0.006) was independently associated with a shorter OS.

Summary/Conclusions: In our DLBCL cohort, treated with a uniform first-line chemotherapy regimen, BMI by BMB complemented IPI in predicting those patients with a higher risk for relapse or progression, while IPI defined a subset of patients with a worse survival. In this cohort, BMI by PET/CT could not independently predict a shorter PFS and/or OS.
27.7 months (IQR, 14.6–46.1), low PB-CD11b+CX3CR1+ cell group had significantly better PFS (3-year, 77.1% vs 58.7%; P=0.006) and OS (3-year, 86.6% vs 58.4%; P=0.004) than high PB group. No significant survival differences were observed between high and low BM-CD11b+CX3CR1+ cell groups. Uni- 

Summary/Conclusions: Our study represents PB-CD11b+CX3CR1+ monocytes can be used in differentiating patients with high risk for early death and are associated with risk stratification by the NCCN-IPI, possibility of potential therapeutic target in DLBCL.

PRIMARY ANALYSIS OF THE EFFECT OF HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE TREATMENT OF 110 CASES OF T CELL LYMPHOMA

C. Li1,2, D. Yang3, X. Chen4, J. Chen1, T. Wang5, Q. Zou1, C. Gu1, D. Wu1,2
1The First Affiliated Hospital of Soochow University, 2Jiangsu Institute of Hema- tology, 3Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: T cell lymphoma(T-NHL) is a rare and heterogeneous group of lymphoid malignancies with mostly poor outcome with conventional treatment. Recent studies have suggested that Hematopoietic stem cell transplantation(HSCT) has a better curative effect and is superior to traditional chemotherapy.

Aims: To investigate the effect of HSCT in the treatment of T cell lymphoma.

Methods: The clinical data of 110 patients with T cell lymphoma treated by HSCT from January 2006 to August 2016 in our center were retrospectively analyzed.

Results: (1)110 T-NHL patients, 70 males and 40 females, aged 7-64 years (median age 26 years). Disease subtypes: 35 cases of T-cell lymphoblastic lymphoma(T-ALL), 3 cases of subcutaneous panniculitic T cell lymphoma(SPTCL) and 1 case of hepatosplenic T cell lymphoma(HSTCL). Transplantation type: 56 cases of autologous hematopoietic stem cell transplantation (auto-HSCT), 54 cases of allogeneic hematopoietic stem cell transplantation (allo-HSCT). The follow-up was ended in December 2016, the duration of follow-up ranged from 2 to 130 months (median follow-up time was 22 months).

(2)56/110 patients with auto-HSCT, 3 year overall survival (OS) and disease-free survival (EFS) were 76.5% and 60.2%, respectively. (3)36/56 patients with non-CR1 status before auto-HSCT, 3 year OS and EFS were 47.8% and 36.9%. The OS and EFS of the two groups were significantly different (P=0.001). (4)36/56 cases were young and high-risk patients (age≥60 years, IPI score ≥3). 25/54 cases treated with allo-HSCT, 3 year OS and EFS were 61.7% and 58.9%, respectively. (5)45/110 cases were young and high- risk patients (age<60 years, IPI score ≥3). 20/56 patients with non-CR1 status before auto-HSCT, 3 year OS and EFS were 60.6% and 40.2%. The OS and EFS of the two groups were significantly different (P=0.001).

Summary/Conclusions: HSCT can improve the efficacy of T cell lymphoma. Auto-HSCT in first complete remission (CR1) enables T-NHL patients with
greater benefit. Allo-HSCT can cure some T-NHL patients, which can be considered for the treatment of young and high-risk T-NHL patients.

E957
SHORT COURSE OF R-HYPERCVAD/MITX/ARA-C FOLLOWED BY ASCT AS FIRST-LINE THERAPY IN MANTLE CELL LYMPHOMA PATIENTS PROLONGS PROGRESSION FREE SURVIVAL TO MORE THAN 9 YEARS. SINGLE CENTER EXPERIENCE
M. Andrade-Campos1,2,*, S. Mercadal1, E. Domingo Domenech1, V. Paredes Hena1, C. Aguillera Gomez1, A. Oliveira Ramos1, E. de la Banda3, F. Cleriment3, R. Parody Porras1, A. Fernandez de Sevilla1,4, A. Sureda1, E. Gonzalez Barca1,4
1Department of Hematology, Institut Català d’Oncologia Hospitalat, IDIBELL, Barcelona, 2ISCIBER de Enfermedades Raras, CIBERER, ISCIII, Zaragoza, 3Pathology Department, Hospital Universitario de Bellvitge, IDIBELL, 4Department of Clinical Sciences, University of Barcelona, Barcelona, Spain

Background: Mantle cell lymphoma (MCL) is considered an incurable disease with an historical median overall survival around 3-4 years with short progresses free survival (PFS) periods. Regimens that include high dose cytarabine and consolidation with autologous stem cell transplant (ASCT) have become standard therapy for fit patients. The median PFS reported after 4-6 cycles HyperCVAD followed by ASCT consolidation is 4.5 years (Ahmadi et al, BMT 2012). Nevertheless, toxicity is high and many patients cannot obtain stem cells for transplant. In this setting, some groups use 6-8 cycles R-HyperCVAD without ASCT consolidation, achieving the same median PFS of 4.6 years (Romaguer et al, Br J Hematol 2010). Based on this we have reviewed our experience using a short course of HyperCVAD followed by transplant consolidation.

Aims: To analyze our experience treating fit patients with MCL in first line with a short course of 2 cycles of R-HyperCVAD followed by consolidation with ASCT.

Methods: from January 2002 to August 2016, the patients diagnosed with MCL treated in first line with a short course of 2 cycles of R-HyperCVAD and ASCT were included in this retrospective analysis. International working group response assessment criteria were used, PFS was calculated from the date of start therapy until date of relapse/progression or last contact.

Results: During the study period 85 MCL patients were registered: 7 (8.2%) did not receive immediate therapy, 44 (52.4%) were not eligible for intensive therapy due to comorbidities or age and 33 (39.3%) were treated with R-HyperCVAD. Clinical characteristics at diagnosis of these 33 patients were: MIP ratio: 26/7 (78.8%/21.2%), median age: 63 y.o (limits: 40-73), ECOG 0-1: 26 (86.7%), Ann Arbor stage III-IV 28/31 (90.3%), MIPI score: low risk: 5 (16.7%), intermediate risk: 17 (56.7%), high risk: 8 (26.7%). Thirty (90.9%) patients completed the 2 cycles of R-HyperCVAD. Reasons for discontinuation were: 2 deaths for sepsis and 1 CNS progression. Intent to treat response rate was: CR 26 (78.8%), PR 2 (6.0%), progressive disease 3 (9.0%), not evaluable 2 (6.0%). Among the 28 patients in CR / PR considered eligible for consolidation with ASCT, 8 patients were not transplanted: 4 (14.3%) had harvest failure (all before plerixafor availability), 2 had persistent toxicity (prolonged neutropenia and severe mucositis) and were not considered for ASCT, 1 rejected, 1 unknown cause. Conditioning regimen was BEAM/LACE in 18 (90%) patients and cyclophosphamide-TBI in 2 (10%). One patient died 10 days after infusion for sepsis. With a median follow-up of 35 (1-131) months, the median PFS was 21 (95%CI: 21.2-38.9) months (8.08 years) for the whole group, 114 (47.3-180.7) months (9.4 years) for the transplanted patients vs 21 (3.1-38.9) months (1.8 years) for the not transplanted group. The median OS was 123 (47.3-180.7) months (9.4 years) for the transplanted group and 21 (3.1-38.9) months (1.8 years) for the not transplanted patients. The median OS was 123 (47.3-180.7) months (9.4 years) for the transplanted patients and 21 (3.1-38.9) months (1.8 years) for the not transplanted group. The median OS was 123 (47.3-180.7) months (9.4 years) for the transplanted patients and 21 (3.1-38.9) months (1.8 years) for the not transplanted group.

Conclusion: R-HyperCVAD followed by ASCT consolidation is 4.5 years (Ahmadi et al, BMT 2012). Nevertheless, toxicity is high and many patients cannot obtain stem cells for transplant. In this setting, some groups use 6-8 cycles R-HyperCVAD without ASCT consolidation, achieving the same median PFS of 4.6 years (Romaguer et al, Br J Hematol 2010). Based on this we have reviewed our experience using a short course of HyperCVAD followed by transplant consolidation.

Figure 1. Summary/Conclusions: A short course of R-HyperCVAD achieves a very high remission rate in fit patients with MCL. Stem cells could not be obtained in a small proportion of patients, all of them before the use of plerixafor. Two thirds of the patients could complete the planned therapy with ASCT consolidation, and those patients have an excellent outcome, with a PFS of more than 9 years.

E958
THE FREQUENCY OF INCIDENTAL MALIGNANCIES DETECTED BY PET/CT SCANS IN PATIENTS WITH LYMPHOMA AND THE ASSOCIATED CLINICAL IMPLICATIONS
J. Falconer1,*, G. Kidson-Gerber2, E. Wegener2
1Hematology, Concord Repatriation General Hospital, 2Hematology, The Prince of Wales Hospital, Sydney, Australia

Background: PET/CT imaging has a well-established role in the investigation of malignant lymphoma. Given the widespread clinical applications, unexpected findings are occasionally identified. Whilst there is substantial information pertaining to additional primary cancers identified on PET/CT in patients with solid organ malignancy, there is a relative paucity of data in patients with lymphoma.

Aims: The primary aim was to identify the frequency of incidental second malignancies identified by PET/CT scans in patients with lymphoma. Qualitative data related to histological diagnosis and staging, interruptions or obstacles to lymphoma therapy, therapy for the second malignancy and the overall impact upon prognosis were also reviewed.

Methods: A total of 550 PET/CT images were performed in 255 patients at The Prince of Wales Hospital, Sydney Australia between January 2013 – March 2016. Patients with both Hodgkin’s and Non-Hodgkin’s lymphoma, with PET/CT imaging performed for all medicare-approved indications were included. All PET/CT reports suggestive of an incidental second malignancy prompted further review of electronic medical records, MOSAIC cancer database and paper medical records. Where a clear diagnosis of second malignancy was confirmed, information regarding histological findings and staging, as well as the implications of this diagnosis related to treatment of the underlying lymphoma and impact on overall prognosis was collected.

Results: 510 PET/CT scans in 259 patients had confirmed diagnoses of lymphoma. Patients aged 17 to 96 were included in the study, with a median age of 62 years. Of the 259 patients included (M=155; F=104), 55 patients had a diagnosis of Hodgkin’s lymphoma and 204 patients a diagnosis of Non-Hodgkin’s lymphoma. A total of 33 out of 259 patients with a diagnosis of malignant lymphoma had PET/CT findings suspicious for an underlying second malignancy (12.7%). Of the 33 patients, 19 underwent further investigative testing, with a total of 8 patients having a biopsy proven histological diagnosis of a second malignancy (3.1%). Qualitative information was gathered regarding the patients who did not have further investigation.

Summary/Conclusions: The frequency of incidental malignancies detected by PET/CT imaging in patients with lymphoma was found to be comparable to other similar international retrospective studies. The majority of incidental second malignancies were early stage and gastrointestinal in origin. Further retrospective as well as prospective data may assist in the establishment of guidelines, to address a standardized diagnostic approach to investigating incidental lesions discovered on PET/CT imaging that are suggestive of a second malignancy.

E959
CLINICAL IMPACT OF KARYOTYPIC EVOLUTION ON THE PROGNOSIS OF DIFFUSE LARGE B CELL LYMPHOMA
Y. Mizuno1, T. Kobayashi1, N. Uoshima1, E. Kawata2, H. Uchiyama3, Y. Chinen1, S. Horike1, J. Kuroda1
1Hematology, Kyoto Prefectural University of Medicine, 2Hematology, Japanese Red Cross Kyoto Daini Hospital, 3Hematology, Japanese Red Cross Kyoto Daichi Hospital, Kyoto, Japan

Background: The acquisitions of additional chromosomal abnormalities are generally accompanied by the emergence of therapeutic resistance and eventually lead to poor treatment outcome in cancers. However, the actual clinical impact of karyotypic evolution on prognosis differs depending on the type of hematologic malignancy. Although several prognostic indexes, including the International Prognostic Index (IPI), revised IPI (R-IPI), National Comprehensive Cancer Network (NCCN)-IPI, and Kyoto Prognostic Index (KPI) which we have developed (Kobayashi T. Blood Cancer J 2016), have the determinants of non-Hodgkin lymphoma, there is a relative paucity of data in patients with lymphoma.

Aims: We in this study investigated the clinical impact of karyotypic evolution on the treatment outcome of DLBCL.

Materials and Methods: We retrospectively analyzed the medical records of 465 DLBCL patients who were diagnosed and treated with either rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone (R-CHOP) or with a R-CHOP-like regimen at three independent institutes in Kyoto, Japan, between January 2006 and April 2014. We analyzed the relationship between the number of subclones and prognosis utilizing the Kaplan-Meier curve and Cox proportional hazards regression analysis. We also utilized Fisher’s exact test to investigate the correlation between the number of subclones and the conventional prognostic indexes, i.e. R-IPI, NCCN-IPI, and KPI. This study was conducted in accordance with the ethical principles of the Declaration of Helsinki.
and was approved by the institutional review boards of all participating institutions.

**Results:** Among the 465 DLBCL cases, karyotypic analyses by G-banding were performed on biopsied tumor specimens before the start of treatment in 181 patients. Among the 181 patients, metaphase spreads were available for G-banding in 120 patients. Neither overall survival (OS) nor progression free survival (PFS) was statistically significantly different between the patients with available metaphase and no available metaphase spreads. Based on the result of G-banding, we next divided the 120 patients with available metaphase spreads into two groups, i.e., patients with karyotypic abnormalities accompanied by ≥2 subclones and patients with 0-1 subclones. We found that the presence of ≥2 subclones was significantly associated with poor OS (3 year OS rates of patients with ≥2 subclones and 0-1 subclones were 67.6% and 82.8%, respectively (p=0.035), and tended to associate with a shorter PFS. Among the 120 patients with available metaphase spreads, the R-IPI-defined high-risk patients and IPI-defined high-risk patients were significantly more frequent in the group of patients with ≥2 subclones. Ages and genders were not significantly different between patients with ≥2 and with 1-2 subclones.

**Summary/Conclusions:** DLBCL is a cytogenetically and molecularly heterogeneous disease entity. Specific chromosomal abnormalities have been associated with the shorter survival, except double or triple hit lymphomas. However, in this study, it was possible to divide DLBCLs into two groups based on karyotypic evolution, i.e., DLBCLs with 0-1 subclones and with ≥2 subclones, because the OS was the most markedly different between these two groups. In our study, more subclones were associated with poor prognosis, suggesting the significance of karyotypic evolution in DLBCL. In conclusion, our study suggests that more advanced cytogenetic clonal evolution underlies the development of high-risk disease feature in DLBCL.

**REGIMENT INTENSIFICATION MAY IMPROVE OUTCOMES IN PATIENTS WITH HIGHER RISK HUMAN IMMUNODEFICIENCY VIRUS (HIV) RELATED AGGRESSIVE B-CELL LYMPHOMAS**

1Department of Internal Medicine, University of South Florida Morsani College of Medicine, Tampa, 2Hematology Oncology, Mercy Clinic Oncology and Hematology, Joplin, 3Malignant Hematology, 4Bone Marrow Transplant, H.Lee Moffit Cancer Center & Research Institute, Tampa, 5Malignant Hematology, George Washington Cancer Center, Washington D.C., United States

**Background:** Despite effective combination antiretroviral therapy for HIV, there remains an increased incidence of HIV related B-cell Non-Hodgkin lymphomas (NHL). The introduction of early antiviral therapy and effective chemotherapy have led to improved outcomes overall. Regimen intensification (RI) in HIV associated B-cell NHLs has shown improved survival, especially in the rituximab era (Barta et al, Blood 2013).

**Aims:** To examine the effect of RI on the overall survival (OS) and progression free survival (PFS) compared to CHOP based chemotherapy according standard risk stratification.

**Methods:** Patients with HIV associated aggressive B-cell NHL were identified between 2001- 2015 at Moffitt Cancer Center. Patients with primary central nervous system lymphoma, T-cell NHL and indolent NHLs were excluded. Patients received R-CHOP or intensive chemotherapy (IC) including DA-EPOCH, hyperCVAD or CODOX/IVAC as initial treatment. Data collected included age, gender, demographics, disease baseline characteristics, CD4 count, HIV viral load, treatment regimen, response, and outcomes including relapse and OS. The IPI score was calculated, and patients were divided into two groups: lower risk group (low and low-intermediate IPI risk) and higher risk group (high-intermediate and high). Descriptive statistics were used for baseline characteristics. Kaplan Meier method was used to estimate PFS and OS, and the log-rank test was used to compare OS and PFS between lower and higher risk groups.

**Results:** A total of 83 patients were included. The M:F ratio was 9.4. Median age was 45 years (y) (range 25 – 65). Two thirds of patients were Caucasian. The median time from HIV to NHL diagnosis was 29 months (range 0 – 284). Eighty two percent presented with stage III/IV disease. Bulky disease was present in 27%, elevated LDH in 66%, and CD4 count<100/µL at diagnosis in 22% patients. Fifty percent of patients were on HAART therapy at time of lymphoma diagnosis (DFS). Chemotherapy regimens included: R-CHOP (n=30, 36%), CHOP (n=12, 15%), DA-EPOCH-R (n=27, 33%), DA-EPOCH (n=1, 1%), hyperCVAD (n=11, 13%) and CODOX/IVAC (n=2, 2%). The median follow up was 2.7 y (95% CI 2.0-3.4). The median OS and PFS for the whole cohort was 5.9 and 4 y, respectively. The median OS was 4 y (95% CI 1.5-6.5) for patients who received CHOP based regimen and was not reached (NR) for patients who had IC (p=0.44). Based on the IPI, the median OS was NR for the lower risk group compared to 1.8 y in higher risk group (p=0.025). Among patients who received CHOP, the median OS for those with lower risk disease was NR compared to 1.8 y in patients with higher risk disease (p=0.2). Among patients who received CHOP, the median PFS for those with lower risk disease was NR compared to 1 y in patients with higher risk disease (p=0.05). For patients who received IC, the median PFS was NR among lower and 1.4 y higher risk groups (p=0.34).

**Summary/Conclusions:** The IPI score remains prognostic in HIV related B-cell NHLs. There was a trend for improved OS and PFS using IC regimens. CHOP treatment remained associated with worse outcome among higher risk patients while IC regimens may overcome the higher risk factors based on the IPI.

**E961**

**EPSTEIN-BARR VIRUS LATENT MEMBRANE PROTEIN 1-MEDIATED OVEREXPRESSION OF MYC AND BCL2 CAN PREDICT POOR PROGNOSIS IN PATIENTS WITH EXTRANODAL NK/T-CELL LYMPHOMA, NASAL TYPE**

J.-H. Wang1, X.-W. Bi2, Z.-J. Xia1, W.-Q. Jiang2, H.-Q. Huang2, L. Wang1

1Hematologic Oncology, 2medical oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

**Background:** Recently double-hit lymphoma or double protein expressor lymphoma has been identified as a distinct group of diffuse large B cell lymphoma with poor prognosis. However, the expression status, clinical and prognostic effect of combined overexpression of MYC and BCL2 in extranodal NK/T-cell lymphoma, nasal type (ENKTL) are not known.

**Aims:** This study aims to explore the clinical and prognostic effect of combined overexpression of MYC and BCL2 in ENKTL.

**Methods:** Paraffin-embedded lymphoma samples from 53 patients with newly diagnosed ENKTL were studied using immunohistochemistry for MYC and BCL2, and fluorescent in situ hybridization (FISH) for MYC and BCL2 were done on 5 tissue sections with highest percentages of both MYC and BCL2 positive lymphoma cells.

**Results:** The median percentage of MYC-positive lymphoma cells and BCL2-positive lymphoma cells were 20% (range, 5% -45%) and 70% (10% -95%), respectively. Using median scores as cutoffs, we assigned each patient an IHC double-hit score (DHS) that ranged from 0 to 2. Using this DHS, 15 patients (28.3%) had a DHS of 0, 24 patients (45.3%) had a DHS of 1, and the remaining 14 patients (26.4%) had a DHS of 2. FISH analysis was performed on 5 tissue sections with DHS of 2, and none of them had MYC or BCL2 rearrangement. The DHS was not associated with patients’ age, gender, disease stage, LDH level, B symptoms, performance status, or local tumor invasiveness. However,
patients with tumor localized in extranodal sites seemed to have higher expression of BCL2 and higher DHS than nasal lesions (P=0.014 and 0.042, respectively). In univariate survival analysis, either high expression of MYC or BCL2 was significantly correlated with inferior PFS and OS (P<0.05). According to the DHS, patients with ENKTL could be divided into three significantly different risk groups for PFS and OS (3-year PFS rate for DHS 0, 1, and 2 was 60%, 41%, and 21%, respectively, P=0.008; 3-year OS rate for DHS 0, 1, and 2 was 79%, 49%, and 33%, respectively, P=0.015). In multivariate survival analysis, it was found that DHS was an independent prognostic factor for both PFS and OS (P=0.006 and 0.011, respectively).

Summary/Conclusions: Our study demonstrated that DHS can help identify patients with newly diagnosed ENKTL who are at a high risk for a poor clinical outcome, which needs to be validated in prospective clinical trials with patients treated uniformly.

E962
SOLUBLE INTERLEUKIN-2 RECEPTOR AS A PREDICTIVE MARKER FOR SPONTANEOUS REGRESSION OF OTHER IATROGENIC IMMUNODEFICIENCY-ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS: A RETROSPECTIVE STUDY
1Department of hematology and Clinical Immunology, Yokohama City University Graduate School of Medicine, 2Department of Hematology, Yokohama City University Medical Center.

Background: Patients treated with immunosuppressive drugs (ISD) for autoimmune diseases are at an increased risk of developing other iatrogenic immunodeficiency-associated lymphoproliferative disorders (OI-LPD). Some patients with OI-LPD shows spontaneous regression after withdrawal of ISD, but some require chemotherapy. The factors that are associated with spontaneous regression and outcomes of chemotherapy remain uncertain.

Aims: The aims of our retrospective study are to assess the clinical factors that predict spontaneous regression of lymphoma after ISD withdrawal in patients with OI-LPD and to evaluate the outcomes of patients who underwent chemotherapy without spontaneous regression.

Methods: We collected data from all patients with autoimmune disease who were pathologically diagnosed with OI-LPD between January 2002 to October 2016 at Yokohama City University Hospital, and Yokohama City University Medical Center.

Results: The patients included 12 males and 28 females, with a median age at diagnosis of 65 years (range 30-81). Methotrexate (MTX) was administered to all patients at any point of the clinical course before OI-LPD. The median time from diagnosis of autoimmune disease to OI-LPD development, and the median duration of MTX administration were 12 months (range 1-564), and 129 months (range 11-564), respectively. The histological findings of OI-LPD showed the appropriate cut-off of sIL-2R levels to be 2400 U/mL for predicting spontaneous regression in patients with OI-LPD. Because CR rates with chemotherapy in patients without spontaneous regression are low, evaluation of sIL-2R in patients with OI-LPD may be useful for an early withdrawal of ISD, resulting in a higher chance of spontaneous regression.

E963
PROGRAMMED DEATH-1 PROTEIN EXPRESSION AND ITS RELATION WITH HISTOLOGICAL AND CLINICAL VARIABLES IN MYCOSIS FUNGOIDES
C. Vasquez1, S. Novelli2,*, A. Mozos1, P. Garcia Muret3, A.C. Caballero2, J. Sierra2, J. Briñes2
1Pathology, 2Hematology, 3Dermatology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Mycosis fungoides (MF) is a T-cell malignancy with affinity for the skin. In early stages, treatment directed to the skin can induce long-lasting remissions. However, advanced stages are characterized by short-duration remissions and progressive disease. The programmed death cell surface protein-1 (PD-1) is expressed on activated T cells. Interactions between PD-1 and its ligands control the induction and maintenance of peripheral T-cell tolerance during the normal immune response. These interactions may also play a role in the immune evasion of tumors in which PD-1 ligand is overexpressed.

Aims: To described histologic characteristics and the proportion and intensity of PD1 expression by tumor cells, as well as the presence of PD1 positive lymphocytes in the epidermis in patients with MF. To identify histologic variables that might have an impact in clinical outcome.

Results: Methotrexate (MTX) was administered to all patients at any point of the clinical course before OI-LPD. The median time from diagnosis of autoimmune disease to OI-LPD development, and the median duration of MTX administration were 12 months (range 1-564), and 129 months (range 11-564), respectively. The histological findings of OI-LPD showed the appropriate cut-off of sIL-2R levels to be 2400 U/mL for predicting spontaneous regression in patients with OI-LPD. Because CR rates with chemotherapy in patients without spontaneous regression are low, evaluation of sIL-2R in patients with OI-LPD may be useful for an early withdrawal of ISD, resulting in a higher chance of spontaneous regression.

Methods: Histological preparations of 85 patients diagnosed with MF were evaluated. Survival analysis was performed with the Kaplan-Meier method. A univariate analysis was performed with clinical variables (stage and age) and anatomopathological variables (i.e. intensity of the inflammatory inflamma-
trate, epidermotropism, cellular atypia, tumor density, presence of folliculotro-
pism and phenotypic alterations) and the proportion and intensity of PD1
expression by tumor cells, the presence of PD-1 positive lymphocytes in the
epidermis. Likewise, a Pearson correlation analysis was performed between
the degree of atypia and the ratio of PD-1 expression, PD-1 intensity, and loss
of CD7 expression in tumor cells. Statistical analysis was performed using the
IBM SPSS Statistics version 21.0.

Results: The median follow-up was 125 months (range 6-450 months).
Characteristics of patients are in table 1. The overall survival (OS) at 10 years was
81%. OS in the early stages was 85% vs. 64% in advanced stages (p<0.05).
The OS for patients <60 years was 85%, and 75% for patients ≥60 years
(p=0.05). Regarding istologic findings, the degree of atypia was the only variable
that had an impact in OS.(see Figure 1) The presence of atypia grade 1 had an
OS of 88%, grade 2 of 75%, and grade 3 of 50% (p=0.05). We performed a
correlation analysis between degree of atypia and the ratio of PD-1 expres-
sion, PD-1 intensity, and loss of CD7 expression. A positive correlation was
detected, however it was weak (r<0.5).

Summary/Conclusions: MF tumoral cells express PD-1 protein in a high pro-
portion of cases being a potential therapeutic target. Advanced disease, age ≥60
years and the degree of atypia of the tumoral infiltrate had an impact on survival.

---

E964
CIRCULATING MICRONRNAS AS BIOMARKERS IN DIFFUSE LARGE
B-CELL LYMPHOMA: A PILOT PROSPECTIVE LONGITUDINAL CLINICAL
STUDY
C. Boyry1, A. Wannez2, C. Chatelain1, J.-M. Dogne1
1Department of Pharmacy, University of Namur, Namur, 2CHU UCL Namur, Université Catholique de Louvain, Yvoir, Belgium

Background: Diffuse large B-cell lymphoma (DLBCL) is highly heterogeneous
in terms of phenotype and treatment response in patients. These characteristics
make its prognosis difficult to establish and hinder the use of new personalized
treatments in clinical practice. In this context, there is currently a necessity to
define new biomarkers enabling a better definition of DLBCL subtypes, prog-
nosis evaluation and an overview of the resistance to chemotherapeutics. We
decided here to focus on circulating microRNAs that are found in all biological
fluids. This accessibility makes them good candidates for biomarkers studies.

Aims: This research aims at studying microRNAs found in plasma from DLBCL
patients and at investigating their potential as biomarkers of survival in these
patients. For this purpose, a plasma biobank was created with samples from
DLBCL patients at different times of their treatment. This follow-up of microR-
NAS level during the course of treatment is particularly innovative in this study.

Methods: A plasma biobank from DLBCL patients was set up at the Centre
Hospitalier Universitaire (CHU) UCL Namur Yvoir, Belgium (ethical agreement
number B039201419613). Informed consents of all patients were obtained. In
this way, blood samples from patients were taken before any treatment (C0), at
the administration of the second and the fourth chemotherapeutic cure (C2) and
C4) and at the remission review (C5). In the case of an autograft, a sample was
taken at the post-graft review (Cpg). The first step of this study was the selection
of the microRNAs that will be quantified in all the samples of the biobank and
that would potentially be used as biomarkers. To this end, a quantification of
377 microRNAs was performed by TaqMan® Low Density Array on the plasma
samples of two selected DLBCL patients and one healthy donor with no history
of cancer. These DLBCL patients were selected based on their highly different
response to treatment. One of them obtained a complete remission after a
R-
CHOP treatment, while the other presented a refractory disease to the same
treatment. Thereafter, we determined some criteria to use in a scoring system
to evaluate their potential as biomarkers. In this way, one point was given to a
microRNA each time it meets the criteria enabling it to be defined as a potential
diagnostic, prognostic and/or remission biomarker, biomarker of a disease pro-
gression, biomarker of an inherent resistance to treatment, and/or biomarker of
an acquired resistance to treatment.

Results: On the 377 microRNAs quantified into the plasma of the 3 selected
donors (2 DLBCL patients and 1 healthy donor), 81 microRNAs were detected.
Three microRNAs obtained the highest score of 5 points: miR-197, miR-20a and
miR-451. Four points were attributed to miR-122, miR-19b and miR-19a.
Two additional microRNAs were also selected: let-7e, for its prognostic value
at C0, C2 and C4 and miR-21, for its numerous citations in the literature.

Summary/Conclusions: miR-197, miR-20a, miR-451, miR-122, miR-19a, miR-
19b, let-7e and miR-21 have been selected in this study and are currently quan-
tified in the plasma of the entire biobank. Since then, 19 patients have been
included in the study and the potential of these microRNAs as biomarker are
statistically evaluated.

E965
COMBINED CHEMOTHERAPY PLUS RADIATION THERAPY IS MORE
EFFECTIVE IN LIMITED-STAGE DIFFUSE LARGE B-CELL LYMPHOMA OF
THE TONSIL
S.-N. Lim1,2
1Internal Medicine, Haeundae Paik Hospital, Busan, Korea, Republic Of

Background: Primary extranodal non-Hodgkin’s lymphomas of the head and
neck account for 10-20% of all non-Hodgkin’s lymphomas. Primary tonsillar
lymphoma accounts for less than 1% of head and neck malignancies, although
the tonsil is the most common primary extranodal site of head and neck non-
Hodgkin’s lymphomas.

Aims: The purpose was to evaluate the prognostic factors and treatment out-
come of patients with diffuse large B-cell lymphoma (DLBCL) of the tonsil.

Methods: In all, 114 patients with DLBCL of the tonsil with stage I or stage II,
treated at multicenter in Korea, from September 1995 to April 2011, were includ-
ed. The median age was 59 years and the majority of patients (61%) were male.
Systemic symptoms were present in 6% of patients. International prognostic
index (IPI) score was 0 in 54 patients (48%), 1 in 40 (35%), 2 in 14 (12%),
and 3 (3%). Ten patients (8%) showed elevated level of lactate dehydrogenase
(LDH). Treatment consisted of a combination of chemotherapy (CTx) and radio-
therapy (RTx) for 38 patients (34%) and 72 patients (65%) received CTx only.
Among those receiving RTx, the median RTx dose was 39 Gy.

Results: After median follow-up of 32 months (range 0.4-106 months), event
free survival (EFS) and overall survival (OS) were 25.9% and 42.5%, respect-
ively. Significant prognostic factors included: age (≥ 60 year-old vs <60 year-
old), LDH level (> upper normal limit and ≤ upper normal limit), IPI score (0-1
vs 2-3), and treatment (CTx plus RTx vs CTx only). On multivariate analysis, LDH
disease (hazard ratio [HR], 10.522; 95% confidence interval [CI], 2.548-43.449,
p<0.001) and treatment (HR, 12.393; 95% CI 2.151-71.410) were independent
prognostic factor of EFS and age (HR, 8.920; 95% CI 1.089-73.053, p=0.043),
LDH (HR, 8.316; 95% CI 1.914-36.127, p=0.005), and treatment (HR, 8.943;
95% CI 1.089-73.425) retained statistical significance in OS.

SEQUENTIAL TREATMENT WITH BENDAMUSTINE, RITUXIMAB AND
DEXAMETHASONE FOLLOWED BY RITUXIMAB CONSOLIDATION AND
LENALIDOMIDE MAINTENANCE FOR FRAIL ELDERLY PATIENTS WITH
AGGRESSIVE B-NON HODGKIN LYMPHOMA
1L. Mettvier1, A. Bruno1, R. Bianco1, S. Annunziata1, R. Fontana1, B. Serio1, C. Martorelli1, R. Guariglia1, R. Rosamilio1, B. Marcelli Graziosi1, C. Selleri1,2
1Hematology, AOU San Giovanni di Dio e Ruggi D’Aragona, Salerno, Italy
2Department of Pharmacy, University of Salerno, Italy

Background: Frail elderly patients with aggressive B non-Hodgkin Lymphoma
(a-B-NHL) in most cases show comorbidities such as to preclude the use of
anticlycine-based standard regimen. Although significant advances have
recently been achieved in the therapy of older patients with a-B-NHL, there is
still need for treatment strategies able to overcome the impact of drug toxicity
in elderly frail patients.

Aims: The safety and efficacy of bendamustine and rituximab plus dexamethas-
one (RD-Bena) regimen were prospectively investigated in 14 elderly and
frail patients with newly diagnosed a-B-NHL.

---

E968
Abstract withdrawn.
Methods: Fourteen (4 female, 10 male) consecutive frail elderly patients (mean age: 79 years; range 68–86 years) with a B-NHL (11 DLBCL, 1 Burkitt NHL, 1 Burkitt-like NHL and 1 Mantle cell lymphoma) were enrolled in a phase II study with bendamustine 70mg/m² i.v. on days 1 and 2, rituximab 375mg/m² i.v. on day 1and oral dexamethasone 20mg total dose on days 1-4 for four cycles. Frailty criteria were age > or =80 years, or age > or =70 years associated with 1 or more comorbidities or at least one grade 3-4 toxicity according to the cumulative illness rating scale (CIRS), as well as not self-sufficient or the presence of geriatric syndromes.

Results: Patients who showed complete (CR) or partial response (PR) after the fourth induction cycle of RD-BENDA started a consolidation course with four weekly doses of rituximab (375mg/m² i.v.) followed, in the case of persistency of CR or PR, by a maintenance treatment with monthly courses of lenalidomide (10mg/m², days 1-21). All patients performed G-CSF prophylaxis to avoid febrile neutropenia. Patients with progressive disease after RD-BENDA started maintenance treatment with monthly courses of full dose lenalidomide. PEM index (L3-SMI) and those determined by pectoralis muscle SMI (PM-SMI) were used for the assessment of the therapy response after RD-BENDA induction course and after rituximab consolidation. After a median follow-up of 6 months (range 2-18), the overall response rate was 81%, with CR and PR of partial response rates of 63 (n=7) and 21% (n=2) respectively. Two patients died due to multiple organ failure and disease progression after 1 and 3 months from diagnosis, respectively. In our frail 80+ elderly patient cohort, the sequential treatment strategy was well-tolerated. After R-BENDA cycles, grade II infectious disease was observed in 2/11 patients (18%) and DNA-CMV reactivation was detected in other 2 additional patients (18%). However, 2 out of five patients who started maintenance lenalidomide treatment discontinued therapy for renal and hematological grade 3 toxicity. At the time of analysis, the estimated median 18-month progression free survival (PFS) and overall survival (OS) were 75 and 66%, respectively.

Summary/Conclusions: Our preliminary data show that sequential treatment with RD-BENDA followed by four weekly doses of rituximab and finally by lenalidomide maintenance is a feasible and safe therapy option in frail elderly a-B-NHL patients, but needs to be assessed in a larger subsequent trial.

E968
CLINICAL RELEVANCE OF SARCOPENIA IN DIFFUSE LARGE B-CELL LYMPHOMA - TWO ARE BETTER THAN ONE
S.-I. Go1, M.J. Park2, G.-W. Lee2*
1Internal Medicine, 2Radiology, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of

Background: Sarcopenia is known to be associated with poor clinical outcome in patients with diffuse large B-cell lymphoma (DLBCL). There is no consensus concerning the optimal method to define sarcopenia in DLBCL.

Aims: In this study, given the uncertainty about the optimal SMI to define clinically meaningful sarcopenia in DLBCL, we compared the characteristics and clinical outcome between sarcopenic patients determined by L3 skeletal muscle index (L3-SMI) and those determined by pectoralis muscle SMI (PM-SMI) who were treated with standard of care R-CHOP therapy. Furthermore, the synergistic role of L3- and PM-SMIs as prognostic markers was also investigated.

Methods: We retrospectively reviewed 193 DLBCL patients treated with rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) therapy. Sarcopenia was classified by the region where the pretreatment skeletal muscle index (SMI) was measured.

Results: Both the sarcopenia-L3 and sarcopenia-pectoralis muscle (PM) groups had increased incidences of severe treatment-related toxicities and treatment discontinuation compared with the non-sarcopenia-L3 and non-sarcopenia-PM groups, respectively. The sarcopenia-L3 and non-sarcopenia-L3 groups had 5-year overall survival (OS) rates of 40.5% and 67.8% (p=0.001), respectively. The sarcopenia-PM and non-sarcopenia-PM groups had 5-year OS rates of 35.9% and 69.0% (p<0.001), respectively. When the sarcopenia-L3 alone and sarcopenia-PM alone groups were compared, there were no differences in baseline characteristics, treatment toxicity, or survival. In multivariate analysis, when compared with the non-sarcopenia-both group, OS was significantly worse in the sarcopenia-both group (HR, 2.480; 95% CI, 1.284-4.792; p=0.007), but not in patients with either sarcopenia-L3 alone or sarcopenia-PM alone (p=0.151).

Summary/Conclusions: L3- and PM-SMIs are equally useful to define sarcopenia, which is related to intolerance to R-CHOP therapy and to worse survival in patients with DLBCL. More prognostic information can be obtained when these two SMIs are combined to define sarcopenia.

E969
INTENSIFIED TREATMENT REGIMENS IMPROVE EVENT-FREE AND OVERALL SURVIVAL IN YOUNGER NEWLY DIAGNOSED HIGH-RISK PATIENTS WITH B-LARGE CELL LYMPHOMA: A PROSPECTIVE OBSERVATIONAL STUDY OF KROHEM
S. Basic-Kinda1,*, M. Lucijanic2, I. Hude1, Z. Prka1, Z. Mitrovic1, I. Radman1, T. Valkovic3, D. Radic-Kristo4, D. Lozi3, D. Nemer5, V. Peljza6, I. Aurer1
1Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, 2Division of Hematology, Department of Internal Medicine, University Hospital Dubrava, Zagreb, 3Division of Hematology, Department of Internal Medicine, University Hospital Centre Rijeka, 4Medical School, University of Rijeka, Rijeka, 5Division of Hematology, Department of Internal Medicine, University Hospital Merkur, Zagreb, 6Medical School, University of Osijek, Osijek, 7Division of Hematology, Department of Internal Medicine, University Hospital Centre Split, Split, 8KroHem, University of Zagreb, Zagreb, Croatia

Background: Standard therapy for newly diagnosed B-cell large lymphoma (B-LCL) is R-CHOP. Patients with high-risk disease have unsatisfactory outcome, and randomized trials have suggested that intensified regimens, such as R-CHOEP14 and DA-R-EPOCH, improve treatment results in younger patients.

Aims: We performed this analysis to compare response rates, event-free (EFS) and overall survival (OS) rates of newly diagnosed patients with high-risk disease treated with R-CHOEP21 and more intensive regimens (R-CHOEP14 and DA-R-EPOCH).

Methods: Outcomes of B-LCL patients younger than 60 with aIPI ≥2 treated at two different centres with R-CHOEP14 and DA-R-EPOCH were collected retrospectively from patient files and compared to outcomes of patients with same characteristics treated with R-CHOEP21 from the registry of KroHem, the Croatian Cooperative Group for Hematologic Diseases. All three regimens were administered according to standard guidelines for 6-8 cycles. Patients in PR or with initial bulky disease were irradiated after the end of systemic treatment. Twelve patients treated with DA-R-EPOCH were autografted in 1st remission.

Results: 54 patients were treated with R-CHOEP21, 40 with R-CHOEP14 and 22 with DA-R-EPOCH. R-CHOEP14 and DA-R-EPOCH treated patients did not differ in response rates, EFS and OS and were grouped together for further analysis. R-CHOP treated patients had less frequently bulky disease (25% vs 49%, P=0.007) than more intensively treated patients; there was no difference in age, gender, stage, elevated LDH or PS ≥2. Patients receiving R-CHOP had similar response rates as those receiving more intensive regimens (80% vs 85%, P=0.405), but inferior EFS (HR 2.12, 95% CI [1.09-4.12], P=0.028) and OS (HR 2.15, 95% CI [1.07-4.3], P=0.034) (Figure 1). 5-year EFS rates were 38% and 78% and 5-year OS rates 50% and 80% for R-CHOEP21- and more intensively treated patients, respectively. Differences in outcomes between R-CHOP and intensified regimens remained significant in a multivariate Cox regression model adjusted for age, gender and presence of bulky disease (HR 2.45, 95% CI [1.15-5.4], P=0.026 for OS and HR 2.46, 95% CI [1.16-5.24], P=0.019 for EFS).

Figure 1.
Summary/Conclusions: Our data suggests that the addition of etoposide to R-CHOP and increase in dose-intensity improves EFS and OS of younger patients with newly diagnosed high-risk B-LCL. R-CHOP14 and DA-R-EPOCH seem to be similarly effective in this setting.

E970
HIGH COMORBIDITY INDEX ALONG WITH HIGH NCCN-IPI STRONGLY INFLUENCE SURVIVAL OF DIFFUSE LARGE B CELLS LYMPHOMA PATIENTS: SERBIAN LYMPHOMA GROUP EXPERIENCE

I. Jelčić1,‡, D. Antić2, M. Todoric Balint3, B. Andjelic2, O. Marković3, I. Petković4, V. Nikolić2, J. Bila2, V. Djurasinović3, A. Sretenović1, V. Vuković1, M. Smiljančić1, S. Sretenović2, B. Minjačević2, I. Aurer16, I. Petković4, V. Nikolić2, J. Bila2, V. Djurasinović3, A. Sretenović1, V. Vuković1, M. Smiljančić1, S. Sretenović2, B. Minjačević2, I. Aurer16, I. Petković4, V. Nikolić2, J. Bila2, V. Djurasinović3, A. Sretenović1, V. Vuković1, M. Smiljančić1, S. Sretenović2, B. Minjačević2, I. Aurer16, I. Petković4, V. Nikolić2, J. Bila2, V. Djurasinović3, A. Sretenović1, V. Vuković1, M. Smiljančić1, S. Sretenović2, B. Minjačević2, I. Aurer16

Background: A few studies have validated the prognostic significance of the NCCN International Prognostic Index (NCCN-IPI) so far. However, some patients with low risk according to NCCN-IPI have poor survival, and thus clinical parameters, that might better characterized patients within risk groups, need to be explored.

Aims: The aim of this study was to evaluate prognostic significance of current indexes such as International Prognostic Index (IPI), NCCN-IPI, and the influence of comorbidities on the overall survival (OS) of patients with newly diagnosed diffuse large B cell lymphoma (DLBCL).

Methods: A total of 708 patients (383 males/345 females) with the median age of 58 years (range 18-89) were included in the study. Majority of patients received R-CHOP (Rituximab, Cyclophosphamide, Doxorubicin, Vincristine, Prednisone) protocol, 652 (92.1%), while 29 (4.1%) received R-EPOCH (Rituximab, Etoposide, Cyclophosphamide, Doxorubicin, Vincristine, Prednisone), and 27 (3.8%) received R-CVP (Rituximab, Cyclophosphamide, Vincristine, Prednisone).

Results: According to the Ann Arbor classification, stage I and II had 332 patients (46.9%), while stage III and IV had 376 patients (53.1%). Bulky disease was present in 201 patients (28.4%), and B symptoms in 437 patients (61.7%). Poor European Cooperative Oncology Group (ECOG) performance status (≥2) had 201 patients (28.4%), and B symptoms in 437 patients (61.7%). At least one comorbid condition had 309 patients (43.6%), while high Charlson Comorbidity Index (CCI) had 44 patients (6.2%). Majority of patients had cardiovascular disorders (223, 31.5%), endocrinological (63, 8.9%), neuro- (20, 2.8%), reumatological (20, 2.8%), previous malignancy (19, 2.7%), pulmonary (18, 2.5%), psychiatric (13, 1.8%), nephritic (8, 1.1%), autoimmune (6, 0.8%), and other (13, 1.8%). According to IPI, low, low intermediate, high intermediate and high risk had 332 patients (46.9%), 174 (24.6%), 132 (18.6%), and 37 (5.1%), respectively, while according to NCCN-IPI, 133 (19.6%) patients had low risk, 335 (47.3%) low intermediate, 198 (28.0%) high intermediate, and 36 (5.1%) high risk. Overall treatment response (ORR) was achieved in 615 patients (86.9%). Disease relapse was confirmed in 116/615 patients (18.9%). The patients with B symptoms (Log Rank=12.50, p<0.0001) and bulky disease (Log Rank=14.79, p<0.0001) had inferior OS compared to those without B symptoms or bulky disease. All parameters incorporated in IPI, as well as in NCCN-IPI, were significantly associated with OS (p<0.01). Moreover, the patients with at least one comorbidity had inferior OS (Log Rank=5.41, p=0.20), as well as those with high CCI ≥2 (Log Rank=7.59, p=0.006). Regarding OS, IPI (Log Rank=97.36, p<0.0001), and NCCN-IPI (Log Rank=102.29, p<0.0001) confirmed its prognostic significance. Furthermore, the patients with high CCI had significantly inferior median OS in the high risk group according to IPI (19 months vs 37 months), and NCCN-IPI (12 months vs 19 months).

Summary/Conclusions: NCCN-IPI represents useful prognostic index in DLBCL patients, and can better describe patients within risk groups, compared to IPI. Moreover, comorbidities contribute to inferior survival through frailty, drug dose reduction and poorer tolerability.

E971
SUBSTITUTING DOXORUBICIN WITH ETOPOSIDE IN R-CHOP RESULTS IN A REGIMEN WITH SIMILAR EFICACY FOR TREATMENT OF NEWLY DIAGNOSED ELDERLY PATIENTS WITH B-LARGE CELL LYMPHOMA (B-LCL)

I. Hudic1,‡, S. Basic-Kinda1, I. Radman1, S. Dotlic2, M. Kralki3, M. Vodanovic1, P. Rosevic1, L. Galunic-Bilic4, M. Dobrencic56, A. Ostojić1, D. Dujmović1, I. Aurer16

1Division of Hematology, Department of Internal Medicine, 2Department of Pathology and Cytology, 3Department of Radiology, 4Department of Oncology, 5Department of Nuclear Medicine, University Hospital Centre Zagreb, 6Medical School, University of Zagreb, Zagreb, Croatia

Background: R-CHOP is standard front-line treatment for B-LCL. However, anthracycline-induced cardiac toxicity limits its use in elderly and patients with preexisting heart disease. R-CEOP, in which doxorubicin is substituted with etoposide, has been suggested as a potential solution of this problem, but reports on the efficacy of this regimen vary substantially, especially in patients with non-GC DLBCL. We have been using this regimen regularly for front-line treatment of patients with B-LCL and preexisting heart disease and present here our experience.

Methods: We performed a retrospective analysis of all newly diagnosed B-LCL patients treated with R-CEOP at our centre from 2011 to 2016 and compared them to patients 60 years or older treated during the same period with R-CHOP: the standard regimen used at our centre for non-frail elderly without significant cardiac comorbidities. The dose of etoposide in R-CEOP was 50mg/m² iv or 100mg/m² orally daily for 3 days. Both regimens were given every 3 weeks for 6-8 cycles. Patients with initial bulky disease or in PR after systemic treatment were irradiated.

Results: 31 patients, 15 male and 16 female, received R-CEOP and 48, 25 male and 23 female, R-CHOP. Patients in the former group were older (median age 77 y, range 58-87 vs median age 66 y, range 60-83), had more often low performance status (81% vs 31%) and advanced disease (84% vs 54% stage 3 and 4) resulting in a significantly higher proportion of patients with IPI 3-5 (74% vs 40%, p=0.019). Proportions of patients with increased LDH were similar between the groups. There were no significant differences in frequency of grade 3-4 toxicity between the regimens; 48% of patients in both groups required emergency hospitalization; thrombocytopenia or anemia occurred in 16% of R-CEOP and 23% R-CHOP treated patients, infections in 32% and 31% and cardiovascular events in 16% and 21%. However, 7 patients (23%) in the R-CEOP group died during treatment due to adverse effects in comparison to 4 (8%) in the R-CHOP group. Efficacy was similar, 65% responded to R-CEOP and 79% to R-CHOP. After a median follow-up of survivors of 27 mo, 3-y OS was 55% in the R-CEOP group and 52 in the R-CHOP group; 3-y EFS was 50% and 50%, respectively (figure). Outcomes of patients with GC and non-GC DLBCL categorized according to Hans’s algorithm were similar irrespective of treatment.

Figure 1.

Summary/Conclusions: Long-term outcomes of newly diagnosed B-LCL patients treated with R-CEOP seem as good as those achieved with R-CHOP irrespective of cell of origin. Observed differences in treatment-related mortality were most probably caused by differences in age, comorbidities and performance status. R-CEOP should be considered as a regimen of choice for B-LCL patients with cardiac contraindications for anthracycline treatment.

haematologica | 2017; 102(s2) | 399

Madrid, Spain, June 22 – 25, 2017
POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDERS: A SINGLE-CENTER CASE SERIES

C. De Miguel1,2, B. Navarro1, J. Martín2, P. Martín2, G. Anze1, A. Alarcón1, R. Forés1, C. Bellas2, J.R. Cabrera1, C. De Miguel1,*, B. Navarro1, J. Martín2, P. Martín2, G. Anze1, A. Alarcón1, R. Forés1, C. Bellas2, J.R. Cabrera1
1Hematology, 2Pathology, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain

Background: Post-transplantation lymphoproliferative disease (PTLD) is a complication of both solid organ transplant (SOT) and haematopoietic cell transplant (HCT) and represent a very heterogeneous group.

Aims: The objective of this study is to evaluate the epidemiology, clinical features, characterization and therapeutic management of this disease.

Methods: We evaluated a total of 52 patients diagnosed between May 1995 and February 2017. We analyzed the following data: type of transplantation, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.

Results: Among the 52 patients, 31 were men (59.6%) and 21 women. PTLD after SOT were 45 (86.5%), of which 16 were after liver transplant (35.6%), 14 cardiac (31.1%), 9 pulmonary (20%), 4 renal (8.9%) and 2 double (cardiac-pulmonary and cardiac-renal) (4.4%). There were 7 PTLD after HCT, 2 identical HLA family donor, 2 unrelated donor, 2 dual umbilical cord blood and 1 autologous. Of the 52 PTLD, 48 were B lymphomas (92.3%), of which 26 were diffuse large B-cell lymphomas (DLBCL) (54.2%), 7 polymorphic (14.6%), 7 low-grade (14.6%), 4 Burkitt lymphomas (8.3%), 1 Hodgkin’s lymphoma (2.1%) and 1 diffuse non-classifiable. Other 4 PTLD were T lymphomas (8.7%), 2 anaplastic, 1 T/NK lymphoma, and 1 gamma/delta T lymphocytosis. 35/52 PTLD were EBV+ (67.3%). The median time of immunosuppression was 123 months in renal transplant, 93 months in liver, 85.5 months in cardiac, 51 months in lung and 3 months in HCT. Histologically, it was 96 months in T lymphomas and 80 months in B lymphomas, being 51 months in EBV+ and 124 months in EBV-. Fifty percent of Burkitt lymphomas were diagnosed after lung transplant, while 85% of low-grade lymphomas were diagnosed after liver transplant. Clinical stage was III/IV in 73% of the patients (38). Among the 52, 45 received treatment (86.5%), 37 with immunochemotherapy (82.2%) and 8 with Rituximab monotherapy (17.8%). Three patients responded to reduction of immunosuppression (5.8%) and 3 did not receive any treatment for early death (5.8%). At the time of writing, 19 patients remain alive (36.5%) and 33 have died. The median survival of these patients was 19.5 months (0-198).

Summary/Conclusions: PTLD constitute a very heterogeneous group. Its appearance is much earlier in the HCT than in the SOT and, within this latter group, it is earlier after lung transplant and later after renal transplant. The most common type in our series is DLBCL. The majority are related to EBV, so post-transplant monitoring is essential, and its diagnosis is earlier than in EBV-. Most low-grade lymphomas appear post-liver transplant, either in relation to virus reactivation or autoimmune diseases. Survival is significantly lower than in other primary LPS. -AR-SA-We analyzed the following data: type of transplantation, immunosuppression used in both induction and maintenance, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.

SURVIVAL OUTCOMES AFTER FIRST-LINE THERAPY IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) USING A UNITED STATES (US) ELECTRONIC MEDICAL RECORD (EMR)-BASED COHORT

A. Galaznik1, J. Bell1, L. Hamilton2, A. Ogbonnaya2, A. Raju2, K. Hennenfent2, M. Eaddy2, Y. Shou1
1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA; 2Xcenda LLC, Palm Harbor, United States

Background: In the rituximab era, the recommended first-line therapy (1LT) in DLBCL patients who can tolerate combination therapy is rituximab combined with chemotherapy, for refractory/relapsed disease, high-risk chemotherapy with stem cell transplant, combination chemotherapy, or single-agent rituximab are considered. While the efficacy of rituximab has been shown in clinical trials, few studies have evaluated survival outcomes in patients seen in routine clinical care.

Aims: We evaluated survival outcomes in a US population of newly diagnosed DLBCL patients seen in routine clinical care.

Methods: In this retrospective study, adult patients ≥18 years old with newly diagnosed DLBCL who initiated 1LT met the index date. Following the index date, initiation of 1LT for DLBCL was required. For the assessment of the survival outcomes, patients were evaluated from the date of treatment initiation until death, loss to follow-up, or end of study (09/30/15). Median progression-free survival (PFS) (defined as initiation of second-line therapy, evidence of supportive care >30 days after the end of a line of therapy, or death), median overall survival (OS), and PFS and OS rates at 2 years following initiation of 1LT were evaluated using unadjusted Kaplan-Meier analyses.

Results: 1,436 newly diagnosed DLBCL patients who initiated 1LT met the patient selection criteria. 54.0% were male, and the mean age was 66.4 years (SD: 13.7). At baseline, 27.4% of patients had a Charlson Comorbidity Index of ≥2, and the most common comorbidities were diabetes (20.3%), chronic pulmonary disease (15.5%), and moderate to severe renal disease (9.5%). In 1LT, 92.1% of patients received combination therapy, with R-CHOP (63.5%) being the most common combination therapy. 7.9% of patients received monotherapy upfront, with rituximab being the most commonly used single agent. At 2 years following initiation of 1LT, the Kaplan-Meier OS and PFS were 79.2% and 67.3%, respectively. Median OS was not reached, and median PFS was 53.9 months (95% confidence interval: 45.2, 61.5). OS and PFS were also compared among patients receiving monotherapy vs combination therapy in unadjusted analysis. At 2 years, OS was 80.2% for patients receiving combination therapy vs 67.4% (P=0.0093) for patients receiving monotherapy. Also at 2 years, PFS was 68.3% for patients receiving combination therapy vs 55.1% (P=0.0051) for patients receiving monotherapy.

Summary/Conclusions: In this population of patients with newly diagnosed DLBCL receiving 1LT survival outcomes at 2 years were significantly improved for patients treated with combination therapy vs monotherapy. Future analysis will explore the differences in clinical characteristics of patients treated with monotherapy vs combination therapy in the 1LT setting.
E974

AN EXPERIENCE WITH LONG ACTING FACTOR VIII PROPHYLAXIS IN PAEDIATRIC AND YOUNG ADULT PATIENTS WITH HAEMOPHILIA A
S. Verma1, A. Tripathi1, G. Suni1, N. Kumar1, R. Kushwah1, A. Kumar2, P. Kumar1
1K G. Medical University Lucknow, Lucknow, India

Background: Hemophilia is an X linked inherited bleeding disorder. Recurrent Joint bleeds and muscle bleeds are the common manifestations leading to long term comorbidities in hemophilia. High dose factor prophylaxis has been proven to be very effective in preventing joint complications in western world. We look for a cost effective and feasible way for Indian patients in terms of reduced dose and frequency of factor infusion. Data on prophylaxis with low dose long acting factor infusion on twice weekly dosing schedule is limited.

Aims: To study the efficacy and safety of long acting factor VIII (Eloctate) for tertiary prophylaxis in pediatric and young adult patients with moderate and severe haemophilia A.

Methods: Thirty eight patients with moderate and severe haemophilia A without inhibitors and age range from 1 to 25 years were included in this study. Patients were initially observed for 4 months during which they received therapeutic doses of long acting factor VIII, ELOCTATE (Factor VIII with Fc Fusion Protein) on episodic basis after clinical bleed. In next 4 months they received prophylactic ELOCTATE, given intravenously at doses of 20 unit/kg body weight on twice weekly schedule. Annual bleeding rates, school absenteeism, emergency visits, aspects of quality of life and joint scores were compared during observation and prophylaxis period.

Results: Total number of bleeds during observation and prophylaxis period was 607 and 90 respectively. Annual bleeding rate was 47.9 during observation period and 7.1 during prophylaxis. There was 85.1% reduction in bleeding rates on prophylaxis. School/college absenteeism was 3.1 days/month and 0.84 days/month during observation and prophylaxis respectively. Emergency visits were significantly more during observation. None of the patients developed inhibitors and two patients had superficial thrombophlebitis during prophylaxis. Quality of life assessment using KIDSCREEN QOL questionnaire showed moderate to marked improvement in quality of life domains during prophylaxis.

Summary/Conclusions: Low dose, twice a week, long acting factor VIII prophylaxis can be a reasonable option for patients with haemophilia A in developing countries. It significantly reduces joint bleeds, school absenteeism, Joint scores significantly without risk of inhibitor formation and also improves all domains of quality of life.

NOVEL MUTATIONS IN THAI CHILDREN WITH CONGENITAL FACTOR VII DEFICIENCY
D. Soothingkul1,2, T. Pusongchai1, R. Ittiwit1, P. Komvilaissak2, C. traiwiree2, K. Surapanonda1
1Department of Pediatrics, Chulalongkorn University, Bangkok, 2Department of Pediatrics, Khon Kaen University, Khon Kaen, Thailand

Background: Congenital factor VII (FVII) deficiency is a rare autosomal recessive coagulation disorder resulted from mutations in the FVII gene (F7). The disease severity is not correlated with FVII levels but might be determined by molecular defects in F7.

Aims: To delineate the phenotypic and genotypic characteristics of patients with congenital FVII deficiency.

Methods: We described demographic data, clinical manifestations, and outcome of patients with congenital FVII deficiency. F7 mutation analysis was performed by PCR-direct sequencing.

Results: Of the ten patients diagnosed with FVII deficiency, five (50%) were males. The median age (range) at diagnosis was 19 days old (1-730). Consanguinity was found in 50% of the patients. Of the nine patients (90%) classified as severe, six patients presented with intracerebral hemorrhage within the first month of life, two presented with gastrointestinal bleeding and one presented with hemarthrosis. There were eight different alterations identified. Four have been previously reported (c.1091G>A (p.R364Q), c.1238G>A (p.R413Q), c.1256C>T (p.T419M), and c.681G>T (IVS6+1T)). Four were novel (c.1192G>T (p.R397H), c.3227A>G (p.L1080R), c.3276G>A (p.L1093R), c.2723G>A (p.L908R)).

Conclusion: The novel mutations identified in this study provide new insights into the pathogenesis of congenital FVII deficiency and may have therapeutic implications. Further studies are necessary to determine the clinical significance of these mutations.
(1-3 units packed red blood cells). 100% excellent-good outcomes similar to longer factor replacement schedules were noted. No deaths or thromboembolic events were noted. One patient required re-admission for post-op hematoma following gynecologic procedure. Thirty-four (37.7%) patients were discharged either same day or after overnight observation. Von Willebrand factor (VWF) is necessary to form a platelet plug by recruiting Factor VIII and platelets to damaged vessels walls. We believe that four days is sufficient time for the formation a stable platelet plug and further downstream hemostasis is presumably VWF-independent. Here, we demonstrate safety and efficacy of a two to four day regimen of Humate-P, with only one person requiring re-admission for a post-operative hematoma. Current guidelines for surgical prophylaxis of VWD are based on expert opinion and lack level 1 evidence. Prolonged exposure may place patients at risk for unnecessary side effects, including thromboembolism and protracted hospitalization, and also causes financial toxicity. One unit of Humate-P costs 1.2 USD, which translates to enormous cost savings. Cumulatively, we were able to save ~1.5 million USD in these 90 surgical events using our abbreviated schedule.

Summary/Conclusions: Perioperative dose of 40U/kg for 2 days (one dose pre-op and one post-op) for extensive dental procedures and for 4 days (one dose pre-op and for 3 days post-op) for minor and major surgical procedures are associated with excellent hematologic outcomes and significant cost savings. However, this is single institutional data with limited number of patients and there remains a need for further studies to better define the exact dosing and duration of surgical prophylaxis.

E978
AUDIT ON MANAGEMENT OF HIGH INTERNATIONAL NORMALIZED RATIO (INR) IN WARFARINISED INPATIENTS
H. Hendra1, V. Gorur1,*, W. Nagi1
1Haematology, Broomfield Hospital, Chelmsford, United Kingdom

Background: Warfarin is the commonest used oral anticoagulant with an effective anticoagulant. The British Committee for Standards in Haematology guidelines recommend administration of 25-50µg of four factor Prothrombin Complex Concentrate (PCC) and intravenous (IV) Vitamin K 5mg for patients with major bleeding, 1-3mg of Vitamin K intravenously for those with minor bleeding and 1-5mg of Vitamin K orally for patients with INR >8 and who have no signs of bleeding.

Aims: The aim of this audit was to compare our hospital’s performance against the above guidelines.

Methods: A total of 76 patients admitted between 01/08/2015-31/01/2016 were analysed retrospectively.

Results: There were 103 incidents with INR level 5-8 and 24 with INR >8 in these 76 inpatients. Bleeding was documented in 18/127 cases, which included 6 incidents of major and 12 incidents of minor bleeding. In major bleeding, warfarin was withheld and Vitamin K administered. However, 4/6 (66.7%) of these patients got a dose different to 5mg advocated. Also, PCC was prescribed in only 50% of these patients. While 9/12 (75%) patients with minor bleeding received Vitamin K, only 3 of these 9 patients received the recommended dose of 1-3mg IV. Vitamin K was unnecessarily given to 9/83 (10.8%) non-bleeders with an INR between 5-8. Additionally, the recommended dose and route of administration of Vitamin K 1-5mg PO was followed only in 7/16 (44%) of non-bleeders with INR >8.

Summary/Conclusions: Our audit highlighted that there is less than 100% compliance in the recommended dose and route of vitamin K administration. A flowchart containing the guidelines will be designed to improve the management of high INR. To increase the awareness of this issue, teaching sessions for junior doctors and nursing staff are planned. A re-audit will be conducted once these steps are in place.

E979
NOVEL AND RECURRENT F7 MUTATIONS IN KOREAN PATIENTS WITH COAGULATION FACTOR VII DEFICIENCY
H. Kim1,*, K.-Y. Yoo2, K.-O. Lee3, S.-H. Kim1, H.-J. Kim1
1Laboratory Medicine & Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, 2Korea Hemophilia Foundation, 3Samsung biomedical Research Institute, Seoul, Korea, Republic Of

Background: Coagulation factor VII deficiency is one of rare hereditary bleeding disorders with relatively limited clinical and genetic data. Aims: This study aimed to characterize F7 gene mutational patterns of Korean patients with coagulation Factor VII deficiency including their clinical and laboratory variability.

Methods: F7 gene mutations of total 16 unrelated Korean patients with Factor VII deficiency were identified by direct sequencing analyses of all exons and flanking intronic sequences. Variants were assigned according to the recently released criteria of 2015 ACMG standards and guidelines.

Results: A total of 14 mutations (pathogenic or likely pathogenic) were detected including four novel mutations (Glu66Lys, c.681+3A>T, Glu66Alafs, Ile290del).

Six (38%) patients have 2 mutant alleles and three mutations were recurrently identified. The most frequent mutation detected in this study was Cys389Gly detected in 37% (11/30) patients, validating the data of our previous patient cohort.

Summary/Conclusions: Correlation of genetic data with coagulation laboratory and clinical findings suggested the presence of modifiers, which warrants further investigation in a larger cohort of patients for better clinical prediction and management in this rare bleeding disorder.

UTILITY OF CD157 IN A FLAER BASED SINGLE TUBE FIVE COLOR COMBINATION FOR SCREENING OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONE

1Hematology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

Background: Fluorescent Aerolysin (FLAER) based flow cytometric analysis of polymorphs and monocytes is the gold standard for the screening of paroxysmal nocturnal hemoglobinuria (PNH) clone. In recent years CD157 has been identified as a PNH marker which targets both polymorphs and monocytes. It can be used in a single tube five color combination to screen polymorphs and monocytes simultaneously.

Aims: The objective of this study was to analyze the utility and advantage of CD157 in the PNH screening along with its ability to replace CD24 and CD14.

Methods: Our routine protocol for PNH screening included single tube six color antibody cocktail in following combination: FLAER-AF488, CD24-PE, CD15-PerCP-Cy5.5, CD14-PerC7, CD64-APC, CD45-APC-H7. We assessed the utility of single tube 5 color combination of FLAER-AF488, CD15-PE, CD15-PerCP-Cy5.5, CD64-APC, CD45-APC-H7 for PNH screening and compared the results with the routinely used 6 color panel. Laboratory cutoff for CD157 was defined by running 10 samples from healthy individuals. Sensitivity analysis was assessed in spiking experiments by diluting a PNH positive sample with defined by running 10 samples from healthy individuals. Sensitivity analysis was assessed in spiking experiments by diluting a PNH positive sample with healthy individuals to assess the performance of the method. The PNH clone size obtained from CD24/CD14 and CD157 was assessed by analysing a total of 30 samples across a wide range of PNH clone size (0.06-97.3%).

Results: CD157 was sensitive at the level of 10^-4 and better. Frequency of cells with PNH phenotype in normal samples were found to be <0.002%. The CVs of intra-/interassay precision analysis ranged from 0.92/6.2% to 3.2/4.6% for granulocytes and 1.9/2.5 to 5.3/8.9% for monocytes. The PNH clone size, as obtained by CD157 based analysis was highly comparable to those obtained by CD24/CD14 based assay (R²=0.993). CD157 was found much better than CD24/CD14 in identifying the type II PNH clones. There was no false positive or false negative result. The cost of analysis was found to be approximately 15% lesser than the routinely used 6 color assay.

Summary/Conclusions: CD157 is a robust, reliable and potentially useful universal marker for PNH screening. Its inclusion in a single tube five color FLAER based panel is a cost effective approach which is ready to replace CD24/CD14 from routine PNH screening.

IMMUNOPHENOTYPIC DYSPLASTIC FEATURES IN PATIENTS WITH APLASTIC ANEMIA

Y. Davydova, E. Parovichnikova, I. Galtseva, E. Mikhailova, N. Kapranov, A. Kohno, L. Kuzmina, V. Troitskaya, Z. Fidarova, T. Moiseeva, V. Savchenko

1Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Multicolor flow cytometry (MFC) of bone marrow (BM) is a promising additional approach to the diagnosis of myelodysplastic syndromes (MDS). Aplastic anemia (AA) as MDS characterizes by cytopenias and dysplastic features in BM by morphology are absent. It is well known that up to 15% of AA transformed into MDS over time. It is possible to suggest that in some cases of AA immunophenotypic abnormalities can also be identified.

Aims: To study and compare the presence of dysplastic features by MFC in AA and MDS without excess of blasts.

Methods: The study included 14 patients with AA (8m, 6f, median age 33), 28 patients with MDS de novo without excess of blasts by morphology (13m, 15f, median age 59). MDS group included 3 patients with 5q-syndrome, 4 - RCUD, 3 - RARS, 18 - RCMD. 20 patients with cytopenias constituted the control group (4m, 16f, median age 42) due to B-12 deficiency anemia, iron-deficiency anemia, Fanconi anemia, hereditary anemia, β-thalassemia, ITP, hepatitis C, multiple myeloma, Burkitt’s lymphoma. BM of 33 healthy donors was analyzed for the reference values. MFC was performed according to International Leukemi- anet by 6-color cytometer BD FACS Canto II. We enumerated the proportion of CD34+ myeloid cells from CD45+ cells (normally ~2%), the proportion of CD19+ (B-cell progenitors) from CD45+ cells (normally ~5%), the expression of CD34, CD45, CD117, CD7, CD56 on CD34+ myeloblasts. Among granulocytes we analyzed: their proportion, granularity, CD14, CD64, CD10, CD56 expression and patterns CD16vsCD13, CD16vsCD11b, CD13vsCD11b. Among of monocytes we measured: their proportion, CD64, CD56 expression and analyze patterns CD10vsCD11b, CD10vsCD15, CD11bvsHLA-DR. The final MFC conclu- sion was done by scale Ogata/Wells (van de Loosdrecht, 2013): A - does not correspond to MDS; B - reveals some features which commonly appears in MDS; C - results are consistent with MDS.

Results: Among MDS patients without excess of blasts assessment “B” and “C” scores were obtained in 78.6% (sensitivity). Increased proportion of CD34+ myeloblasts was in 35.7% of cases, increased CD56 and CD7 in 42.9%. The most common abnormalities were: increased CD66 (53.6%), abnormal patterns (39.3%), low granularity (35.7%) in granulocytes; increased proportion (21.4%) and abnormal patterns (28.6%) in monocytes. 64.3% (n=9) patients with AA (A) were assessed as “A”, 21.4% (n=3) - “B” and 14.3% (n=2) - “C”. Among MDS patients without excess of blasts assessment “B” and “C” scores were obtained in 53.6% cases. Increased proportion of CD34+ myeloblasts was in 35.7% of cases, increased CD56 and CD7 in 42.9%. The most common abnormalities were: increased CD66 (53.6%), abnormal patterns (39.3%), low granularity (35.7%) in granulocytes; increased proportion (21.4%) and abnormal patterns (28.6%) in monocytes. 64.3% (n=9) patients with AA (A) were assessed as “A”, 21.4% (n=3) - “B” and 14.3% (n=2) - “C”. Among MDS patients without excess of blasts assessment “B” and “C” scores were obtained in 53.6% cases. Increased proportion of CD34+ myeloblasts was in 35.7% of cases, increased CD56 and CD7 in 42.9%. The most common abnormalities were: increased CD66 (53.6%), abnormal patterns (39.3%), low granularity (35.7%) in granulocytes; increased proportion (21.4%) and abnormal patterns (28.6%) in monocytes. 64.3% (n=9) patients with AA (A) were assessed as “A”, 21.4% (n=3) - “B” and 14.3% (n=2) - “C”.

Summary/Conclusions: Flow cytometry MDS study with Ogata/Wells scale has a high sensitivity and specificity. Immunophenotypic abnormalities characterizing dysplastic features can also be found in AA patients up to 35% of cases. Increased expression of CD66 on CD34+ myeloblasts, granulocytes and monocytes is commonly found in AA patients. Perhaps the appearance of MFC dysplastic features foreshadows the MDS-transformation of AA, but requires further prospective studies.

SURGICAL MANAGEMENT OF PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) – DATA FROM THE SPANISH PNH REG-ISTRY

S. De La Iglesia1, 2, C. Notario McDonell 2, A. Gaya Valls 3, M.T. Cedena

1Madrid, Spain, June 22 – 25, 2017
Efficacy of Eculizumab in Paroxysmal Nocturnal Hemoglobinuria (PNH) Patients With or Without Aplastic Anemia: Prospective Study of Korean PNH Cohort on Eculizumab.

1 Internal Medicine, Korea University Guro Hospital; 2 Samsung Medical Center; 3 Soon ChunHyang University School of Medicine; 4 Yonsei University College of Medicine, Seoul; 5 Chungnam National University, Daejeon; 6 Asian Medical Center, Seoul; 7 Dong-A University Hospital, Busan; 8 Chonnam National University Hwasun Hospital, Hwasun; 9 SoonChunHyang University Hospital, Seoul; 10 Pusan National University Hospital, Pusan; 11 Ulsan University Hospital, Ulsan; 12 Gachon University Gil Medical Center, Incheon; 13 Yonjung University Hospital, Daegu; 14 Yonsei University Wonju College of Medicine, Wonju; 15 St. Vincent Hospital, The Catholic University of Korea, Suwon; 16 Seoul St. Mary’s Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a hematopoietic stem cell disease characterized by the intravascular lysis of red blood cells. PNH patients often have underlying bone marrow failure (BMF), with aplastic anemia (AA) as the most frequently associated type. Eculizumab, a humanized monoclonal antibody that binds specifically to human complement protein C5, has been used in Korea since 2012.

Aims: The purpose of this study was to determine whether eculizumab-treated patients show clinical benefit and reduced risk of complications regardless of concomitant AA in a Korean population.

Methods: Forty-six PNH patients ≥18 years of age diagnosed by flow cytometry and treated with eculizumab for more than 6 months were analyzed in the prospective Korean PNH registry. Patients were categorized into two groups: PNH patients with concurrent AA (PNH/AA) and without (classic PNH). Patients with severe AA/PNH were excluded. Biochemical indicators of intravascular hemolysis, hematological laboratory values, transfusion requirement, and PNH-associated complications assessed by the treating physician were reported every 6 months after enrollment.

Results: The median age of the study population was 49 years (range, 18-73 years) at eculizumab initiation and the median duration of eculizumab treatment was 34 months (range, 6-44 months). Median LDH fold x upper limit of normal was 7.29 (range 2.4-23.7) and GFI-deficient granulocytes was 92.8% (range, 15.7-100%) at the time of eculizumab treatment. PNH-related signs and symptoms were thromboembolism (TE, n=19), renal failure (n=20), pulmonary hypertension (n=5), and severe/recurrent abdominal pain requiring opioids (n=17). Of 46 total patients, 12 (26%) were classified as having PNH/AA and 34 with classic PNH. There were no substantial differences in laboratory findings, transfusion requirement, or clinical outcomes between the two groups. Treatment with eculizumab induced a rapid inhibition of hemolysis. At the time of 6 month follow-up, LDH level decreased to near normal levels in all patients and this effect was maintained until 36 months follow-up regardless of concomitant AA. Mean hemoglobin level significantly increased from the first 6 months of eculizumab treatment and the effect (hemoglobin above 10 g/dl) was sustained throughout 36 months in both groups. Transfusion-independence was achieved by 54.3% within the first 6 months of treatment and 86.4% by the last 36 months (83.3% in PNH/AA vs 87.5% in classic PNH). The mean number of RBC units transfused was significantly reduced from 8.5 units during the previous 6 months to 1.6 units for the first 6 months in total PNH patients (Fig). There were no significant differences in clinical outcomes (ie, LDH and transfusion unit per every 6 months) with eculizumab between the two groups. All TE (n=19) patients in whom 6 received concomitant anticoagulation therapy were resolved on the eculizumab; one classic PNH patient had recurrence of TE at the same site after discontinuation of anticoagulation therapy while on eculizumab. Among 9 patients who had baseline eGFR less than 60 ml/min/1.73m², 5 patients (56%) showed improvement of eGFR during the eculizumab treatment and 4 patients stabilized eGFR.

Figure 1.

Table 1.

Summary/Conclusions: Our findings lead us to recommend to perform the intervention within 24 hours of the administration of Ecu in programmed surgery for which it is necessary to program the dose. While in urgent surgical interventions put a new dose on the day of the intervention independently of the previous dose. Also the normal ECU dose could be increased or an extra dose be administered in order to minimize the risk of hemolysis in high-risk patients or in those with a previous history of surgery-related hemolysis.

E984

Efficacy of Eculizumab in Paroxysmal Nocturnal Hemoglobinuria (PNH) Patients With or Without Aplastic Anemia: Prospective Study of Korean PNH Cohort on Eculizumab.

Background: Patients with PNH often need surgery due to disease-related complications. However, surgery, anesthesia, and possible surgical complications, including inflammation and acids, can trigger complement activation, making surgery an important risk factor for hemolysis (Ando K, et al. Ann Hematol 2012;91:1987-8; van Bijnen ST et al. Eur J Haematol 2011;87:376-8).

Aims: Here we report data on the clinical management and treatment results of patients with PNH undergoing surgery.

Methods: We collected data on 14 surgical interventions of 11 patients (8 males; age, 25-76 years). All patients had a high prevalence of PNH clone cells (55-99%) in PMN) and were receiving eculizumab (Ecu). Types of surgery were: 6 laparoscopic cholecystectomies, a transsurgical intrahepatic portosystemic shunt, a distal splenoportal shunt, a laparoscopic Achilles allograft ligation, a gastrectomy, an emergency appendectomy, and 3 urologic interventions. Ten patients received ECU 900mg, while one (patient E; surgery 6) received 1200mg since he had developed hemolysis at a previous surgical intervention (surgery 5). In two cases (patient G; surgery 8; patient H; surgery 11), an additional dose of ECU was administered before surgery. Patient H (surgery 11) had developed hemolysis at previous surgical interventions (surgery 5 and 9). In most cases, either the date of the ECU dose was taken into account when scheduling surgery or the ECU dose was moved forward to coincide with the date of surgery. The time between the last ECU dose and surgery was normally one day (range, 1-8).

Results: In nine cases, transfusions were required due to hemorrhagic complications. Patient I (surgery 12) had a thrombotic event leading to acute myocardial infarction one week after surgery. Increased hemolysis was observed (increased LDH and/or presence of hemoglobinuria) in five cases (patients E, H, I and K; surgeries 5, 9, 10, 12 and 14) during the week following surgery. Two of these patients (patients E and H) later underwent additional surgery (surgery 6, and surgeries 10 and 11, respectively). The pre-surgical ECU dose was increased in surgery 6 (patient E) and an extra dose was administrated in surgery 11 (patient H) and no hemolysis was observed. (See Table 1).

Summary/Conclusions: Our findings lead us to recommend to perform the intervention within 24 hours of the administration of Ecu in programmed surgery for which it is necessary to program the dose. While in urgent surgical interventions put a new dose on the day of the intervention independently of the previous dose. Also the normal ECU dose could be increased or an extra dose be administered in order to minimize the risk of hemolysis in high-risk patients or in those with a previous history of surgery-related hemolysis.
Summary/Conclusions: Clinical outcomes with eculizumab were significantly improved compared with the baseline in patients with both PNH/AA and classic PNH. This study demonstrated that eculizumab has a beneficial role in the management of patients with PNH/AA, similar to that of classic PNH, by inhibiting hemolysis and reducing transfusion requirements, thus resulting in the improvement of clinical signs and symptoms.

E985

DIAGNOSIS AND FOLLOW-UP OF THE CLONES OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA BY FLOW CYTOMETRY

S. Oukid1,*, S. Taoussi1, N. Rekab1, M.T. Abad1
1Hematology, EHS ELCC CAC, Bida, Algeria

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a very rare chronic disease associated with a clonal expansion of one or several hematopoietic stem cells carrying acquired somatic mutations of PIG-A gene resulting in GPI-AP deficient blood cells and great susceptibility to complement mediated cell lysis. Diagnosis of PNH is of importance and flow cytometry (FC) is a required tool for this. We report 33 cases of PNH diagnosed and monitored by FC.

Aims: To show the interest of flow cytometry for the diagnosis and follow-up of PNH clones in some risky haemopathies.

Methods: A PNH clone has been researched in 234 patients since August 2009 to January 2017. The PNH clone was investigated for bone marrow aplasia with or without haemolysis, regenerative hematologic anemia with negative direct coombs test (DCT), myelodysplasia (MDS), unexplained cytopenia and extramedullary hematopoiesis. The search for the PNH clone by FC is based on the analysis of the following monoclonal antibodies: FLAER and CD59 for neutrophils, Flear and CD59 with gating on CD45 for monocytes and CD59 with gating on Glycoporphin A for red blood cells. We judged that the patient has a PNH clone when the deficiency is >50% on at least two markers highlighted on two different lines. FC surveillance is provided in the absence of a deficit or in the case of the reappearance of a single-line deficit.

Results: Out of 234 cases analyzed, 201 cases (85%) showed absence of PNH clone and 33 cases (14%) had a PNH clone. There are 14 women and 19 men; Sex ratio (M/F) = 1.35, mean age = 42.27 years (17-73). Among patients that should be screened for positive PNH clone we have bone marrow failure: 25 positive (21.9%) in 114 cases screened, hemorrhagic anemia with negative direct coombs test: 4 positive/63 cases (6.34%), thrombosis: 2 positive/28 (7.14%), one negative case of AML2, myelodysplasia with 02 (11.2%) positive/18 cases and cytopenias: 0 positive/13 cases. The types of PNH was type II in 3 cases (9%), type III in 24 cases (72.8%) and mixed deficits in 6 cases (19.2%). The mean degree of CD59 deficiency was 29.4% (5-82) on red blood cells 48.21% (5-95) on neutrophil (N); the mean degree of Flear was 55.33% (6-99) on N in 22 cases ; the mean degree of CD14 deficiency on monocytes was 44% (7-97) in 17 cases, the mean degree of Flear (8 cases) was 51.8% (12.9-92). During surveillance, PNH clone appeared in 02 cases and clone size increase in 08 cases. Therefore we have shown that the decrease of NK-T cells accompanies the decrease of PNH clone sizes among the granulocytes by dual-reagent and conventional flow cytometry. The decrease of NK-T cells was observed in 17 cases out of 19 cases (89.5%) and in 5 cases out of 6 (83.3%) in cases of PNH clone (21.9%) and in the group where a moderate deficit was observed, there are not biological signs of NK-T cells.

Summary/Conclusions: NK-T cells play an important role in the regulation of Th1:Th2 balance. The role of NK-T cells in development of aplasia of hemoysis in AA now is broadly studied. Nevertheless, up to this moment, the decrease of NK-T cells may be considered as a possible mechanism of this phenomenon. It is suggested, that NK-T cells play an important role in regulation of Th1:Th2 balance. The role of NK-T cells in development of aplasia of hemoysis in AA now is broadly studied. Nevertheless, up to this moment, the decrease of NK-T cells may be considered as a possible mechanism of this phenomenon.
TREATMENT OF REFRACTORY APLASTIC ANEMIA WITH ELTROMBOPAG: EXPERIENCE OF A CENTER
M. Gomes1,*, M.J. Teles2, F. Ferreira1, J.E. Guimarães1
1Clinical Hematology, 2Clinical Pathology, São João Hospital Centre, Porto, Portugal

Background: Eltrombopag, a thrombopoietin receptor agonist, was approved in 2008 for the treatment of immune thrombocytopenic purpura. More recently, benefits demonstrated in the proliferation and maintenance of hematopoietic stem and progenitor cells (HSTC) led to its use and approval in the treatment of severe aplastic anemia (AA) refractory to immunosuppressive therapy.

Aims: In this report, we evaluated response to eltrombopag in patients with refractory AA and severe side effects.

Methods: Retrospective analysis of six patients with a diagnosis of aplastic anemia and thrombocytopenia (platelet count ≤30,000/μL), refractory to immunosuppressive therapy and ineligible for allotransplant, treated with eltrombopag. Patients characteristics, response, clinical evolution and adverse effects were evaluated.

Results: Four patients were female and median age at diagnosis was 66 years (36-76). Previous treatments included horse antithymocyte globulin (1), cyclosporine (4), intravenous immunoglobulin (1), corticosteroids (4) and danazol (1). Treatment with eltrombopag was associated to cyclosporine in four patients; two cases had chronic renal failure and consequent contraindication to cyclosporine. The median duration of treatment with eltrombopag at the time of this analysis was 7 months (3-12). At 3 months, all patients had platelet counts >30,000/μL (median increase, 16,500/μL). Five patients improved hemoglobin levels (median increase, 2.2g/dL); 3 of them were previously dependent on red cell transfusions, and no longer needed transfusions. Four patients increased neutrophil counts (median increase, 1110/μL). All but one patient received a maximum dose of 150mg per day. Only one patient needed temporary discontinuation due to hepatic abnormalities, that were rapidly resolved. One other patient had mild elevation of liver enzyme levels. No other relevant side effects occurred.

Summary/Conclusions: Treatment with eltrombopag was associated with hematologic response of one or more hematopoietic lineage, independence of several adhesion molecules on the surface of CLL cells from patients treated with ibrutinib has been evaluated to analyze the effect of treatment on the relationship between the microenvironment, that promotes cell survival and proliferation, and the leukemic cells with the consequent cell mobilization and increased drug exposure.

Methods: In a cohort of 101 CLL patients treated with ibrutinib (420mg/die) and rituximab (375mg/m2/week) in the GIMEMA LLC1114 trial, we evaluated, before and after 15 days of therapy, the surface expression on leukemic cells of several adhesion molecules. In detail, using 8 color antibody combinations (all from Becton Dickinson, BD, San José, CA) we evaluated the MIF expression (using the FACSCanto II, BD) of CD11a, CD18, CD34, CD40, CD43, CD44, CD49e, CD62L, CD62L, CD81, CD86, CD154, CD184, CD185 on CD5/CD19+ leukemia cells.

Results: The number of CD5/CD19+ did not increase after 15 days of treatment (52.8±58.5 vs 53.4±51.5 x 10⁹/L; p<0.06) probably because of the concomitant rituximab administration, which ‘masks’ the mobilization effect induced by ibrutinib. We observed a significant down-modulation of CD62L (461±435 vs 171±146; p<0.0001), a molecule (L-selectin) that has been reported as the key factor controlling the binding of CLL cells to the endothelial walls in vivo. CD69 expression resulted also significantly decreased (4744±784 vs 438±716; p<0.0041), is expressed on CLL cells in the tissue microenvironment, both in the bone marrow and in lymph nodes. We observed the significant down-modulation of the expression of CD43 (3265±2282 vs 2515±1826; p<0.0063); this antigen is utilized in CLL for the detection of minimal residual disease (MRD) and does therefore not seem a reliable marker in patients treated with ibrutinib. On the contrary, CD81 expression, another antigen utilized for MRD detection, resulted unchanged after 15 days of treatment. CD185 expression was significantly decreased (1502±1327 vs 804±687; p<0.001), while we unexpectedly observed the up-modulation of CD10 (621±531 vs 1171±147; p<0.001) and CD19 (2244±2022 vs 3162±1877; p<0.003): both antigens participate in the BTK signaling pathway. CD40, that interacts with activated CD4+ T cells, resulted down-modulated (722±467 vs 395±262; p<0.0001). CD38 and CD49d, when expressed in >20% of the leukemic cells, resulted significantly (p<0.028 and p<0.021) down-modulated: both molecules have a role in the crosstalk between the leukemic cells and the microenvironment.

Summary/Conclusions: Within an ancillary biologic study of the GIMEMA LLC1114 protocol we observed a significant down-modulation in the expression of several adhesion molecules on the surface of CLL cells of patients treated with ibrutinib. Since these molecules promote the binding of the leukemic cells with the microenvironment, these results help to elucidate the mobilization process of CLL cells from the different compartments observed with ibrutinib and support its progressive efficacy over time in controlling the disease. A follow-up clinical analysis will define a possible correlation between these findings and response to treatment.
Background: The gene expression profile of chronic lymphocytic leukemia (CLL) cells revealed a homogeneous phenotype related to memory B cells accompanied by an aberrant expression of several proteins. For example, lipoprotein lipase (LPL), typically expressed in adipocytes, is readily detected in CLL cells. However, unlike their normal counterparts which are resting cells, CLL cells do proliferate. What energy source CLL cells use and which metabolic pathway they recruit is currently unknown. Because the gene expression profile of CLL cells is skewed towards that of adipocytes, and because they proliferate at similar rates, we hypothesized that like adipocytes CLL cells utilize free fatty acids (FFA).

Aim(s): Determine whether CLL cells are capable of utilizing FFA for energy production. (B) Determine whether lipid metabolism in CLL is LPL dependent. (C) Determine why LPL is aberrantly expressed in CLL cells.

Methods: Peripheral blood (PB) and bone-marrow derived lymphocytes were obtained from previously untreated patients with CLL. Imaging of CLL cells was done by electron microscopy, and PB lymphocytes were stained for Oil red O. Confocal microscopy studies helped in determining the cellular localization of LPL. To study the capacity of CLL cells to utilize FFA we developed an assay that measured the oxygen concentration in the sera of cultured CLL cells prior to and after adding FFA. In addition we measured the oxygen consumption of CLL cells derived from ibrutinib-treated patients. We used an immuno precipitation (CHIPIF) and luciferase assays to study the binding of STAT3 to the LPL promoter.

Results: To study whether CLL cells are capable of utilizing FFA we cultured primary CLL cells and measured the concentration of cultured media-dissolved O2 (dO2) prior to and after adding FFA, assuming that if the cells oxidize the acid, dO2 levels will drop. Indeed, after 48 hours incubation with FFA dO2 levels were markedly reduced as compared with the dO2 media levels of CLL cell incubated without FFA. Remarkably, unlike cultured normal B cells which do not change their dO2 levels of cultured CLL cells did not change their dO2 levels. Intriguingly, the levels of dO2 remained unchanged if CLL cells were incubated in the presence of FFA and ibritunib. Similarly, the dO2 levels of CLL cells obtained from ibrutinib-treated patients remained constant, suggesting that ibritunib disrupts the capacity of CLL cells to utilize FFA. Oil Red O staining of CLL bone marrow smears detected lipid deposits and electron microscopy confirmed the presence of lipid vacuoles in the cytoplasm of peripheral blood CLL cells but not in normal B cells, suggesting that like adipocytes, CLL cells store lipids in intracytoplasmic lipid vacuoles. Similar to adipocytes CLL cells express LPL which mediates the uptake of lipid particles into the cells and catalyzes the hydrolysis of triglycerides into FFAs. Indeed, we detected LPL in the cyto- plasm and in the cytoplasm of CLL cells. Furthermore, using small interfering RNA (siRNA) we knocked-down LPL mRNA levels and found that LPL-siRNA reduced the capacity of CLL cells to utilize FFA, suggesting that the lipid metabolism in CLL is LPL dependent. Because STAT3 is constitutively active in CLL cells, and because the LPL gene harbors STAT3 binding sites, we sought to determine whether STAT3 activates the LPL gene. Indeed, transfection of luciferase reporter gene constructs driven by LPL promoter fragments into MM1 cells revealed that STAT3 activates the LPL promoter. In addition, CHIPIF confirmed that STAT3 activates the LPL gene. Furthermore, transfection of CLL cells with STAT3-shRNA downregulated LPL transcripts and protein levels, confirming that STAT3 activates the LPL gene.

Summary/Conclusions: Our data suggest that CLL cells undergo metabolic reprogramming and use strategies normally utilized by adipocytes. This process is driven by constitutively activated STAT3 and is inhibited by ibritunib.
ence or absence of IL-4. Most of the investigated samples in this series showed increased surface FcγR expression and increased surface IgM expression after IL-4 treatment, but a few cases showed only reduced FcγR expression and no change in IgM expression. Interestingly, these samples also showed greater anti-IgM induced phosphorylation of SYK, PLCγ2, AKT and ERK, suggesting that downregulation of FcγR is the primary mechanism through which IL-4 regulates the BCR signaling capacity of PB CLL cells. FcγR is downregulated by IL-4 and shows reduced expression in LN CLL cells, which could represent a mechanism to allow CLL cells to respond more effectively to stimulation with antigen encountered in the appropriate context.

Summary/Conclusions: These data show that FcγR is a negative regulator of BCR signaling in CLL cells. Overexpression of FcγR could be at least in part responsible for the reduced BCR signaling capacity of PB CLL cells. FcγR is downregulated by IL-4 and shows reduced expression in LN CLL cells, which could represent a mechanism to allow CLL cells to respond more effectively to stimulation with antigen encountered in the appropriate context.

TRANSCRIPTION FACTORS AND CHECKPOINT INHIBITORS EXPRESSION WITH AGE: MARKERS OF IMMUNOSENESCENCE?
L. Dang1, K. Williard-Clark2, S. Garraud2, H. Duvillier1, J.-N. Lodewyckx2, C. Solinas2, C. Gu-Trantien2, B. Stamatopoulos1, C. Sibille3, D. Bron1,
1Clinical and Experimental Hematology, 2Molecular Immunology, 3Anatomopathology, INSTITUT JULES BORDET, ULB, Brussels, Belgium

Background: Aging is characterized by a progressive decline in immune surveillance that favors tumor development in older patients. One mechanism used by malignant cells to escape immune surveillance is the upregulation of the MHC class I molecule and the upregulation of BACH2 gene as a candidate TSG. We thus examined the expression of specific transcription factors (BACH2 and PRDM1) and checkpoint inhibitors (PD-1 and PD-L1) in the T cells from different populations for their potential role in immunosenescence.

Methods: Peripheral blood mononuclear cells were isolated from whole blood using Lymphoprep (Stemcell Technologies) density gradient centrifugation. Lymphocyte subsets (CD19+, CD3+CD4+; CD3+CD8+) were isolated for subsequent molecular analyses using the MACS Technology (Milteny), with the purity of each lymphocyte subpopulation between 95%–99%. PD-1 (PDCD1), PD-L1 (CD274), IL-4, IFNG, BACH2 and PRDM1 mRNA transcripts were quantified using qRT-PCR. BACH2 and BLIMP1 (PRDM1) protein expression were examined by Western blotting.

Results: Blood samples were obtained from 60 healthy volunteers and 41 untreated B-cell lymphocytic leukemia (B-CLL) patients (median 67yo). Healthy donors (HD) between the ages of 20 to 90 years subdivided into <50 yrs (median: 36yo) and ≥50 yrs (median: 65yo). BACH2 mRNA expression in the HD groups is significantly down-regulated in CD4+, CD8+ T cells and CD19+ B cells from the older HD group (p=0.0012; 0.0045 and 0.0367, respectively). BACH2 expression was further reduced in CD4+, CD8+ T cells and CD19+ B cells from CLL patients compared to HD well balanced for age (p=0.001; <0.0001 and 0.0043). PRDM1 mRNA expression was inversely correlated with BACH2 in CD4+, CD8+ T cells and CD19+ B cells (r=0.61; 0.71 and 0.85, respectively). Curiously, PRDM1 was as –expected –significantly upregulated in CD19+ B cells and CD8+ T cells (p=0.0034; p=0.0017) from B-CLL patients but not in their leukemic B cells. Western blotting analysis demonstrated that BACH2 and BLIMP1 (PRDM1) protein expressions in the T and B cell subpopulations were significantly correlated with transcript expression. BACH2 and BLIMP1 protein expression was up-regulated in CD4+, CD8+ T cells (p=0.0153 and 0.0214) in the older HD group and also up-regulated in the T cells from B-CLL patients (p=0.0014 and 0.0023) when compared to age-matched HD population. High PD-1 mRNA expression was correlated with increased age in HD B cells (p=0.04) with a further increase detected in both T cells (p=0.001). We also observed an inverse correlation between BACH2 and PD-1 in CD4+, CD8+ T cells (r=0.62 and 0.68); and between BACH2 and PD-L1 in CD19+ B cells (r=0.66).

Summary/Conclusions: These data suggest that down-regulation of BACH2/PRDM1 and up-regulation of PD1/PD-L1 mRNA expression in major lymphocyte subsets from CLL patients and older healthy controls are significantly correlated with the aging immune cells and could be part of the immunosenescence process.

T-CELL EXHAUSTED PHENOTYPE IS ENHANCED DURING DISEASE PROGRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)
I. Jiménez1, S. Bobillo2, P. Abríngue2a, C. Palacio2, J. Carabia1, M.J. Terol3, M. Crespo1, F. Bosch1
1Experimental Hematology, 2Hematology, Vall d’Hebron Institute of Oncology, Barcelona, 3Hematology, INCLIVA Biomedical Research Institute, Valencia, Spain

Background: The different biological mechanisms leading the clinical progression of CLL from early stages are currently not fully elucidated. Different prognosis factors that show a higher probability of progression, such as BCL2, IGHV mutational status, 2nd genetic hit and low CD38 expression of CLL cells, are not able to identify an important proportion of patients that eventually progress. Clinical progression from early stages to an advanced CLL is associated with a certainly reduced acquisition of molecular changes that are not able to explain the fifty percent of the CLL cases progressing. CLL cells are dependent on survival and proliferative signals from the microenvironment and are able to evade immune anti-tumoral responses using different mechanisms, which is a crucial feature for cancer development. T-cell dysfunction is one of the main sources of impaired anti-tumor immunity. In CLL, T cells show functional defects and have increased expression of the exhaustion markers PD1, CD244 and CD160 compared to T cells from healthy individuals. Taking this into account, we hypothesize that changes in the microenvironment, and particularly in T-cell exhaustion component, are contributing to the clinical progression of CLL.

Aims: In order to explore the role of the immune system in the progression of CLL we studied the immunophenotype of T cells from CLL patients using paired samples at diagnosis and progression.

Methods: A total of 14 CLL patients (median age, 69 years; median time to progression of 29.5 months) and 6 patients diagnosed with CLL that did not experience clinical progression during a median follow up of 34 months were included in the study. Multicolor flow cytometry was performed in matched samples at two time-points: diagnosis and progression before treatment or diagnosis and follow-up. We studied T-cell differentiation status based on CD45RA and CCR7 expression and the inhibitory receptors PD1, CD244, CD160, LA3, TIM3 and CTLA4. We also analyzed the expression of the transcription factors BACH2/PRDM1 and Eomes.

Results: We observed a significant increase in CD8+ absolute numbers (P=0.0107) and a significant decrease of the CD4:CD8 ratio (P=0.0012) with progression. T cells increased their effector memory (EM) CD45RA-CCR7- phenotype during progression (EM CD4+ = P=0.0353; EM CD8+ = P=0.0023), CD244 expression was significantly increased during progression in absolute numbers and subsets (P=0.0169 for CD8+ T cells subset and P=0.0166 as well as in the PD1+ EM subset (EM PD1+CD4+; EM PD1+CD8+ = P=0.0024). Interestingly, we did not observe these changes in CLL patients that did not progress where the absolute numbers of cells expressing PD1 were either diminished or maintained during the follow-up, pointing out an important role of PD1 in regard to CLL progression. We observed that the percentage of CD8+ T cells expressing PD1 were either diminished or maintained during the follow-up, pointing out an important role of PD1 in regard to CLL progression. We observed that the percentage of CD8+ T cells expressing PD1 were either diminished or maintained during the follow-up, pointing out an important role of PD1 in regard to CLL progression. We observed that the percentage of CD8+ T cells expressing PD1 were either diminished or maintained during the follow-up, pointing out an important role of PD1 in regard to CLL progression. We observed that the percentage of CD8+ T cells expressing PD1 were either diminished or maintained during the follow-up, pointing out an important role of PD1 in regard to CLL progression. We observed that the percentage of CD8+ T cells expressing PD1 were either diminished or maintained during the follow-up, pointing out an important role of PD1 in regard to CLL progression.

Summary/Conclusions: T cells from patients with progressed CLL show a more severe exhausted phenotype compared to diagnosis, which is characterized by an effector memory subset with higher expression and co-expression of PD1, CD244 and CD160, as well as higher levels of the transcription factor Eomes, indicating that the terminal exhausted phenotype (Eomes+) is predominant. These changes may contribute to the immune evasion that facilitates the progression and to the immunosuppressive scenario that dominates advanced CLL stages. Functional assays to explain why this T-cell subset is enhanced during progression are currently ongoing.

E996
EARLY SPECIFIC INCREASED EXPRESSION OF SURFACE IGBM BUT NOT OF OTHER ASSOCIATED MOLECULES APPEARS TO REFLECT ANTIGEN DROPOUT AND DISENGAGEMENT IN CLL PATIENTS ON IBRUTINIB THERAPY
1Haematology Oncology Group, Cancer Sciences Unit, University of Southampton, Southampton, United Kingdom, 2Padua University School of Medicine, Department of Hematology and Clinical Immunology, Padua, Italy, 3Haematology Branch, University of Padua, Padua, Italy, 4Cancer Sciences Unit, University of Southampton, 5Haematology Department, University Hospital Southampton NHS Trust, Southampton, United Kingdom

Background: B cell receptor (BCR) signaling through surface IgM (slgM) is key to the survival and proliferation of normal and chronic lymphocytic leukemia (CLL) cells, and can be targeted effectively by the BTK inhibitor ibrutinib. Chronic exposure of the BCR to (super)antigen leads to downmodulation of slgM,
but not of sIgD, levels and signaling capacity. This is evident in the circulating CLL B-cells which are characterized by variably reduced sIgM levels/signaling. The variability influences outcome and cases with relatively higher sIgM levels/signaling capacity, but not sIgD, have more rapid progression, likely due to a proliferative component.

**Aims:** The aim of this study was to investigate the effect of ibrutinib in vivo on the dynamics and function of sIgM and of other surface molecules associated with the BCR complex on the circulating CLL cells of patients during the early phases of therapy (first 3 months).

**Methods:** Peripheral blood mononuclear cells were collected from 12 CLL patients prior to (pre-) and at 1 week, 1 month and 3 months following commencement of single agent ibrutinib therapy. Expression of BCR-complex associated sIgM, sIgD, CD19 and other surface markers was assessed by flow cytometry. Signaling capacity following sIgM stimulation was measured by immunoblotting. Following biotinylation of cell surface proteins, the N-glycosylation pattern of the μ chain was assessed by immunoblotting as a readout of sIgM maturation. Expression of sIgM was obtained from all patients (REC: H228/02/02).

**Results:** At week 1 of ibrutinib therapy, there was a dramatic increase in the expression of sIgM on the circulating CLL cells (mean fold increase 1.6, P=0.001), while expression of sIgD and CD19 remained constant. At this time point, increased sIgM expression associated with full N-glycan maturation of sIgM heavy-chain, indicative of recovery from antigen engagement at tissue sites. Also, the sIgM levels correlated with increased anti-igM mediated SYK phosphorylation (r=0.64, P=0.03), to indicate functionality upstream of BTK. Sequential assessment at month 1 and 3 revealed that sIgM levels were similar to that observed prior to therapy, with preserved upstream signaling ability. In marked contrast, the other BCR complex associated molecules sIgD, CD19 and CD20 all reduced expression (P<0.001). Reduction of these markers was also accompanied by reduction of cell size and of other surface markers while overexpression of autophagy marker LC3B2 was documented.

**Summary/Conclusions:** Our data point to two major events dissociating sIgM expression and function from other BCR-complex associated molecules. In the initial phase, the increased sIgM expression and maturation, with no changes of other BCR-associated molecules, appears consequent to lack of antigen encounter, likely due to inhibition of chemokine-mediated entry to tissue sites. In the later phases the circulating CLL cells will suffer lack of tissue derived growth/differentiation stimuli. In their absence, CLL cells will reduce expression of several markers and cell size, possibly explained by autophagocytic mechanisms aiming to protect the circulating CLL cells from death unless ibrutinib therapy is withheld.

**E998**

**ROLE OF THE COMBINATION MEK1/2 INHIBITOR BINIMETINIB AND AKT INHIBITOR MK2206 IN CLL**

S. Sandhu1,2,*, S. Mulligan2,3, G. Best2

1Acute Medical Unit, Royal Melbourne Hospital, Parkville, 2Northern Blood Research Centre, Kolling Institute of Medical Research, 3Haematology, Royal North Shore Hospital, St Leonards, Australia

**Background:** Clinical trials of ibrutinib and idelisib demonstrate the efficacy of B-cell receptor-targeted therapies for CLL. We sought to investigate the efficacy of targeting both the BCR and the MAPK-ERK1/2 signaling pathways.

**Aims:** To evaluate the role of targeting the Ras-Raf-MEK1/2-ERK1/2 together with the PI3K-AKT pathways as a potential novel approach in treating chronic lymphocytic leukemia. In particular, assessing the efficacy of MEK1/2 inhibitor, binimetinib (MEK162), in combination with either a PI3K inhibitor, idelisib or an AKT inhibitor, M2206.

**Methods:** All experiments conducted on primary CLL cells were co-cultured with CD40L-expressing stroma which mimics the support conferred by the tumour environment. Firstly, the effects of M2206 and idelisib at doses varying from 1 to 40µM were tested on primary CLL cells. Secondly, binimetinib and M2206 were tested as single agents and in combination at 20µM against primary CLL cells. Thirdly, binimetinib at 20µM combined with varying doses of idelisib on primary CLL cells. The mechanisms underlying the effects of binimetinib in combination with M2206 in primary CLL cells were investigated by western blotting with changes in the expression of phosphorylated and total forms of AKT, MCL-1, and ERK1/2 assessed. Expression of B-actin was used as a loading control.

**Results:** MEK2206 is effective against CLL cells co-cultured with stromal cells in a dose dependent manner. It was also observed that the primary CLL cells co-cultured with the CD40L-expressing stroma were significantly more sensitive to M2206 than to idelisib (Figure 1A). No cytotoxic effects of binimetinib
were observed while the combination with MK2206 was significantly more effective than either drug alone, suggestive of synergy between the two drugs (Figure 1B). The analysis of binimetinib at 20μM with idelalisib failed to demonstrate any additive effects or suggestion of synergy between the two drugs (Figure 1C). Binimetinib treatment led to an increase in the activity of AKT and a decrease in ERK1/2 phosphorylation. MK2206 completely abrogated the activation of AKT and MCL-1 phosphorylation when combined with binimetinib (Figure 2A). Although we observed a reduction in AKT phosphorylation following idelalisib alone, it had no effect on the levels of AKT activity induced by binimetinib or the levels of phosphorylated MCL-1 protein. This result was irrespective of the dose of idelalisib used (Figure 2B). We explored the possibility that protein kinase C (PKC) may be involved in binimetinib-induced downregulation. Using the pan-PKC inhibitor GF109203X (GFX), we demonstrated that inhibition of PKC significantly reduces binimetinib-induced phosphorylation of AKT with no effect on the activity of ERK1/2-MAPK (Figure 2C). This data suggest a role for PKC in the regulation of AKT activity in CLL cells.

Summary/Conclusions:

Dual inhibition of MAPK-ERK1/2 and AKT signaling may be effective at targeting the proliferative/drug-resistant compartment of CLL that resides in the tumour microenvironment.

E999
TARGETING HIF-1Α AND ITS REGULATORY PATHWAYS AS A STRATEGY TO HAMPER LEUKEMIA-MICROENVIRONMENT INTERACTIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA

C. Vitale1,2,3, V. Grigio1,2, M. Todaro1,2, C. Riganti3, I. C. Salaroggia3, C. Salvetti1,2,4, I. Rigoni5,2,4, M. Foglietta7,8, B. Castellà1,2, M. Boccadoro1,2,4, M. Massaia1,2,4, M. Coscia1,2,4

Background: The CXCL12/CXCR4 axis has a fundamental role in the microenvironment-mediated protection of chronic lymphocytic leukemia (CLL) cells from spontaneous and drug-induced cell death. The binding of CXCL12 with CXCR4 activates multiple intracellular pathways, including RhoA- and Ras-dependent signaling. We have previously shown that co-culture with stromal cells (SC) induces in CLL cells the activation of RhoA/RhoA kinase and Ras/ERK1-2 signaling, the upregulation of Akt, and an increased activity of the transcription factor HIF-1α (Rigoni et al., Oncotarget 2015).

Aims: The purpose of this study was to identify new potential pharmacological targets involved in the CXCL12/CXCR4 axis in order to impair the protection exerted by SC towards spontaneous and fludarabine-induced apoptosis in CLL cells.

Methods: Peripheral blood was collected from 62 patients with CLL. In selected experiments, the M2-1084 murine SC line and the HS-5 human SC line were used. Patient-derived bone marrow SC were generated from 12 patients with CLL. Where indicated, cell cultures were treated with recombinant CXCL12 (100 ng/ml), CXCR4 inhibitor AMD3100 (5 μM), fludarabine (F-ar-A, 10 μM), simvastatin (1 μM), ERK1-2 kinase inhibitor PD98059 (10 μM), HIF-1α inhibitor BAY87-2243 (1 μM), and PI3K inhibitor idelalisib (10 μM). RhoA and Ras activities were evaluated by an ELISA-based assay and by pull-down assay, respectively. ERK1-2, HIF-1α amount in whole cell extracts and in nuclear fraction, and HIF-1α phosphorylation were evaluated by Western Blot. RhoA kinase, Akt and HIF-1α activities were measured with specific immunosay kits. CXCL12 was quantified by ELISA. Cell viability was determined by Annexin-V/propidium iodide immunostaining and flow cytometry analysis.

Results: The exposure of CLL cells to recombinant CXCL12 led to the activation of RhoA- and Ras-dependent signaling, and to the downstream upregulation of HIF-1α. The CXCR4 antagonist AMD3100 completely abrogated the positive regulation exerted by both CXCL12 and SC, thus unveiling the key role of the CXCL12/CXCR4 axis in the SC-induced modulation of these signaling pathways. Thehibition of Ras and RhoA activity by simvastatin, and the inhibition of ERK1-2 and HIF-1α by PD98059 and BAY87-2243 effectively blocked the SC-induced expression and activity of HIF-1α, significantly impairing the SC-mediated protection of CLL cells, both in absence and presence of fludarabine. Similar effects were observed by targeting the PI3K/Akt pathway with idelalisib. We then investigated whether targeting RhoA- and Ras-dependent signaling could modulate HIF-1α also at the SC level. Simvastatin and BAY87-2243 effectively inhibited HIF-1α expression both in SC lines and in patient-derived SC. Moreover, simvastatin significantly reduced the secretion of CXCL12, which is a known transcriptional target of HIF-1α. Summary: Our data demonstrate that the targeting of HIF-1α and its regulatory pathways, both at the tumor cell and at the SC level is an appealing strategy to overcome the microenvironment-mediated protection toward spontaneous and fludarabine-induced apoptosis in CLL cells.

Anna Hospital, Ferrara, 5Department Medical Sciences, University of Milan, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Chemomunotherapy with fludarabine, cyclophosphamide and rituximab (FCO) is the optimal front-line treatment for fit chronic lymphocytic leukemia (CLL) patients. IGHV mutations and FISH lesions are predictive markers of response and progression-free survival after FCR. Minimal residual disease (MRD) is the single best post-treatment predictor of long-term outcome after FCR, independent of biologic prognostic markers.

Aims: To explore whether conventional biologic markers (i.e. IGHV mutations, FISH lesions) and TP53, NOTCH1, BIRC3 and SF3B1 mutations can predict the obtainment of a MRD negativity after first-line treatment of CLL patients with FC and ofatumumab (FCO).

Methods: Eighty young (≤65 yrs) and fit CLL patients from 15 Italian centers were enrolled in the GIMEMA LLC0911 first-line trial and treated with 6 cycles of FCO. CLL diagnosis, treatment requirement and response were defined according to the 2008 wCLL guidelines. MRD was evaluated in responding patients by 8-color flow cytometry in the peripheral blood (PB) and bone marrow (BM) 2 months after the end of induction (month +8), and every 6 months thereafter: flow negative cases were analyzed by RQ-PCR, according to the guidelines. The association between CLL biologic markers and MRD clearance after FCR was tested by Fisher’s exact test: logistic regression models were used to estimate the risk values in univariate and multivariate analyses.

ISOCHROMOSOME 17q, UNBALANCED TRANSLOCATIONS AND 8q GAIN REPRESENT ADVERSE PROGNOSTIC FACTORS IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WITH 17p DELETION. A GFCH STUDY.
E1002
THE MICROENVIRONMENT REGULATES THE EXPRESSION OF MIR-21 AND TUMOR SUPPRESSOR GENES PTEN, PIAS3 AND PDCD4 THROUGH THE BCR SIGNALING PATHWAY IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL).

et al, 2013), the high and intermediate risk groups (del17p/TP53/BRCA2+ or del11q/NOTCH1/53F8B1+) showed a significantly lower probability of achieving a MRD negativity (36%, 10/28) than the low and very low risk groups (12/-negative FISH/del13q/WT for 4 genes: 81%, 29/36) (p=0.0003). The 40 flow cytometry MRD- cases were also evaluated by RC-PCR: 22 (55%) were reclassified as MRD+. By combining the two methods, 47/65 (72%) were MRD+ and 18/65 (28%) MRD- at the end of FC. Mutated (M)-IGHV status was significantly associated to a molecular MRD- (12 MRD-15 MRD+ 44%) compared to unmutated (UM)-IGHV cases (5 MRD-/32 MRD+, 13%) (p=0.0092). Moreover, when M-IGHV status is reinforced by the absence of del17p/TP53mut/del11q, the association with a deep MRD negativity got stronger (12 MRD-15 MRD+ 44% compared to 5 MRD-/32 MRD+, 13%) (p=0.0036). A multivariate model including FISH lesions, gene and IGHV mutations supports the independent role of FISH and IGHV profile in predicting MRD negativity by flow and RC-PCR, respectively.

Summary/Conclusions: In CLL patients treated with the FCO combination (LLC0911 Gimema trial), GFR detection significantly improved after 6 months. The IGHV status, cell of origin (CO) and disease aggressiveness defined the largest differences in MRD- rates. Eight out of 10 patients maintained a good quality of response.

Results: First, we observed that miR-21 expression was significantly higher in patients with high expression of ZAP-70. Subsequently, using stably transfected cells we found that miR-21 expression was significantly increased upon BCR crosslinking, which was enhanced by ectopic expression of ZAP-70. We also observed that inhibition of both MAPK and STAT3 pathways impairs the regulation of miR-21 expression. The BCR is one of the key players involved in the crosstalk between CLL cells and the microenvironment. Furthermore, it has a critical role in pathogenesis and prognosis of CLL. Accordingly, different factors related to increased BCR signaling are adverse prognostic factors in CLL, such as IGHV genes, high expression of ZAP-70 and increased serum levels of CCL3. Expression of ZAP-70 in CLL cells has been related to enhanced response to BCR stimulation, as well as to increased response to diverse microenvironmental stimuli from the microenvironment. MI-21 is an oncogenic microRNA that has been found to be overexpressed in a wide variety of neoplasms where it participates in oncogenic events such as proliferation, resistance to treatment, and metastasis: its overexpression in CLL has been associated to refractoriness to fludarabine and to shorter overall survival and higher probability of progression.

Aims: In order to further elucidate the molecular mechanisms defining bad prognosis CLL by further elucidation of the role of ZAP-70 in the crosstalk between CLL cells and the microenvironment, we studied the relationship between ZAP-70 protein and miR-21 and how it is influenced by the microenvironmet.

Methods: Peripheral blood mononuclear cells (PBMC) from 48 patients diagnosed with CLL were isolated by Ficoll-Paque Plus density gradient centrifugation. Ramos B-cells stably transfected with a vector encoding for ZAP-70 protein fused with Green fluorescent protein (GFP) or GFP only as a control were treated with Akt (LY294002), MAPK (PD98059) and STAT3 (USI-124) inhibitors for 1 hour. BCR was stimulated with F(ab)2 anti-IgM. PBMC were co-cultured with bone marrow stromal cells with CD40L and CpG to mimic the microenvironment found in proliferation centers. After 48 hours CLL cells were harvested to analyze cell viability, cell proliferation and mRNA expression. Expression levels of the primary miR-21, miR-21, PTEN, PDCD4 and PIAS3 were measured by QRT-PCR.

Results: First, we observed that miR-21 expression was significantly higher in patients with high expression of ZAP-70. Subsequently, using stably transfected Ramos B-cells with ZAP-70 protein we found that pri-miR-21 and mature miR-21 levels were significantly increased upon BCR crosslinking, which was enhanced by ectopic expression of ZAP-70. We also observed that inhibition of both MAPK and STAT3 pathways impairs the regulation of miR-21 expression after ZAP-70 activation. Moreover, the induction of miR-21 expression after ZAP-70 activation also induced downregulation of the tumor suppressor gene PTEN, and the tumor suppressor genes PDCD4 and PIAS3. In vivo, miR-21 was shown to regulate the proliferation of primary CLL cells induced ZAP-70 and miR-21 expression, as well as downregulation of the putative miR-21 targets. Interestingly, the increase in miR-21 after co-culture was significantly impaired by irbritinib, indicating that the BCR signaling pathway is involved in its regulation in primary CLL cells. Furthermore, miR-21 co-culture-induced increased CLL survival correlated with miR-21 upregulation.

Summary/Conclusions: In conclusion, stimuli from the microenvironment are capable of regulating expression of miR-21 and tumor suppressor genes with various chromosome partners, the most frequent being the recurrent der(17;18)(q10;q10) (n=32, 13%), followed by translocations involving chromosomes 8, 13, 14, 21, 15. Unbalanced translocations involving 17p and chromosome 8 (n=26, 11%), lead either to del8p (n=17), gain8q (n=6), or del8q (n=3). The other 17p abnormalities were: deletion 17p (n=45, 19%), monosomy 17 (n=15, 6%), isochromosome 17q ([i(17q)] (n=9, 4%) and ring of chromosome 17 (n=4, 1%). Among the additional abnormalities accompanying the 17p- unbalanced translocations were found in 121/195(63%) of patients. Combining FISH and K, del13q was detected in 71/118(60%) of cases, del8p in 40/189(21%), tr12 in 30/195(15%), gain8q in 13/105(12%), and del11q in 20/161(12%). By univariate analysis, the parameters which were associated with a significantly shorter survival were: age ≥65 years: 21 patients (n=21), 8q(der)/17p- (n=17) (69 months vs 179, p=0.0375), the presence of unbalanced translocations in addition to 17p- (153 vs 223 months, p=0.03), and gain8q (74 vs 123 months, p=0.014). Monosomy 17, a total number of abnormalities ≥6 and gain8q predicted a shorter TTF. By multivariate analysis, age ≥65 years, stage B/C and gain8q remained significant for OS.
impact of recurrent mutations on progression-free survival in CLL patients treated with front line rituximab-based regimens.

Methods: Peripheral blood samples from CLL patients (N=17) were obtained and analysed before (day 0) and 24 hours (day 1) after RTX administration (375mg/m², single agent).

Results: It was described that CLL cells that interacted with stromal cells in vivo can be characterised by relatively weak cell-surface expression of chemokine receptor CXCR4 and high expression of activation marker CD55 and CD5. However, despite the fact that RTX has clinical outcome of patients with CD20-positive B-cell malignancies, including CD20-positive CLL (oon et al., 2001). We analysed blood samples obtained from CLL patients treated with RTX as a single agent and indeed, we observed that RTX preferentially and nearly completely eliminates the CXCR4dimCD55bright subpopulation after the first RTX dose (8.3% pre-RTX vs 2.1% post-RTX, P<0.0001). We further demonstrated that CXCR4 dim signalling efficiency of the CXCR4dimCD55bright subpopulation, since CD20 was proposed to play a role in BCR signalling. We observed that CXCR4dimCD55bright CLL cells have higher immunoglobulin (IgM) expression (~2-fold, P<0.005) which was coupled with higher responsiveness to BCR crosslinking with anti-IgM (P<0.005). Moreover, CXCR4dimCD55bright cells also have higher levels of CD19 (1.8-fold, P<0.0001), which is an important component of BCR complex that augments signal transduction. Furthermore, we demonstrated that CXCR4dimCD55bright cells have higher phosphorylation of several proteins involved in PI3K/BCR/NFkB signalling pathway (P<0.05) compared to CXCR4dimCD55bright cells obtained from the same patient. This led us to hypothesize that the down-regulation of BCR signalling is likely of physiological importance for PI3K/BCR signalling. Indeed, we observed significant reduction in phosphorylation of tyrosine-protein kinases associated with PI3K/BCR signalling after silencing of CD20 by siRNA in B cells.

Summary/Conclusions: We showed that CXCR4dimCD55bright CLL subpopulation in peripheral blood of CLL patients has the highest surface levels of CD20 and is therefore preferentially and effectively eliminated by RTX. These CLL cells likely represent the most “aggressive” subclone of CLL cells since they have relatively high proliferative and BCR signalling capacity.
B cells we performed a co-immunoprecipitation assay, followed by Western blotting analysis, at steady state and after IgM (10µg/ml) stimulus. We also evaluated the interaction between c-Cbl and Lyn after treatment with 17-DMAG (500nM), a potent HSP90 inhibitor.

**Results:** We demonstrated that c-Cbl is overexpressed (p<0.001, Student’s t test in CLL B lymphocytes with respect to normal B cells. We found that in neoplastic B cells c-Cbl did not co-immunoprecipitate with Lyn neither after BCR trigger. We obtained similar results when we treated neoplastic B lymphocytes with 17-DMAG to dissociate the Lyn-Hsp90 complex: after 1h, 2h and 4h of treatment we immunoprecipitated Lyn demonstrating that neither before nor after IgM stimulation c-Cbl interacts with this kinase. These results support the hypothesis that c-Cbl is not involved in Lyn turnover. Data obtained from 10 independent experiments showed that in CLL neoplastic cells the phosphorylation on Y700 increased after 5' and 10' of IgM stimulus, highlighting the involvement of c-Cbl in BCR signaling.

**Summary/Conclusions:** These preliminary results prompt us to investigate the role of c-Cbl in the development of neoplastic clone. In CLL cells c-Cbl is overexpressed with respect to normal B cells, and upon BCR engagement it undergoes Y700 phosphorylation. However, c-Cbl is unable to stably interact with Lyn suggesting an altered c-Cbl function that contribute to affect cell homeostasis.

**Background:** CLL B cells inability to reach programmed cell death is due to intrinsic defect and extrinsic factors. Among the intrinsic fault there is the misregulation of the phosphorylation pattern. Reversible protein phosphorylation is a fundamental post-translational modification by which virtually all cellular events are regulated. The crucial players involved in this dynamic process are protein kinases and protein phosphatases, which are placed at the different levels of cellular signaling. The Src Family Kinase (SFK) Lyn is a key factor in the dysregulation of survival and apoptotic pathways of malignant B cells in CLL. One of the effects of Lyn’s action is the spatial and functional segregation of the tyrosine phosphatase SHP-1 into two pools, one beneath the plasma membrane in an active state promoting pro-survival signals, the other in the cytosol in an inhibited conformation and unable to counter the elevated level of cytosolic tyrosine phosphorylation.

**Aims:** Because CLL is characterized by a high level of Lyn-dependent tyrosine phosphorylation in the cytosol, we focused our attention on compounds capable of directly or indirectly driving the activation of SHP-1 which in turn could counter the action of Lyn and induce cell demise. The goal is to discover new therapeutic strategies to defeat a still incurable disease as CLL.

**Methods:** B cells were collected from 37 CLL patients. Freshly isolated CLL cells incubated with increasing concentrations of nintedanib (0-24 μM) and MP07-66 (2,2-diethoxyethyl[4-(hexyloxy)phenyl]methyl)amine) for 24 and 48 hours with/without a layer of Mesenchymal Stromal Cells (MSCs). Caspase dependence was demonstrated using the pan-caspase inhibitor z-VADfmk.

**Results:** We performed in vitro phosphatase activity assays on the cytosolic pool of SHP-1 in the presence of increasing concentrations of nintedanib, a recently discovered kinase inhibitor recently shown to trigger SHP-1 activity. Nintedanib treatment could activate the phosphatase (at Ser591), and inhibited, form of SHP-1 and to induce apoptosis, depending on the caspase activation, after 24h and 48h at marked level. Interestingly, we recently demonstrated that Ser591 phosphorylation of SHP-1 could be dephosphorylated by PP2A. In this scenario, the restoration of PP2A activity by a fingenolin-like analogue devoid of immunosuppressive action, called MP07-66, and the subsequent dephosphorylation of PP2A substrates, was shown to trigger apoptosis, like nintedanib, in a caspase-dependent manner. Since our data suggest that the activation of either PP2A or SHP-1 triggered by specific small molecules caused stimulation of each other’s activity, we treated CLL cells with nintedanib and PP2A and MP07-66 together demonstrating an improved effect when used in combination.

Similar results, in all the conditions, were obtained in presence of a MSC layer, showing the capability of these treatments to counteract the protective action of tumor microenvironment.

**Summary/Conclusions:** In conclusion, our findings indicate that phosphatase activators may represent a new weapon against this form of leukemia. Overall, these data corroborate the hypothesis that the inhibition of PP2A is central to CLL cell viability and that its activation is facilitated by the supportive action of SHP-1, as demonstrated by the effect produced by the simultaneous use of the respective activators.

**TARGETING NAPROTONICLES TO CHRONIC LYMPHOCYTIC LEUKEMIA: EXPLOITING THE PROPERTIES OF CXCR4**

C. McCallion1, A. Booth1, J. Adams2,3, K. Rees-Unwin2, A. Peters1, A. Pluen4, S. Webb1, J. Burth1

1School of Chemistry, University of Manchester, Manchester, 2School of Chemistry, University of Leeds, Leeds, 3Institute of Cancer Sciences, 4School of Pharmacy, University of Manchester, Manchester, United Kingdom

**Background:** Nanoparticle carriers of therapeutic agents (“drug delivery vehicles”) can be used to deliver drugs to specific cells through the incorporation of a “targeting ligand”. Targeting provides the therapeutic benefit of achieving high local drug concentrations while reducing off-target effects against other cells; the combined ligand/delivery vehicle system can also be manipulated to determine the uptake pathway or modulate biological effects. The CXCR4 chemokine-receptor is an attractive target for drug delivery vehicles. It is overexpressed in cancers including chronic lymphocytic leukaemia (CLL) (Doman ska et al., 2013) and binding to its ligand (CXCL12) may induce proliferation, survival or entry into protective cellular niches (Ganju et al., 1998). Targeted nanoparticles that can bind and antagonise CXCR4 could therefore allow specific drug delivery to cancer cells while simultaneously blocking CXCL12-induced chemoprotection.

**Aims:** A drug-design strategy was developed to synthesise and evaluate a novel CXCR4 targeting motif (BAT1) with structural similarity to Plerixafor, a CXCR4-antagonist in clinical use. A key design principle was to incorporate a polyethylene glycol (PEG) tether with a functional end-group to provide an attachment point for cargoes, particularly liposomes. The evaluation aim was to assess the effectiveness of BAT1 to deliver a chemotherapy cargo to CLL cells within an ex vivo culture system.

**Methods:** A three-step synthesis was used to generate BAT1 (Figure 1A); its structure and purity was confirmed using NMR, MS and HPLC. Bioactivity testing employed primary CLL lymphocytes. Assays evaluated: CXCR4 binding-affinity (flow cytometry competition assays), cell-binding characteristics (immunocytofluorescence) and blockade of CXCL12-induced signalling (immunoblot). Initial targeting assessment used a fluorescent label (Cy5) conjugated to the functional PEG tether. Cholesteryl chloroformate was then selected to conjugate BAT1 to PEGylated liposomes.

**Results:** The binding affinity of BAT1 (Figure 1B) was demonstrated using competition assays (CXCL12, anti-CXCR4 ab, and the bis(cyclo)drug Plerixafor). The studies confirmed BAT1 had high affinity for CXCR4 receptors expressed on primary CLL cells. Immunocytofluorescence comparison with its native ligand confirmed binding of BAT1 to the CLL cell surface, while immunoblotting demonstrated blocking of CXCL12-induced signalling (Figure 1C and 1D). The fluorescent moiety Cy5 was covalently linked to the functional PEG tether. Cholesteryl chloroformate was then selected to conjugate BAT1 to PEGylated liposomes.

**Results:** We performed in vitro phosphatase activity assays on the cytosolic pool of SHP-1 in the presence of increasing concentrations of nintedanib, a recently discovered kinase inhibitor recently shown to trigger SHP-1 activity. Nintedanib treatment could activate the phosphatase (at Ser591), and inhibited, form of SHP-1 and to induce apoptosis, depending on the caspase activation, after 24h and 48h at marked level. Interestingly, we recently demonstrated that Ser591 phosphorylation of SHP-1 could be dephosphorylated by PP2A. In this scenario, the restoration of PP2A activity by a fingenolin-like analogue devoid of immunosuppressive action, called MP07-66, and the subsequent dephosphorylation of PP2A substrates, was shown to trigger apoptosis, like nintedanib, in a caspase-dependent manner. Since our data suggest that the activation of either PP2A or SHP-1 triggered by specific small molecules caused stimulation of each other’s activity, we treated CLL cells with nintedanib and PP2A and MP07-66 together demonstrating an improved effect when used in combination.

Similar results, in all the conditions, were obtained in presence of a MSC layer, showing the capability of these treatments to counteract the protective action of tumor microenvironment.

**Summary/Conclusions:** In conclusion, our findings indicate that phosphatase activators may represent a new weapon against this form of leukaemia. Overall, these data corroborate the hypothesis that the inhibition of PP2A is central to CLL cell viability and that its activation is facilitated by the supportive action of PP2A and SHP-1, as demonstrated by the effect produced by the simultaneous use of the respective activators.

**Figure 1.**

**Summary/Conclusions:** A novel bis(cyclo) CXCR4 antagonist and targeting motif – BAT1 – has been synthesised. BAT1 demonstrates high affinity for the CXCR4 receptor, supporting targeted delivery to CLL cells. Receptor binding is associated with simultaneous blockade of CXCL12-mediated signal initiation and effect, and therefore biological modulation of target cell behaviour. BAT1

haematologica | 2017; 102(s2) | 413
is readily attached to liposomes through the PEG moiety, which will allow chemotherapy delivery using stealth-liposomes (Allen and Cullis, 2013). Liposome size and composition will be used to drive pathway-specific uptake to different intracellular compartments. BAT1 therefore offers significant potential to enhance therapy in CLL.

**E1008**

**THE ROLE OF THROMBOPOIETIN AS A TOOL OF IMMUNE MODULATION IN CHRONIC LYMPHOCYTIC LEUKEMIA**

S. Ringelstein-Harlev1,*, M. Fanadka2, N. A. Horowitz1, T. Katz1  
1Department of Hematology and Bone Marrow Transplantation, Rambam Health Care Campus,  
2Bruce Rappaport Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, Israel

**Background:** Thrombopoietin (TPO) is the major regulator of platelet production, synthesized mainly by liver cells. The TPO receptor (TPO-R) is known to be expressed on platelets, megakaryocytes and CD34+ cells. It has been reported that patients with immune thrombocytopenic purpura, treated with TPO-R agonists, developed alterations in the T-cell repertoire and pattern of cytokine secretion from B- and T-cells. Thus, clinical activity of these agents could be attributed in part to immune modulation. In chronic lymphocytic leukemia (CLL), characterized by aberrant T-cell responses, high TPO serum levels coexist with low levels of TPO gene transcripts in the malignant cells. These observations could imply that TPO acts as an immune modulator in CLL.

**Aims:** The aim of the current study was to explore the role of TPO in T-cell modulation in CLL.

**Methods:** B-cells and CD4+ T-cells were isolated from peripheral blood mononuclear cells (PBMCs) of untreated CLL patients (Rai stages 0-IV) and healthy donors. First, the percentage of CD4+CD25+FOXP3+ T-cells was assessed. The next step was to assess T-cell proliferation in response to TPO stimulation. TPO mRNA expression was measured by qPCR.

**Results:** CD4+ T-cells of CLL patients expressed significantly higher levels of TPO-R (CD110) compared to T-cells of healthy donors, with a mean fluorescent intensity of 76±148 and 498±206, respectively (p<0.05, n=6). Stimulation of proliferating CD4+ T-cells with TPO significantly increased the number of cells retaining in GO (from 75±5.4% to 8.6±6.4%; p<0.05, n=8), whereas proliferation of healthy donor T-cells remained unaffected by TPO (11.5±5.7% and 11.4±5.7% of cells in GO; p=NS; n=6). Additionally, TPO stimulation resulted in a 24% increase of Treg levels in patient T-cells (from 2.1±1.7 to 2.6±1.7%; p<0.01; n=8). However, the Treg levels were not altered in healthy donor T-cells subjected to TPO. TPO increased the percentage of CD4+CD25+FOXP3+ T-cells by 0.74%±0.7 and 0.74%±0.8; p=NS; n=5), which is similar to their proliferation response to this growth factor. To determine whether CLL cells could be the TPO source in this disease, CLL mRNA expression in the malignant cells was assessed, demonstrating a baseline ct value of 721±296, which significantly increased to 1033±342 (p<0.05; n=6) upon ODN activation.

**Summary/Conclusions:** Treatment with TPO increased ROR1 expression in CLL cells. Infection with CLL patient T-cells with TPO significantly increased T-cell proliferation and TPO mRNA expression in the malignant cells. These observations could imply that TPO acts as an immune modulator in CLL.

**NORMAL SERUM PROTEIN ELECTROPHORESIS IDENTIFIES AN IMMUNE LENALIDOMIDE PROGNOSIS GROUP AMONG IGHM MUTATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA, WITH A MEDIUM TFS OVER 18 YEARS**

J. Chauzeix1,2,*, N. Bargues1, M.-P. Laffort1, M. Deveza1, V. Combeau1, V. Renat1, E. Guérin1, F. Trimoreau1, N. Dmytruk3, J. Feuillard1, N. Gachard1, D. Rizzo1  
1Department of Hematology and Bone Marrow Transplantation, Rambam Health Care Campus, 2Bruce Rappaport Faculty of Medicine, Technion, Israel

**Background:** Approximately 36% of patients with chronic lymphocytic leukemia (CLL) have abnormal serum protein electrophoresis (SPE), either with hypogammaglobulinemia or with monoclonal immunoglobulin (Ig) peak. In this study, we compared locally recruited patients with normal and abnormal SPE.

**Aims:** The aim was to identify prognosis parameters.

**Methods:** A total of 189 patients (132 abnormal SPE and 57 normal SPE) were compared locally recruited patients with normal and abnormal SPE respectively. Mutated IGHV status was found in 65% in normal SPE and 56% with abnormal SPE.

**Results:** In this series, 73%, 19% and 8% of patients were at Binet stage A, B and C respectively, and 30% had a normal SPE at diagnosis. Ninety six percent of patients with normal SPE were at Binet stage A, versus 63% of patients with abnormal SPE (Chi2 test : p<10-5). Median lymphocytosis at diagnosis was lower in patients with normal SPE (12.82 G/l versus 19.54 G/l in abnormal SPE; Fisher test : p=0.00169). Regarding genetic prognostic factors, we found that 58% of cases with normal SPE had a good prognosis profile (mutated IGHV and/or isolated del13q, with no other genetic abnormality detected), meanwhile 65.2% of patients with abnormal SPE exhibited at least one poor prognosis marker (unmutated IGHV, mutation of SF3B1, NOTCH1, or BIRC3 mutations (determined by high through put and Sanger sequencing), and cytogenetic abnormalities such as del17p, del11q, del13q and trisomy 12 (assessed by standard caryotype, FISH analysis and QMPSF).

**Results:** In this series, 73%, 19% and 8% of patients were at Binet stage A, B and C respectively, and 30% had a normal SPE at diagnosis. Ninety six percent of patients with normal SPE were at Binet stage A, versus 63% of patients with abnormal SPE (Chi2 test : p<10-5). Median lymphocytosis at diagnosis was lower in patients with normal SPE (12.82 G/l versus 19.54 G/l in abnormal SPE; Fisher test : p=0.00169). Regarding genetic prognostic factors, we found that 58% of cases with normal SPE had a good prognosis profile (mutated IGHV and/or isolated del13q, with no other genetic abnormality detected), meanwhile 65.2% of patients with abnormal SPE exhibited at least one poor prognosis marker (unmutated IGHV, mutation of SF3B1, NOTCH1, or BIRC3 mutations (determined by high through put and Sanger sequencing), and cytogenetic abnormalities such as del17p, del11q, del13q and trisomy 12 (assessed by standard caryotype, FISH analysis and QMPSF).
median TFS of 4 years (log rank test: p=0.0003). Thus, patients with normal SPE and IGHV mutated status constitute a group with excellent prognosis.

Summary/Conclusions: In conclusion, normal SPE was associated with good outcome with decreased accumulation of side genetic events (in particular, SF3B1 mutations). This analysis shows a bias in IGHV repertoire according to SPE status. These results also clearly suggest that patients with a normal SPE and unmutated IGHV are an extremely quiet CLL natural history. This could be either due to the weaker activity of the disease and/or to the absence of adverse consequences of a concomitant paraprotein.

HSP70 EXPRESSION IS MODULATED BY ITS MASTER REGULATOR HSF1 VIA SIGNALING PATHWAYS IN CHRONIC LYMPHOCYTIC LEUKEMIA

F. Frezzato1,2, F. Raggi1,2, B. Accordini1, S. Bresolin1, S. Severini1,2, V. Martini1,2, V. Tramarico1,2, L. Martinello1, A. Visentin1,2, S. Imbergamo1, E. Scomazzon1, M. Faccoli1,2, F. Piazza1,2, G. Basso1, G. Semenzato1,2, L. Trentin1,2,∗
1Department of Medicine, University of Padua, 2Venetian Institute of Molecular Medicine (VIMM), 3Department of Women’s and Children’s Health, University of Padua, Padova, Italy

Background: The search for molecules involved in apoptosis resistance/ increased survival of B cells from Chronic Lymphocytic Leukemia (CLL) is still ongoing since this disease remains not definitively understood. We recently found that the Heat Shock Protein of 70kDa (HSP70), expressed in response to a wide variety of stress signals and allowing cells to survive to lethal conditions, was particularly overexpressed in neoplastic B cells from CLL. Moreover, the Heat Shock Factor 1 (HSF1), the major responsible for the transcription of HSP70, is itself overexpressed in CLL and strictly correlated to HSP70. In response to stress, HSF1 becomes phosphorylated, forms homomers, binds DNA and activates heat shock gene transcription. HSF1 is regulated by a fine balance of activatory/inhibitory phosphorylations mediated by kinases belonging to pathways triggered by RAS (i.e. PI3K/AKT/mTOR and RAF/MEK/ERK).

Aim: Since HSP70 is overexpressed in CLL neoplastic B cells and most of “HSF1-phosphorylating actors” belong to signalling pathways taking part from RAS, being the PI3K/AKT/mTOR and the RAF/MEK/ERK pathways, we are herein aimed at gaining information and dissecting this network in CLL B cells.

Methods: In a Reverse Phase Protein Array (RPPA) study, previously performed from 57 CLL patients and 11 healthy volunteers, we evaluated the activation/expression of key signalling proteins. Herein, we focused on HSP70, AKT-Ser473, SAPK-JNK-Thr183/Tyr185 and PDK1-Ser241. Cluster and separated analyses have been performed.

Results: We divided our patients in HSP70-high and HSP70-low considering as cut-off the value of the median of HSP70 expression levels calculated by RPPA and demonstrated that the examined proteins behave in a different way between patients expressing high or low levels of HSP70. HSP70-high patients present high AKT-Ser473, an inhibitor of GSK3β that, in the inhibited form, prevents HSF1 inhibition. By contrast, HSP70-low patients have high MEK1/2-Ser217/221 and ERK-Thr202/Tyr204, known to negatively regulate HSF1. Intriguingly, p38MAPK-Thr180/Tyr182 which has been described to both activate and inhibit HSF1 at different sites, is overexpressed in those patients presenting low levels of HSP70.

Summary/Conclusions: These data would suggest that, in CLL, HSP70 expression is regulated by the modulation of HSF1 activity through the activation of one or the other way triggered by RAS. In particular, an activation of the PI3K/AKT/mTOR pathway leads, as result, to a higher expression of HSP70 while an activation of the RAF/MEK/ERK signalling rather results in HSP70 down regulation. The dissection of signalling pathways connected to HSP70-HSF1 axis in CLL will contribute to define the biology and understand the pathogenesis of this disease.

E1012

THE INTERPLAY BETWEEN TH17 AND TREGS: A NEW IMMUNOSUPPRESSIVE INSIGHT IN CHRONIC LYMPHOCYTIC LEUKEMIA

S. De Matteis1,2, R. Napolitano1, A. Lucchesi2, D. Cancini2, A. Cuneo2, G.M. Rigoli2, E. Volta2, G. Musaraca2
1Bioscience Laboratory, 2Hematology Unit, IRCCS Istituto Scienz, Madrid, Spain, June 22 – 25, 2017

Background: Chronic lymphocytic leukemia (CLL) is the most frequent leukemia in the Western world and it is characterized by the clonal expansion of CD5 positive B cells. In CLL, different T cell dysfunctions have been described, probably related to the interaction with malignant B cells. TH17 and regulatory T cells (Tregs) are subpopulations of T lymphocytes which play a fundamental part in inflammatory response and immune tolerance. However, their role in the immunopathogenesis of CLL has not yet been fully clarified.

Aims: The aim of this study is to clarify the interplay between TH17 and Tregs in the pathogenesis of CLL.

Methods: After obtaining the patient’s informed consent, peripheral blood was collected from 30 untreated CLL patients and 30 age-matched healthy volunteers (HV). Cytokine production was evaluated before and after a 48 h culture of CD4+ T cells in complete medium with IL-6 (o/n), followed by a 5 h stimulation with PMA, ionomycin and Monensin (PIM), or with anti-CD4 APC and anti-CD28 PE or anti-CD4 APC and anti-CD79a PE. Statistical analysis were carried out using the paired and unpaired two-tailed Student’s ts tests and confirmed with the non-parametric Wilcoxon signed-rank test.

Results: In CLL patients we observed a reduced production of IFN-γ and IL-4, respectively from TH1 and TH2 and an increase of IL-17A from TH17, compared to HV. All the observed differences were statistically significant. We also evaluated the ability of CD4+ T cells to secrete IL-17A, IL-10 or both. We reported a statistically significant increase in the frequency of CD4+ IL-17A-producing cells in CLL patients compared to HV, whereas the percentage of IL-17A+/IL-10+ cells remained unchanged. In order to evaluate the functional effects of the observed alterations, we analyzed IFN-γ+/CD4+ T-cells-mediated response after stimulation with C. Albicans for 48 h, with or without depletion of IL-17A-secreting cells. The frequency of IFN-γ-producing T cells resulted statistically significant increased in patients than HV before IL-17A-secreting T cells depletion. Conversely, after IL-17A+ CD4+ T-cells depletion, we didn’t observe significant differences in term of IFN-γ production. We also observed increased IL-23 plasma levels in patients compared to HV. In addition our data highlighted a significantly higher frequency of CD4+ CD25+FoxP3+ T cells (Tregs) in CLL samples, with a statistically significant increase in Tbet+ Tregs, RORγt+ Tregs and GATA-3+ Tregs subpopulations (Figure 1).

Figure 1.

Summary/Conclusions: Our results reported a down-regulation of IFN-γ and IL-4 producing T cells, associated to an increased frequency of Tregs and their subsets in CLL patients, probably trying to overcome the deficit of effector T cells. On the other hand, we observed a rise in IL-17A secreting T cells related to the increased IL-23 production by dendritic cells in order to restore TH17 pool, without changing the percentage of IL-17A+IL10+ cells. These data support the idea of the protective function of TH17 that show an effector and not a regulatory T phenotype. Starting from these observations, this study could pave the way to further researches and applications in the comprehension of the biological and regulatory mechanisms of TH17 and Tregs, supporting the study of a pioneering antitumor therapy in CLL.

Universidad de Murcia, IMIB, Murcia, Spain, 2Translational Hematology and Oncology Research Department, Cleveland Clinic, Cleveland, United States, 3Hematology and Oncology Department, Hospital Morales Meseguer, Centro Regional de Hemodonación. Universidad de Murcia, IMIB,CIBERER, Murcia, Spain

Background: Recently, it has been shown that CDK6-mediated repression of CD25 is required for induction and maintenance of NOTCH1-induced T-cell acute lymphoblastic leukemia.

Aims: The aim of this study was to identify the NOTCH1 mutational status detected by deep sequencing in a cohort of 138 patients and to correlate it with the immunophenotypic profile and CD4+ and CD69 expression.

Methods: We performed targeted NGS sequencing of blood samples, collected at diagnosis, from 138 CLL patients. We designed a TruSeq Custom Amplicon
containing 13 genes and covering 28,099 bases. Paired-end sequencing was performed with Miseq v2.2 chemistry, and a mean depth of 96-fold coverage was obtained. Every patient underwent, at baseline, a flow cytometry characterization with a panel including (slg), (slg,k), CD19, CD5, CD11b, CD81, CD10, CD79b, CD29, CD38, FMC7, CD22, CD45, CD103, CD11c, CD25, ZAP70, CD11a, and CD24. CD4K and CD6K expression levels were quantified by RT-qPCR.

Results: With a median age of 66 y.o. (range, 31-89) and a slight male predominance, the median follow up time of our cohort was 43 months (24-104). We found that 38/138 (28%) patients harbored at least one mutation, with NOTCH1 (n=16, 12%), ATM (n=12, 9%), TP53 (n=9, 7%), and SF3B1 (n=8, 6%) being the most frequently mutated genes. Those patients with a single mutation showed a lower CD25 expression (24 mean fluorescence intensity units (MFU)) than those without a mutation (43 MFU); p=0.03. We could not validate the recently reported association between the presence of NOTCH1 mutations and a low expression of CD25. In our cohort, the MFI expression in NOTCH1 mutated and non-mutated patients was 163 and 146 units, respectively (p>0.05).

We measured CDK4 and CDK6 expression in the CD19+ sorted fraction RNA of 7 NOTCH1 mutated cases and 11 non mutated cases, without finding significant differences (0.26 vs 0.27 for CDK6, 0.025 vs 0.022 for CDK4; p>0.5 in both cases).

Summary/Conclusions: We found a significant inferior expression of CD25 when activating NOTCH1 mutations are present in CLL patients. The relationship found between these two variables, with an inverted direction to that found in physiological conditions, has also been shown in the setting of NOTCH1-mutated T acute lymphoblastic leukemia. In CLL cases, it seems to be independent of CDK4/6 expression, prompting further studies assessing CDK4 and CDK6 regulators.

1Cancer Research Center/Hospital Universitario de Salamanca, SALAMANCA, MADRID, Spain
2Hospital Virgen Blanca, LEÓN, 3Hospital del Bierzo, PONFERRADA, 4Hospital Río Carrión, PALENCIA, 5Hospital General, SEGOVIA, 6Hospital Río Hortega, Valladolid, 7Hospital Santa Bárbara, SORIA, 8Hospital Clínico Universitario, VALLADOLID, 9Hospital Juan Ramón Jiménez, HUELVA, 10Hospital Miguel Servet, ZARAGOZA, 11Hospital Virgen del Puerto, PLASENCIA, 12Hospital Universitario Infanta Leonor/Universidad Complutense de Madrid, MADRID, Spain

Background: Next-Generation sequencing (NGS) studies have revealed a number of recurrently mutated genes in chronic lymphocytic leukemia (CLL). It is reasonable to argue that evaluation of the newly gene mutations as prognostic markers would help to improve prognostic classification of CLL patients. Interestingly, gene mutations could help us to refine the prognosis in the group of CLL patients with other prognostic markers associated with good prognosis.

Aims: To analyze the presence of mutations of a panel of genes by NGS and its prognostic impact in patients with CLL, focusing in the groups of patients with good prognosis characteristics.

Methods: Amplicon-based NGS was performed using 454 platform in 147 CLL patients to evaluate the mutational status of 6 genes (TP53, NOTCH1, SF3B1, XPO1, FBXW7 and MYD88). Samples were obtained at diagnosis or before treatment in all cases. 70.1% were Binet A and 53% had 13q deletion (13q-). A cut-off 2% was applied to define variants. All the mutations were validated.

Results: 1. NGS analysis showed that 37.4% of CLL patients (55/147) showed mutations in any of the analyzed genes. The frequency of mutations was 16.3% for NOTCH1, 10.2% for SF3B1, 6.8% for TP53, 4.8% for XPO1, 3.4% for FBXW7, and 1.4% for MYD88. The presence of mutations in any of these genes except to MYD88 (mutated CLL) was significantly associated with clinical progression (60.0% for mutated CLL vs. 38.2% for unmutated CLL; P=0.05). Interestingly, mutated CLL patients showed a shorter time to first treatment (TFT) than unmutated CLL patients (30 months vs. 88 months; P=0.006). By contrast, MYD88 mutations were detected in CLL with mutatedIGHV and 13q-. Of note, 23.6% of the mutations had a mutational load of ≥15% and thus would not have been detected by capillary Sanger sequencing. CLLs with mutations in MYD88 had a shorter TFT than those without mutations (18 vs 88 months; P=0.018), and similar to CLL patients with mutations in >15% of cells (P=0.370). In addition, 14.5% of mutated CLL patients showed 2mutations. Patients with more than one mutation had a shorter TFT than CLL patients with one mutation (7 months vs 31 months). 3. In the group of CLL patients with 13q-, 32.8% of them showed mutations in any of the analyzed genes. Interestingly, CLL patients Binet A with mutations (except to MYD88) showed a shorter TFT than CLL patients without mutations (31 vs 131 months, P<0.001). Besides this, CLL with 13q- as the sole cytogenetic alteration and gene mutations had also a shorter TFT that unmutated 13q- CLL patients (P<0.001).

Summary/Conclusions: 1) CLL patients with mutations in TP53, NOTCH1, SF3B1, XPO1 and FBXW7 show a worse prognosis than CLL patients without mutations. 2) Gene mutations in TP53, NOTCH1, SF3B1, XPO1 and FBXW7 in a low percentage of the cells are associated with a shorter TFT. 3) Among CLL patients with good prognostic characteristics (Binet A and 13q-), gene mutations help us to define the prognosis of the patients.

E1015

ALTERED COMPLEX C5 IS ASSOCIATED WITH COMPROMISED COMPLEMENT ACTIVITY IN CHRONIC LYMPHOCYTIC LEUKEMIA

A. Braester1,2,*, M. Barhoum1, R. Michélas3

1Haematology, Gailie Medical Center, Naharya, 2Faculty of Medicine, Bar-llan University, Safed, Israel

Background: The therapeutic monoclonal antibodies used for the treatment of Chronic lymphocytic leukemia (CLL) mediate anti-tumor effects through sev-eral mechanisms including antibody-dependent cell-mediated cytotoxicity (ADCC), and phagocytosis. CDC efficacy thus depends on the expression level of the target B-cell antigen, the integrity of apoptotic cascades within tumor cells, the functional capacity of effector cells, and the availability and activity of the complement (C) system. Published data indicate deficiency of one C protein or more in most CLL patients, as well as additional factors that may affect C activity. The role of structural abnormalities of C complexes in affecting C function has not been investigated.

Aims: To study the structural integrity of circulating C complexes, focusing mainly on C5, and to establish its importance for C activity in CLL.

Methods: Blood samples were obtained from 35 (28 Binet A and 7 Binet B) CLL patients and 10 healthy controls (HC). Biochemical and haematologatric parameters, and CLL staging were recorded. The isoforms of two C components, C3 and C5 were studied by Western blot analysis. The activity of the C system before and after in-vitro activation via the classical or alternative pathways was followed by the levels of C5b-9, the terminal product of C activation. C activation was also studied in-vitro activation with normal C5 isoforms. It is reasonable to argue that evaluation of the newly gene mutations as prognostic markers would help to improve prognostic classification of CLL patients. Interestingly, gene mutations could help us to refine the prognosis in the group of CLL patients with other prognostic markers associated with good prognosis.

Results: C3 expression was significantly lower in serum from CLL patients than in HC and CLL patients with normal C5 expression after in-vitro activation with normal C5 (commercial) was significantly lower in sera from CLL patients compared to sera from the other subjects’ groups.

Summary/Conclusions: The data indicate a possible link between the activation potential of the C system in CLL patients and alterations in the complexity structure of C5. The differences in C activation via the classical and alternative pathways may indicate disturbance in the classical pathway in patients with abnormal C5. The exact mechanisms by which abnormal C5 distracts the C activity need further clarification. Yet, the appearance of abnormal C5 in CLL patients with good prognostic characteristics (Binet A and 13q-) may assist clinicians in refining and personalizing the immunotherapeutic approach, improving CDC and consequently the therapy results.

ASSOCIATION OF CGP-STIMULATED KARYOTYPE WITH TIME-TO-FIRST TREATMENT FOR CLL
1Bone Marrow Transplantation, Ospedale Pausilipon, Napoli, Italy, 2Leukemia, MD Anderson Cancer Center, Houston, United States, 3Ematologia, PO San Giuseppe Moscati, Avessa, Italy, 4Chao Family Comprehensive Cancer Center, California, United States

Background: Prognostic factors correlate with clinical outcomes, independent of treatment. B cell receptor (BCR) signaling pathway inhibitors can nullify the prognostic impact of some markers, such as IGHV mutation status. CpG-stimulated metaphase karyotype can identify clonal cytogenetic abnormalities in CLL that may not be seen with standard non-stimulated karyotype or by FISH. Complex cytogenetics, defined as 3 or more chromosome abnormalities in 2 or more metaphases was the highest-risk feature for shorter progression-free and overall survival in patients receiving ibritinib for relapsed/refractory CLL. Complex karyotype is not uncommon among relapsed/refractory CLL cases, particularly those who previously received genotoxic chemotherapy.

Figure 1.

Aims: The aim of this study is to report the incidence and the impact of CpG-stimulated karyotype in the treatment of naive CLL.

Methods: We evaluated 501 treatment-naive patients with CLL at MDACC between July 2013 and June 2016. CpG-stimulated metaphase karyotype of CLL cells from blood or bone marrow was performed by culture of mononuclear cells for 72 hrs in media containing CpG-685 (20ug/ml), phorbol 12-myristate 13-acetate (PMA; 0.04ug/ml) and Pokeweed mitogen (PWM; 0.1ug/ml). Banding and analyses were by standard laboratory procedures. Twentty metaphases were analyzed per culture and patients were categorized as having diploid karyotype, a single, 2 or 3 or more(complex) clonal chromosome abnormalities present in more than 1 metaphase by CpG-stimulated karyotype. The frequency and distribution of chromosome abnormalities with other prognostic factors and time-to-first treatment from diagnosis (TTFT) were analyzed (Table 1, Figure 1).

Results: The majority (69%) of patients had diploid cytogenetics. Higher-risk prognostic features such as del17p, del11q, unmutatedIGHV and ZAP70 expression were associated with presence of complex karyoypetype abnormalities. Shorter TTFT from diagnosis was associated with 1, 2, and complex clonal chromosome abnormalities compared to diploid karyotype (p<0.0001). A model was developed, which identified patient characteristics independently associated with shorter TTFT including: 1 or more clonal chromosome abnormality by CpG stimulated karyotype; unmutatedIGHV; 3 involved lymph node sites; and CD38 expression (>30%).

Study Conclusions: In conclusion, CpG-stimulated karyotype identified 1 or more clonal chromosome abnormalities in nearly a third of untreated patients and was a significant independent prognostic factor for TTFT. Models for TTFT may be useful in identifying patients at high-risk for needing treatment sooner and thereby useful for early intervention clinical trials.

COMPARISON OF THE CHRONIC LYMPHOCYTIC LEUKEMIA INTERNATIONAL PROGNOSTIC INDEX (CLL-IPI) WITH THE BARCELONA-BRNO PROGNOSTIC MODEL: ANALYSIS OF 1299 NEWLY DIAGNOSED CASES
1Hematology, Hospital Annunziata, Cosenza, Italy, 2Hematology, Mayo Clinic, Rochester, United States, 3Oncology, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland, 4Hematology, Catholic University Hospital “A. Gemelli”, 5Hematology, Università La Sapienza, Rome, 6Hematology, Pugliese-Ciaccio Hospital, Catanzaro, 7Hematology, 7SS Molecular Diagnostics IRCCS S. Martino-IST, Genova, 8Hematology, Hospital Annunziata, Cosenza, 9Hematology, Università La Sapienza, Roma, 10Immunology, Consiglio Nazionale delle Ricerche, Istituto di Biomedicina ed Immunologia Molecolare, Reggio Calabria, Italy, 11Direzione Clinica, Dipartimento di Medicina Clinica e Informatica, Maggiore Hospital, University of Milano and Hematology CTO, 12Biotecnology Research Unit, Azienda Sanitaria Provinciale di Cosenza, Aprigliano, 13Hematology, University of Milano and Hematology CTMO, Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, 14Direzione Scientifica IRCCS-, San Martino IST, Genova, 15Hematology, Department of Translational Medicine, PO, Novara, Italy

Background: In the last two decades, a plethora of clinical, serological and biological markers have been identified that are significantly associated with the prognosis of chronic lymphocytic leukemia (CLL) patients. Recent research has focused on the development of scoring systems capable of integrating the major prognostic parameters. A recent prognostic index called CLL International Prognostic Index (CLL-IPI), built on clinical, serological, and biological parameters (TP53 deletion and/or mutation, IGHV mutational status, β2M, clinical stage, and CD38 expression) has been validated and recommended. Recently, Bartlett et al. reported a new prognostic model with the aim of simplifying the CLL-IPI, proposed a prognostic model comprising only two biomarkers (IGHV mutational status and FISH cytogenetics).

Aims: We performed a comparison of the CLL-IPI with the Barcelona-Brno prognostic model in an independent series of Italian and United States (U.S.) patients.

Methods: Databases from 4 Italian and 1 U.S. centers including roughly 3700 newly diagnosed CLL patients were used to compare the CLL-IPI with the Barcelona-Brno prognostic model. Baseline data regarding age, Rai stage, IGHV mutational status, β2M and fluorescence in situ hybridization (FISH)-detected cytogenetic abnormalities were available for 1299 cases. Del17p was used as the sole marker of TP53 status. The CLL-IPI and the Barcelona-Brno prognostic model were calculated using the methods proposed. The accuracy of the prognostic models was assessed by the Harrell C index (an index of discrimination), the explained variation in mortality (an index combining discrimination and discrimination), and the Akaike information criterion (AIC, an index comparing two non-nested prognostic models). The lower the AIC, the higher the prognostic accuracy of a predictive model.

Results: The median age of the 1299 patients was 63 years (range 27-92) with 61.3% males. The majority of patients had Rai stage 0 (57.9%). According to the CLL-IPI, 51.3% of patients were classified as low-, 28.7% as intermediate-, 16.2% as high-, and 3.8% as very high-risk. The 5-year OS probabilities were: 95% for low-risk, 89.9% for intermediate-risk, 70.1% for high-risk, and 32.8% for very high-risk cases (P<0.0001; Harrell C index=73%, P<0.001) (Figure 1A). According to the Barcelona-Brno prognostic model, 58.1% of patients were classified as low-, 31.8% as intermediate-, and 10.1% as high-risk. The 5-year OS probabilities were: 92.2% for low-risk, 83.6% for intermediate-risk, and 68.2% for high-risk cases (P<0.0001; Harrell C index=65%); P<0.001) (Figure 1B). The AIC showed the superiority of the CLL-IPI compared to the Barcelona-Brno prognostic model in predicting OS (CLL-IPI, AIC=3432.167 versus Barcelona-Brno prognostic model, AIC=3549.492). Accordingly, the explained variation in mortality provided by the CLL-IPI was 42% (P<0.001), a figure higher than that due to the Barcelona-Brno prognostic model.
E1019
INCREASED VIRUS-SPECIFIC IMMUNE RESPONSES PARALLELED BY A PNEUMOCOCCUS-SPECIFIC-IMMUNODEFICIENCY STATE AND HYPOGAMMAGLOBULINEMIA: ALREADY EMERGE IN HIGH-COUNT MONOCLONAL B LYMPHOCYTOSIS PRIOR TO CLL
I. Criado1,*, S. Muñoz-Criado2, A. Rodríguez-Caballero1, W.G. Nieto1, A. Romero-Furones3, P. Fernández-Navarro4, M. Alcoceba5, T. Conteras6, M. González5, A. Orfao1, J. Almeida1
1Department of Medicine, Cancer Research Center (IBMCC, CSIC-USAL), 2Centro de Microbiología, Universidad de Salamanca, 3Centre de Atención Primaria de Salud Miguel Armiño, 4Centro de Atención Primaria de Salud de Ledesma, 5Service of Hematology, 6Service of Biochemistry, University Hospital of Salamanca, Salamanca, Spain

Background: Monoclonal B lymphocytosis (MBL) represents a high incidence of infections, due to an associated immunodeficiency state that includes hypogammaglobulinemia. Even more, it has been recently shown that the earlier stages of disease, i.e. high-count monoclonal B lymphocytosis (MBL), subjects also have increased risk for infection. Aim: To evaluate the status of the humoral immune response in CLL at different disease stages, as well as in pre-leukemic MBL and MBL low count (MBLb) cases, vs healthy controls, through quantitation of soluble plasma levels of specific antibodies against ubiquitous and pulmonary infection-associated pathogens.

Methods: A total of 249 subjects (119 males/130 females; aged 68±11y) including 91 healthy donors, 71 CLL-like MBLb, 29 CLL-like MBLb and 58 MBL cases (32 Binet A, and 26 Binet B/C patients) were studied. Detection of clonal CLL-like B cells was performed by high-sensitive 8-color flow cytometry. Quantification of plasma antibody-isotypes and specific immunoglobulins against CMV (cytomegalovirus), EBV (Epstein Barr Virus), influenza virus and S.pneumoniae were performed by nephelometry and commercial ELISA kits, respectively. Individuals who had received vaccination against Influenza and/or Pneumococcus (cytomegalovirus), EBV (Epstein Barr Virus), influenza virus and S.pneumoniae were not included. Results: Total immunoglobulin (Ig) titers tended to decrease with disease progression, independently of the isotype. In contrast, specific IgM and IgG titers against CMV, EBV and influenza virus did not vary among groups, with the
exception of VCA-EBV IgG titers, that were higher in CLL vs the other groups. Strikingly, the IgG levels for the three viruses tended to gradually increase, from healthy individuals to stage B/C CLL. These findings were more pronounced (p<0.05) for IgG and to a lesser extend also for IgM, when the ratios between the virus-specific IgG/total IgG levels of the same isotype were calculated, except for Influenza-specific IgG, that showed the same trend but without statistical significance. Repeating CMV DNA load, only 3177 individuals (1 MBL1) and 2 CLL- were found to be positive (below the limit of quantitation), while EBV DNA load was detected in plasma from 7191 (all being Binet A CLL) at median levels of 3.6 copies/ul. In contrast to the virus-specific IgG, IgG plasma levels against S.pneumoniae progressively diminished through progression of the disease, leading to the overall lower gammaglobulin levels.

Summary/Conclusions: Both MBL1 and CLL patients present relatively high levels of specific Ig against human host viruses in parallel to progressively lower levels of anti-S.pneumoniae antibodies, which might reflect (asymptomatic) chronic reactivation of humoral immune responses against host viruses and progressively decreased protection against other microorganisms, denoting a severe pathogen-specific humoral immunodeficiency state not reflected by the overall plasma immunoglobulin levels. Alternatively, these results might point out a potential role of ubiquitous viruses in the pathogenesis of the disease. Further analyses are necessary to establish the potential relevance of such asymptomatic humoral immune responses against host viruses in the expansion of the tumor B-cell clone and progression from MBL to CLL.

1Scienze Mediche, Azienda Ospedaliero Universitaria Arcispedale S. Anna, 2Department of Morphology, Neurology and Embryology, University of Ferrara, 3Laboratorio per le Tecnologie delle Terapie Avanzate (LTITA), University of Ferrara, Ferrara, Italy

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease, running an indolent course in some patients and a clinically aggressive course in others. Risk assessment is important in clinical practice and prediction of outcome and response to treatment is very useful in an era in which several chemomunotherapy combinations and effective mechanism-driven treatments are available.

Aims: We investigated whether an extended genetic characterization including mutational screening by next generation sequencing (NGS) and karyotype analysis could allow for a refinement of our capability to predict outcome in newly diagnosed CLL patients with high-risk features, as defined by the presence of unmutated IGHV gene and/or 11q22/17p13 deletion by FISH and/or TP53 mutations.

Methods: 101 patients were included in this study. TP53 disruption was defined by the presence of 17p13 deletion by FISH and/or TP53 mutation by NGS. Cytogenetic analysis was performed using CpG-oligonucleotide DSP30. Each patient was categorized according to the following classification: favorable group (isolated 13q14 deletion or normal karyotype), unfavorable group (deletions of 11q22 or 17p13, or complex karyotype, ie, at least 3 chromosome aberrations); intermediate group (all other karyotypic abnormalities). A cut-off of 98% homology to the germline sequence to discriminate between IGHV mutated and unmutated cases. Mutational screening was performed with Ion Torrent PGM NGS platform on 20 CLL-related genes by using a 5% cut off.

Results: Cytogenetic analysis showed favorable findings in 30 patients, unfavorable in 34 cases and intermediate in 36 cases. A complex karyotype was present in 21 patients. By NGS, 95 somatic mutations were observed in 56/101 (55.4%) cases; 80 nonsense mutations, 5 nonsense mutations and 10 frameshift deletions. 16 cases (15.8%) showed mutations in the TP53 gene, 11 (10.9%) in the NOTCH1 gene, 11 (10.9%) in the SF3B1 gene, 8 (7.9%) in the ATM gene, 5 (4.9%) in the BIRC3 gene, 5 (4.9%) in the PTEN gene, 4 (4.0%) in the MYD88 gene, 4 (4.0%) in the RAF1 gene, 4 (4.0%) in the POT1 gene, and 18 (17.8%) cases in the remaining 11 genes. 26/56 (46.4%) mutated patients presented two or more mutations. The presence of mutations was associated with unmutated IGHV status (p=0.040) and the complex karyotype (p=0.047). TP53 disruption correlated with the presence of ≥2 mutations by NGS (p=0.001) and a complex karyotype (p=0.012). By multivariate analysis an advanced Binet stage (p=0.001) and an unfavorable karyotype (p=0.011) predicted for a shorter time to first treatment (TTFT), while TP53 disruption (p=0.019) and the unfavorable karyotype (p=0.028) predicted for a worse overall survival (OS). A shorter time to chemofractoriness (TTCR) was associated with TP53 disruption (p=0.001) and unfavorable karyotype (p=0.025). Patients with both unfavorable karyotype and TP53 disruption presented a dismal outcome (median OS and TTCR of 28.7 and 15.0 months respectively).

Summary/Conclusions: A comprehensive analysis of chromosomal aberrations and gene somatic mutations in high-risk CLL showed that the cytogenetic profile was independently associated with a shorter TTFT, OS and TTCR. Since karyotyping using novel mitogens may contribute to the refinement of prognosis in high-risk CLL patients, the introduction of this technique in future CLL trials seems warranted to identify those patients that could be ideal candidates for consolidation treatment or novel treatment combinations.

E1021

**SHOULD CLL-IPI BE USED TO ASSESS OVERALL SURVIVAL OF EVERY CLL PATIENT? A SYSTEMATIC REVIEW AND META-ANALYSIS**

S. Mola1,*, L. Di Giannarelli2, R. Mirabelli1, L. Levato3

1Hematology-Oncoology Department, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy, 2Bastiatric Unit, IRCCS Regina Elena, Roma, 3Hematology-Oncoology, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy

Background: A weighted grading approach based on five independent prognostic factors (i.e, TP53 status, IGHV mutational status, Sm2-microglobulin, clinical stage and age) has been used by an international Working Group to generate the chronic lymphocytic leukemia international prognostic index (CLL-IPI). Although the robustness of CLL-IPI has been confirmed in recent validation studies it remains unclear whether CLL-IPI has the greatest validity and should be preferred to guide clinical decision in CLL.

Aims: To shed light on this important research question, we conducted a systematic review which includes all published studies which used CLL-IPI to prognosticate overall survival (OS) in CLL.

Methods: A comprehensive MEDLINE search using “CLL-IPI” as Medical Subject Headings (MESH) allowed to identify at the cut-off time of February the 28, 2017 "seven hits” with only "four" citations considered pertinent. The search was extended to the conference proceedings of annual meetings of ASH, EHA and ASCO of last two years recognized “three” additional citations.

Results: Overall 6720 patients from seven evaluable studies were suitable for the present analysis aimed at assessing the impact of CLL-IPI on OS. The majority of patients (4953 or 73.7%) came from studies of external validation of CLL-IPI while 17% (1192) and 8.5% (576) had been used to generate (training) and to internally validate the model. Patient distribution into the four risk categories of CLL-IPI was heterogeneous thus reflecting the CLL phase (i.e., at diagnosis, at time of first treatment and at relapse) of patients within different studies. Accordingly, patients diagnosed as having low-, intermediate- and very- high risk CLL-IPI ranged respectively between 9% and 58%, 25% and 39%, 14% and 52% and 2% to 9%. Next we evaluated the 5-year OS of patients stratified into each of the four CLL-IPI risk groups using either “G” or “P” test to assess the heterogeneity across different studies. The 5-year survival probability was 91% for low-risk group (95% CI, 90-91%; Q=55.2; P< 0.00; I2, 87%), 80% for intermediate-risk group ( 95% CI, 79-82%; Q=49.36; P<0.00; I2, 86%), 60% for high-risk group (95% CI, 57-62%; Q=42.78; P<0.00; I2, 86%), 23% (95% CI, 19-27%; Q=18.1; P=0.01; I2, 67%).
Background: Oral anticancer medications (OAMs) present several advantages compared with intravenous cytotoxic chemotherapy, including greater convenience for the patient. However, OAMs require that a patient be actively involved in regular drug administration over an extended period of time (Schneider SM, et al. Semin Oncol Nurs. 2011;27(2):133-141). Adherence to OAMs significantly impacts patient outcomes; poor adherence may result in inferior survival and outcomes, higher hospitalization rates, treatment resistance, and increased healthcare costs (McCue DA, et al. Pharmacotherapy. 2014;34(5):481-494).

The Canadian YOU&i™ patient support program (PSP) was developed to improve adherence to long-term ibrutinib therapy using research-proven techniques for promoting positive behavioral changes, i.e. cognitive behavioral therapy, psycho-social support, and a nurse coaching component. Results from the program are presented here.

Aims: To evaluate patient adherence to ibrutinib, and patient and physician satisfaction with the YOU&i™ PSP

Methods: Using evidence-based literature reviews and global/local market research, various patient-centered barriers to treatment adherence were identified. The survey was cultivated using the Morsky Medication Adherence Scale score, which informed nurse coaching frequency. Adherence was delineated by prescription refill compliance. Patient and physician questionnaires were used to gauge satisfaction with the YOU&i™ PSP.

Results: As of 20 January 2016, a total of 903 patients with CLL were enrolled in the YOU&i™ PSP. A total of 552 patients were included in the adherence analysis. Of these, 86% opted in to receive the nurse coaching component. At 2 months from treatment initiation, patients who received nurse coaching demonstrated an adherence rate of 92.3%, as compared with 63.5% for patients who did not receive nurse coaching (85% CI, 17.5±41.0; p <0.0001). At 9 months, the adherence rates were 89.9% vs 60.8% (95% CI, 17.5±41.4; p <0.0001). By 9 months, adherence rates were 81.7% vs 71.1% (95% CI, -4.4 to 28.4; p =0.141). At study conclusion, 12 month adherence rates were 76.6% vs 72.2% (95% CI, -18.9 to 32.4; p =0.715). Discontinuation rates were similar in all patients, regardless of nurse coaching status at 9 and 12 months. Patients reported satisfaction rates of >90% in surveys conducted at both 3 months and 12 months of program enrollment. Of physicians surveyed at 3 months, 96% reported that the YOU&i™ PSP was helpful in supporting patient needs.

Figure 1.

Summary/Conclusions: The current analysis provides insight into adherence patterns of patients on long-term ibrutinib treatment. These results are consistent with the literature showing that PSPs like the YOU&i™ PSP can help to improve adherence rates (Schneider SM, et al. J Adv Pract Oncol. 2014;5(3):163-172). The information obtained from long-term adherence data can help to inform future trials examining patterns of adherence with OAMs. Nurse coaching may be helpful in supporting early adherence by addressing side effects that occur more frequently at treatment initiation. Moreover, changes in disease or health status that arise over the first 12 months of therapy may provide information that allows a PSP to adapt to patients’ evolving needs over the treatment journey. A better understanding of long-term adherence patterns may allow programs such as the Canadian YOU&i™ PSP to target adherence support more precisely, thereby optimizing patient outcomes.

E1024

SINGLE-AGENT IBRUTINIB VS REAL WORLD TREATMENT FOR PATIENTS WITH TREATMENT-NAÏVE (TN) CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): AN ADJUSTED COMPARISON OF RESONATE-2™ WITH THE CLLEAR AND LYON-SUD DATABASES

1Department of Internal Medicine – Hematology and Oncology, University Hospital Sud, Brussels, Belgium; 2Department of Medicine, Medical University, Brno, Czech Republic; 3Hospices Civils de Lyon, Université Claude Bernard, Centre Hospitalier Lyon-Sud, Pierre Bénite, France, 31st Department of Internal Medicine – Hematology, General Faculty Hospital, Prague, 4Department of Hemato-oncology, University Hospital, Olomouc, Czech Republic, 5Janssen EU HEMAR Statistics & Modelling, Beersel, Belgium, 6Janssen EMEA HEMAR, High Wycombe, United Kingdom, 7Janssen-Cilag EMEA Medical Affairs, Dublin, Ireland, 8Janssen Pharmaceuticals, Paris, France, 994th Department of Medicine – Hematology, Charles University Hospital and Medical Faculty, Hradec Králové, Czech Republic

Background: The phase 3 RESONATE-2™ study demonstrated significant improvement of progression-free survival (PFS) and overall survival (OS) with ibrutinib (ibru) vs chlorambucil (chl) in TN (aged ≥65 years) CLL patients. In the absence of direct comparison of single-agent ibru with other frequently used treatments in this patient population, this retrospective observational study in the CLLEAR (Chronic Lymphocytic Leukemia Registry) and Lyon-Sud databases utilizes evidence against standard of care as observed in clinical practice can provide useful insights on the relative efficacy of ibru.

Aims: To investigate the relative treatment effect on PFS and OS for ibru vs real world (RW) treatment in daily clinical practice in TN CLL patients by adjusting for differences in patient-level data from RESONATE-2™ vs RW data from the CLLEAR (Chronic Lymphocytic Leukemia Registry) and Lyon-Sud databases.

Methods: CLLEAR holds medical records for CLL patients from seven academic centers across the Czech Republic. Lyon-Sud database holds medical records from patients from hospitals in the Lyonnais. This retrospective observational study compared PFS and OS in 1st LoT of patients from RESONATE-2™ vs those from the CLLEAR (Chronic Lymphocytic Leukemia Registry) and Lyon-Sud databases.

Results: CLLEAR holds medical records for CLL patients from seven academic centers across the Czech Republic. Lyon-Sud database holds medical records from hospitals in the Lyonnais. This retrospective observational study compared PFS and OS in 1st LoT of patients from RESONATE-2™ vs those from the CLLEAR (Chronic Lymphocytic Leukemia Registry) and Lyon-Sud databases.
pared between ibru and RW treatment using patient-level data from RESONATE-2™ (n=136) and pooled patient-level data from the two cohorts. To adjust for differences in patient characteristics between the trial population and both cohorts, a multivariate Cox proportional hazards model was fitted on patient-level data to estimate the hazard ratio (HR) for ibru vs RW treatment, with age, sex, disease stage (based on Rai/BINET), and deletion 11q presence/absence included as covariates.

**Results:** Median age at treatment initiation for CLLEAR (n=418) and Lyon-Sud (n=110) was 73 and 71 years, respectively, vs 73 for ibru patients from RESONATE-2™. The proportion of male patients was 63% in CLLEAR and 57% in Lyon-Sud vs 65% in RESONATE-2™. The median follow-up was 35.7 months (mo) for Lyon-Sud and 16.8 mo in CLCLEAR vs 29.1 mo for RESONATE-2™. Adjusted HR for ibru vs physician choice in CLCLEAR and Lyon-Sud were 0.23 (95% CI: 0.14, 0.39) and 0.25 (0.14, 0.43) for PFS, and 0.29 (0.11, 0.79) and 0.39 (0.18, 0.83) for OS, respectively. Fludarabine/cyclophosphamide/rituximab (FCR, n=117), bendamustine+R (BR, n=91), CH alone (n=43), CH+R (n=45), and other R-containing regimens (n=154) were the most commonly used treatment regimens across both RW cohorts. Older age, male gender, advanced disease stage and del11q positive status were independent risk factors for PFS and OS. The adjusted HRs (pooled estimates) for ibru vs the two most commonly used regimens were 0.30 [0.17-0.53] (FCR) and 0.33 [0.16-0.68] (BR) for PFS, and 0.44 [0.20-0.95] (FCR) and 0.53 [0.13-0.83] (BR) for OS (Figure 1). Estimates of HR vs regimens in the cohorts were consistent across both databases.

**Figure 1.**

Summary/Conclusions: This adjusted comparison of patient-level data from RESONATE-2™ with RW data from CLCLEAR and Lyon-Sud demonstrates ibru to be more effective compared with RW treatment, with a 4.1% improvement in PFS and a 3-fold improvement in OS. When comparing ibru with the most commonly used RW treatments, statistically significant benefits for ibru were consistently observed vs all treatment regimens on PFS and for most comparisons on OS. These results further support the existing evidence that ibru significantly improves PFS and OS vs common regimens used in TN CL settings, and has important implications for clinical practice.

E1025

**CHARACTERISTICS, TREATMENT, AND OUTCOMES OF ≥80 YEAR OLD PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) ENROLLED TO PROSPECTIVE TRIALS OF THE GERMAN CLL STUDY GROUP (GCLLSG).** B. Eichhorst1, M. Hallek1, V. Goede1

1Department of Internal Medicine, German CLL Study Group, University Hospital of Cologne, Cologne, Germany

Background: People over 80 years are the fastest growing age group in western populations. Clinical management of ≥80 year old patients (pts) with CLL remains a challenge due to the very limited amount of data currently available for this age segment. Two retrospective studies reported observational data on characteristics, treatment, and outcomes of ≥80 year old pts not enrolled in a clinical trial (Bairey et al., Meunier et al.). It is therefore of little interest as ≥80 year old pts who were treated for CLL within clinical trials, however.

**Aims:** To study the characteristics, treatment, and outcomes of pts aged ≥80 years who received their first therapy within prospective trials of the German CLL Study Group (GCLLSG).

**Methods:** Trial populations of seven clinical trials of the GCLLSG (CLL1, CLL5, CLL7, CLL8, CLL9, CLL10, CLL11; total N=3552) were reviewed and screened for pts ≥80 years at frontline treatment. Clinical, laboratory, and genetic data of identified pts were pooled. Time-to-event data were analysed by Kaplan-Meier methodology. Independent prognostic factors for survival were identified by multivariate analysis using Cox regression modelling with stepwise selection procedures.

**Results:** Among 3552 reviewed GCLLSG trial participants, 152 were aged ≥80 years at initiation of firstline treatment. A majority of these pts were identified from CLL1 (n=132) while the remaining were from CLL1 (n=3), CLL5 (n=1), CLL7 (n=3), CLL8 (n=2), CLL9 (n=9), and CLL10 (n=2). Median age was 82 years (range 80-90). Concomitant diseases were present in 99% of the pts and median cumulative illness rating scale (CIRS) score was 8 (0-18). Median creatinine clearance was 46 ml/min (range 17-99 ml/min). Idiopathic genenic aberrations were 1q deletion as a sole abnormality in 27%, trisomy 12 in 10%, 11q deletion in 9%, and 17p deletion in 16% of pts. (IGHV was unmutated in 69% of the pts. Distribution of CLL-1PI risk groups was as follows: 6% low, 19% intermediate, 61% high, and 14% very high. Most pts had Binet Stage B (36%) or C (43%). Chemoimmunomotherapy with chlorambucil plus obinutuzumab (CLB-OB) or chlorambucil plus rituximab (CLB-R) was administered to 61 (40%) and 56 (37%) pts, respectively. Remaining pts received chlorambucil alone (CLB, n=19), fludarabine (F, n=10), fludarabine/cyclophosphamide (FC, n=1), fludarabine/cyclophosphamide/rituximab (FCR, n=2), or 5-flouracil/rituximab (BR, n=3). Rates of grade 3 or 4 neutropenia and infections were 35% and 13%, respectively. Premature treatment discontinuations occurred in 15% of cases and were mostly due to adverse events. The total overall response rate was 92% with 13% complete remissions. Median observation time for all pts was 40.7 months. Median progression-free survival (PFS) and treatment-free survival (TFS) were 17.2 and 32.3 months, respectively. A total of 47 pts (31%) received at least one further line of treatment. Median overall survival (OS) was 48.3 months, with adverse events (22%) and progressive CLL (16%) being the most frequent causes of death. Standardized mortality ratio was calculated and showed a 1.99 (CI 1.54-2.53) increased risk of death as compared to an age- and sex-matched general population. Independent prognostic factors for OS were 17p deletion and elevated serum thymidine kinase.

**Figure 1.**

**Summary/Conclusions:** Findings suggest that antileukemic therapy (including chemoimmunotherapy) is feasible and efficacious in ≥ 80 year old pts with CLL. However, such pts are still highly underrepresented in clinical trials and even with modern treatment live shorter than age-matched controls of the general population. Broader recruitment of these pts to prospective trials and evaluation of targeted therapies therefore appears imperative to improve outcome of CLL in this age segment.

E1026

**THE ROLE OF CD200 IN THE DIAGNOSIS OF CHRONIC LYMPHOCYTIC LYMPHECIA.** A. Mora1,2,*, E. P. Vicente1,2, C. Cuellar1,2, R. Bosch2, L. Blanco3, R. Martino2, J. M. Ubeda1, J. Sierra1,2, C. Moreno1,2, J. Nomdedeu3

1Laboratory of Oncology and Hematology, Transplantation Institute, Instituto de Biomedica Research, IIB Sant Pau, 2Department of Hematology, 3Laboratory of Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

**Background:** Clinic, morphologic, immunophenotypic and genetic features are the basis for the diagnosis of B-cell malignancies. It is considered that the diagnosis of CLL requires the presence in peripheral blood of >5x109/L monoclonal B lymphocytes with a distinctive immunophenotype (i.e. SmIgweak, CD5+, CD19+, CD23+). Based on immunophenotypic characteristics, Matutes et al. devised in 1994 a immunophenotypic score based on a few markers (CD5+, CD23+, FMC7, SmIgweak and CD22weak) each of them receiving a score of 1 if present or 0 if absent. A total score of 4 or 5 is typical of CLL whereas those cases scoring 0 or 1 correspond to other B-cell malignancies, mostly lymphomas. Nevertheless, clinical and immunophenotypic features of CLL may overlap with other B-cell malignancies. CD200 has been identified in other lymphoid disorders between November of 2015 and January of 2017. Immunophenotyping was performed using a Canto Flow Cytometer (Becton Dickinson) and samples were stained with routine combinations plus CD200. The Matutes Score was calculated as follows: FMC7, CD22 and CD22 were considered score 1 when present or 0 if absent. A total score of 4 or 5 is typical of CLL whereas those cases scoring 0 or 1 correspond to other B-cell malignancies, mostly lymphomas. Nevertheless, clinical and immunophenotypic features of CLL may overlap with other B-cell malignancies. CD200 has been identified in other lymphoid disorders.
(MFI) was calculated as a relative expression between MFI positive population and MFI negative population. Multivariate analysis was used to assess statistical significant differences in accuracy among individual markers and scoring systems. The treating physician made the final diagnosis of the different B-cell malignancies according to IWCLL and WHO criteria. Logistic regression including sensitivity, specificity and accuracy values, were used to evaluate statistical differences in diagnostic precision between different combinations of markers as well as individual markers.

**Results:** Flow cytometry analysis was performed in 99 patients, including 62 cases with a diagnosis of CLL (62.6%) and 37 cases with a “no-CLL” diagnosis (37.4%). Matutes score was 4-5 in all CLL cases and ≤3 in “no-CLL” cases. CD20, CD23 and CDS were the most consensual markers for CLL (90.3%, 96.8% and 100.0% of sensitivity respectively). Moreover, CD79b and FMC7 had a good discriminant value (80-85% sensitivity). For “no-CLL” cases the most reliable markers were SmIg, FCME and also CD20. The analysis of the accuracy is shown in the table. Of note, CD200 as a single marker was found to be a reliable marker for distinguishing CLL and “no-CLL” cases (90.9%; p<0.001; 90.3% sensitivity, 91.9% specificity) showing a significantly higher accuracy than CD5, CD23 and SmIg as individual markers (p<0.001). The accuracy of CD200 did not vary when comparing% of positive cells of MFI. In contrast, the accuracy for SmIg significantly increased from 67.7% to 78.5% when using MFI% values (according to the cut-off established by ROC curves), being lower in CL than in “no-CLL” cases (71.0% vs 86.5%, p<0.001). Finally, the addition of CD20 to the Matutes score system and using a cut off ≥4, improved its accuracy from 88.9% (95% CI: 88.2-95.6) to 98.0% (95% CI: 94.7-100.0) and showed a better sensitivity.

**Table 1.**

### Summary/Conclusions: These results confirm CD200 as a valuable marker in the diagnosis of CLL

---

**COMPARISON OF CHROMOSOME BANDING ANALYSIS AND GENOMIC MICROARRAY TECHNIQUES FOR THE DETECTION OF COMPLEX KARYOTYPES IN CHRONIC LYMPHOCYTIC LEUKEMIA**

A. Puiggros1,2,*, A. Gómez-Llonín1,2, S. Ramos1,2, M. J. Calasanz3, L. Blanco4, R. Collado5, M. A. Pizarro2, M. Ortega2, A. Battile2, E. Abelá2, E. Gimeno2, P. Abriquet2, F. Carbonell2, C. Moreno2, F. Bosch2, B. Espinol2,1

1Laboratori de Citogenètica Molecular, Hospital del Mar, 2Grup de Recerca Translacional en Neoplasticies Hematològiques, Programa de Recerca en Cancer, Institut Hospital del Mar d’Investigacions Mèdiques (IMIM), Barcelona, 3Unidad de Citogenética y de Genética Hematológica, Departamento de Genética, Hospital Universitario Ramón y Cajal, Madrid, 4Servei d’Hematologia, Hospital Universitari de la Santa Creu i Sant Pau, Barcelona, 5Servicio de Hematología, Consorcio Hospital General Universitario, Valencia, Spain

**Background:** Well-established poor prognostic factors in chronic lymphocytic leukemia (CLL) include del17p and del11q in ≥11% and del11q ≥3 del17p ≥3 (≥11% del11q and del17p) by FISH. Genomic complexity detected by either chromosome banding analysis (CBA) or genomic microarray techniques, but underestimated by FISH, predicts an impaired outcome in CLL. Of note, none of these techniques is still routinely performed and standard criteria for risk stratification based on genomic complexity is lacking.

**Aims:** 1. To assess the complexity detected by genomic arrays in patients with complex karyotype by CBA; 2. To compare both methods regarding the number and type of aberrations detected in order to categorize patients based on genomic complexity.

**Materials and Methods:** A total of 24 CLL patients with complex karyotype (≥3 abnormalities, CK) by CBA were included (Median age: 73; 15 males (63%)). Median time from diagnosis to CBA/microarray analysis was 3 months (range, 0-160), and 4 patients (16%) had received prior treatment. The cohort was enriched in del17p and del17p33 (47% and 42%, respectively). DNA from peripheral blood mononuclear cells was isolated and lymphocytes were hybridized to Cytogenetics Whole-Genome 2.7 Mb (n=2) or CytoScan HD (n=22) array, results were analyzed with Chromosomal Analysis Suite Software (Affymetrix). Number, size and type of aberrations detected were compared between techniques.

**Results:** A median of 3.5 aberrations (range: 3-9) were detected by CBA, being significantly lower than the copy number abnormalities (CNA) identified by microarrays (median 5, range: 1-28; P=0.018). The median size of the CNA was 5.4Mb (range: 0.1-174Mb). Current recommendations for microarray analyses suggest that only CLL known abnormalities and CNA >5Mb should be considered for clinical interpretation (Schoumans et al, 2016). When applying this cut off, 42% of the initially detected CNA (74/177) were omitted and no significant differences in the number of abnormalities by each technique were found (P=0.334). CNA ≤1Mb did not involve any chromosomal altered region in the corresponding karyotype. Thus, their omission probably would not affect the stratification based on complexity. In contrast, most of the CNA between 1 and 5Mb involved small CNA associated to apparently balanced translocations by CBA, and in some cases revealed a higher genomic instability than the previously recognized by CBA (i.e. multiple deletions defined as a single one or a monosomy by CBA). Indeed, four cases showed chromothripsis not detected by CBA which has been associated with impaired outcome (Salaverria et al, 2015). Of note, genomic microarrays failed to detect some balanced translocations or subclonal aberrations by CBA, which probably were represented in a minor proportion of the sample but expanded during CBA culture. Thus, eight patients (21%) could only be considered complex by CBA, as by microarray analyses <3 CNA were detected. The present study is ongoing; additional cases have been collected in order to statistically assess the clinical impact on survival of the complexity detected by microarrays.

**Summary/Conclusions:** 1. The number of chromosomal abnormalities detected in CLL patients differs if assessed by CBA or genomic microarrays. 2. The current 5Mb cut-off to define clinically relevant CNA should be revisited, as it could underestimate genomic instability (contiguous small deletions, chromothripsis). 3. More studies should be performed to establish standard criteria for prognostic stratification of CLL patients based on genomic complexity consistent with the results from both techniques.

**ABNORMAL SERUM FREE LIGHT CHAINS RATIO ASSESSMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: A SIMPLE YET POWERFUL TEST CORRELATING WITH CLINICAL OUTCOME AND MINIMAL RESIDUAL DISEASE**

F. Durrieu1,*, M. Le Bourou1, F. Bijou2, A. Schmitt2, J. Blanchi1, G. Etienne2

1Laboratory of hematology, 2Hematology Department, Institut Bergonie, Bordeaux, France

**Background:** An abnormal serum Free Light Chain (sFLC) ratio has been shown to be significantly associated with poor outcome in chronic lymphocytic leukemia (CLL) Yegin ZA et al, Eur J Haematol 2010, suggesting that this parameter may discriminate different biological subgroups.

**Aims:** As the technic is easily implementable in routine lab and cost effective, we evaluated the sFLC levels (kappa + lambda) and kappa/lambda (K/L) ratio in CLL patients in this prospective study. The relationship between abnormal sFLC levels (K+L) and K/L ratio, minimal residual disease (MRD) assessed by flow cytometry (FCM) and disease evolution was evaluated.

**Methods:** Diagnosis was confirmed by 10-color FCM immunophenotyping of blood lymphocytes on a Navios (Beckman Coulter). Serum FLC kappa and lambda chains were measured by nephelometry using the Freelite™ immunoassay. The normal free kappa chains level was defined as within the range of 3.3-19.4mg/L, and the normal lambda chains level within the range of 5.71-26.30mg/L. A normal sFLC kappa/lambda (K/L) ratio was therefore defined as between 0.26 and 1.65 (a ratio above 1.65 indicating an excess of kappa light chain, and a ratio below 0.26 indicating an excess of lambda light chain). The cumulative level of kappa plus lambda (K+L) was also evaluated. Most patients received combined chemo-immunotherapy or entered clinical trials whenever possible. The ROC methodology was used to establish the best cut-off value of sFLC ratio level to discriminate treated patients from those who remained treatment-free.

**Figure 1.** Results: Main patients characteristics are detailed [N=147, M/F:75/72, 111 in early disease, Del1p in 11 patients and Del1q in 15]. Median age was...
69 years (range 34 to 86). Ninety patients were untreated during the follow-up period. Median follow-up duration was 30 months (range 0 to 101). Furthermore, sFLC measurement was assessed in 57 patients who progressed during the study and required treatment according to international guidelines. ROC curve analysis determines cut-off level of K/L ratio at 1.88. Abnormal sFLC was observed at diagnosis in 50.9% (N=29) of all treated patients. The mean ± SD ratio of sFLC in the untreated patients group and in the treated patients group was 1.51±2.08 and 2.80±3.75 respectively (p=0.0082). Considering the sFLC levels (kappa + lambda), the mean±SD in the untreated patients group and in the treated patients group was 29.1±17 and 53.0±19.1 respectively (p<0.0001).

Treatment systematically induced a modification of the sFLC K/L ratio. Interestingly, after treatment completion, the persistence of an abnormal sFLC K/L ratio was associated with positive MRD determined by FCM with a 82% specificity and a 95% positive predictive value. Moreover, median time to treatment income for patients in early stage disease with ratio >1.88 was 12 months while it is not reached in those with ratio ≤1.88 (p<0.0001) (figure 1).

Summary/Conclusions: This study confirms the clinical value of sFLC K/L ratio determination as a technically simple, standardized and cost-effective test to improve risk stratification of patients with low risk CLL at diagnosis, at the end of the treatment and during follow-up. Determination of the sFLC K/L ratio during the follow-up of treated patients provides additional information regarding the response to therapy in patients with an abnormal K/L ratio. In this study, persistence of an abnormal sFLC K/L ratio after treatment was strongly associated with positive MRD and could serve as a predictive as well as a prognostic biomarker for residual disease detection and clinical outcome.

E1029

PLATELET FUNCTION ASSAYS FOR STRATIFICATION OF BLEEDING RISKS IN CLL PATIENTS ON IBRUTINIB TREATMENT

E. Nikitin1, E. Dmitrieva1, A. Ignatova1, A. Polevaya1, D. Polokhov2, A. Fedotov2, E. Seregin2, A. Pshonkin2, M. Panteleev2, V. Ptushkin3

1Outpatient department for hematology oncology and chemotherapy, S.P.Botkin hospital, 2Molecular hemostasis laboratory, National Scientific and Practical Center of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation

Background: Ibrutinib therapy in chronic lymphocytic leukemia (CLL) is associated with frequent bleeding complications, explained by inhibition of BTK, which mediates downstream signaling of GPVI and GP Ib receptors in platelets. Detailed characterization of platelet functional impairment can help predict and possibly prevent severe bleeding on ibrutinib. Here we investigate platelet functional activity in CLL patients before initiation of ibrutinib and at different time points during treatment.

Aims: A longitudinal study on the impact of ibrutinib on platelet function, severity and frequency of bleeding.

Methods: Forty-three patients with relapsed and refractory CLL and 10 healthy donors were included in the study. Platelet functional activity was characterized by flow cytometry before and after activation with SFLLRNP plus collagen-related peptide. Levels of CD42b, CD61, CD62P, PAC1, annexin V binding, and megakaryocyte release were determined. Aggregation with collagen, ADP and ristocetin were measured. All tests were performed before initiation of treatment, at weeks 2, 4, 8 and at 6 months. Bleeding complications were scored using ITP-specific Bleeding Assessment Tool.

Results: Among 43 CLL patients, 29 (67%) were men, the median age was 65 (range 31 to 83 years). Four patients with del(17p) received ibrutinib as a first line. In 39 previously treated patients the median number of prior treatments was 3 (range, 1-6). Del17p or TP53 mutation was found in 11 (25%) patients. Only 1 patient received anticoagulant and antiplatelet drugs. Median duration of ibrutinib treatment was 8.2 months (range 2.2-10.9). At least one bleeding episode occurred in 23 patients (53%). Among patients with bleeding, 14 (61%) had grade 1 events, 7 (30%) had grade 2 and 2 (9%) had grade 3 events. Bleeding frequency decreased with time on ibrutinib; only 4 patients still had bleeding episodes after 6 months. The patients with bleeding had significantly lower mean platelet count that those without (120 versus 170 thousands per microliter, P=0.0001) and higher lymphocytosis (74 versus 45, P<0.05). Their activation of integrins in response to stimulation was greatly impaired (9% versus 26%, P<0.0001; while the 95% confidence interval for healthy controls 63-137%), and there was a significant difference in GPVI activity as well (2% versus 14%, P=0.01; normal range is 7-35%). Importantly, the integrin activation allowed risk stratification: a person with more than 9% integrin activation had less than 10% risk to develop bleeding while the one with less than 9% integrin activation had a risk of more than 40%. There was no difference in dense- or alpha-granule release between the patient groups, and these indicators remained in their normal ranges. There were also significant differences in aggregation assays with ADP (25±16% versus 36±18% for bleeding and non-bleeding patients, p<0.001), collagen (38±19% versus 53±20%, P<0.001), and ristocetin (53±22% versus 62±20%, P=0.02). Interestingly, the patients with bleeding had negative correlation with platelet aggregation with collagen level.

Summary/Conclusions: Both classic aggregation assays and flow-cytometry-based techniques demonstrate impaired platelet function in the bleeding CLL patients compared with non-bleeding ones. The level of integrin activation appears to be the most sensitive and able to identify patients with different bleeding risks.
E1031

CLL: IS LYMPHOCYTE DOUBLING TIME (LDT) A RELEVANT PROGNOSTIC PARAMETER IN THE ERA OF PROGNOSTIC BIOMARKERS?

T. Bauman1,2, J. Delgado3, P. Mozos4, V. Ortiz-Maldonado5, R. Santacruz2, M. Aymeirc3, M. Aymeric5, N. Villamor3, D. Costa5, A. Carrió5, E. Montserrat1

1Hematology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain. 2Hematology Department, Hospital de Clínic, Asunción, Paraguay. 3Hematopathology Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: In CLL, tumor doubling time is reflected by the pace at which lymphocytes increase in blood (lymphocyte doubling time or LDT). However, since LDT is rarely available at the time of diagnosis, its role in assessing prognosis in patients in CLL is controversial.

Aims: To reassess the prognostic significance of LDT in a large series of patients.

Methods: Retrospective single-center study based on 629 patients diagnosed with CLL/SLL. LDT was measured at the time of diagnosis if prior WBC counts were available or calculated after diagnosis by linear regression analysis, usually over a treatment-free period of 2 months and including at least three WBC counts.

Results: 140 patients displayed short LDT (<12 months) and 489 long LDT (>12 months). The median follow-up was 13.4 years (6.1-22.5) and 11.2 years (2.3-30.9), respectively. Patients with short LDT were younger (p<0.005), had lower clinical stage (p<0.001), higher ANC (p<0.001) as well as increased serum LDH (p<0.001) and B2-microglobulin (B2M; p=0.035) levels and also a tendency towards lower levels of Hb and platelet counts. A short LDT was also associated with an increased expression of ZAP70 and CD38, unmutated IGHV (all p<0.001) and poor FISH cytogenetics (del17p, del11q) (p<0.001). Additionally, patients with a short LDT presented more frequently mutations in NOTCH1 (p<0.001), ATM (p=0.029), TP53 (p=0.035) and a tendency to more mutations in SF3B1 (p=0.102). The proportion of patients treated in each group was markedly different (80% vs 46%) as it was the median time to treatment (TTT, 1.4 vs 9.4 years; p<0.001). Type of treatment (mainly, chemo<immuno>therapy) did more frequently treated with alkylating agents than purine analogues.

Conclusions: In our series, infiltrative cytopenia and/or progressive lymphadenopathy/splenomegaly constituted the IT in most (95%) CLL patients. In spite of being enriched in favorable biological prognostic factors (mutated IGHV genes, low ZAP70 expression and favorable-risk cytogenetics), MF patients had a shorter age-adjusted OS from first-line therapy compared to LM patients. Further studies should address whether this result also applies to patients treated with novel agents.

E1032

INDICATIONS FOR TREATMENT IN CHRONIC LYMPHOCYTIC LEUKAEMIA: CLINICO-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT

P. Mozos1, A. Rivas-Delgado1, T. Bauman1, V. Ortiz-Maldonado1, A. Navarro1, D. Costa2, M. Aymeric3, N. Villamor3, E. Montserrat1, J. Delgado1

1Hematology, 2Pathology, 3Hematopathology Unit, Pathology, Hospital Clinic de Barcelona, Institut d’Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain

Background: Chronic lymphocytic leukemia (CLL) is characterized by the progressive accumulation of monoclonal CD5+ B cells in the bone marrow and lymphoid tissues. International guidelines recommend initiation of treatment only in case of infiltrative cytopenia, progressive splenomegaly or lymphadenopathy, short lymphocyte doubling time (LDT), B symptoms and/or refractory disease (RC). These criteria are based on experts’ consensus and considered equally relevant for treatment initiation, even though little evidence exists concerning the relative value of each individual criterion.

Aims: To describe the clinico-biological characteristics and prognosis of CLL patients according to the criteria that prompted the initiation of first-line treatment.

Methods: We identified 530 consecutive patients with CLL who received first-line therapy from 1978 to 2014 and had their indication(s) for treatment (ITT) recorded. Massive/progressive lymphadenopathy and massive/progressive splenomegaly were grouped together as lymphoid mass (LM). Infiltrative ane-
Methods: We reviewed all CLL samples that were submitted for the investigation of TP53-deletion through FISH, in our Lab, between January 1st 2011 and February 28th 2017. Results obtained on tests performed on whole mixed cellularity samples were compared with results obtained directly in FACS purified CLL clonal lymphocytes.

Results: We analyzed 410 samples tested for the deletion of TP53 in our lab during the study period. The majority of patients (63.2%) were male. Although FACS separation of neoplastic cells was only introduced within the last two years of the study period, it accounted for 39.0% of all tested samples. This poor prognostic aberration was identified in 15.8% of patients in the overall cohort, with no differences in the incidence of a positive finding between mixed cellularity samples and FACS purified samples (15.6% vs 16.2%, respectively, p=NS). In contrast, the average proportion of positive cells within a positive sample was markedly different between mixed cellularity samples and FACS-processed samples, increasing nearly three-fold through the purification of the sample, from 24.0±15.9% to 62.9±33.3%, p<0.001. In fact, in 57.7% of all patients who were tested after FACS separation of CLL cells, the TP53-deleted clone was larger than 50% of neoplastic clonal lymphocytes, making it the primary clone.

Summary/Conclusions: We observed that the pre-processing of the sample through the FACS-supported purification of CLL neoplastic lymphocytes revealed that the TP53-deleted clone was nearly three-fold larger than suggested by the mixed cellularity sample, increasing from an average of a quarter of all cells, to nearly two-thirds. This finding uncovered that the TP53-clone was, in fact, the primary major clone within the neoplastic lymphocyte population in the majority of patients. Considering the poor prognosis conferred by the aberration, and its impact on current treatment decisions, it is quite significant to correctly identify a primary deletion-positive clone, instead of mislabeling it as a secondary minor clone.

E1034
PRIMARY PEGFILGRASTIM PROPHYLAXIS VERSUS FILGRASTIM GIVEN "ON DEMAND" FOR CLADRIBINE - INDUCED NEUTROPENIA IN HAIRY CELL LEUKEMIA

1The Ruth and Bruce Rappaport Faculty of Medicine, Technion, Haifa, 2Department of Hematology, Sourasky Medical Center, Tel aviv, 3Department of Hematology, Hadassas University Hospital, Jerusalem, 4Department of Hematology, Rabin Medical Center, Petah-Tikva, 5Department of Hematology, Meir Medical Center, Kfar-Saba, 6Hematology Unit, Kaplan Medical Center, Rehovot, 7Department of Hematology & Bone Marrow Transplantation, Ram-bam Health Care Campus, Haifa, 8Hematology Unit, Emek Medical Center, Afula, 9Department of Hematology, Shaare Zedek Medical Center, Jerusalem, 10Hematology Unit, Galilee Medical Center, Naharia, 11Hematology Unit, Ziv Medical center, Zefat, 12Department of Hematology, Soroka Medical Center, Beer-Sheva, 13Department of Hematology, Hadassas University Hospital, Jerusalem, 14Hematology Unit, Bnai-Zion Medical Center, Haifa, Israel.

Background: Major advances in the treatment of patients with HCL were made in the 1980’s after the introduction of two purine analogues: pentostatin and cladribine. Both these agents dramatically altered the clinical course and outcome of all cells, to nearly two-thirds. This finding uncovered that the latter complications may result in life-threatening infections. The major significant short-term toxicity of therapy with cladribine are neutropenia, NF and hospitalization in patients with HCL treated with cladribine, for 5–7 days given either sub-cutaneously or via intra-vascular route. Based on the script data: 71% of patients experience grade 4 neutropenia (absolute neutrophil count [ANC] <500x109/l), and 42% develop NF. The latter complications may result in life-threatening infections, as well as hospitalization.

Aims: In this retrospective study, we compared the incidence and duration of neutropenia, NF and hospitalization in patients with HCL treated with cladribine following pegfilgrastim as primary prophylaxis versus daily filgrastim given on demand according to the absolute neutrophil count.

Methods: The study population included 202 patients with HCL, diagnosed and followed in 12 medical centers in Israel during 1985-2015. Patients who were treated with cladribine, for 5-7 days given either sub-cutaneously or via intra-vascular, for 5-7 days. Medical records were evaluated for details of disease at diagnosis, including date of diagnosis, age, sex, ethnicity, complete blood count results, and spleen size at diagnosis. The efficacy of pegfilgrastim and filgrastim was assessed by evaluating the incidence of neutropenia (defined as ANC <1000x109/l), number and length of hospitalizations due to NF, severity of infections and the number of days from the last day of therapy until recovery of ANC to >1000x109/l.

Results: Mean follow up was 7.5 years (0.1-40), with 5 and 10 years’ survival of 96% and 90.62% respectively. The median age at diagnosis was 53 years, and 81.8% were males. First line therapy with cladribine was given to 159 patients, while 43 patients of these 50.3% required hospitalization for the administration of broad-spectrum antibiotics due to NF. The risk factor to develop NF was WBC < 0.6 109/l, and ANC < 0.3109/l. Twenty eight patients were treated with pegfilgrastim as primary prophylaxis 24 hours after the last day of therapy with cladribine, while 75 patients received filgrastim on demand due to neutropenia. Median hospitalization days, and Nadir duration was 8 and 18 days respectively in both groups (p=0.71, p=0.44).

Table 1.

Summary/Conclusions: Infectious complications post cladribine treatment, remains high, with an incidence of 50.3%. For all parameters analyzed, including the percentage of febrile patients, number of febrile days, and NADIR duration the results of primary pegfilgrastim prophylaxis and filgrastim given on demand were similar. According, we conclude that it remains the treating physician’s choice to decide on which type of filgrastim to use and when to administer it.

E1035
REDUCED HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA ACHIEVING COMPLETE REMISSION TO FIRST-LINE THERAPY

S Heitner Enschede1, J. Samp1, A. Guerin2, R. Foster3, B. Meissner1, A. Rokito3, G. Gauthier2.

1AbbVie, Inc., North Chicago, United States, 2Analysis Group, Inc., Montreal, Canada, 3Analysis Group, Inc., New York, United States.

Background: Most targeted therapies in the management of chronic lymphocytic leukemia (CLL) lead to high overall response rates but complete remissions are rare. Achieving complete remission (CR) is associated with improved clinical outcomes such as longer time to progression; however little is known about the economic benefits associated with achieving CR.

Aims: The objective of the study was to compare healthcare resource utilization among CLL patients initiated on first-line treatment who achieved CR versus those who did not.

Methods: This was a retrospective chart review study. From July to August 2016, 93 US oncologists/hematologists provided data abstracted from medical charts of their CLL patients who initiated a first-line CLL treatment between January 2010 and December 2014. The study collected patient demographics, clinical characteristics, response to first-line therapy, and the number of all-cause hospitalizations between first-line therapy initiation and end of the data follow-up (i.e., patient’s date of death, end of care, or data collection date, whichever occurred first). Patients were selected based on their best response to first-line therapy (i.e., CR, partial remission [PR], stable disease [SD] and progressive disease [PD]) as defined by the physician according to iwCLL 2008 criteria. The targeted number of patients in each category was a priori determined based on rates of response observed in clinical trials. The incidence of all-cause hospitalization was compared between patients who achieved CR and those who did not (including patients with PR, SD or PD) using univariate and multivariate generalized linear models with a Poisson distribution. As patients had different follow-up, incidence rates were reported per-patient-month (PPPM). Multivariate regression models were adjusted for age, gender, selected comorbid conditions, time from CLL diagnosis to first-line initiation, and Eastern Cooperative Oncology Group (ECOG) status.

Table 1.

Results: Patient-level data was collected for 179 patients who achieved CR and 151 patients who did not achieve CR (120 patients with PR, 25 with SD, and 6 with PD). Average time from CLL diagnosis to first-line initiation was 8.4 months for patients who achieved CR and 13.3 months for those who did not. The majority of patients were male (65%), the average age was 63 years, and 80% of patients had an ECOG of O or 1 at first-line therapy initiation. The medi-
an follow-up after first-line therapy initiation was 30 months. Over that period, patients who did not achieve CR had statistically significantly higher incidence of all-cause hospitalization compared to patients who achieved CR (0.021 vs 0.006 PPFPM; unadjusted incidence rate ratio [IRR]=3.30, p<0.05). After adjusting for potential confounders, the incidence of all-cause hospitalization was 2.4 times higher for patients who did not achieve CR compared to those who did (IRR=4.0, p<0.05).

Summary/Conclusions: Results from this study showed that achieving CR to first-line therapy (vs. not achieving CR) is associated with reduced frequency of all-cause hospitalizations. This suggests that, in addition to the clinical benefit associated with CR achievement, treatment strategies in CLL that improve CR may help reducing the economic burden of CLL management for both patients and payers.

E1036

RITUXIMAB (R) USED AS A SINGLE AGENT FOR AUTOIMMUNE HEMOLYTIC ANEMIA (AIHA) IN TREATMENT NAÏVE CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS INDUCES ALSO SIGNIFICANT DISEASE RESPONSE WITHOUT TOXICITY

S. Sachanias1,*, G. Pangalis2, M. Moschogiannis1, X. Yiakournis1, P. Tsirkinidis1, E. Koulieris1, C. Kalpadakis3, E. Poppis4, T. Vassilakopoulos5, M. Angelopoulou5

1Hematologic, Athens Medical Center, Psychiko Branch, 2Hematologic, Athens Medical Center, Psychiko Branch, 3Hematologic, Athens Medical Center, Psychiko Branch, 4Hematologic, University Hospital, University of Crete, Heraklion, 5Hematologic, Laikon General Hospital, University of Athens, Athens, Greece

Background: There are very few effective treatment options for steroid refractory AIHA of CLL or for CLL patients(pts) that are unable to receive corticosteroids. R has been noted to be active in certain autoimmune hemolytic disorders while experience with single-agent R in untreated CLL pts is very limited.

Aims: To report our experience concerning the use of R as a treatment of AIHA occurring during the first course of treatment in naïve, CLL pts by analyzing concomitantly its efficacy and safety as a single agent in CLL therapy

Methods: 15 pts diagnosed with CLL who received R due to AIHA were included in this study. Staging was performed at diagnosis (Binet system). Pts were placed on R at the standard dose I.V of 375mg/m2 once weekly for 6 consecutive weeks because of contraindication of corticosteroids administration

Results: Pts’ median age was 60 y(range, 42-83 y), (8 out of 15, males), 10 having disease stage A and B. Two were presented with splenomegaly and 1 with B-symptoms. 12 pts (83%) had leukemoid lymphocyte counts of more than 50x10^9/L. Median time from diagnosis, the AIHA diagnosis and to 1st R infusion was 59 mos. All 15 pts completed the 6-week course of R and were assessable for response. The median WBC and the median absolute lymphocyte count(ALC) before R administration and after the end of 6-week course are shown in the Table. Resolution of the AIHA effect was achieved in all pts whereas in 4 there was a persistence of positive DAT without evidence of active hemolysis. After the end of 6-weekly R infusion (B) showed also a disease response. 12 pts experienced PR (80%) and 1 CR (6%). All pts with advanced disease also responded entering PR. Resolution of splenomegaly was documented in both splenomegalic pts. After a median follow up of 84, 5 mos from CLL diagnosis, 14 pts are alive, 9 maintain their disease response while 5 were in need of therapy due to CLL progression, after a median time of 18 mos from the last R infusion. Among them 4 were placed on FCR (2CR, 2PR) and 1 on R-Bendamustine(PR). Median PFS has not reached. All pts received the entire first dose on day 1 of treatment. There was only grade 3 infusion related reaction in a patient with WBC>400x10^9/L without need for hospitalization. None of the pts experienced severe tumor lysis syndrome, pulmonary insufficiency, myelosuppression or opportunistic infections.

Summary/Conclusions: A) R is an effective agent for AIHA treatment with concomitant significant activity against CLL and therefore could be the standard of care for CLL pts with AIHA, especially for the cohort of pts with comorbidities. B) We confirm previous data that: 1) single-agent R induces significant respons-
es in treatment naïve CLL pts 2) R is well tolerated and its administration is not associated with myelosuppression or immunosuppression 3) R as a single agent could be an excellent first-line treatment option for pts who are very elderly or who have a poor performance status

E1037

ATTAINMENT OF COMPLETE REMISSION IS SIGNIFICANTLY ASSOCIATED WITH FAVORABLE LONGER SURVIVAL OUTCOMES IN RELAPSED/REFRACTORY (R/R) CLL: A META-ANALYSIS

V.U. Ekta1,*, C.P. Fox2, R.S. Taylor3, T.I. Inocencio1, G. Pena4, J.C. Mahler4, S.J. Snedecor4

1Pharmacist International, Bethesda, United States, 2Nottingham University Hospitals, Clinical Hematology, Nottingham, 3University of Exeter Medical School, Exeter, United Kingdom, 4AbbVie, Inc., North Chicago, United States

Background: Chronic lymphocytic leukemia (CLL) is an incurable neoplasm of B lymphocytes, associated with a heterogeneous clinical course. Complete response (CR) with/without minimal residual disease in first-line chemiomunotherapy has been associated with more favorable progression-free survival (PFS) and overall survival (OS). However, patients (pts) with R/R CLL and/or those with TP53 abnormalities (ie, 1p7 deletion and/or TP53 mutation) are less likely to achieve deep responses and experience poorer outcomes. Therefore, less is known about the relationship between CR and survival outcomes in R/R CLL pts.

Aims: To quantify this association, we generated meta-analytic estimates of PFS and OS reported in clinical trials using the proportion of study patients with CR as a predictor variable.

Methods: We performed a systematic literature review of PubMed/EMBASE up to Nov 2014 and congress abstracts 2012–2014. Randomized controlled trials and observational studies evaluating any treatment in R/R CLL pts were eligible for inclusion. Data were extracted from publications as median survival, the proportions of pts surviving at specific follow-up times, or individual event occurrence proportions from Kaplan-Meier (KM) curves, along with the proportion of pts with CR. Data were synthesized to estimate overall OS and PFS including population-level CR as a covariate using a Weibull proportional hazards model within a Bayesian meta-analysis framework.

Results: 74 published studies of treatment outcomes in R/R CLL pts were identified from the peer-reviewed literature and congress abstracts. 56 of these studies reported the proportion of CRs together with either OS or PFS outcomes and were included in the analysis. Individual pt data were extracted from KM curves of 29 studies generating 5176 individual pt OS and PFS data points in addition to 54 study-level data points including 3638 pts. There were no clinically meaningful differences in study or pt characteristics among the included studies that were not also associated with CR, our variable of interest. The hazard ratio (HR; and 95% credible interval, the Bayesian analog to confidence intervals) of survival for each 10% increase in CR among a study population was estimated to be 0.64 (0.60, 0.68). Estimated median OS for hypothe-
cal populations with 0% CR, 25% CR, or 50% CR were 20.4 mo, 44.7 mo, and 61.9 mo. Corresponding median PFS estimates were 10.0 mo, 21.9 mo, and 30.3 mo. (Figure 1).

Figure 1. [Graph showing survival outcomes with different CR rates.]

Summary/Conclusions: The attainment of CR is significantly associated with longer OS and PFS outcomes in R/R CLL at the study level. Moreover this can be expressed linearly, with each 10% increase in CR rate corresponding to a 36% reduction in the risk of progression or death. To our knowledge, this is the first meta-analysis to quantify the relationship between CR and survival outcomes in R/R CLL pts. It must be noted that these results reflect the study (population) level CR versus survival association and therefore do not necessarily represent the expected survival gain associated with an individual achieving CR. Further, CR is less likely to be achieved in pts with TP53 abnormalities, a factor not explicitly considered in our analysis. These results synthesize data from 56 clinical trials and strongly support the importance of achieving CR to improve long-term outcomes in R/R CLL pts. In particular, the prognostic association between CR and TP53 abnormalities, treatments focused on improving the likelihood of CR in these hard-to-treat pts are likely to confer the greatest impact on survival outcomes.

Table 1.
E1038
APPLICATION OF THE CLL-IPI AND THE MDACC PROGNOSTIC INDEXES IN A LOCAL COHORT OF CLL PATIENTS
I. González-Gascón Y Marín1,*, M. Poza1, M. Hernández-Sánchez2, A.E. Rodríguez-Vicente2, M.S. Infante1, C.C. Muñoz Novas1, C. Heras1, M.A. Foncillas1, J.M. Hernández-Rivas2, J.A. Hernández1
1Hospital Universitario Infanta Leonor, MADRID, 2IBSLA, IBMCC, Centro de Investigación del Cáncer, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: New prognostic scores have been developed in order to better discriminate the clinical course of CLL patients, along with Rai and Binet clinical staging systems. These scores, such as that proposed by the MDACC group, and recently the CLL-IPI combine clinical and biological variables with prognostic value.

Aims: In this study we investigated the validity and reproducibility of these scores in a local cohort of patients with CLL.

Methods: We made a retrospective analysis including 650 unselected CLL patients newly diagnosed and previously untreated from a single institution. The final analysis has been limited to the 486 cases with complete data to apply the MDACC score, and to the 258 cases with complete data to apply the CLL-IPI score.

Results: Median age was 67 years old (25-90). With a median follow-up time of 46 months, 394 patients were alive, and 187 had received any treatment for CLL at the moment of the analysis. Median overall survival (OS) of the series was 173 months (127-220), and median time to first treatment (TTFT) 106 months (82-130). The MDACC score was applied to 486 cases giving 0 to 9 points to each case according to: age, b2-microglobulin levels, absolute lymphocyte count, sex, Rai stage, and number of involved lymph node groups. As shown in the Table, stratification of patients using the MDACC score allowed the prediction of prognosis for both TTFT (P=0.000) and OS (P=0.000). 162 patients were classified as low risk, 302 as intermediate risk, and 21 as high risk. Due to missing data, the CLL-IPI score could only be applied to 258 patients giving 0 to 10 points to each case according to 17p deletion, IGHV mutational status, β2-microglobulin, clinical stage, and age. As shown in the table, 126 patients were classified as low risk, 79 as intermediate risk, 46 as high risk, and 7 as very high risk. We also found significant differences in terms of OS (P=0.000) and TTFT (P=0.000) using this score.

Table 1.

Summary/Conclusions: In this study we confirm that both scoring systems are also easily applicable in clinical practice. The new CLL-IPI score is able to discriminate the clinical course of CLL patients, along with Rai and Binet clinical stage, and with classical parameters has not been significantly modified, indicating the need for more effective therapies in these patients. Importantly, the prognostic significance of classical prognostic variables has not changed after the introduction of more effective therapies. Finally, similar studies are warranted in patients treated with novel agents.

E1039
CHRONIC LYMPHOCYTIC LEUKEMIA: PROGNOSTIC VALUE OF CLINICAL STAGES AND CLASSICAL PROGNOSTIC PARAMETERS DEPENDING ON TREATMENT MODALITY
T. Baumann1,*, J. Delgado1, P. Mozas1, V. Ortiz-Maldenado1, R. Santacruz2, M. Rozman3, M. Aymerich1, N. Villamor1, D. Costa1, A. Carrió1, E. Montserrat1,2
1Hematology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain, 2Hematology Department, Hospital de Clínicas, Asunción, Paraguay, 3Hematopathology Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: Prognostication is a key component in the management of patients with chronic lymphocytic leukemia (CLL). Prognostic factors however may change as a result of the introduction of more effective therapies.

Aims: To investigate whether the prognostic value of classical parameters has changed over time.

Methods: Retrospective single-center study of prognostic factors and outcome in patients with CLL diagnosed before (n=454) and after (n=903) 1995 when purine analogs and subsequently chemoimmunotherapy (CIT) were introduced in CLL treatment at the Hospital Clinic, Barcelona.

Results: The median follow-up was 8.3 years (0.1-3.30) for the overall series and 24.9 years (21.9-33.0) and 7.8 years (0.1-21.3) for patients diagnosed before and after 1995, respectively. Patients diagnosed before 1995 were older (p<0.001), had more advanced clinical stage (p<0.001), higher ALC (p<0.001), shorter LDT (p<0.001), and more often anemia (p<0.001) and thrombocytopenia (p<0.001) and increased serum LDH levels (p=0.019) than those diagnosed thereafter. There were no differences in B2-microglobulin (B2M) levels and ZAP70 or CD38 expression. Mutated IGHV was more frequently detected in patients diagnosed before 1995 (75% vs 55%; p<0.001). The proportion of patients receiving treatment did not differ between groups [42% (28-49%) at 46% (42-49%) at 6 years; p=0.08]. The type of therapy given to patients diagnosed before and after 1995 was: alkylating agents (91% vs 34%); purine analogs (4% vs 27%); CIT (0% vs 31%); other (5% vs 8%); (p<0.001). The response rate was lower in patients diagnosed before 1995 (57% with 9% CR vs 61% with 36% GR; p<0.001) and overall survival (OS) was shorter (median: 8.0 vs 10.1 years; p<0.001). The median OS in patients diagnosed before and after 1995 broken down by clinical stage was: stage A: 10.1 vs 10.9 years (p=0.1); stage B: 4.5 vs 9.2 years (p<0.001); stage C: 3.8 vs 8.8 years (p=0.2).

In both groups of patients univariate analyses demonstrated a correlation between OS and clinical stage (both p<0.001), age >70 years (both p<0.001), B2M (both p<0.001), short lymphocyte doubling time (LDT) (both p<0.001), unmutated IGHV (both p<0.001), and ZAP70 (p<0.015 and p<0.001). High-risk FISH correlated with OS in patients diagnosed after 1995 (p<0.001). In patients diagnosed before 1995, the number of subjects with available FISH was too small for a meaningful analysis. In multivariate analysis (age >70 years, advanced clinical stage short LDT increased B2M, diagnosis before 1995) only age (HR 2.7 (95% CI: 2.1-3.4), p<0.001), LDT (HR 2.5 (1.9-3.2), p<0.001) and B2M (HR 2.8 (2.2-3.8), p<0.001) showed independent prognostic significance for OS. IGHV mutational status, ZAP70 and high-risk FISH cytogenetics correlated with OS but these were not included in multivariate analyses because of the many patients with missing information.

Summary/Conclusions: Survival of patients with CLL in intermediate-risk (stage B) disease has dramatically improved over the last years. In contrast, the outcome of patients with either low (stage A) or high (stage C) stage has not been seen significantly modified throughout the need for more effective therapies in these patients. Importantly, the prognostic significance of classical prognostic variables has not changed after the introduction of more effective therapies. Finally, similar studies are warranted in patients treated with novel agents.
patients (27.4%). Overall, 80.3% of FAS patients did not experience therapeutic failure and 85.9% did not experience disease progression during the 2-year observation period. By the end of the study, median PFS had not been reached; 2-year PFS rate was estimated as 85.9%. Improvements from baseline were observed after 6 cycles of treatment across all EQ-5D domains. No relapses or deaths occurred in the FAS; however, 2 subjects in the Safety Population experienced fatal serious ADRs (myocardial infarction [n=1]; acute pneumonia, infections and toxic shock, and atrial fibrillation [n=1]). In concurrence with the Phase 3 trial results, hematologic disorders (19.9%; anemia, neutropenia, thrombocytopenia), most of which were Grade ≥2 in severity, were the most common ADRs (Safety Population; Table 1).

**Summary/Conclusions:** First-line therapy with bendamustine plus rituximab was well tolerated in this Russian CLL population, including elderly patients and patients with renal dysfunction or other comorbidities. Additionally, combination therapy resulted in high rates of treatment response in the CLL. These data confirm the value of bendamustine as a first-line agent for CLL in routine clinical practice in Russia.

**Background:** BCR-ABL1 kinase domain (KD) mutations are an important mechanism of resistance of chronic myeloid leukemia (CML) patients developing during the tyrosine kinase inhibitors (TKI) treatment. However, mechanisms underlying KD mutation acquisition in TKI-resistant CML cells are not yet well understood.

**Aims:** We studied an acquisition of mutations in the KD after an exposure of de novo and relapsed (grown in optimal growing medium for 24 months) KCL-22 cells to imatinib (IM). In addition, we examined kinetics of mutated sub-clones in established IM-resistant KCL-22R culture after dose-reduction of IM. We also studied changes in the expression profile of KCL-22 cultures early after exposure to IM.

**Methods:** The occurrence and kinetics of expansion of BCR-ABL1 mutant sub-clones were studied using next-generation deep sequencing in KCL-22 cells treated with 0.4 µM IM and in established IM-resistant KCL-22R cells at 4 µM IM. In other set of experiments, KCL-22R cells were sorted according to the CD38 expression to explore whether CD38 is associated with the acquisition of BCR-ABL1 mutations as suggested by Wang et al. (2014). A protein array was used allowing analysis of 576 proteins per sample. DNA damage pathway-RT Profiler PCR arrays were applied for gene expression analysis.

**Results:** No BCR-ABL1 KD mutations were detected in de novo untreated KCL-22 cells; however T315I and E255K appeared after the exposure of the cells to 0.4 µM IM. PCR array revealed increased expression of SUMO 1 ligase and ERCC2 involved in the nucleotide excision repair pathway. Notably, we also found a significant decrease of G2/M-checkpoint protein GADD45A whose deficiency is associated with mutagenesis (Holland et al., 2001). During the first culture period, T315I slowly emerged whereas E255K was not detectable. Later, E255K-bearing cells also became detectable and increased over time. A similar time-dependent expansion of mutant-bearing sub-clones was seen in the KCL-22R cells growing at 4 µM IM. Interestingly, a mutant-clone switch from T315I to E255K in KCL-22R was accelerated after IM reduction from 4 µM to 1 or 2 µM. Moreover, the emerging of E255K sub-clones was accompanied by rapid decrease of CD38 expression in KCL-22R cells. Profiling of transitional KCL-22R culture, carrying both T315I and E255K sub-clones, revealed that T315I transcripts were expressed only in the CD38+ subpopulation, while E255K was detected only in CD38- cells. Unlike to de novo KCL-22 cells, BCR-ABL1 mutations were repeatedly not detected in relapsed KCL-22R sub-clones, except for a follow-up of 60 days after the cells exposure to 0.4 µM IM. Neither BCR-ABL1 upregulation nor gene amplification was detected in these cells. We identified considerably upregulated (D7, DTX3, ETV6, GLUL, HCLS1, HIF1α, IGF1R, MAP2K7, MYH11, TPS3) or downregulated (BAD, BID, MCL2 NOTCH3, PDKPK1) proteins early, 4 weeks after the exposure to IM. Increased expressions of HIF1α and IGF1R proteins are known to ensure proliferation, while decreased expressions of pro-apoptotic proteins BAD and BID enhance survival of CML cells in the presence of TKIs.

**Summary/Conclusions:** Our observation suggests the ability of KCL-22 cells to survive and proliferate early after the exposure to IM. BCR-ABL1 mutations development seems to be related to a mutagenesis of imatinib on de novo KCL-22 cells, but not on relapsed KCL-22 cells that activated signaling pathways ensuring their survival and growing in the presence of tyrosine kinases inhibitor.

**Background:** Chronic myeloid leukemia (CML) is a clonal hematopoietic malignancy characterized by a chromosomal translocation that results in the BCR-ABL fusion gene. CML stem cells (CML-SC) have been identified as important for disease progression.

**Aims:** To evaluate the expression of CD26 in CML-SC from peripheral blood (PB) and bone marrow (BM) of CML patients.

**Methods:** PB and BM samples were stained with antibodies against CD26 and CD34. Flow cytometry analysis was performed using a FACSCalibur flow cytometer (BD Biosciences).

**Results:** CD26+ CML-SC were detected in 30% of PB and 10% of BM samples. The percentage of CD26+ CML-SC was significantly higher in patients with advanced stages compared to chronic phase.

**Conclusion:** The detection of CD26+ CML-SC in PB and BM by flow cytometry is a simple and rapid diagnostic tool for the management of CML.
Pharma, Milano, 4Dept. Clinical and Experimental Medicine, Pisa, 5Hematology, University of Firenze, Firenze, 6Ematology 2 A.O. Città della salute e della Scienze di Torino, Torino, 7Hematology Unit, Dept. of Medical Sciences, Bone Marrow Transplant Center, R. Binaghi Hospital, Cagliari, Italy

Background: Diagnosis of Chronic Myeloid Leukemia (CML) implies documenting in bone marrow (BM) or in peripheral blood (PB) Philadelphia (Ph) chromosome by cytogenetics, molecular BCR-ABL1 fusion by FISH or BCR-ABL1 rearrangement by RT-PCR. In clinical practice, at the earliest, 24-72 hrs are needed to confirm CML by any of these assays. Latey, characterization of CML leukemia stem cells (LSCs) from BM samples by CML patients (pts) showed a specific co-expression of dipeptidylpeptidaseIV (CD26) within the CD34+/CD38─/Lin─ stem cell fraction and CD26 appeared a robust biomarker for identifying CML LSCs within the normal BM compartment. We recently demonstrated that CD34+/CD38+/CD26+ LSCs can be easily identified by flow-cytometry also in PB during treatment with tyrosine kinase inhibitors.

Aims: We investigated accuracy and specificity of flow cytometry PB CD34+/CD38+/CD26+ LSCs identification as a new tool for the diagnosis of CML.

Methods: Pts with clinical suspicion of CML entered the study after written informed consent and all were evaluated for CD26+LSCs, cytogenetics, FISH and/or BCR-ABL1 RT-PCR analysis. CD34+/CD38−/CD26+ population was investigated in PB and when possible simultaneously in BM samples using a flow-cytometry 4-color staining procedure. 2.0x106 leucocytes were incubated with BD Pharmingen CD45/500 (c.201), CD34/FLTC (c.581), CD38/APC (c.HIT2), CD26 (c.M-A261) and negative controls. Acquisition and analysis of at least 1.0x106 CD45+ cells were done by FACSCanllo II with DIVA 8 software (BD, Biosciences). CD26+ cells were identified by sequential gate. CD45+ and CD34+ gates were performed on viable cells identified by FSC/SSC light properties and CD34+/CD38− population was gated applying a narrow gate excluding all CD38+ cells (Fig.1).

Results: Pts samples from 107 pts with myeloproliferative features were evaluated for CD26+LSCs. Leucocytes median value was 52x10⁶/µL (range 5-40x10⁶). In 83/107 (77.5%) pts we showed CD34+/CD38-/CD26+ LSCs in PB and in 83/93 (100%) the diagnosis of CML was confirmed by cytogenetics, FISH and RT-PCR analysis. Median value of circulating PB CD26/µL was 14 (range 2,7-698) and a positive correlation with leukocyte count (p<0.01) was found. In 53/107 (49.5%) pts analysis was performed contextually in BM samples. All CD26+ PB-BM matched pairs (49/53) showed superimposable results in terms of absolute number of CD26+LSCs/µL (19.18 and 18.73 respectively) while the percentage of CD26+ cells within the CD34+/CD38− fraction appeared lower in BM than in PB samples (median 28,18 and 37,33; range 0,87-77,14 respectively).

Overall, we found that PB-BM matched pairs (49/53) showed superimposable results in terms of absolute number of CD26+LSCs/µL (19.18 and 18.73 respectively) while the percentage of CD26+ cells within the CD34+/CD38− fraction appeared lower in BM than in PB samples (median 28,18 and 37,33; range 0,87-77,14 respectively). Furthermore we have compared the percentage of CD26+PB-BM matched pairs (49/53) showed superimposable results in terms of absolute number of CD26+LSCs/µL (19.18 and 18.73 respectively) while the percentage of CD26+ cells within the CD34+/CD38− fraction appeared lower in BM than in PB samples (median 28,18 and 37,33; range 0,87-77,14 respectively). Furthermore we have compared the percentage of CD26+ cells within the CD34+/CD38−/Lin− stem cell fraction and CD26 appeared a robust biomarker for identifying CML LSCs within the normal BM compartment. We recently demonstrated that CD34+/CD38+/CD26+ LSCs can be easily identified by flow-cytometry also in PB during treatment with tyrosine kinase inhibitors.

Aims: We investigated accuracy and specificity of flow cytometry PB CD34+/CD38+/CD26+ LSCs identification as a new tool for the diagnosis of CML.

Figure 1.

Summary/Conclusions: Flow-cytometry evaluation of PB CD34+/CD38−/CD26+LSCs is a feasible, very rapid (about 3 hrs from sample handling to results) and highly specific alternative/complementary diagnostic tool for CML. To validate these data in a larger cohort of patients we are developing a pre-treated lymphoblastoid antibody mixture (lyotube, BD Biosciences) to maximize sensitivity and to optimize standardization and working time, with the further aim to monitor stem cells minimal residual disease in CML patients.

MAINTENANCE OF LEUKAEMOGENIC POTENTIAL OF BCR/ABL+ CELLS REQUIRES PAK2 BUT NOT PAK1

A. Hreiz, T. Kovar, K. Koerger1, L. Edlinger1, I. Menzl1, G. Hoermann2, E. Grundschobler1, Z. Bago-Horvath3, V. Sexl1

1Institute of Pharmacology and Toxicology, Veterinary University of Vienna, 2Department of Laboratory Medicine, 3Clinical Institute of Pathology, Medical University of Vienna, Vienna, Austria

Background: p21-activated kinases (PAKs) are key nodes in oncogenic signalling pathways that control growth, survival, and motility of cancer cells. Their activity is increased in many human cancers and the increase is associated with a poor prognosis. To date, PAK deregulation has mainly been studied in solid tumours, where PAK1 and PAK4 are the main isoforms deregulated. They have also been reported to have direct interactions with miRNA with an important regulatory effect in disease development such as chronic myeloid leukemia (CML).

Aims: In this study, we aimed at the correlation of T-UCR and miRNA-T-UCR pairs in CML, according to tyrosine kinase inhibitor (TKI) therapy, clinical risk scores and molecular response.

Methods: We analysed peripheral blood samples from 45 CML patients and 15 healthy controls. Two panels of 481 T-UCR and 752 miRNA probes were used for RT-qPCR analysis. Differential expression was evaluated using the Mann-Whitney test followed by Benjamini-Hochberg multiple testing correction.

Results: CML samples presented significantly different expression of u.164 (p<0.01), u.118 (p<0.01), u.125 (p<0.01), u.391 (p<0.01), u.153 (p<0.01), u.141 (p<0.01), u.143 (p<0.05) and u.145 (p<0.05), when compared to healthy controls. This latter T-UCR (u.145) was associated with development and immune regulation pathways. We analysed Sokal, Hasford and EUTOS risk scores and found u.236 (p<0.0001), u.39 (p<0.05) and u.7 (p<0.05) to be associated with EUTOS low risk. Concerning therapy, dasatinib was correlated with u.143 (p<0.05), while imatinib doses, u.4 (p<0.05) and u.3 (p<0.05) inversely correlated with 400 and 800mg daily, respectively. Molecular response in CML samples presented a signature including u.187 (p<0.001), u.107 (p<0.05), u.409 (p<0.05), u.198 (p<0.05), u.309 (p<0.05), u.102 (p<0.05), u.294 (p<0.05) and u.361 (p<0.05). Major molecular response was identified by the altered expression of u.198 (p<0.05), u.215 (p<0.05) and u.210 (p<0.05). The negative regulation of T-UCRs by miRNAs, involving T-UCR-miRNA interaction, was associated with upregulated (miR-720, miR-886-3p, miR-1274a, miR-101 and miR-129) and downregulated (miR-489 and miR-1973) microRNAs.

Summary/Conclusions: In the present study, we identified T-UCRs signatures and miRNA-T-UCR pairs associated with CML, risk scores, TKI therapy and molecular response. The expanded knowledge of RNA biology in general, together with the recent interest in the multitude of newly discovered elements such as T-UCRs, could help to improve CML therapy.

MIRNA PROFILING OF CIRCULATING EXTRACELLULAR VESICLES IN CML PATIENTS WITH MUSCULOSKELETAL PAIN ASSOCIATED WITH DISCONTINUATION OF TYROSINE KINASE INHIBITORS

K. Ohyashiki1,*, M. Asano1, T. Umezu2, S. Katagiri1, C. Kobayashi2, T. Tauchi1, M. Gotoh1, K. Ando1, S. Okabe1, J. Ohyashiki2

1Institute of Hematology, 2Department of Molecular Oncology, Institute of Medical Science, Tokyo Medical University, Tokyo, Japan

Background: Clinical trials of TKI discontinuation are still ongoing, approximately 60% of CML patients who achieved a deep molecular response for more than 2 years maintained a major molecular response after discontinuation of imatinib. However, the long-term prognosis and/or adverse events after TKI cessation remain unclear. Recent reports showed that transient musculoskeletal pain after stopping TKIs is more frequent, affecting up to 30% of CML patients after stopping imatinib.

Aims: Recent evidences suggest that extracellular vesicles (EVs) that contain genetic element such as DNA, RNA, and miRNA, are important mediators of intercellular communication. We therefore studied molecular study to ascertain the possible correlation between musculoskeletal pain and EV-miRNA expression.

Methods: We investigated circulating EV-miRNAs in five CML patients who did not experience musculoskeletal events and five patients with musculoskeletal pain after stopping TKIs, as well as three healthy individuals. Peripheral blood was obtained approximately 3 months after successful TKI cessation in CML patients. Exosomes were extracted by using Total Exosome Isolation Reagent (Invitrogen, Carlsbad, CA, USA) and EV-miRNA profiling was performed with a TaqMan Low-Density Array (Thermo Fisher Scientific, Carlsbad, CA, USA), as reported previously. The relative expression level of each gene was calculated by using the comparative thresholds cycle (Ct) method. Synthesis of the study was approved by the institutional review board of Tokyo Medical University (no. 930 approved 24 June 2008 and no. 3052 approved 9 June 2015).

Results: Three-way analysis of variance (ANOVA) performed for healthy controls and CML patients with and without musculoskeletal pain revealed elevated EV-miR-140-3p to be the most significant value (P=0.00778). A t-test analysis using R software identified 10 differentially expressed EV-miRNAs for CML patients with and without musculoskeletal pain: seven miRNAs were upregulated (miR-107, miR-145, miR-140-3p, miR-539, miR-495, miR-299-5p, miR-425) and three were downregulated (miR-218, miR-218, miR-523) in CML patients with musculoskeletal pain. The up-regulated EV-miR-140-3p in all CML patients decreased after release of musculoskeletal pain.

Summary/Conclusions: CML patients with increased EV-miR-140-3p achieved levels similar to those of healthy controls after relief from musculoskeletal pain but further research should investigate whether upregulation of EV-miR-140-3p expression in peripheral blood is correlated with musculoskeletal events in CML patients after TKI cessation.

SOLUBLE AND MEMBRANE-BOUND RECEPTOR–LIGAND IMMUNE CHECKPOINTS AND CHRONIC MYELOID LEUKAEMIA: CORRELATIONS WITH MOLECULAR RESPONSE AND TYROSINE KINASE INHIBITOR THERAPY

P. Rodrigues-Santos1,2,3,*, J.S. Almeida2,3, P. Couceiro2,3, V. Alves1,3, J.R. Simplicio2, L. Růžičková4, P. Freitas-Tavares4, M. Santos-Rosa1,3

1Instituto de Imunologia, Faculdade de Medicina da Universidade de Coimbra, 2Laboratório de Imunologia e Oncologia, Centro de Neurociências e Biologia Celular, 3Centro de Investigação em Meio Ambiente, Genética e Oncobiologia (CIMAGO), Faculdade de Medicina da Universidade de Coimbra, 4Serviço de Hematologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Blockade of immune checkpoint seems to unleash the potential of the antitumor immune response in a fashion that is transforming human cancer therapeutic. Soluble and membrane-bound receptor–ligand immune checkpoints are the most druggable forms using agonist antibodies (for co- stimulating pathways) or antagonist antibodies (for inhibitory pathways). Although its implications in immune response during chronic myeloid leukemia (CML) therapy without consistent biochemical abnormalities in CML patients (n=55), divided according to molecular response to imatinib, dasatinib, nilotinib, bosutinib, ponatinib and Interferon-alpha 2b (IFN-α 2b) therapy, were included in this study. Multi-parametric flow cytometry was used for the analysis of the
expression of several immune checkpoint inhibitors (BTLA, GITR, LAG-3, PD-1, PD-L1, PD-L2, TIM-3, CD137/4-1BB) by different T, B, NK, monocyte and dendritic cell subsets. A 14-plex panel including BTLA, GITR, HVEM, IDO, LAG-3, PD-1, PD-L1, PD-L2, TIM-3, CD28, CD80, CD137, PD-1, and CD152 (CTLA-4) was analyzed by xMAP technology (Luminex®).

**Results:** Expression of CD137 by several lymphocyte subsets and PD-1 by regulatory T cells (Tregs) and natural killer (NK) cells were found significantly altered in CML patients under TKI therapy. These associations were observed for the cell population frequency expressing the receptor, and also for density of these molecules. Increased plasmatic levels of BTLA, HVEM, PD-1, PD-L1, and CD137 were associated with good molecular response to therapy. PD-1, PD-L1, TIM-3 and CD137 were found increased in patients that achieved MR4.5.

**Summary/Conclusions:** Some immune checkpoint inhibitors seem to be affected by TKI therapy in CML and their cell expression and plasmatic levels correlates to molecular response. Similar observations were described for other types of cancers, including solid tumors. Soluble and membrane-bound receptor–ligand immune checkpoints could represent interesting targets for future therapeutic monitoring and for pharmacologic interventions in CML.

**TYROSINE KINASE INHIBITORS SIGNIFICANTLY CHANGE THE EXPRESSION OF POLYCOMB GENES IN CHRONIC MYELOID LEUKEMIA**

S. Grassi1,*, S. Palumbo2, E. Arrigoni3, E. Ciabatti4, G. Ercolano5, F. Guerrini4, Y. Shokeen1,*, N.R. Sharma2, V. Taneja3, S. Minhas1, M. Jauhri1, S. Aggarwal1

1Department of Medical Oncology, Sir Ganga Ram Hospital, Delhi, 2School of Biotechnology and Biosciences, Lovely Professional University, Jalandhar, 3Department of Research, Sir Ganga Ram Hospital, Delhi, India

**Background:** It has been reported that, notwithstanding their clinical success, tyrosine kinase inhibitors (TKIs) are not able to eradicate the leukemic stem cell (LSC) in patients with chronic myeloid leukemia (CML). Different mechanisms have been hypothesized, especially those linked to the niche (increased BM1 resulting a good predictive molecular marker (Crea, 2015).

**Aims:** To identify prognostic and susceptibility genetic markers in CML

**Methods:** Enrolled CML patients (n=18) were segregated as responders (n=10) and failures (n=8) as per ELN, 2013 guidelines. Healthy controls (n=5) were also enrolled. DNA from blood of subjects was subjected Next Generation Sequencing (NGS). Mutations present in one patient group and absent in opposite group were considered as prognostic markers, whereas rare mutations, present in more than 50% of enrolled patients and absent in healthy controls, were considered as susceptibility markers

**Results:** We discovered mutations in genes associated with cancer or cancer related functions in different patient groups as markers. Five of them: rs116201358, rs17882014, rs4014956, rs52897880 and rs2274329 in C8A, HLA-DRB1, UNC93B1, APOH and CA6 genes respectively, were present in responders; rs4945 in MFGE8 was present in failures. Mutations in HLA-DRB1 (rs17878891, rs11554462, c.239C>G), HLA-DRB5 (rs137863146), RPHN2 (rs193179333), CYP2F1 (rs11695855), KCNJ12 (rs76684759), FUT3 (rs151218854), BM01 (rs28370522) and PRSS1 (rs144422014) were present in half or more patients

**Summary/Conclusions:** We discovered potential genetic markers, which can help in predicting response to IM as frontline therapy. Susceptibility markers can be used as panel for to configure individuals prone to CML

**FEATURES OF THE A2455G POLYMORPHISM OF GENE CYP 1A1 IN PATIENTS WITH CML**

K. Karimov1,*, N. Abdurahmanova1, K. Boboev1

1Institute of hematology and blood transfusion, tashkent, Uzbekistan
Background: Chronic myeloid leukemia (CML) is the most common myelo-proliferative disorder characterized by the reciprocal translocations t(9;22) (q34; q11), leading to the formation of chimeric oncoprotein BCR-ABL on the 22q-chromosome. It is known that the protein products of the genes of cytochromes ensure homeostasis at the cellular and tissue level, carrying out the metabolism of toxic compounds that can damage the genome of the cells. Present study assesses the role of genotypic variants of the A2425G polymorphism of CYP1A1 gene in the development of hematological malignancies. However, the adverse roles of genotypic variants for this gene in oncogenesis of BCR-ABL-positive patients with CML have studied not enough.

Aims: Evaluation the role of A2425G polymorphism of CYP1A1 gene in the formation the mutant clone of tumor and development of CML.

Methods: The work is performed on DNA samples isolated from the peripheral blood of the patients in the clinic of scientific research Institute of Hematology and blood transfusion in Uzbekistan. We studied 146 patients with CML. The control group was formed from 217 individuals of Uzbek nationality, without of any cancer disease. The diagnosis of CML verified in accordance with the International nomenclature ISCN. Standardized PCR with detection in real-time was carried out on a thermal cycler Rotor-Gene 6000 (Corbett Research, Australia), using a set of primers and probes AmpliSens® Leucosis quantum M-bcr-AFRT (InteraLabServis, Russia). Testing A2425G polymorphism of CYP1A1 gene was performed on a programmable thermal cycler of the company “Applied Biosystems” (USA) using test systems company “Litech” (Russia) according to the manufacturer’s instructions. Statistical analysis of results was carried out using the statistical software package “2009 OpenEpi, Version 2.3”.

Results: The frequencies of allele A and G are as follows: 87.7% and 12.3% in patients with CML, and 93.3% and 6.7% in the control group, respectively. The frequency distribution of genotypes A/A, A/G and G/G in patients was significantly different compared to the control group (χ²=4.6; P=0.03; OR=1.8; 95% CI 1.046-3.166). The homozygous genotype was 1.8 times significantly higher compared with patients not having this genotype (χ²=6.8; P=0.01; OR=2.0; 95% CI 1.046-3.916). Our results suggest that the G allele and the heterozygous genotype A/G A2425G polymorphism of CYP 1A1 gene is important markers of increased risk in formation of malignant tumor cells and development of CML in Uzbekistan (P<0.05). In this case, homozygous genotype A/A of A2425G polymorphism of CYP 1A1 gene has a protective character in relation to risk of CML.

Chronic myeloid leukemia - Clinical

E1051

HEMATOLOGIC TOXICITY GRADE III-IV IS ASSOCIATED WITH LOWER SURVIVAL IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH TYROSINE KINASE INHIBITORS

L.F. Casado Montero1, J.V. García-Gutierrez2, P. Giraldo3, M. Perez-Encinas4, R. de Paz5, J. Martínez-Lopez6, G. Bautista7, S. Osorio8, M.J. Requena9, L. Palomera10, M.J. Peñarrubia11, C. Steegmann15.1Hematology, Hospital Virgen de la Salud, Toledo, 2Hematology, H Ramon y Cajal, Madrid, 3Hematology, IIS Aragon, Traslational Research Unit, Zaragoza, 4Hematology, Hospital Clínico de Santiago de Compostela, Santiago de Compostela, 5Hematology, Hospital la Paz, 6Hematology, Hospital 12 de Octubre, 7Hematology, Hospital Puerta de Hierro, 8Hematology, Hospital Universitario Gregorio Marañón, 9Hematology, Hospital Universitario Severo Ochoa, Madrid, 10Hematology, Hospital Clínico Universitario Lozano Biesa, Zaragoza, 11Hematology, Hospital Clínico Universitario Valladolid, Valladolid, 12Hematology, Hospital General de Ciudad Real, Ciudad Real, 13Hematology, Hospital Universitario Infanta Leonor, 14Hematology, Spanish Registry of CML and GELMC, 15Hematology, Department of Hematology and IIS-IP, Hospital Universitario de la Princesa, Madrid, Spain

Background: TKIs introduction in the treatment of chronic myeloid leukemia (CML) has offered an outstanding improvement in survival outcomes. These results were obtained from clinical trials but little is known about long-term toxicity and their translation to real life. In addition, clinical trials results are mainly based on the analysis of the therapy of interest (experimental or control), but the descriptions of the subsequent treatment sequences due to failure or intolerance are normally lacking.

Aims: To analyze the long-term toxicity of patients outside clinical trials in clinical trials. The setting was a multicentric, hospital-based registry.

Methods: Toxicity grade III-IV and survival and their potentially associated variables were studied.

Results: Demographics, risk and treatment distribution: 893 patients (533 men, 360 women) with a median age at diagnosis of 52 y (14-94y) were included with a follow up of 85±7 months (m) from diagnosis, 78.6±6 m from first treatment, and 69±6 m from first TKIs. 151 patients (16.9%) were over 70. The risk distributions were as follows: Sokal: low (L) 48%, intermediate (I) 37% and high (H) 14%; Euro score: L 50%, I 45% and H 5%; EUTOS LT: L 70%, I 23% and H 7%. Treatment groups were the following: Group 1: IFN alpha and then imatinib or 2° GTKIs (221 patients); Group 2: imatinib only (404 patients); Group 3: imatinib and then nilotinib, dasatinib or both due to failure or intolerance (177 patients) and Group 4: 2° GTKIs in first line (93 patients). Hematologic toxicity grade III-IV. Figure 1 shows the incidence through the years (all group of treatments). From 800 patients treated with imatinib (first c second line) 67 (8.3%) had grade III-IV toxicity, and 26 had to switch treatment due to toxicity. From 166 patients treated with dasatinib (29

Figure 1. Evolution of hematologic toxicity grade 3-4 with time (all treatments sequences included).
in 1st line, 114 in 2nd, 56 in 3rd) only 13 had hematologic toxicity and 6 had to switch, 14 had pleural effusion grade III-IV and 9 had to switch. From 115 patients treated with nilotinib (49 in 1st line and 66 in 2nd) only 10 had hematologic toxicity and 10 switched treatment. Survival: Estimated survival by 10 years was 80%. Variables associated with survival: In the univariate survival analyses (log rank test) either from diagnosis, first therapy or first TKIs, the Sokal, Eutus, Euro and EUOTUS LT scores, as well as age over 70y were the only statistically significant variables associated with survival. Hematologic toxicity grade III-IV was associated with lower PFS or OS (figure 1). In the multivariate analysis (Cox model), only hematologic toxicity grade III-IV and age over 70y were independent variables.

Summary/Conclusions: 1. These results show that the probability of survival by 10 years is roughly 80%, and extend the findings of our previous work showing that this probability is not different across different sequential treatments (imatinib 1st line or post-IFN, or switched to 2GTKis due to intolerance or failure) (1). This fact reinforces the potential value of available TKI therapies. 2. Hematologic toxicity grade III-IV in the first two years identified a group of patients with worse survival outcome. 3. Patients over 70 years have shorter survival due to reasons different than progression. 4. Second GTKis showed better hematologic toxicity profile.

E1052

5-YEAR EFFICACY OF DASATINIB AND IMATINIB IN NEWLY DIAGNOSED PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) WITH DOSE MODIFICATIONS FROM DASISION

A. Hochhaus1,*, E. Jabbour2, H. Kantarjian2, F. Guilhot3, V. Kota4, T. P. Hughes5, A. Hochhaus1,*, E. Jabbour2, H. Kantarjian2, F. Guilhot3, V. Kota4, T. P. Hughes5, 1Hematology, AKITA UNIV., 2Pharmacy, AKITA UNIV. HOSPITAL, Akita, Japan

Background: Multiple dosage strengths are approved for dasatinib (DAS), permitting dose-optimization strategies for patients who experience adverse events (AEs). In a 2-year retrospective analysis of DASISION, efficacy was maintained in DAS- and imatinib (IM)-treated patients with dose reductions or interruptions to manage AEs (Jabbour ASH 2011); cytogenetic and molecular response rates were higher for patients given DAS vs IM, even when daily doses were modified. Longer term follow-up is needed to fully understand the potential impact of dose reductions on efficacy.

Aims: To evaluate the effect of dose reduction for any AE and for pleural effusion on efficacy in DAS- or IM-treated patients from DASISION.

Methods: Treatment-naïve patients with CML-CP in DASISION (NCT00481247) were randomized to receive either DAS (100mg once/day; N=259) or IM (400mg once/day; N=260). Dose reductions for AEs (up to 2) were allowed: DAS: 80mg, then 50mg; IM: 300mg, then 200mg. Five-year molecular and cytogenetic response rates in all patients were assessed retrospectively.

Table 1.

Results: Patients on DAS maintained higher molecular response rates than patients on IM, whether or not they had dose reductions for an AE; these rates were similar in patients with and without dose reductions in each arm (table). 95 (37%) DAS- and 44 (17%) IM-treated patients had dose reductions at any time due to AEs. Median time to first DAS dose reduction was 289 days (range: 22-2123), and median time to first IM dose reduction was 160 days (range: 31-2052). For patients with reductions due to any cause, median average daily dose was DAS 83mg and IM 328mg; for DAS patients with reductions due to pleural effusion, median average daily dose was 82mg. Median duration of treat-

ment (excluding interruptions) was 54 months (range: 3-70) for patients who had a DAS dose reduction and 57 months (range: 2-71) for patients who had an IM dose reduction. Changes in level of response were tracked for patients who achieved complete cytogenetic response (CCyR) or major molecular response (MMR) before or after the first dose reduction (table). Many patients maintained or increased to CCyR or MMR following dose reductions for any AE. Hematological toxicity (9%) was the most common AE resulting in dose reduction for IM, and pleural effusion (12%) was the most common for DAS.

Summary/Conclusions: Reducing DAS doses to 80mg or 50mg was a safe and effective means of managing patients who experienced AEs in this 5-year retrospective analysis of DASISION. These results were consistent with previous reports and continued to show that efficacy was not affected by dose reductions for any cause, including pleural effusion. Notably, there was no loss of CCyR following dasatinib dose reductions. Molecular responses remained higher for DAS vs IM irrespective of dose reductions due to AEs.

E1053

EFFECT OF PLASMA TROUGH CONCENTRATION OF Nilotinib and Polymorphisms of Drug Transporter Genes on the Frequency of Adverse Events in Chronic Phase of Chronic Myeloid Leukemia: STAT1 and STAT2 Trials

N. Takahashi1,*, T. Niloka2, M. Abumiya2, S. Takahashi1, M. Miura2

1Hematology, AKITA UNIV., 2Pharmacy, AKITA UNIV. HOSPITAL, Akita, Japan

Background: STAT trials (STAT1 and STAT2) are multicenter, phase II, single-treatment arm, open-label clinical studies designed to evaluate the efficacy and safety of two-year consolidation by nilotinib (NIL) for achieving a deep molecular response (DMR) or successful treatment-free remission (TFR) in patients with chronic phase chronic myeloid leukemia (CML).

Aims: In this report, we focus on the adverse events (AEs), especially anemia and liver dysfunction observed in the STAT trials. Additionally, we analyzed the relationship between laboratory abnormalities and pharmacokinetics (PK)/pharmacogenetics (PGx) of NIL.

Methods: AEs were assessed according to the Common Terminology Criteria for Adverse Events (CTCAE) v4.03. Safety evaluations were conducted throughout the study. Plasma trough concentrations of NIL were determined with high-performance liquid chromatography (HPLC) at 1 month (1M), 3M, 6M, 12M, and 24M in the STAT trials. Genotyping of CYP3A5*3 [6986A>G (rs776746)], ABCB1 [3435T>C (rs1045642)], ABCG2 421C>A [rs2231142], and UGT1A1*6, *27, and *28 was performed using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). All genotype frequencies were tested for Hardy-Weinberg equilibrium.

Results: Between July 2011 and December 2012, CML patients were recruited in the STAT trials. NIL was administered twice daily (600mg/day) for 2 years according to the study protocol. A total of 76 and 96 patients were analyzed as a safety data set in STAT1 and STAT2, respectively. In STAT1, 18 patients who achieved a confirmed DMR were switched from STAT1 to STAT2. These patients entered both trials, and safety data had not been collected in STAT1 after entering STAT2 to avoid double counts. The PK/PGx data of 147 of 154 patients were available and were evaluated in this study. Median trough concentrations of NIL were 1265 ng/ml at 1M, 1154 ng/ml at 3M, 974 ng/ml at 6M, 735 ng/ml at 12M, and 781 ng/ml at 24M. Although any-grade AEs were reported in patients in STAT1 and 55 patients in STAT2, the most common drug-related hematological and non-hematological AEs were elevated total bilirubin (28.6%), anemia (24.5%), elevated ALT (21.1%), and elevated AST (18.4%). The incidence of these AEs, except for anemia, was significantly associated...
high-titre concentration of NIL (Figure 1). There were statistically significant differences in median concentrations of NIL or the grades of each AE. Based on the results of the analysis using Cox proportional-hazards model, the trough concentration of NIL [hazard ratio=1.001 (1.000-1.002), P=0.004] and ABCG2 421A/ [hazard ratio=3.044 (1.155-8.027), P=0.024] were independent factors for the elevated ALT. Similarly, the trough concentration of NIL [hazard ratio=1.001 (1.000-1.002), P=0.001] and UGT1A1 1/1 [hazard ratio=0.475 (0.246-0.919), P=0.027] were independent factors for the elevated total bilirubin.

Summary/Conclusions: In this study, we identified the relationship between NIL trough concentration and liver dysfunction. Our finding suggests that therapeutic drug monitoring might help avoid drug interruption and discontinuation because of AEs, especially liver dysfunction.

E1054 VERY EARLY MOLECULAR RESPONSE (VEMR) WITH FRONTLINE DASATINIB TREATMENT IS A STRONG PREDICTOR OF LONG-TERM BCR-ABL1 TRANSCRIPT LEVELS IN CHRONIC MYELOID LEUKEMIA PATIENTS: PCR-DEPTH STUDY

1Int. Background: In BCR-ABL1 tyrosine kinase inhibitor (TKI) treated chronic phase chronic myeloid leukemia (CP-CML), early molecular response (EMR) at 3 months is currently identified as being one of the most important prognostic factors. Sokal risk score and dose intensity during first 3 months were strongly associated with achievement of EMR. As our results is a novel kinase inhibitor with improved potency, identification of very early molecular response (VEMR) would be beneficial.

Aims: We evaluated the possibility of the VEMR at 1 month predicting long-term outcomes in newly diagnosed CP-CML patients treated with dasatinib.

Methods: In our observational, open-label study, 102 patients with CP-CML were enrolled to receive dasatinib at a dose of 100mg once daily. The primary end point was complete molecular response (CMR) by 18 months. Secondary end points including molecular response (MR) by 1, 3, 6, 12, 18, 24 months, time to and duration of MMR and CMR and safety were tested. A receiver operating characteristic (ROC) curve from BCR-ABL1 transcript level on Day+28 was calculated to predict EMR and MMR at specific timepoints.

Results: Median age was 49 years (19-81 years) and 61 patients were male. With median follow-up duration of 28 months (0.9-33.8 months), 80 (78.4%) out of 102 patients were still on dasatinib treatment and 22 patients discontinued dasatinib (9 due to treatment failure (n=2) or adverse events (n=8) or other reasons (n=9)). The BCR-ABL1 mutations, assessed in 10 patients after dasatinib discontinuation, were detected in 3 patients which were all T315I mutation. The cumulative CMR by 18 months and MMR by 24 months were 20.5% and 79.6% respectively. In safety analyses, grade 3/4 thrombocytopenia (30.3%) was the most common. Pleural effusion occurred in sixteen (15.6%) patients which were mostly grade 1/2. The cut-off value of BCR-ABL1 transcript on Day+28 was 40% by ROC curve analysis. Among 95 patients who had available molecular data of both D+28 and 12 months, fifty nine (62.1%) patients had less than 40% of BCR-ABL1 transcript (VEMR) on Day+28. Long-term (D+12) patients achieved MMR by 12 months. However, only 27.8% (10 out of 36 patients) of patients without VEMR achieved MMR (p<0.0001). Among 85 patients who had available molecular data of both D+28 and 24 months, fifty two (61.2%) patients achieved VEMR. In 52 VEMR patients, 46 (88.5%) patients achieved MMR at 24 months. However, only 48 (86.9%) patients achieved MMR at 12 months. MMR rate was highest at 3 months after the date of ponatinib's approval.

Summary/Conclusions: Our study shows that VEMR at 1 month can be a strong predictor for further molecular responses as well as long-term outcome. Therefore it would be helpful to monitor BCR-ABL1 transcript level at 1 month in patients who treated with more potent TKIs.

E1055 SURVIVAL OUTCOMES IN PATIENTS WITH CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML) RECEIVING THIRD- OR SUBSEQUENT LINE (3L) TREATMENT PRIOR TO THE AVAILABILITY OF PONATINIB

D. Stellato1, L. McGarry2,*, H. Huang3, S. Hastings1, T. Delea1
1Policy Analysis Inc. (PAI), Brooklyn MA, 2ARIAD Pharmaceuticals, Inc., Cambridge, MA, United States

Background: PACE was a phase 2 single-arm trial of ponatinib, a 3rd-generation tyrosine kinase inhibitor (TKI), in 449 highly-refractory patients with CML or Philadelphia-chromosome positive (Ph+) acute lymphocytic leukemia (ALL) or who had the BCR-ABL1 T315I mutation. Overall survival (OS) for 3L CP-CML patients in PACE at 1, 2, 3 and 4 years was estimated to be 91%, 83%, 80%, and 79%, respectively. Expected survival for 3L CP-CML patients prior to the availability of ponatinib has not been documented.

Aims: To estimate OS in patients with CP-CML receiving 3L treatment prior to ponatinib via a systematic literature review.

Methods: Studies were identified from a review by Lipton et al. (2015), updated with studies identified from searches of electronic databases (MEDLINE, EMBASE, Cochrane Libraries) and abstract databases of key conferences. Landmark and median survival were extracted from study reports. Pseudo-individual patient data (IPD) for survival outcomes were derived from digitized Kaplan-Meier (KM) survival curves then pooled and analyzed using KM methods.

Results: Fifty six studies (717 patients) were identified that reported median, landmark, or KM curves for survival outcomes for CP-CML patients receiving 3L treatment without ponatinib. KM curves for OS were obtained for 6 arms (3 nilotinib and/or dasatinib; 3 other TKIs) OS at 1, 2 and 3 years based on the pooled IPD is reported in the Table. To avoid confounding of OS from post-progression treatment with ponatinib, 1 study was excluded that included follow-up after the date of ponatinib’s approval.

Table 1.
Aims: Both NGS and droplet digital PCR (ddPCR) were used in this prospective study. NGS screened all known mutations in the BCR-ABL1 KD and ddPCR targeted only the 3 most common mutations, T315I, E255K and Y253H, which represent approximately 75% of the ABL1 mutations. Patients eligible for the study were i) CML patients with failure or warning to all lines of TKI therapy according to the 2013 ELN-guidelines, with no suspected lack of adherence and ii) CML patients with known diagnosis and/or molecular relapse. Monitoring was performed when clinically appropriate.

Methods: Total BCR-ABL1 RNA was transcribed into a long range cDNA covering the kinase and the regulatory and the SH2/SH3 domains of either p190 or p210 BCR-ABL1 transcripts (exons 4 to 10). For NGS, primers designed with the Ampliseq™ Designer Software were generated according to the Ampliseq™ protocol. The overall number of BCR-ABL1 mutated samples was 18 (15 CML and 3 Ph+ ALL), representing 30% of the cases. Among these samples, 27 mutations were found. 9 samples presented with one mutation: T315I (2), E255K (3), G250V (1), F359I (1), M237T (1) and E255A (1) and 9 harboured combined mutations: T315I + E255K (6) and T315I + Y253H (3). A high frequency (85%) of T315I, E255K and Y253H mutations was also observed (23/27). As far as these 3 mutations are concerned, reproducibility to determine mutational burden was found to be very high between NGS and ddPCR.

Results: Advancements in sequencing technologies and further lowering sensitivity levels contribute to optimal management of CML and Ph+ ALL patients and improve treatment outcome. The earlier a mutation in the kinase domain is detected, the earlier an informed choice can be made regarding optimal subsequent TKI treatment.

E1057

CLINICAL AND IMMUNOLOGICAL EFFECTS OF NILOTINIB IN COMBINATION WITH PEGYLATED INTERFERON-α2B IN PATIENTS WITH SUBOPTIMAL MOLECULAR RESPONSE ON IMATINIB (NORDUTCHCMCL009)

Background: Chronic myeloid leukemia (CML) is a disease of hematopoietic stem cells resulting from oncogenic chromosome translocation that leads to the formation of the BCR-ABL1 fusion gene. Treatment of chronic phase (CP) CML has dramatically changed since the emergence of the first-in-class tyrosine kinase inhibitor (TKI) imatinib, and treatment based on TKI has improved the outcome in the majority of CP-CML patients. Nowadays, second generation TKIs are available and brought about faster and deeper molecular responses, and lower disease progression rate than imatinib. On the other hand, longer treatment duration and the increased types of TKIs gave rise to various kinds of unexpected adverse events (AEs). In 2011, drug-induced peripheral arterial occlusive disease (PAOD) was first reported, followed by vascular AEs (VAEs) including ischemic heart disease (IHD) and cerebral infarction (CI). Furthermore, it became clear that the incidence of VAEs increased with the dose and treatment duration, therefore VAEs are considered a more fatal complication of TKI treatment. However, there is no available data about the incidence of VAEs in Japanese patients.

Aims: To investigate the vascular safety issue and estimated the 1000 person-years risk of developing VAEs during TKI treatment, including imatinib, nilotinib, and dasatinib, using 3 risk assessment tools among 320 Japanese patients who were enrolled in the CML Cooperative Study Group.

Methods: A surveillance data of 320 patients enrolled in the CML Cooperative Study Group was conducted. All patients were diagnosed with CML-CP from April 2001 to January 2016, whose median age was 57 years old (15-80) and median time of follow up was 64.2 months. Patients who developed VAEs were analyzed using 3 risk assessment tools (SCORE chart, Framingham risk score, Suitsa-score) to estimate the patients 10-year risk of VAEs.

Results: Among the 320 newly diagnosed CML-CP patients, 16 (5.0%) cases of VAEs were reported during the study period. Seven cases were treated by imatinib, 3 cases by nilotinib, 2 cases by dasatinib, 4 cases were switched from imatinib to nilotinib, and 1 case was a switch from dasatinib to nilotinib. The VAEs were 9 IHD, 5 CI, and 2 PAOD cases. Results from the 3 risk assessment tools are as follows: SCORE (2 low, 9 moderate, 1 high, 4 very high risk), Framingham score (3 low, 5 moderate, 7 high risk), and Suitsa-score (13 low, 1 intermediate, 5 high risk). The incidence rate of IHD, CI, and PAOD cases were 5.26 and 2.92 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.78 and 3.34 in the age-adjusted

haematologica | 2017; 102(s2) | 435

Madrid, Spain, June 22 – 25, 2017
matched general population, respectively. Among the 320 newly diagnosed CML-CP patients, 16 (5.0%) cases of VAEs were reported during the study period. Seven cases were treated by imatinib, 3 cases by nilotinib, 1 case by dasatinib, 4 cases were a switch from imatinib to nilotinib, and 1 case was a switch from dasatinib to nilotinib. The VAEs were 9 IHD, 5 CI, and 2 PAOD cases. Results from the 3 risk assessment tools are as follows: SCORE (2 low, 9 moderate, 1 high, 4 very high risk), Framingham score (3 low, 5 moderate, 7 high risk), and Suita-score (13 low, 1 intermediate, 1 high risk). The incidence rate of IHD and CI per 1000 person-years were 5.26 and 2.92 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.787 and 3.342 in the age-matched general population, respectively.

Summary/Conclusions: The incidence rate of IHD per 1000 person-years were higher in the nilotinib- and lower in imatinib- and dasatinib-treated CML patients, and the patients showed almost the same rate of CI as compared with the age-matched general population, even though the incidence of VAEs were lower in Japanese compared to the European cohort. More patients were estimated to have very-high and high risk of VAEs in the SCORE and Framingham risk score assessment tools as compared with the Suita-score tool.

E1059

UPDATE OF CMREGISTRY: AN OBSERVATIONAL, MULTI CENTER, PROSPECTIVE FOLLOW-UP REGISTRY OF PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA WITH A HIGH PROBABILITY OF OBTAINING A DEEP MOLECULAR RESPONSE >CMR4 (IS)

J.M. Alonso-Dominguez1,2, E. Olavarria3, M. Perez Encinas4, R. de Paz Arias5, R. Ayala Diaz2, L.F. Casado Montero6, F. Ferrer Marin7, G. Bautista8, V. Conesa Garcia9, C. Mba10, J.L. Stegmann11
1Hematology Department, Hospital Universitario Fundacion Jiménez Díaz, Madrid, Spain, 2Hematology Department, Hammersmith Hospital, London, United Kingdom, 3Hematology Department, Hospital Clinico de Santiago, Santiago, 4Hematology Department, Hospital La Paz, 5Hematology Department, Hospital Doce de Octubre, Madrid, 6Hematology Department, Hospital Virgen de la Salud, Toledo, 7Hematology Department, Hospital Morales Meseguer, Murcia, 8Hematology Department, Hospital Puerta Hierro, Madrid, 9Hematology Department, Hospital General de Elche, Elche, 10Hematology Department, Fundación Investigación Hospital de la Princesa III-IP, 11Hematology Department, Hospital de la Princesa, Madrid, Spain

Background: Since the introduction of Tyrosine Kinase Inhibitors (TKI), many patients diagnosed of Chronic Myeloid Leukemia (CML) in chronic phase achieve a deep molecular response. Around 50% of these patients are expected to maintain their molecular responses even after discontinuation of their TKI treatment. Several clinical trials are exploring the best way of stopping TKI treatment and evaluating patient and disease characteristics that could predict relapse after treatment discontinuation.

Aims: This is an update of the CMRegistry study aimed at collecting clinical data and molecular information from Spanish CML patients that have achieved a series of molecular milestones to any of the tyrosine kinase inhibitors in order to monitor their progress and the achievement of a stable deep molecular response: >MR4 (IS).

Methods: CMRegistry is an observational, multi-center and prospective study. CML patients treated with any of the tyrosine kinase inhibitors who are likely to achieve, or have already achieved, a deep molecular response (>MR4.0 (IS)) are included. This likelihood of achieving >MR4 is defined, for the purposes of the study, as a bcr/abl ratio of: 1) ≤1% at 3 months from start of TKI therapy; 2) ≤0.1% at 6 months from start of TKI therapy; or 3) ≤0.01% any time point during treatment. Clinical data have been collected using a specific CRF. All data were registered in an anonymous manner. The BCR-ABL ratios in the IS have been provided by standardized labs in Spain.

Results: From June 2014 to February 2017, 976 patients were registered in the study. Median age was 51 years (15-88). The Sokal risk groups were as follows: 1121 patients low risk, 307 intermediate risk and 129 high risk. Cytos classification yielded 714 patients in the low risk and 79 in the high risk categories. The majority of patients received first-line treatment with imatinib (626 patients), dasatinib (39 patients) or nilotinib (87 patients). Of note, 5 patients received bosutinib, 1 patient ponatinib and 74 patients were treated with Interferon previous to TKI administration. So far 14 patients have died of non-CML related conditions such as carcinoma (2 patients), ischemic heart disease, respiratory failure and sepsis. Interestingly, 2 patients developed progression of their CML to accelerated phase and blast crisis (1 patient each) with no deaths. At present, 104 patients (11%) have achieved a MR4.0, 174 patients (18%) a MR4.5 and 123 patients (13%) have obtained a complete molecular remission (undetectable bcr-abl transcripts with a sensitivity of at least 10-5).

Summary/Conclusions: Almost one thousand CML patients have been included in this spanish prospective study owing to their promising molecular response that would predict for a sustained deep molecular remission. Four hundred and one patients have already achieved a deep molecular response (>MR4 (IS)) and could be enrolled in prospective discontinuation studies.

E1060

ANALYSIS OF DASATINIB AND IMATINIB 5-YEAR EFFICACY AND SAFE-TY BASED ON BASELINE COMORBIDITY AND AGE IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) IN DASISION

G. Saglio1,*, J.E. Cortes2, A. Hochhaus3, N.P. Shah4, E.L. Atallah5, M. Abaskhara6, L. LP, M.J. Mauro7
1University of Turin, Turin, Italy, 2The University of Texas MD Anderson Cancer Center, Houston, United States, 3Universitätsklinikum Jena, Jena, Germany, 4University of California San Francisco School of Medicine, San Francisco, 5Froedtert & the Medical College of Wisconsin, Milwaukee, 6Bristol-Myers Squibb, Princeton, 7Memorial Sloan Kettering Cancer Center, New York, United States

Background: Patients with CML often have comorbidities, which may influence treatment-related decisions and impact response and survival. In a retrospective analysis of 1-year data from the phase 3 DASISION study, the overall safety or response in dasatinib- or imatinib-treated patients was not substantially impacted by baseline comorbidities, although certain adverse events (AEs) trended higher in patients with ≥1 vs 0 comorbidities (Khoury ASH 2010). Further analysis is warranted to determine how comorbidities may impact long-term outcomes.

Aims: To evaluate the impact of baseline comorbidities and patient age on 5-year safety and efficacy in dasatinib- or imatinib-treated patients from DASISION.

Methods: In DASISION (NCT00481247), patients were randomized to receive dasatinib 100mg/day (N=259) or imatinib 400mg/day (N=260). For this retrospective analysis, patients were grouped as having 0 or ≥1 baseline comorbidity, by baseline disorder (diabetes mellitus, hepatobiliary disease, hyperlipidemia, cardiovascular disorder, or pulmonary condition), or by age group (<46 years, 46–65 years, >65 years). Safety (treatment-related AEs in ≥10% of patients) and efficacy (response rates by 5 years and median times to response) were assessed for each group and treatment.

Table 1.

</table>
Results: The number of patients with 0 or ≥1 comorbidity was similar in the dasatinib (66 [25%]; 193 [75%]) and imatinib (67 [26%]; 193 [74%]) arms, respectively; most (>90%) patients were <65 years old. In patients with 0 or ≥1 baseline comorbidity, the median average daily dose was comparable within arms and discontinuation rates (36%-39%) were similar within and across arms (table). The overall safety profiles were comparable in the 0 and ≥1 comorbidity groups in both arms, other than somnolence (AEs) which had a 22 times higher frequency in patients with ≥1 vs 0 comorbidities; the majority of these were grade 1/2 AEs (table). The incidence of peripheral edema increased with patient age for both imatinib and dasatinib (<46 years: 5% each; 46–65 years: 12% and 10%; ≥65 years: 21% and 20%). In this analysis, the increased incidence of pleural effusion (PE) in dasatinib-treated patients was most highly associated with increased age: <46 years (16%) vs 46–65 years (37%) vs >65 years (60%). PE incidence did not appear to be related to baseline pulmonary comorbidity and was similar in dasatinib-treated smokers (33%) vs nonsmokers (27%). Within each arm, patients with 0 or ≥1 comorbidity (table) and across age groups had similar response rates and discontinuation rates were comparable for patients with ≥1 vs 0 comorbidities in both arms (MR4.5 on dasatinib: 46% vs 32%; MR4.5 on imatinib: 36% vs 22%). Median time to response (months) for patients with 0 or ≥1 comorbidity did not differ within each arm, but was numerically shorter for dasatinib (16.3, 36 or 35) vs imatinib (MR4.5: 42 or 47).

Summary/Conclusions: The superior efficacy of dasatinib over imatinib was shown in previous studies. Response rates and times to response were comparable in patients with 0 or ≥1 comorbidity and trended in favor of dasatinib vs imatinib. Although a few AEs (most grade 1/2) appeared to occur at a higher frequency in patients with ≥1 vs 0 comorbidities in either treatment arm, the overall rates of AEs and discontinuation rates at 5 years in patients who were treated with first-line dasatinib or imatinib did not appear to be substantially affected by baseline comorbidities.

Background: Radotinib is an orally active, selective BCR-ABL1 tyrosine kinase inhibitor (TKI), approved for the first-line and second-line treatment of chronic phase chronic myeloid leukemia (CP-CML) patients in Korea. Earlier 12 and 24 month results demonstrated that radotinib is effective and well tolerated in CP-CML patients with resistance and/or intolerance to BCR-ABL TKIs. Aims: We update the long-term outcome of radotinib treatment in patients failed to BCR-ABL1 TKIs with a minimum follow-up of 36 months. Methods: Ph+ CP-CML patients who failed prior TKI therapy were enrolled between July 2009 and November 2011. All patients were treated with radotinib 400mg twice daily. Cytogenetic and molecular assays were performed at base-line, every 3 months, and at treatment failure. Safety parameters were also analyzed. Probabilities of overall survival (OS) and progression free survival (PFS) were calculated using Kaplan-Meier method.

Results: A total of 77 CP-CML patients (18 years of age or over) were enrolled. This analysis includes data from last enrolled patient who received at least 36 months of radotinib therapy. With a median follow-up of 45.7 (range 0.9-65.7) months, 31 patients (40.3%) completed 36 months treatment, and 46 patients (59.7%) discontinued the treatment before 36 months. Main reasons of discontinuation were abnormal laboratory test (n=18), adverse events (n=4), treatment failure including disease progression and lack of response (n=18), death (n=2), and other reasons (n=4). Median duration of radotinib exposure was 19.5 (0-36.9) months. Cumulative incidence of complete cytogenetic response (CCyR) by 36 months was 90.0% and of patients achieving CCyR, 45.0% (18/40) achieved MMR. The drug-related safety profiles were consistent with those previously reported and new safety issues have not been observed after 12 months. Most drug-related AEs have developed within 12 months, and have shown minimal increase compared with rates at 12 months follow-up. Estimated OS and PFS at 36 months were 87.6% and 85.7%, respectively.

Figure 1. Summary/Conclusions: The 36 months data supports radotinib treatment in TKI failed CP-CML patients maintains the effective response and high rates of OS & PFS rate. Thus, radotinib demonstrated a promising alternative treatment for patients with TKIs failure.
100 YEARS OF CHRONIC MYELOID LEUKEMIA PREVALENCE IN FRANCE
M. Delord1,2
1Biostatistics, Université Paris 7 - INSERM - UMR-S 717, PARIS, France

Background: The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKIs) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems. The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKIs) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems.

Aims: We present here a fully detailed and comprehensive analysis of the French CML prevalence over a century from 1960 to 2060.

Methods: Prevalence of CML was estimated using a cohort component-based model from estimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Economics Studies, and various hypotheses on the relative survival of CML patients. Prevalence of CML was estimated using a cohort component-based model from estimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Economics Studies, and various hypotheses on the relative survival of CML patients. The number of CML patients is estimated over time and the resulting CML prevalence expressed as a number of CML patients per 100,000 inhabitants.

Results: The CML prevalence in France, expressed in cases per 100,000 inhabitants, was estimated to be around 3 before the 80’s, 0 before the 2002, 17 in 2010, 27 in 2030 where the tendency infects, and 30 after 2040. Considering the 100% relative survival hypothesis, a target CML prevalence were nearly reached by 2060. By simulation, we showed that given constant incidence rates and high relative survival hypotheses, the CML prevalence will be driven by population aging, and that the target prevalence, defined as the maximum CML prevalence, should be nearly reached by 2050 to levels above 30 per 100,000 inhabitants.

Summary/Conclusions: Due to high rates of relative survival observed after introduction of imatinib, the trajectory of the CML prevalence in France, as in other western countries, has changed. Given particular hypothesis on the CML incidence rates, this trajectory will bring the CML prevalence by the mid century to levels fully determined by population aging. For France, we have estimated this level above 30 cases per 100,000 inhabitants.

THE ROLE OF MICRORNAS IN CHRONIC MYELOID LEUKEMIA THERAPEUTIC SELECTION
R. Alves1,2, A.C. Gonçalves1,2, P. Cuenceiro3, P. Rodrigues-Santos3,4, P. Freitas-Tavares5, L. Ribeiro5,6, A.M. Almeida5,7, A.B. Sarmento-Ribeiro1,2,5,*
1Applied Molecular Biology and University Clinic of Hematology, 2CIMAGO, Faculty of Medicine University of Coimbra, 3Immunology and Oncology Laboratory, Center for Neurosciences and Cell Biology (CNC), 4Immunology Institute, University of Medicine University of Coimbra, 5Clinical Hematology Department, Centro Hospital e Universitário de Coimbra (CHUC), Coimbra, 6Hematology Service, Instituto Português de Oncologia de Lisboa Francisco Gentil (IPOL), 7CEDOC, Nova Medical School, Lisbon, Portugal

Background: Chronic myeloid leukemia (CML) is characterized by the presence of BCR-ABL fusion gene. This molecular event becomes the main therapeutic target with Imatinib as first-line treatment. In spite of the continued clinical success of Imatinib on CML treatment, the emergence of resistance to tyrosine kinase inhibitors (TKIs) has stimulated the research of the mechanisms involved. These included those related with target changing (e.g. the presence BCR-ABL gene mutations and amplifications) and with intracellular drug concentrations (e.g. the abnormal levels of influx and efflux transporters such as OCT1/OCTN2 and PgP/BCRP, respectively). MicroRNAs (miRNAs) are important regulators of both mechanisms, and so, could influence TKIs response.

Aims: In this context, we investigated the role of miR-203, miR-21, miR-519c, miR-451 and miR-26 expression levels in TKI response in CML patients, and correlated them with TKI sensitivity, BCR-ABL levels, and disease progression, among other clinical and laboratory data.

Methods: To this end, we assessed the expression levels of miR-203, miR-21, miR-519c, miR-451, miR-26 and miR-16 (endogenous control) by TaqMan MicroRNA Assays in peripheral blood cells from 31 patients with CML at follow-up examinations. We also studied 4 CML cell lines, K562 a cell line sensitive to Imatinib, LAMA-84 a cell line with 4 copies of chromosome Philadelphia (Ph), and 2 Imatinib resistant cell lines models created in our lab (K562-RC and K562-RD). K562-RC cells, generated by continuous exposure to Imatinib, presented an IC50 18x times higher than the parental cell line (K562); in K562-RD cells (created by discontinuous exposure), the degree of resistance is 18x. Statistical analysis was performed with ANOVA and multiple comparison tests, with significance levels of 95% (p<0.05).

Results: The miR-203 and miR-519c expression was not detected in any cell line from a healthy patient. First, we analyzed miR expression levels in CML patients with BCR-ABL levels. Higher levels of tumor suppressor miR-451 were associated with a higher reduction of BCR-ABL levels (lower than 0.1%) in CML patients and patients with higher BCR-ABL present lower levels of expression of miR-451. This miR was also down-regulated in LAMA-84, K562-RC and K562-RD comparing with sensitive cell line (K562; p<0.05). On the other hand, patients with more BCR-ABL content (between 1% and 0.1%) present higher expression of the oncomiRs, miR-21 and miR-26. These miRs were also up-regulated in resistant cell lines. MiR-21 was more relevant for K562-RC cells (4-fold higher than K562). LAMA-84 and K562-RC cell lines showed almost 2 times more expression of miR-26. Next we analyzed if treatment options affected miRs expression. CML patients under Imatinib treatment showed higher levels of miR-451 associated with less expression levels of miR-21 and miR-26. Imatinib had been described to be able to block the BCR-ABL negative feedback on miR-451, increasing miR function. Since miR-21 and miR-26 were also lower expressed, more PTEN is available to block PI3K-AKT-mTOR pathways, decreasing this survival signaling. Opposite profile was observed in patients that changed treatment to a second generation TKI suggesting a different effect of this TKI on microRNA expression.

Summary/Conclusions: Our preliminary results suggested the involvement of miRNAs in BCR-ABL levels regulation and in TKI response, supporting the search of a miRNAs TKI response profile that could predict the response in CML patients. This information could act as powerful tool for the stratification and selection of the best therapeutic approach (lower toxicity and cost effective), contributing to higher survival rates and better quality of life in CML patients.

Work supported by the Faculty of Medicine of the University of Coimbra and Santander Totta Bank, grant reference FMUC-BST-2016-214.

IMPACT OF ABCB1 AND ABCG2 POLYMORPHISMS ON RESPONSE TO IMATINIB AND 2G-TKIS THERAPY IN PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA
M. Tiribelli1,*, S. Di Giusto1, E. Toffoletti1, D. Penna1, D. Griguolo1, G. Maccari1, F. De Marchi1, M. Medeot1, R. Fanin1, D. Damiani1
1Division of Hematology and BMT, Azienda Ospedaliera Universitaria Integrata di Udine, Udine, Italy

Background: Overexpression of multidrug resistance proteins ABCB1 and ABCG2 confers resistance to anticancer drugs, including tyrosine kinase inhibitors (TKIs). Various ABCB1 and ABCG2 single nucleotide polymorphisms可能导致
(SNPs) affect the transporter activity, but their impact on clinical response to imatinib in chronic myeloid leukemia (CML) is discordant; even less is known on their role in patients treated with second generation (2G) TKIs dasatinib and nilotinib.

Aims: To investigate the role of the most common ABCB1 and ABCG2 genetic polymorphism in chronic phase CML patients treated with imatinib and 2G-TKIs.

Methods: We analysed four polymorphisms of ABCB1 (129T>C, 1236C>T, 2677G>T/A and 3435C>T) and two polymorphisms of ABCG2 (34G>A and 421C>A) in 196 CP-CML patients, of whom 139 treated with imatinib (114 in first line and 25 after interferon failure) and 57 treated with dasatinib or nilotinib (22 in first line and 35 after imatinib failure). We compared the rates of optimal response at 3 months (defined as BCR/ABL <10%), at 6 months (BCR/ABL<1%) and at 12 months (BCR/ABL<0.1%), progression-free survival (PFS) and time to treatment failure (TTF) according to the different protein genotypes. TTF was calculated from the start of therapy to any of the following: progression to accelerated or blastic phase (ABP), death, for any cause at any time, treatment discontinuation for primary or secondary resistance or intolerance. PFS was calculated from the start of TKI to ABP or death.

Results: A total of 196 patients with CP-CML (median age 57 years, range 21-84) were included in the analysis. Frequency of ABCB1 and ABCG2 SNPs expression is summarized in Table 1. Considering response to therapy, either in imatinib-treated patients and in those receiving a 2G-TKI, we did not find any significant difference in terms of optimal response at the various timepoints, TTF or PFS for ABCB1 C1236T, G2677T and C3435T and of ABCG2 G34A and C412A polymorphism, even if there was a trend for a worse PFS in the few patients (n=3) with 1236 allele A treated with imatinib. Conversely, we found a lower rate of optimal response at 3 (p=0.1), 6 (P=0.05) and 12 (p=0.02) months in imatinib-treated patients with TC genotype of ABCB1 T129 SNP, though the small number of patients (7) had probably impact on statistical significance. However, TTF was shorter for ABCB1 129T>C patients, both receiving imatinib (P=0.05) and 2G-TKIs (P=0.07), and also PFS was significantly shorter in this cohort (P=0.003).

Summary/Conclusions: With the limits of the low expression rates of some SNPs, our data suggest a lower response in patients harboring 129T>C polymorphism, at least in those receiving imatinib. Other ABCB1 and ABCG2 genotypes do not seem to impact on response to TKI treatment.

E1066

THE INTRODUCTION OF SECOND-GENERATION TYROSINE KINASE INHIBITORS MAY REDUCE THE PROGNOSTIC IMPACT OF HIGH-RISK PATIENTS TO EUROPEAN TREATMENT AND OUTCOME STUDY (EUTOS) SCORE

Background: The discovery of tyrosine kinase inhibitor (TKI) imatinib has revolutionized the conception of chronic myeloid leukemia (CML) as a mortal disease to a long-term controllable disease. The European Treatment and Outcome Study (EUTOS) score is a clinical tool that utilizes imatinib-based objectives to predict treatment response and progression free survival (PFS) in patients with CML in chronic phase (CP). However, it is currently unknown whether the introduction of second generation TKIs (2nd TKIs) affects prognostic score of patients with CML-CP, particularly among those considered high-risk according to EUTOS score.

Aims: Our study aims to highlight the critical role of the introduction of 2nd TKIs on patient prognosis as determined by EUTOS score.

Methods: Patients data was obtained retrospectively from patients enrolled in the CML Cooperative Study Group. Patients with CML-CP who were diagnosed with any TKIs as first line therapy between April 2001 and January 2016 were enrolled to the study and were classified according to date of diagnosis. Those who were diagnosed with CML-CP before March 2009 were classified into the imatinib group, and those diagnosed after April 2009 were classified into the 2nd TKI group, as these patients were able to be treated with 2nd TKIs. The study was approved by the research ethics boards of each institution and was conducted in accordance with the Declaration of Helsinki.

Results: There were 308 patients newly diagnosed with CML-CP during the study period. Of these patients, 104 (34%) were assigned to the imatinib group and 204 (67%) were assigned to the 2nd TKI group. With respect to EUTOS score, 223 patients were classified as low-risk, of which 69 were in the imatinib group and 154 were in the 2nd TKI group. Forty-six patients were considered high-risk, of which 19 were in the imatinib group and 27 were in the 2nd TKI group. EUTOS score was unavailable in 39 patients. With regard to initial TKI, all patients were treated with imatinib in the imatinib group. Among patients assigned to the 2nd TKI group, 149 (73%) were initially treated with any TKI. The median follow-up period for all patients was 48 months (range: 1–185 months). Among patients in the 2nd TKI group, CML-associated death rates were significantly lower than those in the imatinib group. EUTOS high-risk patients score exhibited significantly worse outcomes in EFS, PFS, and CML-associated death compared to those considered low-risk. Most importantly, risk stratification by EUTOS score was predictive of risk-associated clinical outcomes in patients assigned to the imatinib group; however, EUTOS score failed to predict risk-associated clinical outcomes of patients assigned to the 2nd TKI group (see Figure). The EUTOS high-risk patients in the imatinib group showed worse clinical outcomes than those in the 2nd TKI group (hazard ratio [HR] 6.35, 95% confidence interval [CI] 1.79 – 22.6, p=0.0042). However, prognostic effect was less in the 2nd TKI group (HR 3.21, 95% CI 0.59 – 17.6, p=0.18).

Out of 308 patients, 9 progressed to AP/BC and 1 transformed during imatinib therapy and 1 transformed during dasatinib therapy.

Summary/Conclusions: Among patients assigned to the imatinib group, risk stratification by EUTOS score was predictive of clinical outcomes in those that considered high-risk experienced considerably more adverse events (EFS, PFS, or CML-associated death) than those considered low-risk. Our results support the use of 2nd TKIs in treating high-risk patients with CML-CP in order to avoid disease progression. Future large-scale studies are necessary to evaluate the clinical significance of EUTOS scoring in the accurate prediction of prognosis among patients with CML-CP treated with 2nd TKIs.
CHRONIC MYELOID LEUKEMIA DIAGNOSED DURING PREGNANCY: THERAPY TACTICS AND OUTCOMES

1National Research Center for Hematology, Moscow, Russian Federation, 2Hematology, S. Evgeniev Hospital, Tor Vergata University, Rome, Italy, 3Department of Hematology, Seoul St. Mary’s Hospital, 4Leukemia Research Institute, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of, 5Hematology Department, St “Institute of Blood Pathology and Transfusion Medicine UAMS”, Lviv, Ukraine, 6Research Institute of Hematology and Blood Transfusion MOH of Uzbekistan, Tashkent, Uzbekistan, 7Hematology Center after prof. R.H. Yeolyan, Yerevan, Armenia, 8FSBI Scientific Center of Obstetrics, Gynecology and Perinatology of Healthcare Ministry named after V.I. Kulakov, Moscow, Russian Federation

Background: Chronic myeloid leukemia (CML) diagnosed at pregnancy is a serious challenge. Treatment by tyrosine kinase inhibitors (TKI) today is considered harmful for fetus due to possible teratogenicity. On the other hand TKI delay is dangerous for disease progression as no other options have comparable to TKI effectiveness. Pregnancy termination by abortion may be crucial for desired pregnancies as further childbirth is postponed for years until stable deep molecular response (DMR). Due to limited number of cases and ethical issues there is no consensus on how to behave in such delicate cases.

Aims: To describe pregnancy outcomes and therapy tactics for CML diagnosed at pregnancy.

Methods: Information regarding CML diagnosed at pregnancy was collected with participation of countries participating in the observational study of European LeukemiaNet (ELN Pregnancy Registry). The data included CML clinical characteristics at diagnosis, cytotypic and molecular parameters, information of therapy, pregnancy outcomes and data of newborns.

Table 1.

Table 1. Number of pregnancy cases in countries and outcome of pregnancy cases diagnosed simultaneously with CML.

Results: Thirty one women with median age 26 years (range 20-39) were diagnosed with Ph-positive chronic phase CML during pregnancy. That was 11% of all 282 pregnancy cases. In certain countries (Russia) up to 21% of women with CML and pregnancy had the synchronistic onset of these events (table 1). Sokal low/intermediate/high and EUTOS low/high risk score was in 22/5/3 and 28/2 all 282 pregnancy cases. In certain countries (Russia) up to 21% of women with CML diagnosed during pregnancy. Management of this very delicate subset of patients is a challenge especially when a woman refuses from abortion. Individual treatment approach may differ considering pregnancy terms and clinical status. Although normal childbirth is possible using IM after 2nd,3rd trimester, the risks of pregnancy prolongation remain still not well defined. To get the most safe prognosis for mother and child pregnancy in CML should be planned in a stable DMR.

IMPACT OF KIR3DL1*00501 IN TYROSINE KINASE INHIBITOR-TREATED CML

Y. Chabaeva1, S. Kulikov1, A. Turkina1.

Aims: To describe pregnancy outcomes and therapy tactics for CML diagnosed at pregnancy.

Methods: Information regarding CML diagnosed at pregnancy was collected with participation of countries participating in the observational study of European LeukemiaNet (ELN Pregnancy Registry). The data included CML clinical characteristics at diagnosis, cytotypic and molecular parameters, information of therapy, pregnancy outcomes and data of newborns.

Table 1.

Table 1. Number of pregnancy cases in countries and outcome of pregnancy cases diagnosed simultaneously with CML.

Results: Thirty one women with median age 26 years (range 20-39) were diagnosed with Ph-positive chronic phase CML during pregnancy. That was 11% of all 282 pregnancy cases. In certain countries (Russia) up to 21% of women with CML and pregnancy had the synchronistic onset of these events (table 1). Sokal low/intermediate/high and EUTOS low/high risk score was in 22/5/3 and 28/2 all 282 pregnancy cases. In certain countries (Russia) up to 21% of women with CML diagnosed during pregnancy. Management of this very delicate subset of patients is a challenge especially when a woman refuses from abortion. Individual treatment approach may differ considering pregnancy terms and clinical status. Although normal childbirth is possible using IM after 2nd,3rd trimester, the risks of pregnancy prolongation remain still not well defined. To get the most safe prognosis for mother and child pregnancy in CML should be planned in a stable DMR.

IMPACT OF KIR3DL1*00501 IN TYROSINE KINASE INHIBITOR-TREATED CML

Y. Chabaeva1, S. Kulikov1, A. Turkina1.

1National Research Center for Hematology, Moscow, Russian Federation.

Aims: To describe pregnancy outcomes and therapy tactics for CML diagnosed at pregnancy.

Methods: Information regarding CML diagnosed at pregnancy was collected with participation of countries participating in the observational study of European LeukemiaNet (ELN Pregnancy Registry). The data included CML clinical characteristics at diagnosis, cytotypic and molecular parameters, information of therapy, pregnancy outcomes and data of newborns.

Table 1.

Table 1. Number of pregnancy cases in countries and outcome of pregnancy cases diagnosed simultaneously with CML.

Results: Thirty one women with median age 26 years (range 20-39) were diagnosed with Ph-positive chronic phase CML during pregnancy. That was 11% of all 282 pregnancy cases. In certain countries (Russia) up to 21% of women with CML and pregnancy had the synchronistic onset of these events (table 1). Sokal low/intermediate/high and EUTOS low/high risk score was in 22/5/3 and 28/2 all 282 pregnancy cases. In certain countries (Russia) up to 21% of women with CML diagnosed during pregnancy. Management of this very delicate subset of patients is a challenge especially when a woman refuses from abortion. Individual treatment approach may differ considering pregnancy terms and clinical status. Although normal childbirth is possible using IM after 2nd,3rd trimester, the risks of pregnancy prolongation remain still not well defined. To get the most safe prognosis for mother and child pregnancy in CML should be planned in a stable DMR.
Background: Recent reports have demonstrated that tyrosine kinase inhibitors (TKIs) discontinuation can be employed in chronic phase chronic myeloid leukemia (CP CML) patients with sustained deep molecular responses after enough TKI therapy. Consequently, treatment-free remission (TFR) has been a new therapeutic goal. Although 50-70% of patients experienced molecular relapse by several imatinib (IM) discontinuation studies, the most of patients resumed molecular responses (MR) following restart of IM. Aim: To determine molecular response (MR) following second IM discontinuation (Korean Imatinib Dis-continuation Study; KID Study), we have explored molecular kinetics after the first IM discontinuation and after IM resumption for molecular relapse. In patients regaining durable UMRD with IM resumption, we tried second IM discontinuation and compared molecular kinetics between the first IM stop and second IM stop. Methods: CP CML patients who were treated with IM for more than 3 years and had undetectable levels of BCR-ABL1 transcripts determined by quantitative reverse transcriptase polymerase chain reaction (PCR) for at least 2 years were eligible for KID study and in cases of MMR loss after 2 consecutive assessments, IM treatment was re-introduced. After IM resumption for MMR loss, molecular kinetics was evaluated until MMR re-achieved and every 3 months thereafter. The second stop was permitted in the patients who were in second UMRD for at least 2 years. Results: Among patients who lost MMR in 2 consecutive analyses and resumed IM in the KID study, 12 patients (6 men and 6 women) with a median age of 45 years (range, 25-59 years) entered into a second IM discontinuation, after maintaining UMRD at least 2 years. Prior to first discontinuation, the median duration of IM therapy was 68.9 months (range, 38.5-115.1 months) and the duration of sustained UMRD was 32.9 months (range, 24.8-64.5 months). After first attempt of IM discontinuation, they relapsed after a median duration of 3.7 months (range, 1.3-5.4 months). After second IM discontinuation, 6.7 months (range, 3.3-13.6 months) after IM resumption. After sustaining a second UMRD for a median of 25.5 months, IM therapy discontinued for a second time. After a median follow-up of 8.8 months (range, 0.3-38.1 months) after second IM discontinuation, 10/12 patients (83%) and 8/12 patients (67%) lost UMRD and MMR, respectively. Among two patients who lost UMRD but not MMR, one patient showed fluctuation of BCR-ABL1 transcript level with the median duration of 0.1% IS on 9.4 months and another patient have shown gradually increasing BCR-ABL1 transcripts under the level of 0.1%. Eight patients who experienced second relapse (MMR loss) after a median 2.9 months (range, 1.9-30.7 months). The patients who lost MMR, except one patient, were retreated with IM for a median of 7.1 months (range, 0.8-24.8 months); five patients re-achieved MMR at a median of 1.8 months (range, 1.0-10.2 months) and one re-achieved UMRD at 5.5 months.

Summary/Conclusions: Data demonstrated that a second attempt might be possible and the median time to MMR loss after second discontinuation was similar to those of the first discontinuation. But the molecular kinetics after second IM resumption needs longer follow-up with more patients. Further studies on the predictors to select patients for a trial of second TFR and novel strategies such as intermittent therapy will be warranted.

HYDROXYUREA SUPPRESSES BCR-ABL1 T315I+ CML CLONES IN VIVO AND IN VITRO AND SYNERGIZES WITH PONATINIB IN ELIMINATING TKI-RESISTANT CML CELLS

M. Krennweis1,2, J.K. Breu1,2, S. Preunig1,2, S. Hemberger1,2, W.R. Sperner1,2, G. Hoermann1,2, M. Deininger5, T. Lion6, P. Valent1,2, K.V. Gleixner1,2

1Ludwig Boltzmann Cluster Oncology, 2Department of Internal Medicine I/Divi-ision of Hematology and Hemostaseology, Medical University of Vienna, 3Chil-dren’s Cancer Research Institute (CCR), 4Department of Laboratory Medicine, 5Department of Internal Medicine, 6Division of Hematology and Hemostaseology, Medical University of Vienna, Austria

Methods: Two study groups, early molecular response (EMR) at 3 months or 6 months can predict better outcomes in newly diagnosed chronic myeloid leukemia patients treated with radotinib or imatinib. But, to evaluate the significant long-term prognostic value such as overall survival and progression-free survival (PFS) according to 3 months or 6 months were not significantly different in two groups.

Results: In two study groups, early molecular response (EMR) at 3 months were observed in 86.1% of patients in the radotinib 300 mg bid group and 67.9% in the imatinib group (P=0.0179). More patients treated with radotinib 300mg bid who had EMR at 3 months achieved MMR and MR4.5 by 24 months: 73.5% and 38.2% in the radotinib 300mg bid group and 63.6% and 29.1% in the imatinib group, respectively. At 6 months, 73.4% of patients in the radotinib 300mg and 53.1% patients in imatinib group (P=0.0246) achieved 6 months EMR. The patients who had EMR at 6 months in radotinib 300mg bid group were significant higher than MR4.5 in 6 months compared with MR4.5 in 24 months. More patients treated with radotinib 300mg bid who lost EMR in 6 months qRT-PCR was similar to those of the first discontinuation. But the molecular kinetics after second IM resumption needs longer follow-up with more patients. Further studies on the predictors to select patients for a trial of second TFR and novel strategies such as intermittent therapy will be warranted.
HU+ponatinib for 72 hours, and the percentage of viable cells in each sub-clone was analyzed by flow cytometry.

**Results:** HU treatment resulted in WBC stabilization in 3 of 4 patients, but failed to induce a molecular response. However, surprisingly, the percentage of BCR-ABL1 decreased significantly in all 4 patients during HU treatment and was no longer detectable in 3 of 4 cases. Stem cell transplantation could be performed in 2 patients after 2-3 months. In one patient, stable disease over 18 months was obtained with HU-therapy. In one patient, the disease progressed rapidly despite temporary suppression of BCR-ABL 1. In vitro studies, HU was found to block the growth in all cell lines tested and in all primary cell samples (n=7) examined, with IC50 values ranging between 50 and 250 μM. Interestingly, cell lines exhibiting mutant BCR-ABL1 were more sensitive against HU than cell lines expressing BCR-ABL1 WT. HU and ponatinib were found to synergize in inhibiting growth of all cell lines tested, including cells expressing BCR-ABL1 WT or T315I-including compound mutations. Cooperative drug effects were also confirmed in primary CML cells (n=4). In cell line experiments, ponatinib was found to suppress Ba/F3p210WT cells but not Ba/F3p210ΔT315 or Ba/F3p210ΔE255 cells, whereas HU was found to exert stronger effects on cells expressing mutant BCR-ABL1 and the drug combination resulted in complete suppression of all sub-clones.

**Summary/Conclusions:** Our data show that HU exerts strong, sub-clone specific effects in BCR-ABL1 TKI-resistant CML patients. HU and ponatinib produce synergistic growth-inhibitory effects on TKI-resistant CML cells. Clinical studies are now warranted to define the exact value of the drug combination ponatinib+HU in TKI resistant CML.

**Background:** The inhibition of BCR-ABL1 kinase with tyrosine kinase inhibitors (TKIs) has markedly improved the prognosis of chronic myeloid leukemia (CML). Recently, it has been recognized that some CML patients with deep molecular response (DMR) can maintain treatment-free remission (TFR) after TKI cessation. However, there are predictive biomarkers to identify candidates who can safely discontinue TKI therapy. Particularly, BCR-ABL1 assays that are sensitive in the measurement of deep level response may aid in the identification of potential candidates for treatment discontinuation. Xpert® BCR-ABL Ultra detects the most common BCR-ABL1 transcripts below MR4.5 (Molecular Response at 4.5-log reduction) or 0.0032%, which is widely accepted as the clinical threshold that defines candidates who can safely discontinue TKI therapy.

**Aims:** The present studies were designed to verify the limit of detection (LoD) for the Xpert® BCR-ABL Ultra assay below MR4.5 on the International Scale (IS) in clinical samples for both the b3a2 and b2a2 transcripts.

**Methods:** To overcome the challenge of testing numerous replicates requiring large volumes of patient samples, serial dilutions ranging from BCR-ABL/ABL levels of 10% to <0.001% (IS) were prepared as contrived samples using CML cell lines with initial BCR-ABL1 level > 10% (IS) and patient blood from CML-negative patients, ranged from 10% to <0.001% (IS). Twenty-one replicates of each dilution were measured for%BCR-ABL1/ABL1 (IS). Determination of the LoD was performed by the statistical analysis to identify the lowest concentration of%BCR-ABL1/ABL1 (IS) per test that can be reproducibly distinguished from negative samples with 95% confidence. The acceptable precision for%BCR-ABL1/ABL1 (IS) is defined as the ability to detect at least a 3-fold difference for all concentrations tested.

In addition, analytical LoD studies were performed using spike-in CML cell lines and cell-line derived RNAs, carrying either b3a2 or b2a2 transcripts. Furthermore, the clinical sensitivity study was conducted using blood from twelve low BCR-ABL transcripts level CML patients on TKI therapy, who had achieved and maintained MMR (Major Molecular Response) [0.1% (IS)] with reporting below 0.05% (IS).

**Results:** Consistent results were observed in the both the diluted patient blood and spike-in CML cell lines or cell-line derived RNA studies for both the b3a2 and b2a2 transcripts, demonstrating an assay LoD of MR4.5 and below with a less than 2-fold difference at the LoD levels. With the clinical sensitivity study, eleven out of twelve low CML subjects were detected in at least 19 out of 20 replicates tested per subject over a range of 0.038% (IS) (SD=±0.17 Log) 0.0011% (IS) (SD=±0.4 Log). The overall ABL copy number present in clinical samples in each study was at least 5-10 times the required minimal ABL copy number of 122,000 to support a claim of MR4.5 and ≥100,000 for MR5.0.

**Summary/Conclusions:** These LoD evaluations demonstrate that the Xpert® BCR-ABL Ultra assay complies with the international guidelines for assay sensitivity achieving MR5.5 with 5-10 times more than the required ABL copies to confidently identify candidate patients that may benefit from the discontinuation of TKI therapy.

IDENTIFICATION OF INCIDENT CASES OF GAUCHER DISEASE IN SPLENOMEGALY AND/OR THROMBOCYTOPENIA PATIENTS IN SPECIALIZED MEDICAL SERVICES IN COLOMBIA THROUGH THE USE OF A SELECTION ALGORITHM

1 Bogotá D.C., Clínica Los Nogales, Bogotá D.C., 2Bolívar, Universidad de Cartagena, Clínica Bias de Lezo, Cartagena, 3Antioquia, Clínica Sagrado Corazón, Medellín, 4Antioquia, Clínica Vida Prado, Medellín, 5Valle del Cauca, Clínica de Occidente, 6Valle del Cauca, Universidad del Valle, Cali, 7Santander, Hospital San Luis, Bucaramanga, 8Antioquia, Hospital General de Medellín, Medellín, 9Atlántico, Centro Cancerológico del Caribe, Barranquilla, 10San-tander, Unidad de Hematología y Oncología de Santander, Bucaramanga, 11Antioquia, Hospital Universitario San Vicente Fundación, Medellín, 12HUILA, Hospital Universitario Marfil, 13Huila, Hospital Universitario San Juan de Dios, 14HUILA, Hospital Universitario San Juan de Dios, 15Centro Médico del Caribe, Barranquilla, 16Bogotá D.C., Centro de Atención a la Salud de Colombia S.A.S., Bogotá D.C., Colombia

Background: Gaucher disease (GD) varies greatly in severity and organ involvement. Clinical characteristics are usually nonspecific and lead to late diagnosis with irreversible complications. Splenomegaly and thrombocytopenia are the two most common manifestations (Gaucher Registry, 2008), which reported 86% cases with moderate to severe splenomegaly and 60% thrombocytopenia at the time of diagnosis, thus demonstrating why patients are referred to hematologists. A diagnosis of GD is considered after other diagnostic hypotheses have been ruled out. The consensus of international experts on the management of patients with GD established a diagnostic algorithm that is particularly intended for specialists (Mistry, 2010). Straightforward implementation of diagnostic algorithms to support medical specialties in Latin America for early diagnostic testing of GD is required.

Aims: To identify new cases of GD in a selected population with splenomegaly and/or thrombocytopenia referred to Hematology, Pediatric Hematology, Pediatrics and Internal Medicine in Colombia, approved by Ethics Committee (EC). The study has an expected duration of 24 months since EC approval for each center. Eligible subjects are those with three documented criteria: thrombocytopenia <150,000/cell plus anemia (hemoglobin <12.0 g/dL in men and <11.0 g/dL in women) plus/or bone pain plus/or Mon- occlonal Gammapathy of Unknown Significance plus/or Polyclonal Gammapathy in subjects aged 30 years and older; and/or splenomegaly defined as palpable spleen ≥1cm below the costal rib or diagnosed by imaging, and/or Splenectomy by splenomegaly with no known cause. Subjects with prior diagnosis of GD, splenomegaly due to portal hypertension, hematologic malignancies, other hereditary anemia and thalassemia were excluded. Informed consent was obtained for all included subjects. Clinical information was collected from their medical history. The enzymatic activity of the β-glucocerebrosidase was performed in peripheral blood, using dried blood spots (DBS) and/or leukocytes. In subjects with reduced enzymatic activity in DBS, confirmation of diagnosis enzyme activity in leukocytes. Further characterization of the population is ongoing.

Summary/Conclusions: This study suggests that selection algorithm could be implemented in Colombia, supporting specialists in making decisions on diagnosis of Gaucher Disease. Further characterization of the population is ongoing.

Acknowledgements: This study was funded by Sanofi Genzyme Colombia and coordinated by Caiced Colombia.

E1075
IMPACT OF PEROXIREDOXIN 2, GLUTATHIONE PEROXIDASE AND CATALASE INHIBITION ON OXIDATIVE STRESS MODIFICATIONS OF RED BLOOD CELL MEMBRANE AND CYTOSOL

1Facultad de Ciencias, Universidade do Porto, 2UCBIO, REQUIMTE, Labo-ratório de Bioquímica, Departamento de Ciências Biológicas, Faculdade de Farmácia, Universidade do Porto, Porto, Portugal, Porto, Portugal

Background: Several anemias are associated with oxidative stress, namely, sickle cell anemia, β-thalassemia, glucose-6-phosphate dehydrogenase defi-ciency and hereditary spherocytosis. Red blood cells (RBC) are continuously exposed to oxidative stress, mainly due to their primary function as oxygen carriers; therefore, the erythrocytes are equipped with an efficient antioxidant system, however, when its capacity is overwhelmed, the cell is exposed to reactive oxygen species (ROS); triggering oxidative modifications. The antioxidant defense being known, the interplay between these peroxidases is still unclear. The recent report of cononidin A, as a specific Prx2 inhibitor, offers the possibility to further explore the roles and contribution of these enzymes to antioxidant defense.

Aims: To study the importance of Prx2, GPx and CAT inhibition on defense against oxidative stress in normal erythrocytes.

Methods: We performed in vitro assays (n=3) with RBCs from healthy volun-teers, inhibiting Prx2, GPx and CAT, either individually, two-by-two or all three; cononidin A, mercaptothioc acid and sodium azide were used as specific inhibitors of Prx2, GPx and CAT, respectively. Since the RBC membrane is a major target of ROS, we evaluated membrane lipoperoxidation (LPO) and mem-brane bound haemoglobin (MBH), as well as, cytosol’s total antioxidant status (TAS), by spectrophotometric methods.

Results: Concerning TAS we found a trend towards decreasing values with enzyme inhibition (one or more); the lowest value of TAS was observed when all three enzymes were inhibited and, when only two enzymes were inhibited, the lower values were obtained for pairs that included CAT inhibition; when only one enzyme was inhibited, LPO inhibition showed a decrease. Concern-ing MBH, a trend towards increasing values with enzyme inhibition was observed; the lowest value was obtained when all enzymes were active, and the highest when all of them were inhibited; when only one enzyme was inhib-ited, CAT inhibition showed the highest LPO value and when two enzymes were inhibited, LPO was lower for pairs that included GPx. MBH was increased for all enzyme inhibitory conditions, when compared to the condition with all enzymes active, excepting when CAT was inhibited.

Summary/Conclusions: In conclusion, inhibition of these antioxidant enzymes, either alone or simultaneously, leads to oxidative stress modifications within the RBC, as shown by the increase in MBH and membrane LPO, and by the decrease in cytosolic TAS. Moreover, the inhibition of CAT or GPx (either alone or with other enzymes) presented more impact on oxidative modifications than Prx2 inhibition. Our data strengthens the importance of these enzymes in RBC’s

Figure 1.
antioxidant homeostasis, and suggests that inhibition or injury to one (or more) compromises erythrocytes, which might influence clinical presentation in oxidative stress associated anemias.

MOLECULAR BASIS OF PKLR MUTATIONS IN PATIENTS WITH PYRUVATE KINASE (PK) DEFICIENCY: THE FIRST REPORT FROM SOUTHEAST ASIAN POPULATION

S. Riolueang1,*, K. Tachavanich2, S. Ekawattanakit3, V.S. Tanphaichitr2, H. Kanno4, V. Viprakasit5

1Siriraj-Thalassemia Center, 2Department of Pediatrics, 3Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, 4Department of Transfusion Medicine and Cell Processing, Tokyo Women’s Medical University, Tokyo, Japan, 5Department of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Recently we have identified a new form of transfusion dependent hemolytic anemia due to KLF1 mutations causing a trans-acting deactivation of pyruvate kinase genes (PKLR). Mutations of PKLR per se can affect red blood cells metabolism and cause a wide range of clinical manifestation from fetal anemia leading to hydropic fetus, severe neonatal jaundice requiring multiple exchange blood transfusions, chronic to fully compensated hemolytic anemia. Understanding of the molecular basis of pyruvate kinase deficiency (PK def.) might be useful to predict clinical phenotypes and suggest appropriate clinical management of future patients. Moreover, an interaction of PKLR and KLF1 mutations in such patient has not been explored.

Aims: This study aimed to identify the mutation of patients with PK def. for the first time in Southeast Asian populations.

Methods: Seven unrelated patients; 6 from Thailand and 1 from Indonesia have been enrolled after informed consent. We have measured the PK activity of all patients and their parents and siblings using a standard biochemical technique as we have described earlier. A complete genomic analysis of all PKLR’s exons (NM_000298.5) including exon-intron boundaries were selectively amplified and followed by direct Sanger sequencing.

Results: Seven index PK def. patients as confirmed by enzyme activities, age range 9-35 yrs old, were identified (Table 1). Three patients presented with severe hemolytic anemia and required regular blood transfusion; every 3-4 weeks in two (PK-1 and PK-3) and every 10-12 weeks (PK-2) in which one patient (PK-1) has been successfully treated with bone marrow transplantation and became transfusion-free. Three patients (PK-5, -6 and -8) had moderately severe hemolytic anemia and required blood transfusion occasionally. Only one patient (PK-7) from Indonesia had well-compensated anemia and never required blood transfusion. All but one had PK activities lower than 50% of normal range but these activities did not correlate with clinical severity. We found one patient (PK-7) with PKR activity lower than 30%.

PRELIMINARY RESULTS OF GAU-PED STUDY: PREVALENCE OF GAUCHER DISEASE IN PAEDIATRIC PATIENTS SELECTED BY AN APPROPRIATE DIAGNOSTIC ALGORITHM

W. Morello1,*, M. Filocamo2, M. Stroppiano2, M. Di Rocco3, F. Fedeli4, G. Russo5, D. Sperlì6, F. Furlan7, A. Pession8

1Pediciatric Hematology and Oncology Unit, Sant’Orsola-Malpighi University Hospital, Bologna, 2Centro di Diagnostica Genetica e Biochimica delle Malattie Metaboliche, 3Department of Pediatrics, Unit of Rare Diseases, Gaslini Institute, Genoa, 4Pediatric Hematology, Ospedale Niguarda, Milano, 5Pediatric Haematology and Oncology Unit, Azienda Policlinico-Vittorio Emanuele Università di Catania, Catania, 6Pediatric Hematology and Oncology Unit, S. O. “Annunziata”, Cosenza, 7Pediatric Department, Fondazione IRCCS Ca’Granda Ospedale Maggiore Policlinico, Milano, Italy

Background: Gaucher disease (GD) is an autosomal recessive lysosomal storage disease characterized by the deficient activity of beta-glucocerebrosidase (GBA). GBA deficiency results in the accumulation of glucosylceramide in different organs, causing tissue damage. Typical GD features are splenomegaly, peripheral blood cytopenias (mostly thrombocytopenia and/or anemia), growth retardation, bone involvement, gammapathies, increased risk of malignancies and, in some patients, neurological manifestations. Since symptoms are non-specific, the diagnosis can be delayed for years or missed. Enzyme replacement therapy (ERT) with recombinant β-glucocerebrosidase is safe and effective in preventing and/or reversing many clinical manifestations. However, if the diagnosis is delayed for years, major complications cannot be reversed. A useful screening method for GD is based on measuring enzyme activity on a Dried Blood Spot (DBS), while the gold standard test is still considered GBA activity in cellular homogenates. A pediatric algorithm has been proposed to promote timely diagnosis and early access to ERT (figure 1).

Figure 1.

Aims: Since pediatric patients with splenomegaly and cytopenias are usually referred to pediatric hematologists, we have designed the GAU-PED study to seemed to be recurrent since it was found in two families; one homozygous and one compound with N118S. Beside nucleotide mutations, we found a 5006 bp deletion from intron 3 to exon 10 affecting PKLR gene. To detect these mutations in family members and further cases, we developed a long range GAP-PCR analysis to amplify the breakpoint fragment and directly sequenced to determine deletion extend and also ARMS-PCR (c.1641T>TA), PCR-RFLP (c.941T>C), mismatched PCR-RFLP for c.1403C>G, c.1463G>A and IVS9(+3)A>G. Interestingly, one index patient (PK-4) was found with only one known missense mutation (R488Q), however we could not find any mutation in KLF1 of this patient suggesting that she might have other unidentified cis mutation involved gene regulation of PKLR. Due to a limited number of patients, there was no clear genotype-phenotype correlation found in our studied population.

Summary/Conclusions: Seven confirmed cases of PK def. are reported here-in. They showed a wide variation of clinical severity. Molecular basis of PKLR mutations were proven to be beneficial to provide a definitive diagnosis of PK def. and might help suggesting clinical presentation in future cases.

Aims: To evaluate platelet MPs (PMP), tissue factor expressing MPs (TFMPs), endothelial MPs (EMPs) and microparticles expressing single antigens (CD41, CD144 or CD142) in plasma of 43 patients (21 females and 22 males) followed-up for a median of 12 months (range 3-30 months) for a variety of haematological indications.
Methods: MPs were quantified using a flow cytometer, with Acros Dye Mix (Invitrogen) for annexin V binding and Flow-Count fluorospheres (Invitrogen). MPs were stained with PE-conjugated Annexin V for annexin V (annV) expression, and the markers CD41, CD144 and CD142 were added to express MP count as absolute numbers. MPs analyses were performed on a BD FACS Canto cytometer using Megamix-Plus SSC to define the MPs gate.
Results: The prevalence of anemia in the older population was 17.2% and was higher in men than women (20.4% vs 15.2%, p=0.038). Anemia was present in 10.3% of patients aged 60-69, in 20.1% of those aged 70-79 and in 36.5% of patients ≥80 years. Incidence rates of anemia increased significantly with age (60-69 vs 70-79 years, p<0.001; 60-69 vs ≥80 years, p<0.001; 70-79 vs ≥80 years, p<0.001). Anemia was mild in 69.8% of patients, but a severe form was found significantly more often among men aged ≥80 years (p=0.03).
Aims: The prevalence of anemia in the older population was 17.2% and was higher in men than women (20.4% vs 15.2%, p=0.038). Anemia was present in 10.3% of patients aged 60-69, in 20.1% of those aged 70-79 and in 36.5% of patients ≥80 years. Incidence rates of anemia increased significantly with age (60-69 vs 70-79 years, p<0.001; 60-69 vs ≥80 years, p<0.001; 70-79 vs ≥80 years, p<0.001). Anemia was mild in 69.8% of patients, but a severe form was found significantly more often among men aged ≥80 years (p=0.03).
Summary/Conclusions: These preliminary results suggest that MPs levels are abnormal in both congenital and acquired haemolytic conditions. MPs levels correlate with the degree of anaemia and haemolysis and with the duration of disease.

E1079
THE PREVALENCE, ETIOLOGY AND PROGNOSTIC IMPACT OF ANEMIA IN OLDER POPULATION
S.S. Michalak1, J. Rupa-Matysek2, L. GIF2
1Family Medicine Clinic, MEDKOL, Zielona Gora, 2Department of Hematology and Bone Marrow Transplantation, Poznan University of Medical Sciences, Poznan, Poland
Background: The population of people aged ≥60 years is growing rapidly. Anemia represents a common condition among the elderly, however its prevalence and causes are not well known.
Aims: The aim of the study was to evaluate the prevalence, severity and etiology of anemia in the population aged ≥60 years. Risk factors for the development of anemia including concomitant diseases and treatment, were analysed. The association between anemia and hospitalization or all-cause mortality during follow-up was determined.
Methods: Retrospective analysis was performed on 981 Caucasian, outpatient patients aged ≥60 in Poland over 2013-2014 (mean age 68, range 60-99 years, 60% females). The prevalence of anemia, defined according to WHO diagnostic criteria, age-related factors, comorbidities, treatment and laboratory data were studied. Data on the occurrence of common comorbidities (coronary artery disease, heart failure, diabetes, chronic obstructive pulmonary disease, chronic kidney disease, chronic liver diseases, cancer, thyroid diseases), hospitalization, treatment used and all-cause mortality were analysed.
Results: The prevalence of anemia in the older population was 17.2% and was higher in men than women (20.4% vs 15.2%, p=0.038). Anemia was present in 10.3% of patients aged 60-69, in 20.1% of those aged 70-79 and in 36.5% of patients ≥80 years. Incidence rates of anemia increased significantly with age (60-69 vs 70-79 years, p<0.001; 60-69 vs ≥80 years, p<0.001; 70-79 vs ≥80 years, p<0.001). Anemia was mild in 69.8% of patients, but a severe form was found significantly more often among men aged ≥80 years (p=0.03).
Analysis of the etiology of anemia revealed three predominant types: anemia of chronic disease (33.1%), unexplained anemia (28.4%) and deficiency anemia (22.5%, including iron deficiency 13%). In comparison to patients without anemia, those with anemia were older (p<0.001), had a higher prevalence of comorbidities (p<0.001) and were more often hospitalized (p<0.001). In the multivariate logistic regression model, factors increasing the risk of anemia were: age ≥80 years (OR=2.29; 95%CI 1.19-4.42; p=0.013), the number of comorbidities (2 diseases OR=2.85; 95%CI 1.12-7.30; p=0.029, 3 diseases OR=6.28; 95%CI 2.22-17.76; p=0.001, 4 diseases OR=6.44; 95%CI 1.27-17.01; p=0.021) and the number of hospitalizations (OR=1.34; 95%CI 1.13-1.58; p=0.001). At the end of the 2-year follow-up, the cumulative survival among patients without anemia in relation to the group with anemia was 90.76% vs 78.08% and the difference was statistically highly significant (p<0.001). In multivariate model, factors that significantly increased the risk of death in study population were anemia (HR=3.33; 95%CI 1.43-7.74; p=0.005), cancer (HR=3.31; 95%CI 1.47-7.49; p=0.004) and heart failure (HR=2.94; 95%CI 1.33-6.51; p=0.008).
Summary/Conclusions: In patients ≥60 years the incidence of anemia increases with age and male gender. Multiple comorbidities and frequency of hospitalization. The high rate of unexplained anemia indicates the necessity for detailed hematologic diagnosis. The occurrence of anemia among people aged ≥60 years has an adverse impact on survival.

PIEZ01 MECHANOTRANSDUCTIVE PROTEIN MUTATIONS IN RBCS: WHEN THE PHENOTYPE IS BEYOND HYEMOLYTIC ANAEMIA

D. Mota1, 2, S. Martín1, T. Nascimento1, P. Bernardo1, L. Relvas1, A. Oliveira1, E. Cunha1, J. Ribeiro1, C. Bento1, T. Magalhães-Maia1, M. Ribeiro2, J. A. Bueren2, J. C. Segovia1, 2

Background: Piezo proteins are integral membrane proteins with many transmembrane domains broadly expressed, including erythrocytes (RBcs). PIEZ01 proteins play an important role as an osmoreceptor, maintaining RBcs ion homeostasis, functioning as a mechanically activated cation channels. Mutated PIEZ01 proteins have been linked to hereditary xerocytosis (HX), which is characterized by RBcs dehydration with mild to moderate compensated haemolytic anaemia and iron overload. As these clinical features are present in many different clinical conditions, the diagnosis always needs a high level of suspicion. Nowadays, besides peripheral blood smear (PBS) observation, molecular analysis, searching for mutations in PIEZ01 gene, became a tool in the diagnosis of HX.

Aims: Describe 26 patients with HX associated with PIEZ01 mutations belonging to 13 unrelated families, raising awareness of the highly variable phenotype of this patients, and the need of a highly grade of suspicion along with the morphologic evaluation of the PBS.

Methods: Collection of clinical and laboratory data on our 26 patients with HX and hyperferritinaemia due to 10 different identified mutations in PIEZ01. Sanger sequencing was used to identify mutations affecting PIEZ01, encoded by FAM38A gene, and to confirm transmission according to the presence of disease phenotype. In all patients were excluded other known causes of hyperferritinaemia (HF) and haemolytic anaemia.

Results: Of the patients identified as having PIEZ01 mutations, 13 were probands and 13 were identified by family studies. Median age at diagnosis was 43 years (1-80), with female predominance (n=14; 53.9%). 4/13 probands had family history of HX (n=11) or HF (n=2). The common feature of our entire cohort of patients was the presence of xerocytes in PBS. 13/26 patients had reticulocytosis, a median reticulocyte count of 101 x 10^9/L (81.3-456.5), 18/26 patients had HF with a mean value of ferritin of 556ng/mL (161-6617) and 9/26 had both. Of the 26 patients, four had splenomegaly and six gallbladder lysisis (5/6 cholecystectomized), two of them have both. Only 5 patients presented with anaemia (Hb <12g/dL), 2 macrocytic and 3 normocytic. One patient presented with anemia he also had a homozygous hemochromatosis carrier. We detected heterozygous missense mutations in all 26 patients.

Summary/Conclusions: HX is a dominant disorder of RBcs dehydration presenting a great phenotypic variability. As shown in our cohort of patients, the anaemia may not be the main feature, in fact, the presence of xerocytes in PBS and HF were the most frequent characteristics of our patients. We would like to emphasise that in the genomics era the identification of xerocytes in the PBS keeps playing an important role for this diagnostic. Not only because, unlike other haemolytic anaemias, in HX there is a contraindication to splenectomy due to the increased risk of thrombotic events, but also because this pathology is defined by the degree of hemolysis that is not proportional to the degree of hemolysis. This iron overload may be related to a defective iron homeostasis dependent on PIEZ01 function not strictly related with Xerocytosis.

PHYSIOPATHOLOGY OF HEREDITARY XEROCYTOSIS: PIEZ01 GAIN OF FUNCTION MUTATIONS IMPACT HEMOGLOBIN OXYGEN AFFINITY

L. Kiger1, C. Guitton2, K. Ghazal3, M. Feneant-Thibault4, L. Bendelac5, F. Galacteros6, V. Proulle7, L. Garçon8, V. Picard5,*
1IMRB U955, INSERM, Créteil, 2Service de Pédiatrie, 3Service de biochimie, APHP, Hopital Bicêtre, 4Service de biochimie, 5Service d'hématologie biologique, APHP, Hôpital Bicêtre, Le Kremlin Bicêtre, 6Centre de Reference des maladies constitutionnelles du Globule rouge, APHP Hopital Mondor, Créteil, 7Service d’Hématologie, APHP, Hôpital Bicêtre, Le Kremlin Bicêtre, 8Service d’hématologie biologique, CHU, Amiens, France

Background: Dehydrated hereditary stomatocytosis, also called hereditary xerocytosis (HX) is a dominant non-spherocytic chronic hemolytic anaemia characterized by an increased cation leak through the red cell membrane, associated with a high reticulocytosis. In most cases, HX is caused by missense mutations activating Piezo1, a mechanosensitive ion channel. However, the pathophysiology of this compensated hemolysis remains largely unclear.

Aims: We studied the hemoglobin oxygen affinity parameters in HX patients and in hereditary spherocytosis (HS) subjects as controls.

Methods: Fourteen patients from 5 described and 4 unreported families with a HX diagnosis and 15 HS subjects were included. Diagnosis was based on echocytometry and EMA assay. PIEZ01 and KCNJ4 coding regions were analyzed by Sanger sequencing in all HX patients. Hemoglobin oxygen affinity was evaluated using p50 measured on venous blood on a Hemoxanalyser or a Radiometer blood gas analyzer. 2,3 diposphoglycerate (2,3 DPG) levels were measured using a commercialized kit and expressed as a molar ratio 2,3 DPG/hemoglobin.

Results: All the 14 HX patients carried one or two missense mutations in PIEZ01, no gene variation was identified in KCNJ4. Five families (9 subjects) have already been reported, with identified mutations in exons 18, 21, 42 or 51. Five subjects from 4 new families carried new mutations in exons 14, 16 and 22. Fourteen patients for which biochemistry of HX was showed a high likelihood of pathogenicity. For all HX patients, p50 values were under the normal range (mean 21.1, range 19.7-23.4, normal range 25-29 mmHg), contrasting with HS patients for whom p50 was found to be in the normal range (mean 26.1, range 24.6-28.8 mmHg). This indicated a significant increase in the hemoglobin affinity for oxygen restricted to PIEZ01 mutated HX. Of note, p50 was not correlated with the Hb level (mean 139, range 112-180 g/L in HX patients versus 125, range 93-142 g/L in HS patients). Intracellular red cell 2.3 DPG level could be measured in 7 HX patients from 4 families, it was found decreased in all of them (0.43+/-0.06, normal 0.9+/-0.19), providing a pathophysiologal basis for the increased hemoglobin affinity we observed. In particular, we managed to discriminate the HX red cells phenotype from the HS red cells phenotype using a simple mathematical equation involving the p50 value, easily measured on venous blood, represents a useful new diagnosis tool for HX.

SAFETY AND EFFICACY OF MULTI-PATHOGEN-SPECIFIC T CELLS IN A HUMANIZED MODEL OF INVASIVE ASPERGILLOSIS: A PROOF OF CONCEPT STUDY

A. Papadopoulos1, K. Koukoulia1,2, M. Alvanou1,3, M. Anagnostopoulou1,2, T. Vyvanzidis3, E. Siqioti1, M. Gounis1, P. Kaloyannidis3, N. Savvopoulos1,2, T. Vyzantiadis3, E. Siotou1, M. Gounis1, P. Kaloyannidis3, N. Savvopoulos1,2, A. Anagnostopoulou1,2, E. Yannaki1

1Gene and Cell Therapy Center- Hematology Dpt- BMT Unit, George Papanicolaou Hospital, 2School of Biology, Department of Genetics, Development and Molecular Biology, 3School of Medicine, 1st Department of Microbiology, Aristotle University of Thessaloniki, Thessaloniki, Greece, 1Adult Hematology & Stem cell Transplant, King Fahad Specialist Hospital, Dammm, Saudi Arabia

Background: Viral infections, most commonly by cytomegalovirus (CMV), Epstein-Barr virus (EBV), polyoma virus type I (BK), and fungal infections, mainly by Aspergillus Fumigatus (Asp.), are leading causes of transplant-associated mortality in patients undergoing allogeneic hematopoietic stem cell transplantation. Standard treatment with antiviral and antifungal pharmacological agents, is often ineffective or toxic and may lead to resistance. Due to these limitations, adoptive immunotherapy with antigen-specific T cells has emerged as an attractive alternative. Towards unleashing its full potential and treat multiple viral and fungal infections by a single T-cell product, we developed a rapid, simplified and minimally laborious protocol for the generation of multipathogen-specific T cells (mp-STs) that simultaneously target CMV, EBV, BK and Asp, from healthy donors.

Aims: Due to the lack of mouse models recapitulating the clinical condition of multiple opportunistic infections in transplanted hosts, we here aimed to test the in vivo safety of produced mp-STs and provide a proof of concept of their efficacy in a humanized model of invasive aspergillosis (IA).

Methods: mp-STs were generated from healthy donors by pulsing 1.5x10⁷ monocellular cells with viral (CMV, IE1, pp65; EBV; EBNA1, LMP2, BZLF1; BK: Large T, VP1) and Asp peptide mixtures (Crf1, Gel1, SHMT) and culturing for 10 days. The specificity of mp-STs was analyzed by IFN-γ Elispot. A total of 1.5x10⁷ immunomagnetically isolated CD3+cells (donor lymphocyte infusions-DLI) or mp-STs were infused in myelo/immuno-ablated NSG mice which had been intranasally inoculated with Asp conidia or left uninfected. Mice were evaluated by a 5-parameter sickness score and at sacrifice, tissues were assessed by histology and immunohistochemistry.

Results: We generated 23.5±1x10⁷ mp-STs (12-fold expansion). All cell lines were polyclonal expressing central memory markers and specific against Asp [spot forming cells (SFC)/2x10⁵ cells: 315±82] and the targeted viruses, if derived from seropositive donors [SFC/2x10⁵ cells, CMV: 637±267; EBV: 744±158; BK: 578±118]. To first address the safety issue, we asked whether mp-STs can induce acute graft-versus-host disease (aGvHD) in myelo-ablated mice. While DL cell lines developed clinically and histologically confirmed aGvHD and succumbed by day 20, mp-ST-mice survived free of aGvHD until the day of sacrifice (d28). To assess the in vivo functionality of mp-STs against IA, conditioned and Asp-inoculated mice, received mp-STs (n=5), DLI (n=4) or were left untreated (IA control, n=6). All IA- and DLI-mice succumbed to histologically evidenced IA at a median day 6, whereas 60% of mp-ST-mice survived until sacrifice at day 12. While the day 12 survivors presented high T-cell engraftment in the lung (% CD3⁺/CD45⁺: 14±7) with no histological evidence of IA, the two mp-IA-survivors died from IA in the absence of T-cell engraftment. Non-specific DLI failed to control IA despite T-cell presence in 3/4 DL-mice (%CD3⁺/CD45⁺: spleen 58±12, lung: 3±1) which succumbed early, before aGvHD development.

Summary/Conclusions: Overall, engrafted mp-STs effectively controlled IA without evidence of alloreactivity. Based on the robust specificity of our mp-STs against all targeted pathogens and the clinical efficacy of virus-specific T cells, we expect that our "four in one" T-cell product has the potential to also fight the targeted viruses and become a powerful tool for the treatment of multiple, life-threatening post-transplant infections.

DONOR LYMPHOCYTE INFUSION IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES LEADS TO DIVERSITY OF LEUKEMIA-ASSOCIATED-ANTIGEN-SPECIFIC T CELL RESPONSES AND TO REDUCTION IN REGULATORY T CELL FREQUENCY

S. Hofmann1, M. Schmit2, M. Götz2, H. Döhner2, M. Wiesneth3, D. Bunjes2, J. Greiner2,4

1Clinic for Internal Medicine V, University of Heidelberg, Heidelberg, 2Clinic for Internal Medicine III, University of Ulm, 3Institute of Clinical Transfusion Medicine and Immunogenetics Ulm, German Red Cross Blood Transfusion Service Baden-Württemberg–Hessen and Institute of Transfusion Medicine, Ulm, 4Department of Internal Medicine, Diakonie Klinikum, Stuttgart, Germany

Background: Cytotoxic T-cell (CTL) responses against malignant cells play a major role in maintaining remission and prolonging overall survival in patients with hematologic malignancies after allogeneic stem cell transplantation (allo-SCT) and/or donor lymphocyte infusions (DLI). Graft versus leukemia (GvL) effects after allogeneic stem cell transplantation and/or DLI are considered to be T cell-mediated. Many groups described specific T-cell responses against several leukemia-associated antigens (LAA) in different hematological malignancies. However, T cell responses after allo-SCT and DLI are not well characterized.

Aims: In this study, we analyzed LAA-specific T cell responses after allo-SCT and DLI. To this end, we assessed the frequency and diversity of LAA-specific CD8+ T cells using ELISPOT analysis and tetramer assays in 12 patients (5 patients (pts) with acute myeloid leukemia, 2 pts with chronic myeloid leukemia, 3 pts with multiple myeloma and 2 pts with chronic lymphatic leukemia) before and after DLI. Epitopes derived from PRAME, NPM1-mut, RMM-A, WT-1 and other LAA were tested. Moreover, the frequency of regulatory T (Treg) cells was measured and the course of cytokine profiles before and after DLI was analyzed. These immunological findings were correlated to the clinical course in the respective patients.

Methods: In ELISPOT and tetramer assays, an increase in frequency and diversity of LAA-specific T cells was observed in all patients. Cytokine assays using ELISA for the detection of more than 10 cytokines before and after DLI were employed.

Results: Importantly, there was a significant increase from 0 to 7 LAA-derived T cell epitopes (P<0.03) in clinical responders (R) when compared to non-responders (NR). These positive results in R versus NR where confirmed by tetramer-based flow cytomtery assays, where an increase in frequency from 0.5 to 2.3% in the R group of LAA-specific T cell/all CD8+ T cells was observed. Interestingly, the frequency of Tregs in clinical responders decreased significantly from a median 72.9% to 54.6% (P=0.008) while the frequency of Treg expanded over time in non-responding patients. T cell subset analysis did not reveal significant differences before versus after DLI administration. In cytokine assays using ELISA we found a significant increase of IL-4 after DLI.

Summary/Conclusions: Taken together, we detected an increase of specific CTL responses against several LAA after allogeneic stem cell transplantation and donor lymphocyte infusion. Moreover, this study suggests that broader LAA epitope-specific T cell responses as well as decreasing numbers of Tregs contribute to clinical outcome of patients treated with DLI.

GENE-MODIFIED NK-92MI CELLS EXPRESSING A CHIMERIC CD16/CD64-BB-Ζ RECEPTOR EXHIBIT ENHANCED CANCER-KILLING ABILITY IN COMBINATION WITH THERAPEUTIC ANTIBODY

Y. Chen1, F. You1, J. Li1, X. Tang2, G. An1, H. Meng1, L. Yuan3, L. Yang1

1The Cyrus Tang Hematology Center, 2Department of Hematology, Soochow University, Suzhou, Jiangsu, 3Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Natural killer (NK) cells play a pivotal role in monoclonal antibody-mediated immunotherapy through an antibody-dependent cell-mediated cytotoxicity (ADCC) mechanism. NK-92MI is an interleukin-2 (IL-2)-independent cell line, which was derived from NK-92 cells with superior cytotoxicity to a wide range of tumor cells in vitro and in vivo. However, the Fc-receptor (CD16), which usually mediates ADCC, is absent in NK-92 and NK-92MI cells.

Aims: To first address the safety issue, we asked whether LAA-derived T cell epitopes can induce acute graft-versus-host disease (aGvHD) in myelo-ablated mice. While DL cell lines developed clinically and histologically confirmed aGvHD and succumbed by day 20, mp-ST-mice survived free of aGvHD until the day of sacrifice (d28). To assess the in vivo functionality of mp-STs against IA, conditioned and Asp-inoculated mice, received mp-STs (n=5), DLI (n=4) or were left untreated (IA control, n=6). All IA- and DLI-mice succumbed to histologically evidenced IA at a median day 6, whereas 60% of mp-ST-mice survived until sacrifice at day 12. While the day 12 survivors presented high T-cell engraftment in the lung (%CD3⁺/CD45⁺: 14±7) with no histological evidence of IA, the two mp-IA-survivors died from IA in the absence of T-cell engraftment. Non-specific DLI failed to control IA despite T-cell presence in 3/4 DL-mice (%CD3⁺/CD45⁺: spleen 58±12, lung: 3±1) which succumbed early, before aGvHD development.

Summary/Conclusions: Overall, engrafted mp-STs effectively controlled IA without evidence of alloreactivity. Based on the robust specificity of our mp-STs against all targeted pathogens and the clinical efficacy of virus-specific T cells, we expect that our "four in one" T-cell product has the potential to also fight the targeted viruses and become a powerful tool for the treatment of multiple, life-threatening post-transplant infections.

Figure 1. NK-92MihCD16 and NK-92MihCD64 functional validation in vitro and characterization. A. Schematic representation of the CD16-BB-ζ and the CD64-BB-ζ receptor constructs. B. Exogenous CD16 or CD64 expression on surfaces of NK-92MI cells are shown. C. Immunoblot analysis of CD35 fusion protein expression in NK-92MihCD16 or NK-92MihCD64 cells.
Aims: To apply NK-92MI cell-based immunotherapy in cancer, we designed and generated two chimeric receptors which can bind the Fc portion of human immunoglobulins in NK-92MI cells.

Methods: The construct included the low-affinity Fc receptor CD16 (158F) or the high-affinity Fc receptor CD64, with the addition of the CD8α extracellular domain, CD28 transmembrane domains, two costimulatory domains (CD28 and 4-1BB), and the signaling domain from CD3ζ. The resulting chimeric receptors, termed CD16-BB-ζ and CD64-BB-ζ, were utilized to generate chimeric receptor-modified NK-92MI cells, which were named NK-92MIhCD16 and NK-92MIhCD64 cells, respectively.

Results: We found that NK-92MIhCD16 and NK-92MIhCD64 cells significantly improved cytotoxicity against CD20-positive non-Hodgkin's lymphoma (NHL) cells in the presence of rituximab.

Summary/Conclusions: These results suggest that the chimeric receptor-modified NK-92MI cells could potentially enhance the clinical responses mediated by currently available anticancer monoclonal antibodies (mAbs).

Seràgnoli, Bologna, Italy, 6Internal Medicine, Hospital Universitari i Politècnic La Salle, Barcelona, Spain

Background: The PharmaFlow automated flow platform has achieved 85% clinical correlation with AML samples with its novel Nanobody-based assay for bispecific antibody screening that keeps intact both basal effector to target (E:T) ratios and native environment using whole blood or bone marrow samples. In this context, the PharmaFlow platform allows the integration of effective E:T ratios and pharmacological parameters better predict the in vitro response of BsAbs. Because of the high capacity of the PharmaFlow platform, additional immunotoxins were expressed in E. coli and dhuVHH6-PE-LR, were successfully constructed. These recombinant immunotoxins were expressed in E. coli and showed that nanobody immunotoxins have the benefits of easy soluble expression in a prokaryotic expression system.

Methods: For this purpose, different fresh whole Bone Marrow (BM) or Peripheral Blood (PB) were tested with their corresponding BsAbs at 8 different concentrations in different time points (24h-144h). In this sense, we tested 31 AML BM samples (5 paired BM and PB) with the CD123xCD3 (Creative Biolabs) and 7 CLL and 3 B-ALL samples with Blinatumumab (Amgen). When appropriate, basal quantification of TAA was performed by flow cytometry (FCM). The PharmaFlow platform by FCM was used to count by FCM how many tumor cells are killed by every activated T-cells, here called effective E:T ratio. For each sample, 8-colour FCM staining was performed to simultaneously analyze the leukemic population, activated CD4 and CD8 T-cells and the residual normal cells. EC50 and Emax were calculated to evaluate potency or efficacy. Kinetics of activity was measured repeating the dose response curves in 3 different days.

Results: Most of the samples present both cell activation (CD25+) and an effective lysis of tumor cells after BsAbs exposure in a time and dose dependent manner (Figure 1), even starting with low basal E:T ratios (<1:100). For AML, basal quantification of CD123 by FCM density does not reflect a correlation with the in vitro response, in contrast, differences in T-cell cytotoxicity or leukemic immunoresistance were observed between samples in terms of EC50 or Emax, even more marked between CLL samples. The integration of effective E:T ratios, EC50, Emax, and kinetics allow us to generate an in vitro response model and select those samples with higher T-cell cytotoxicity after the different BsAbs exposure. Interestingly, many of the samples for all the BsAbs leave a significant proportion of live cells, even at the higher BsAb concentrations or with a remarkable expansion of activated T-cells that suggest the use of immunecheckpoint to unblock this immunoresistant status.

Summary/Conclusions: We have developed an automated flow cytometry assay for bispecific antibody screening that keeps intact basal effector to target (E:T) ratios and native environment using whole blood or bone marrow samples. In this context, the PharmaFlow platform allows the integration of effective E:T ratios and pharmacological parameters better predict the in vitro response of BsAbs. Because of the high capacity of the PharmaFlow platform, additional immunotoxins were expressed in E. coli and dhuVHH6-PE-LR, were successfully constructed. These recombinant immunotoxins were expressed in E. coli and showed that nanobody immunotoxins have the benefits of easy soluble expression in a prokaryotic expression system.

HUMANIZED CD7 NANOBODY-BASED IMMUNOTOXINS EXHIBIT PROMISING ANTI-T CELL ACUTE LYMPHOBlastic LEUKEMIA POTENTIAL

Y. Yu1,*, J. Li1, X. Zhu2, X. Tang3, Y. Bao4, Y. Huang1, L. Yuan5, L. Yang1,1The Cyrus Tang Hematology Center, Soochow University, Suzhou, 2Department of Hematology, The Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, 3Department of Hematology, The First Affiliated Hospital of Soochow University, Suzhou, 4Binhu Hospital, the First People’s Hospital of Hefei Group, Hefei, 5Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Nanobodies, or named as VHHs, are derived from heavy-chain-only antibodies that circulate in sera of camels. Their exceptional physicochemical properties, possibility of humanization and unique antigen recognition properties make them excellent candidates for targeting delivery of biologically active components. In our previous works, we have successfully generated the monovalent and bivalent CD7 nanobody-based immunotoxins, which can effectively trigger the apoptosis of CD7 positive malignant T cells.

Aims: To pursue the possibility of translating those immunotoxins into clinics, we humanized the nanobody sequences (designated as dhuVHH6), as well as further truncated the Pseudomonas exotoxinA (PE) derived PE38 toxin to produce a more protease-resistant form which is named as PE-LR, by deleting majority of PE domain II.

Methods: Three new types of immunotoxins, dhuVHH6-PE38, dVHH-PE-LR, and dhuVHH6-PE-LR, were successfully constructed. These recombinant immunotoxins were expressed in E. coli and showed that nanobody immunotoxins have the benefits of easy soluble expression in a prokaryotic expression system.

Results: Flow cytometry results revealed that all immunotoxins still maintained the ability to bind specifically to CD7-positive T lymphocytes and showed no binding to CD7-negative control cells. Laser scanning confocal microscopy found that these proteins can be endocytosed into the cytoplasm after binding with CD7-positive cells, and that this phenomenon was not observed in CD7-negative cells. WST-8 experiments showed that all immunotoxins retained the highly effective and specific growth inhibition activity in CD7-positive T cells. All immunotoxins effectively killed primary T-cell acute lymphoblastic leukemia (T-ALL) cells. Further in vivo animal model experiments showed that humanized dhuVHH6-PE38 immunotoxin can tolerate higher doses and extend the survival of NCG mice transplanted with CEM cells without any obvious decrease in body weight. Further studies on NCG mice model with patient-derived T-ALL cells, dhuVHH6-PE38 treatment significantly prolonged mice survival with around 40% survival improvement. However, it is also noticed that despite dhuVHH6-PE-LR showed strong anti-tumor effect in vitro, its in vivo anti-tumor efficacy is disappointed.
Summary/Conclusions: We have successfully constructed a targeted CD7 molecule modified nanobody (CD7 molecule improved nanobody) immunotoxin dhuVH66-PE38 and showed its potential for treating CD7-positive malignant tumors, especially T-cell acute lymphoblastic leukemia.

STATINS MAY IMPROVE CAR-NK IMMUNOTHERAPY IN MM BY PREVENTING LOSS OF BCMA EXPRESSION ON MM CELLS
G. Suhr1,*, L. Perez-Amill2, A. Urbano-Ispuizal1, B. Martin-Antonio1
1Hematology, Hospital Clinic/IDIBAPS/Josep Carreras Leukemia Research Institute, Barcelona, Spain

Background: Chimeric Antigen Receptor (CAR) modified immune cells targeting BCMA against multiple myeloma (MM) has appeared as a feasible immunotherapy strategy to treat MM patients. However, high doses of CAR immune cells are required to achieve a response. Cord blood derived NK cells (CB-NK) is a feasible source of obtain NK cells to modify with a CAR against BCMA. We previously observed that MM cells exposed to CB-NK are able to transfer MM proteins, such as BCMA, both to CB-NK and to adjacent MM cells non-exposed to CB-NK. Furthermore, statins, which are toxic for MM cells, by altering the lipid composition of tumor cell membrane are involved in cell-cell communication. We hypothesized that statins could prevent the loss of BCMA exposed to the loss of BCMA MM cells after CB-NK exposure, allowing infusing a lower CAR immune cell dose in MM patients.

Aims: To evaluate the effect of statins on MM cell proliferation, on the CB-NK immune response against MM, and on BCMA expression in MM cells after CB-NK exposure.

Methods: The cytototoxicity of statins against MM cells was determined in vitro and in vivo in a murine MM model; furthermore, their impact in CB-NK cytototoxicity against MM was also determined in vitro. BCMA expression on MM cells after CB-NK exposure was analyzed by confocal microscopy and by flow cytometry. FACS sorting experiments were performed to analyze BCMA transfer between CB-NK exposed MM cells to neighboring non-exposed CB-NK MM cells.

Results: Atorvastatin and Fluvastatin treatment (1µM) decreased MM cell line ARP1, RPMI, KMM1 proliferation. No effect was detected for U266 MM cells and for K562 non-MM cells. In vivo studies, showed that mice treated for three days with Fluvastatin (1mg/kg) showed significant decreased MM disease progression. Blocking of BCMA decreased CB-NK cytototoxicity against MM cells. Furthermore, pretreatment of MM cells with Fluvastatin (3 µM) increased CB-NK cytototoxicity against all MM cell lines; no impact was observed against K562 non-MM cells. Co-culture experiments showed that, as soon as 30 minutes, CB-NK exposure led to a BCMA transfer from MM cells to CB-NK and to the extra-cellular milieu leading to a loss of BCMA expression on MM cells. Fluvastatin pretreatment prevented loss of BCMA expression. After two days of co-culture, alive MM cells still showed decreased BCMA surface expression, and surprisingly, increased intracellular BCMA expression. Fluvastatin pretreatment partially avoided the loss of BCMA after CB-NK exposure. Furthermore, FACS sorting experiments showed that MM cells exposed to CB-NK, transferred BCMA to neighboring non-CB-NK exposed MM cells which was partially inhibited with Fluvastatin pretreatment.

Summary/Conclusions: Our findings show that besides the anti-MM activity of statins alone, they avoid the loss of BCMA expression on MM cells after immune cell exposure. Preventing loss of BCMA expression on MM cells might improve the efficiency of CAR immunotherapy against BCMA, suggesting the potential of statins as an adjuvant in CAR-NK immunotherapy against MM.

DENDRITIC CELL VACCINATION COMBINED WITH LENALIDOMIDE AND PROGRAMMED DEATH-1 (PD-1) BLOCKADE HAS SYNERGISTICALLY INDUCED A MARKED TUMOR REGRESSION IN A MURINE MYELOMA MODEL
S.-H. Jung1,*, S. Yang2, H.-J. Lee2, M.-C. Vo1, T.J. Lakshimi2, H.-J. Kim1, J.-J. Lee1
1Department of Hematology-Oncoology, 2Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: There is an emerging evidence that the maximal benefit of dendritic cell (DC)-based cancer immunotherapy may be achieved by combination with other therapies that act to immunomodulation and tumor microenvironment.

Aims: In this study, we tried to obtain the best efficacy of immunotherapy using DC vaccination in combination with lenalidomide and PD-1 blockade in a murine myeloma model.

Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimic protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) DCs + lenalidomide, 4) DCs + PD-1 blockade, and 5) DCs + lenalidomide + PD-1 blockade. After treatment, preclinical response and in vivo cytokine responses were evaluated.

Results: DCs combined with lenalidomide and PD-1 blockade showed the best tumor regression among the study groups. These anti-tumor effects have meaningfully related to the decrease of immuno-regulatory populations, such as myeloid-derived suppressor cells (MDSCs), M2 macrophages, and regulatory T cells (Treg) and the increase of effector immune cell populations, including CD4+ and CD8+ T cells, natural killer (NK) cells, and M1 macrophages, accompanied with the activation of cytotoxic T lymphocytes (CTLs) and NK cells in the splenocytes from the treated mice. Moreover, the level of immunosuppressive cytokines, such as TGF-β and IL-10, was significantly reduced in tumor microenvironment.

Summary/Conclusions: DC vaccination in combination with lenalidomide plus PD-1 blockade has synergistically induced a strong antitumor immunity by modulating tumor microenvironment in a murine myeloma model. This protocol will become a promising translational approach to improve the efficacy of immunotherapy in the field of MM.

Background: NGS-based analysis of the immune repertoire (IR) is a powerful tool to monitor disease, adaptive immune responses to disease, vaccination and therapeutic interventions. IR characterization by NGS usually requires large primer panels to cover its extensive combinatorial diversity, and a complex system of synthetic controls to account for differential amplification efficiency across segment combinations. Anchored Multiplex PCR (AMP™) uses molecular bar-coded (MBC) adapters and gene-specific primers (GSPs), enabling NGS-based immune chain mRNA interrogation from a single amp. This eliminates the need for opposing primers that bind within the highly variable V-segment, eliminating complex amp design due to somatic mutation.

Aims: Our goal was to develop an NGS assay based on AMP that would enable IR characterization utilizing a minimal set of unidirectional GSPs and to reduce amplification bias through the use of MBC adapters.

Methods: Upon developing our AMP-based NGS assay, we validated its quantitative reproducibility and sensitivity which is isolated from PBMCs of healthy donors, B-cell chronic lymphocytic leukemia donors and formalin-fixed paraffin-embedded (FFPE) tissue.

Results: We developed the AMP-based NGS assays, Immunoverse™ (IGH and TR gene簇) for B-cell and T-cell repertoire sequencing, respectively. Both assays demonstrated high reproducibility between replicates with quantitative clone tracking down to 0.01%. The ability to determine isotype, clonotype and IGHV mutational status in a single assay was demonstrated. Preliminary TCR assay data indicates that CDR3 sequence capture is possible from FFPE tissue with clonotype calling being driven by input quantity, T-cell content, and, to a lesser degree, mRNA quality.

Summary/Conclusions: AMP-based NGS with MBC quantification and error-correction is a powerful method to characterize the immune repertoire.

SYNERGISTIC ANTITUMOR IMMUNITY BY DENDRITIC CELLS IN COMBINATION WITH POMALIDOMIDE AND DEXAMETHASONE IN A MURINE MYELOMA MODEL
S.-H. Jung1,*, S. Yang2, H.-J. Lee2, M.-C. Vo1, T.J. Lakshimi2, H.-J. Kim1, J.-J. Lee1
1Department of Hematology-Oncoology, 2Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: Pomalidomide (Pom) plus dexamethasone (Dex) could be considered one of the new treatment options in patients with relapsed and/or refractory multiple myeloma (MM). Recently, several diverse agents would be combined to improve the therapeutic efficacy of immunotherapy.

Aims: In this study, we investigated the preclinical efficacy of combined therapy with dendritic cells (DCs) and Pom-Dex in a murine myeloma model.

Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimic protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) Pom + Dex, and 4) DCs + Pom + Dex. After vaccination, preclinical and in vitro immunological responses were evaluated.

Results: Among four treatment groups, DC combined with POM and DEXA strongly inhibited tumor growth, compared with other groups. In vitro immunological analyses revealed that these enhanced anti-tumor effects were closely associated with the decrease of regulatory cell populations, such as regulatory T cells (Tregs) and type 2 macrophages (M2), and the increase of effector cell populations, including activated CD4 T cells, and type 1 macrophages (M1), accompanied with the activation of cytotoxic T lymphocytes (CTLs) and natural killer (NK) cells in the splenocytes from vaccinated mice.

Summary/Conclusions: Our results showed that the DC combined with POM and DEXA synergistically enhance the anti-tumor immunity in a murine myeloma model, by skewing immuno-suppressive status toward immuno-suppresseive status in tumor microenvironment.

haematologica | 2017; 102(s2) | 449

Madrid, Spain, June 22 – 25, 2017
Background: Study of interactions between lymphocytes and mesenchymal stromal cells (MSCs) in vitro revealed increase of HLA-DR expression on T-cells after co-cultivation with some MSCs samples. On lymphocytes derived from one donor the elevation of HLA-DR was observed after co-cultivation with half of MSCs samples (group A), on the others the HLA-DR expression level did not change (group B). MSCs were divided into two groups based on HLA-DR rise on lymphocytes. Study of T-cell subpopulations after interactions with MSCs could explain ineffectiveness of some MSCs as an immunomodulating agent in clinical applications.

Aims: The aim of the study was to discriminate variations in T-cell subpopulations, co-cultured with MSCs from two groups.

Methods: MSCs were isolated from bone marrow of 13 donors for allogeneic hematopoietic cells transplantation and cultured by a standard method. MSCs were seeded 10^6 cells per flask, and then 10^6 allogeneic lymphocytes from single donor were added to all MSC cultures. For lymphocytes activation 5ng/ml phorbolmyristate acetate (PMA) was added to half of these cultures. Lymphocytes were removed from MSCs. Than MSCs were removed from the bottom of the flask by trypsin and expression of HLA-DR on their surface was measured by flow cytometry. Activation markers CD25, CD38, CD69, HLA-DR were studied by flow cytometry as well as distribution of naïve and effector T-cells were analyzed on 4thday of cultivation. p<0.05 was considered statistically significant; all data are presented as medium ± SEM.

Table 1.

Results: Expression of HLA-DR on lymphocytes after 4 days of cultivation without MSCs did not change compared to 1st day. When lymphocytes were co-cultured with some MSCs samples expression of HLA-DR was higher. Elevated percentage of HLA-DR positive cells correlates between CD4+ and CD8+ cells (R²=0.932). Thus samples of MSCs were divided into two groups: in group A proportion of HLA-DR lymphocytes was 3 times greater than in group B. Subpopulations of lymphocytes co-cultured with MSCs from group A and B were compared. Subpopulations which significantly differed between groups A and B are presented in the table. In lymphocytes co-cultured with MSCs there were higher number of naïve cells compared to control (47.4±3.5% and 54.9±2.0% for group A and B vs 36.9±1.4% for lymphocytes cultured without MSCs, p<0.001). Group B showed lower number of EM and TM cells. Differences between groups were more pronounced when lymphocytes were activated. In group B proportion of HLA-DR CD4+ and CD8+ cells was significantly lower, compared to group A and control samples. At the same time the number of CM and PD-1+ CD4+ cells was lower in group B, but number of TE was increased. Investigation of HLA-DR expression on MSC after co-culturing with lymphocytes showed higher level of fluorescence signal (MF) in group A than in group B (635±130 vs 289±18, p=0.03). These data indicated that MSCs from group A had become more immunogenic after interaction with lymphocytes and could not show immunomodulating properties in same way as MSCs from group B.

Summary/Conclusions: The immunomodulatory properties of MSCs depend on the donor. This could explain why administration of MSCs is not always successful. Preliminary study of MSCs prior to their administration may be used to predict their efficiency in the future.

The materials are supported by grant from the Russian Science Foundation, Project № 16-15-00102.
Results: Although a high toxicity and low efficacy were observed with the electroporation technique used, up to 96% colony forming units showed the specific integration. Experimented directed to improve efficacy and reduce toxicity were then conducted. A high percentage of gene edited HPCs were detected by shortening the cell expansion and puromycin selection periods. Importantly, gene edited HPCs were detected after infusion in Immunodeficient (NSG) mice. More recently, site-specific correction has been developed aiming at the correction of PKD patient’s specific mutations.

Summary/Conclusions: Overall, we showed that gene editing in engraftable HPCs is feasible, although the efficiency of the procedure should be further improved prior to consideration of these strategies in the clinic.

E1096
ALTERATIONS IN T-CELLS SUBPOPULATIONS AFTER CO-CULTIVATION WITH MULTIPOTENT MESENCHYMAL STROMAL CELLS

S. Navarro.1,2, S. Quintana-Bustamante.1,2, C. Trigueros.3, M. Villanueva.1,2, M. Lópes-Manzanares.1,2, A.J. Bueno.1,2, J.C. Ramírez.1,2, J.C. Segovia.1,2,1, Instituto Mixta de Terapias Avanzadas, Instituto de Investigación Sanitaria Fundación Jiménez Díaz, 2Hematopoietic Innovative Therapies, CIEMAT/CIBERER, MADRID, 3VIVEBioTECH, San Sebastian, SPAIN

Background: Pyruvate kinase deficiency (PKD) is an autosomal recessive disorder caused by mutations in the PKLR gene. PKD is the most common erythroid inherited enzymatic defect causing chronic nonspherocytic hemolytic anemia. PKD is associated with reticulocytosis, splenomegaly and hepatic iron overload, and may be life-threatening in severely affected patients. To date, allogeneic bone marrow transplantation is the only curative treatment for severely affected patients but has been employed infrequently. Splenectomy confers reduced transfusion-dependence in many patients, but 10-15% of PKD patients remain transfusion-dependant despite splenectomy, which confers increased lifelong transfusion requirements. Precise genetic therapies conducted in pyruvate kinase deficient mice have shown the safety and the efficacy of a new CpoCRPKW-17 therapeutic lentiviral vector that has been granted orphan drug designation (EMA: EU/3/14/1330; FDA: DRU-2016-5168). The use of G-CSF primed halo-identical microtransplantation and the patient who developed CR was consolidated with an HLA-matched sibling transplant.

Results: At day +30, 6 patients were evaluable for response and one patient had died. One patients out of 7 showed PR, then developed CR after a second microtransplantation and the patient who died showed PR at D14 marrow evaluation (8% blast). So collectively objective response rate was 28.6%. The patient who developed CR was consolidated with an HLA-matched sibling transplant at day +75 from the 1st microtransplantation (day +50 from 2nd microtransplantation) Three patients attain engraftment before therapy, D14 and D30 after therapy. Hematopoietic cells percent kinetics (hematopoietic recovery) was assessed by complete blood count every day till Day 14. Hematopoietic cells percent kinetics (Hematopoietic recovery) was assessed by complete blood count every day till Day 40.

Aims: In order to develop a gene therapy clinical trial for PKD we are optimizing transduction procedure compatible with a clinical application.

Methods: Using a GMP-grade lentiviral vector production according to manufacturing process of the GMO VIVeBioTECH (www.vivebiotech.com) using a solid phase bioreactor iCLELLis. These viral batches have been tested for transduction efficiency in healthy cryopreserved cord blood CD34+ cells compatible with a clinical application. Two cycles of transduction showed an increased level of transduction at limiting concentrations of the viral vector, improving the VCN up to 2-fold.

Summary/Conclusions: Transduction optimizations are being carried out in order to reduce the amount of viral vector needed to achieve optimal transduction efficiencies.

E1098

INTERACTION OF MULTIPOTENT MESENCHYMAL STEM CELLS WITH LYMPHOCYTES REDUCES THEIR IMMUNO PRIVILEGED PROPERTY

N. Petina1, N. Kapranov2, Y. Davydova1, I. Galtseva1, M. Bakshinskaya1, N. Drizel1, L. Kuzmin2, E. Parovichnikova2, V. Savchenko2

1Physiology of Hemopoesis Lab., 2Lab. of Immunophenotyping, National Research Center for Hematology, 3Biology Department, sub Department Immunology, Moscow State University im. Lomonosov, 4Bone Marrow Transplantation Department, 5National Research Center for Hematology, Moscow, Russian Federation

Background: Multipotent mesenchymal stem cells (MSCs) are widely used for cell therapy of autoimmune diseases and graft-versus-host disease. MSCs have long been reported to be hyporesponsogenic or ‘immune privileged’. The treatment of MSCs with interferon-g (IFNg) increases their immunomodulating properties, but induce HLA-DR expression on their surface. When administered intravenously MSCs interact with activated and non-activated lymphocytes. It is impossible to follow the fate of MSCs in the recipient’s organism. The only way to study the changes in the properties of MSCs after intravenous administration is in vitro model.

Aims: The aim of the study was to investigate the properties of MSCs after interaction with lymphocytes.

Methods: MSCs were isolated from 13 bone marrow samples used for allo-genic hematopoietic cells transplantation and cultured by a standard method. MSCs were seeded 10⁵ cells per flask and a day later 500 units/mL of IFNg were added for 4 hours to half of the cultures (gMSCs). Some cultures were seeded with 10⁵ allogeneic lymphocytes, to half of these cultures 5mg/ml phytohemagglutinin (PHA) was added for lymphocytes activation (PHA-Lymphocytes) and one or two transduction rounds.

Results: Interaction with lymphocytes induced HLA-DR expression on HE precursors examined, which were then analyzed for hematopoietic re-plating activity and by flow cytometry for hematopoietic cell surface markers.

Results: To estimate the temporal window of TAM activity. CD45.2+ ROSA26ERT2-CreConfetti bone marrow (BM) cells were transplanted into CD45.2+/CD45.1+ recipients treated with TAM three, two, one or zero days before transplant. Only the PB of recipients treated on the same day of transplant showed +/Confetti mice revealed that only mice exposed to TAM in utero at E8.5 and E9.5 had Confetti blood. Thus, specification of HE begins at E8.5 and is complete by E10.5. Next, E11.5 AGMs isolated from CD45.2+ Confetti mice exposed to TAM at E10.5 were cultured as explants for three days under conditions that preserve ongoing HSC specification from HE, dissociated, and then transplanted into CD45.2+CD45.1+ mice. Remarkably, although the CD45.2+ chimerism was high (≈80%) in the blood of recipients, all CD45.2+ blood was negative for the Confetti label, further indicating that HE recruitment is complete by E10.5 and cannot be reactivated during explant culture. Limiting dilution co-cultures of E9.5, E10.5, and E11.5 VE-Cadherin+/CD45− endothelium revealed the frequency of functional HE to be 0.1, 1.1 and 0.19% at these time-points, respectively. Phenotypic analysis of primary hematopoietic colonies revealed cell expressing the C-type lectin-like receptor 2 (CLEC2), which efficiently colonies producing phenotypic HSCs in AA-EC co-cultures. These data suggest the presence of HE precursors with distinct functional output or the existence of a continuum of HE at different stages of maturation.

Summary/Conclusions: We have defined the window of mammalian HE specification. The abrupt loss of ongoing HE recruitment at E10.25 suggests an active mechanism that terminates this process. We also observed large phenotypic and functional variability amongst individual HE precursors examined throughout ontogeny.

E1100

C-TYPE LECTIN-LIKE RECEPTOR 2 SPECIFIES A FUNCTIONALLY DISTINCT SUBPOPULATION OF MEGAKARYOCYTE-BIASED LONG-TERM HEMATOPOIETIC STEM CELLS

T. Kumdose1, H. Tanaka1, R. Fujiiwara1, K. Sano1, K. Setzawa1, Y. Taniuchi1, S. Tanaka1, 2, and M. Ganuza Fernandez1, 2

1Hematology and Rheumatology, Kindai University Faculty of Medicine, Osaka, Japan

Background: Recent studies have supported the model in which hematopoietic stem cell (HSC) compartment consists of functionally distinct subsets with discrete self-renewal and differentiation potentials. However, their immune phenotypes and the functional diversities remain poorly understood. We previously reported that the authentically identified HSC population includes a subset of cells expressing the C-type lectin-like receptor 2 (CLEC2), which give rise to megakaryocyte progenitors (MPs) and megakaryocytes bypassing the pathway from common myeloid progenitor (CMP) to megakaryocyte/erythrocyte progenitor (MEP) (21th Congress of EHA, # P356, 2016).
Aims: In this study, we analyzed in vivo dynamics of CLEC2<sup>high</sup> HSCs to clarify their functional roles in adult hematopoiesis.

Methods: In this experiment, we defined Lin<sup>−</sup> Sca1<sup>−</sup>Kit<sup>−</sup>CD150<sup>−</sup>CD34<sup>−</sup> cells as HSCs and Lin<sup>−</sup>Sca1<sup>−</sup>Kit<sup>−</sup>CD150<sup>−</sup>CD41<sup>−</sup> as MKPs. We performed transplantation assays using HSCs isolated from EGFP transgenic (CAG-EGFP) mice to trace donor-derived HSCs and their progeny, excepting enucleated donor-derived HSCs and their progeny. CLEC2<sup>high</sup> donor-derived HSC populations were detected for up to 12 weeks after transplantation. Also, these subsets were capable of generating all lineages of cells in transplanted mice. Interestingly, CLEC2<sup>high</sup> HSCs generated CLEC2<sup>low</sup>HSCs and CLEC2<sup>low</sup>MKPs, and we observed significantly regulated transition between CLEC2<sup>high</sup> and CLEC2<sup>low</sup> HSCs. CLEC2<sup>high</sup> HSCs generated CLEC2<sup>low</sup>MKPs and their progeny. A total of 115 patients who will receive allo-HSCT were prospectively monitored for the frequency and ROS levels of BM EPCs and their disease status pre-HSCT. Aims: To investigate whether the BM EPCs in subjects with PGF are impaired pre-HSCT and the reconstitution kinetics of BM EPCs, HSCs and their ROS levels post-HSCT. Multivariate analyses revealed that the reduced BM EPCs and the disease status pre-HSCT were independent risk factors for the occurrence of PGF following allo-HSCT.

Summary/Conclusions: We identified that patients with impaired BM EPCs pre-transplant were at a high risk for the occurrence of PGF post-allo-transplant. Multivariate analyses revealed that the reduced BM EPCs and the disease status pre-HSCT were independent risk factors for the occurrence of PGF following allo-HSCT.
Background: GATA4 is a transcription factor expressed in mesoderm and endoderm during development. Members of the family such as GATA1-3, but not GATA4, are critically involved in hematopoiesis. An enhancer (G2) of the mouse Gata4 gene directs its expression throughout the lateral mesoderm and the allantois, beginning at E7.5, becoming restricted to the septum transversum by E10.5, and disappearing by midgestation (Rojas et al., Development, 2005, 132:3405). Our previous work has shown that inactivation of Gata4 using this G2Cre driver is lethal by midgestation (Delgado et al., Hepatology, 2014, 59:2368). The anemia observed in the G2Cre;Gata4floX/floX embryos was attributed to a failure in the expansion of the hematopoietic progenitors in the fetal liver. Interestingly, a small population of hepatic YFP+ cells from G2Cre;R26RYFP embryos was positive for leukocyte and megakaryocyte markers, suggesting that a lineage of hematopoietic cells could derive from GATA4-expressing progenitors.

Aims: To study in our murine models the origin and properties of the hematopoietic lineage derived from progenitors expressing GATA4 under control of the G2 enhancer.

Methods: We analyzed hematopoietic organs of G2-Gata4Cre;R26RYFP mice, adults and embryos, by flow cytometry, RT-PCR and confocal microscopy. Cells obtained from different tissues were cultured and transplanted to analyze in vitro and vivo potential.

Results: YFP+ cells represented about 20% of the hematopoietic system of adult mice and contributed in the same proportion to the lymphoid, myeloid and erythroid lineages. Adult YFP+ hematopoietic stem cells (Figure 1) constituted a long-term repopulating, transplantable population. Fetal YFP+ hematopoietic progenitors were much more abundant in the placenta than in the adult tissues area. These placental YFP+ progenitors were clonogenic in the MethoCult assay and fully reconstituted hematopoiesis in vivo.

Background: The stem cell zinc finger 1 (SZF1) / ZNF589 protein, a member of the C2H2 zinc-finger family, is another FOG1-dependent GATA-1 target. SZF1 protein, which was found to be upregulated with 942 and 180 genes were upregulated and downregulated (> 2-fold), respectively, in the GATA1-overexpressed cells. Noticeably, we found that the expression of PU.1, known as a myelo-lymphoid-promoting transcription factor, was strongly downregulated by GATA1 overexpression, indicating that PU.1 is another GATA1-dependent target (Delgado et al., Development, 2014, 59:2368). In the GATA1-overexpressed cells, we identified a GATA1 peak in the PU.1 promoter (Fujiwara et al, Mol Cell 2009), which contained evolutionarily conserved consensus GATA-binding motif. The PU.1 promoter activity was significantly reduced in GATA1-overexpressed cells, and this effect was completely diminished by disruption of the GATA motif, suggesting that this motif has an important role in GATA1-mediated transcriptional repression of PU.1. Quantitative ChIP analysis demonstrated increased GATA1 chromatin occupancy at both FOG1 and GATA1 loci. Because GATA1 binds to a regulatory element in the GATA1 promoter, the GATA1 target gene (FOG1) is an important regulator of GATA1 target gene expression.

Conclusions: Our results provide important mechanistic insight into the role of GATA1 in the regulation of GATA1-regulated genes and suggest that FOG1 has an important role in regulating the expression of GATA1 target genes. We are currently investigating the transcriptome of the G2-GATA4 lineage in order to answer these questions.

Aims: To study in our murine models the origin and properties of the hematopoietic lineage derived from progenitors expressing GATA4 under control of the G2 enhancer.

Methods: We analyzed hematopoietic organs of G2-Gata4Cre;R26RYFP mice, adults and embryos, by flow cytometry, RT-PCR and confocal microscopy. Cells obtained from different tissues were cultured and transplanted to analyze in vitro and vivo potential.

Results: YFP+ cells represented about 20% of the hematopoietic system of adult mice and contributed in the same proportion to the lymphoid, myeloid and erythroid lineages. Adult YFP+ hematopoietic stem cells (Figure 1) constituted a long-term repopulating, transplantable population. Fetal YFP+ hematopoietic progenitors were much more abundant in the placenta than in the adult tissues area. These placental YFP+ progenitors were clonogenic in the MethoCult assay and fully reconstituted hematopoiesis in vivo.

Figure 1. The side population of the bone marrow from Gata4Cre;R26RYFP mice identified by Hoechst 22422 staining, which contains adult HSCs, includes a fraction of YFP+ cells. (from Scafe et al., 2017).

Summary/Conclusions: A lineage of adult hematopoietic stem cells in mice is characterized by the expression of GATA4 in their embryonic progenitors and probably by its extraembryonic (placental) origin. Both lineages basically characterized FOG1-regulated gene ensemble. The analysis demonstrated that 942 and 180 genes were upregulated and downregulated (> 2-fold), respectively, in the GATA1-overexpressed cells. Noticeably, we found that the expression of PU.1, known as a myelo-lymphoid-promoting transcription factor, was strongly downregulated by GATA1 overexpression, indicating that PU.1 is another GATA1-dependent target (Delgado et al., Development, 2014, 59:2368). In the GATA1-overexpressed cells, we identified a GATA1 peak in the PU.1 promoter (Fujiwara et al, Mol Cell 2009), which contained evolutionarily conserved consensus GATA-binding motif. The PU.1 promoter activity was significantly reduced in GATA1-overexpressed cells, and this effect was completely diminished by disruption of the GATA motif, suggesting that this motif has an important role in GATA1-mediated transcriptional repression of PU.1. Quantitative ChIP analysis demonstrated increased GATA1 chromatin occupancy at both FOG1 and GATA1 loci. Because GATA1 binds to a regulatory element in the GATA1 promoter, the GATA1 target gene (FOG1) is an important regulator of GATA1 target gene expression.

Conclusions: Our results provide important mechanistic insight into the role of GATA1 in the regulation of GATA1-regulated genes and suggest that FOG1 has an important role in regulating the expression of GATA1 target genes. We are currently investigating the transcriptome of the G2-GATA4 lineage in order to answer these questions.
ERYTHROPOIETIN STIMULATES TRANSDIFFERENTIATION OF BONE MARROW PRO-B CELLS INTO BONE-RESORBING OSTEOCLASTS

Methods: K562 (BCR-ABL positive chronic myeloid leukemia in blast crisis)-Luciferase-control or K562-Luciferase-S2F1/ZNF589 cells were directly injected into the femurs of NSG mice and tumor development was monitored by bioluminescence. Furthermore, K562 cells with or without S2F1/ZNF589 overexpression were studied by proliferation assay, cytomorphology, flow cytometry, cell cycle analysis, cyclin B1 expression and beta-galactosidase assay.

Results: K562-dependent tumor growth was efficiently inhibited in NSG mice transplanted with K562-Luc-control-cells, leading to significantly prolonged survival, demonstrating a strong tumor suppressive potential of S2F1/ZNF589 in vivo. In vitro, overexpression of S2F1/ZNF589 dramatically inhibited proliferation of K562 cells, which instead of dying, became giant and dysplastic, without other significant morphological changes and in absence of polyolcy. Cell cycle analysis revealed a blockade in G2/M phase, with cyclin B1 accumulation characteristic for mitotic arrest. As suggested by morphology and beta-galactosidase assay, K562-Luc-control cells were undergoing premature senescence.

Summary/Conclusions: S2F1/ZNF589 controls survival of hematopoietic cells mediated by mitotic arrest and premature senescence, exhibiting tumor suppressive functions in vivo.

E1106 THE FUNCTIONAL RELEVANCE OF DNMT3A SPLICE VARIANTS IN HEMATOPOIETIC DIFFERENTIATION

T. Bozić, J. Frobel1, A. Raić1, S. Heilmann-Heimbach2, T.W. Goecke3, E. Jost4, W. Wagner5,6,1

1Cell and Developmental Biology, 2Anatomy and Anthropology, Sackler Faculty of Medicine, Tel Aviv University, 3Medical Environment, Tel Aviv Sourasky Medical Center, Tel-Aviv, and 4Tel Aviv University, Tel-Aviv, Israel

Background: DNA methyltransferase 3A (DNMT3A) plays a pivotal role for de novo DNA methylation (DNAm) during development. It seems to be of particular relevance in hematopoietic differentiation because it is frequently mutated in acute myeloid leukemia or clonal hematopoiesis. So far, it is unclear how DNMT3A governs hematopoietic differentiation. The multitude of lineage-specific DNAm patterns – it is conceivable that this can at least partly be attributed to alternative splicing of DNMT3A.

Aims: In this study, we followed the hypothesis that specific splice variants of DNMT3A impact on hematopoietic differentiation or DNAm patterns. Therefore we addressed the role of specific splice variants of DNMT3A in hematopoietic stem and progenitor cells (HSPCs).

Methods: Expression of DNMT3A splice variants was modulated in HSPCs; transcript 1+3 (Tr.1+3), transcript 2 (Tr.2), or transcript 4 (Tr.4) of DNMT3A were either knocked down by short hairpin RNA or constitutively overexpressed by lentiviral infection. Expression changes were validated by qRT-PCR. Subsequently, we evaluated the impact on colony formation potential (CFU assay), proliferation (CFSE assay), and the immunophenotype (CD34+ and CD133+). Global DNAm profiles were generated with the Infinium HumanMethylation450 BeadChip platform and gene expression profiles with the Human Affymetrix Genome U133 microarray platform.

Results: Downregulation of either Tr.2 or Tr.4 reduced the proliferation rate of HSPCs significantly (n=3, p<0.05). HSPCs maintained CD34 expression for a proliferation period (CFSE assay), and the immunophenotype (CD34+ and CD133+). Consequently, we evaluated the impact on colony formation potential (CFU assay), these cells were entering premature senescence. Furthermore, K562 cells with or without SZF1/ZNF589 overexpression resulted in opposite and transcript-specific DNAm changes.

Summary/Conclusions: The opposite direction upon overexpression of the same transcripts. Knockdown DNAm levels upon knockdown of Tr.2 and Tr.1+3 (8,905 and 352 CpGs, respectively) resulted in transcript-specific gene expression changes, which may at least partly be attributed to alternative splicing of DNMT3A.

E1107 ERYTHROPOIETIN STIMULATES TRANSDIFFERENTIATION OF BONE MARROW PRO-B CELLS INTO BONE-RESORBING OSTEOCLASTS

N. Deshet-Unger,1 S. Hiram-Bab2, N. Ben-Calif1, A. Kolomansky1,3,4,3 D. K. Raj,1,2,4 T. Lindqvist1,4, Y. Gabei2, and W. Neumann1,5

1Cell and Developmental Biology, 2Anatomy and Anthropology, Sackler Faculty of Medicine, Tel Aviv University, 3Medicine A, Tel Aviv Sourasky Medical Center, 4Tel Aviv University, Tel-Aviv, and 5Department of Obstetrics and Gynecology, RWTH Aachen University, Aachen, Germany

Background: Erythropoietin (EPO) is a crucial kidney-derived hormone responsible for erythropoiesis; however, its extra-erythroid effects are substantial and correlate with EPO receptor (EPO-R) expression in both hematopoietic and non-hematopoietic tissues. Bone turnover is regulated by the coupled actions of osteoblasts, the bone-forming cells, and monocyte-derived osteoclasts, which mediate bone resorption. In this regard, we have recently reported that EPO directly stimulates bone resorption via activation of EPO-R signaling in the monocytic lineage (Hiram-Bab et al., 2015). Monocyte differentiation into osteoclasts relies on macrophage-macrophage colony-stimulating factor (M-CSF) and the receptor activator of nuclear factor kappa B ligand (RANKL). B cells are also known to regulate bone metabolism, chiefly via paracrine signals. Osteoclasts and B cells arise from distinct myeloid and lymphoid progenitors, respectively, which are downstream of a common multipotent progenitor cell.

Aims: We set to determine whether B cells can transdifferentiate to osteoclasts and to assess the effect of EPO on this process.

Methods: Experiments were conducted on C57BL/6j or CD19-Cre;R26R-EYFP, 8-12-week-old female mice in accordance with the approval of the Institutional Animal Care and Use Committee of Tel-Aviv University (M-14-043). BM cells were flushed from femurs, tibiae, and pelvic bone and red blood cells were lysed. Cells were stained with labelled anti-mouse antibodies: PE-B220, FITC-CD19, PerCP-igM, PeCy7-CD43, and APC-M-CSF receptor/CD115; and sorted by flow cytometry. Cells were then cultured in α-MEM containing 10% fetal bovine serum, M-CSF and RANKL. Multinucleated osteoclasts were stained for tartrate-resistant acid phosphatase (TRAP) and pit resorption was assessed.

Results: B cells isolated from BM of CD19-Cre;R26R-EYFP mice cultured with M-CSF and RANKL differentiated into TRAP+ multinucleated osteoclasts that were also positive for EYFP, thus tracing back their B cell origin (Figure 1A). Next, we dissected which B cell progenitor subtype possesses this osteoclastogenic capacity and found that only Pro-B (B220+CD19+CD43HighIgM-) cells formed osteoclasts (18%±6.55 vs. 0.11±0.05 osteoclasts’ area, respectively; n=5 mice in each group, p<0.05). Notably, these patterns were regulated in transgenic mice expressing the receptor activator of nuclear factor kappa B ligand (RANKL), demonstrating a strong tumor suppressive potential of SZF1/ZNF589 in vivo.

Taken together, our data suggest a new physio-pathological role for BM B-cell precursors in bone metabolism via their capacity to differentiate into functional osteoclasts, and a possible role for EPO in this process.

**BONE MARROW MYELOPOIESIS INDEPENDENTLY OF CANONICAL NOTCH SIGNALING**

S. Srinath1,*, K. Miyawaki1, Y. Mori1, H. Iwasaki1, T. Maeda1, K. Akashi1

**Background:** Notch signaling is a highly conserved pathway important in multiple developmental processes. Canonical signaling through all Notch receptors converges on the CSL transcription factor recombination signal binding protein for immunoglobulin kappa J region (Rbpj). In haematopoiesis, Notch is critical for the development of all the hematopoietic stem cells (HSCs) in the embryo and in thymic T cell development. Contrastingly, canonical Notch signaling has been shown to be dispensable for HSC homeostasis in the adult bone marrow (aBM). Recent studies have however suggested a role of Notch in promoting myeloid progenitors development (Mk/E) and development of aBM as well as in suppressing granulocyte-macrophage (GM) progenitor expansion and acting as a tumor-suppressor in myeloid malignancies. However, these findings were largely made through genetic approaches potentially also affecting regulatory pathways that are in turn affected by canonical Notch signaling.

**Aims:** To unambiguously investigate the role of canonical Notch signaling in aBM myelopoiesis, in steady-state and following transplantation.

**Methods:** B6-SJL-Cd45.1, Rbpjfl/fl mice were used. FACS analysis of distinct stages of GM, Mk and E progenitors were applied in mouse hematopoiesis. Gene expression levels were measured by real-time reverse transcription PCR (RT-PCR). In vitro colony assays were performed in mouse colony assays. For transplantation studies, lethally irradiated recipients were competitively transplanted (1:1) and reconstituted assessed 7-9 weeks after transplantation.

**Results:** FACS staining of GM, Mk and E progenitors in aBM of lox-flanked Rbpj mice crossed to both Mx1-Cre and the pan-hematopoietic Vav-Cre strains was applied. As expected, HSCs were unaffected. Not previously investigated, FACS of all three types of aBM progenitors revealed absence of progenitor defects, at any progenitor stages, in Rbpj-deficient mice. To demonstrate that this lack of a phenotype was not due to BM cells escaping Rbpj deletion, we FACS purified HSCs and all GM, Mk and E progenitor stages from Rbpj-deficient mice and verified a virtually complete deletion of Rbpj in all populations. In further agreement with canonical Notch signaling not being required for steady-state generation, maintenance or stepwise differentiation of adult GM, Mk and E progenitors, the number of GM, E and Mk colonies generated from unfractionated aBM cells as well as circulating platelet counts were also unaffected. We next sought to address whether we could uncover a role in the Notch pathway in regulation of GM, Mk and E progenitors by establishing BM chimeras in which Rbpj-deficient progenitors compete with wild type (WT) progenitors for replenishment and differentiation in lethally irradiated recipients. To assess the impact of Notch signaling on lineage development, we analyzed the contribution of HSC and any stages of GM, Mk and E progenitors in mice competitively transplanted with Rbpj-deficient as compared to control WT BM cells. Moreover, transplanted Rbpj-deficient and control progenitors contributed equally well to platelet reconstitution. We next investigated whether loss of canonical Notch signaling might nonetheless impact on expression of genes for key regulators the Mk and E lineages at distinct progenitor stages for these lineages, as previously implicated. Notably, transcript levels of genes encoding key Mk/E regulators were unaffected in Rbpj-deficient Mk/E progenitors. In previous studies, expression of Rbpj target genes in Mk and E progenitors in aBM has been implicated as reflecting activation through Notch signaling. However, since the expression of Notch targets might also be regulated by other pathways besides Notch pathway, we investigated whether the expression of key Notch target genes (Has1, Hes5, and Gfi1) in aBM was dependent on canonical Notch signaling. Neither in HSCs or any Mk/E progenitor was the expression of these Notch genes negatively affected by Rbpj-deficiency, demonstrating that their low expression levels in aBM HSCs and Mk/E is independent of canonical Notch signaling.

**Summary/Conclusions:** Studies implicating canonical Notch signaling as a critical regulator of aBM Mk, E and GM progenitors potentially failed to target only canonical Notch signaling. Herein, we demonstrate that canonical Notch signaling is dispensable for generation and replenishment of Mk, E and GM progenitors in aBM in steady-state as well as following BM transplantation.

**E1111**

**IDENTIFICATION OF NOVEL HUMAN HEMATOPOIETIC STEM CELL SUBPOPULATIONS VIA COMPREHENSIVE SURFACE MARKER ANALYSIS**

T. Jirouma1,*, K. Miyawaki1, Y. Morii1, H. Iwasaki1, T. Maeda1, K. Akashi1

**Background:** All hematopoietic cells are derived from hematopoietic stem cells (HSCs), which exhibit capacities for multilineage differentiation and long-term self-renewal. Human HSCs can be isolated by Fluorescence-activated cell sorting (FACS) with the combination of several surface markers, such as CD34+, CD45RA−, CD38−, and CD90+. The most potent of functionally heterogeneous subpopulations, including multi-potent and/or lineage-biased progenitors (Notta:2016hj) and HSC-like populations with reduced self-renewal capacity (Notta:2011bg); however, prospective isolation of bona fide human HSCs is still challenging due, at least in part, to the lack of specific surface markers.

**Aims:** The goal of this study is to identify a novel HSC-specific surface marker(s) that enables prospective isolation of functionally-distinct HSC sub-populations.

**Methods:** We examined expression levels of 342 cell surface markers in the HSC population (Lin−CD34+CD38−CFDRA−CD90+) by FACS using commercially-available antibodies. Single-cell gene expression profiling of isolated sub-fractions were performed using Fluidigm C1 system in combination with Bio-mark. Differentiation potential of each HSC fraction was assessed by single-cell colony assays in methylcellulose. In vitro lineage tracing in liquid culture were performed to determine hierarchical relationships among subfractions.

**Results:** Among 342 cell surface proteins examined, only CD35, CD115 and CD212 were detected in the HSC fraction. We focused on CD35, which is also known as complement receptor type 1 (CR1), as its expression was most distinct among the three markers. CD35-positive population accounted for 3% of the total human HSCs, defined as Lin−CD34+CD38−CFDRA−CD90+ cells, in adult bone marrow and cord blood. HSCs exhibited multi-lineage reconstitution capacity without lineage-biased differentiation in a single-cell colony assay regardless of the CD35 levels. CD35+HSCs gave rise to CD35−HSCs in lineage tracing experiments, suggesting that CD35+HSCs reside upstream of the human HSC hierarchy, indicating lineage distinct among the three markers. CD35+HSCs, but not CD35−HSCs, are phenotypically homogenous, expressing cell cycle-related genes and lineage-specific markers at low levels.

**Summary/Conclusions:** Our data suggest that HSCs can be further subdivided into subfractions based on CD35 levels. CD35 might be a useful marker to prospectively isolate the most primitive human HSC fraction. In vivo functional assays using xenotransplantation models are currently underway, and the results will be discussed at the meeting.

**DEVELOPMENT OF A 3-DIMENSIONAL CULTURE TO MIMICK THE BONE MARROW MICROENVIRONMENT AND RECAPITULATE DRUG RESISTANCE FOR IN VITRO STUDY**

M. Karimpoor1,*, E. Illangakoon1, A. Reid2, J. Khorashad3, M. Edirisinghe1

1Biomechanical engineering/Pharmacy, University College London, 2Department of Medicine, Imperial College London, London, United Kingdom

**Background:** Chronic myeloid leukemia (CML) is a haematological malignancy caused by the acquisition of the BCR-ABL1 oncogene. Demonstration of the central role of BCR-ABL1 kinase activity in CML pathogenesis led to the development of imatinib, a BCR-ABL1-specific tyrosine kinase inhibitor. Most patients on imatinib attain good clinical and molecular responses, despite the persistent presence of a low level of therapy-refractory leukaemia stem cells (LSCs), which reside in the bone marrow niche. However, in a significant minority of patients these cells eventually provide a reservoir for disease relapse and subsequent malignant progression. A greater understanding of the biology of imatinib-resistant LSCs could therefore be of significant clinical benefit. One of the proposed mechanisms of drug resistance in CML LSCs is close contact with the surrounding microenvironment, however an in vitro model of the bone marrow matrix is currently lacking.

**Aims:** Development of a 3-dimensional culture using fibre scaffolds to mimick bone marrow microenvironment in order to study the mechanism of resistance to anti-leukaemia agents.

**Methods:** Scaffold production: PMMA solution was prepared by dissolving PMMA in chloroform and adding appropriate amount of hydroxyapatite to poly(methyloxysiloxane) (Dow Corning Medical) followed by delivery of 2% hydroxyapatite to PMMA in chloroform and adding appropriate amount of hydroxyapatite to PMMA to produce 3-dimensional scaffolds. The scaffolds were sterilized by γ-irradiation, stored at −20°C and allowed to equilibrate to room temperature before use. We measured the bulk density of the scaffolds by weighing them before and after desiccation in a vacuum oven. We measured the porosity of the scaffolds by imaging them with a white light interferometer (Wyko NT9100; Veeco Instruments, Woodbury, NY, USA) and calculating the porosity from the ratio of the volume of the light beam passing through the sample and the sample itself.

**Results:** We produced a PMMA-based 3D scaffold and compared the growth of CML and AML cell lines grown in this scaffold in the presence or absence of cytotoxic or targeted therapy to that of cells grown in 2D culture. PMMA-HA scaffold was not toxic to the leukemia cells as primary AML cells and also K562 cells grew in the presence of scaffold and also concentrated around the scaffold was not toxic to the leukaemia cells as primary AML cells and also K562 cells grew in the presence of scaffold and also concentrated around the scaffold.
fibre treatments. Treatment of K562 or HL60 cells with imatinib or doxorubicin respectively resulted in a lower level of apoptosis in cells grown on the 3D scaffold compared to those grown in 2D culture. Further development of this 3D culture by adding stromal cells HS-5 to the scaffold reduced even further the sensitivity of K562 or HL60 to imatinib or doxorubicin, respectively.

Figure 1.

Summary/Conclusions: The relative resistance to either imatinib or doxorubicin that we observed in cells grown in 3D culture supports a role for the bone marrow matrix in the protection of leukaemic cells against chemotherapeutic agents. A combination of the PMMA-HA with HS-5 cells made this system more similar to the bone marrow microenvironment as this is a model in which all the basic components of the bone marrow microenvironment such as scaffold, stromal cells and cytokines (secreted by HS-5) are present. The results of this study show adding extra complexity to the microenvironment changes the sensitivity of the cells to therapeutic agents, better recapitulating the situation observed in vitro. Three dimensional cultures using the PMMA-HA-HS-5 model may prove useful in the investigation of therapy resistance in leukaemia and for the discovery of new agents capable of eradicating quiescent leukaemic stem cells.

WHOLE EXOME SEQUENCING REVEALED SEQUENTIAL GAIN OF MUTATIONS IN TWO CASES OF DONOR CELL HAEMATOLOGICAL MALIGNANCY AFTER HEMATOPOIETIC TRANSPLANTATION

J. Suárez González1,2, C. Martínez-Laperche1,2, M. Kwon1,2, G. Rodríguez-Macías3, A. Figuera4, A. Balas5, N. Martínez6, P. Balsalobre2,3, D. Serrano2,3, M.A. Piris7,8, J.L. Vicario5, J. Gayoso2,3, J.L. Diez23, I. Buño1,2,3

1Genomic Unit, Instituto de Investigación Sanitaria Gregorio Marañón y Hospital General Universitario Gregorio Marañón, 2Department of Hematology, Hospital General Universitario Gregorio Marañón, 3Department of Hematology, Hospital of the Princess, 4Department of Histocompatibility, Madrid Blood Centre, Madrid, 5Department of Histocompatibility, Madrid Blood Centre, Madrid, 6Cancer Genomics, IDIVAL, 7Department of Pathology, Hospital Marqués de Valdecilla, Santander, Spain

Background: The leukemic transformation of otherwise healthy donor stem cells provides a useful model to study the mechanisms involved in leukenogenesis.

Aims: We report two cases of donor cell derived haematological malignancy in which whole-exome sequencing (WES) was performed in bone marrow (BM) samples from recipient at different times after allogeneic hematopoietic stem cell transplantation (allo-HSCT) in order to study the dynamics of emergence of mutations that precede the development of donor cell leukemia (DCL) and donor cell myelodysplastic syndrome (DC-MDS).

Results: WES analysis revealed progressive emergence of multiple somatic mutations probably related to the development of leukaemia in bone marrow samples post allo-HSCT (Figure 1). Both SCs showed alterations that may be involved in leukemogenesis. (Case 1: SH263 and case 2: KMT2C, KMT2A, ARHGAP26 and monosomy 7). Somatic mutations, acquired over time, fall into genes that play well-established roles in signalling pathways. Malignant mutations in leukemic subclones that disappear after chemotherapy were indenitified, as well as the acquisition of new mutations in resistant subclones. We propose a possible model of leukemogenesis in these cases (Figure 2).

Summary/Conclusions: The present study reveals a process of sequential clonal expansions, promoting the acquisition of additional somatic mutations in donor hematopoietic cells. Detection of inheritable or acquired gene mutations in donor associated with predisposition to haematological malignancies could have clinical implications for the patients undergoing to allo-HSCT. Although the cause of donor cell derived haematological malignancy onset seems to be multifactorial, the infuion of a SCU with pre-leukemic potential in a context of residual toxicity in recipient as a result of pre-transplant chemotherapy, a post-transplant environment characterized by a decreased immune surveillance may well have played role in these cases. The study of a greater number of DCL cases by next generation sequencing could help to understand this process and to detect new mutations involved in the emergence of AML.

LEUKEMIC STEM CELL-RELATED MRNA EXPRESSION ANALYSIS USING A NOVEL FLOW CYTOMETRY-BASED ASSAY

B. Depreter1,2, K. Vandepoele2, B. De Moorloose1, D. Bensy1, J. Philippé1,3, T. Lammens2

1Department of Clinical Chemistry, Microbiology and Immunology, 2Department of Paediatric Haematology-Oncology and Stem Cell Transplantation, Ghent University, 3Department of Laboratory Medicine, 4Department of Paediatric Haematology-Oncology and Stem Cell Transplantation, Ghent University Hospital, Ghent, Belgium

Background: Gene expression analysis of protein-coding (mRNA) and non-coding RNA in paediatric and adult acute myeloid leukaemia (AML) has become of paramount importance for therapeutic decision-making, revealing prognostic information and for the identification of novel therapeutic targets. AML is a clinically, phenotypically and molecularly heterogeneous haematological malignancy, with different leukaemic cell populations organized in a hierarchical fashion, and leukaemic stem cells (LSCs) residing at the apex herein. Unfortunately, gene expression profiling is commonly performed on unfractionated bulk samples, leading to “expression averaging” of these heterogeneous cell populations. Multicolor flow cytometry (FCM) is capable of distinguishing heterogeneous cell populations based on the phenotypic characterization at a single-cell level. However, fluorochrome-conjugated antibodies are not available for intracellular RNA targets.

Aims: To evaluate the applicability of a novel flow cytometry-based technique, PrimeFlow™ mRNA assay, to measure cell-of-interest RNA expressions in heterogeneous AML samples.

Methods: Technical assessment was performed using six neuroblastoma cell lines with varying levels of MYCN gene amplification. Correlation to expression data obtained by the gold standard RT-qPCR, performance in rare (0.1%) cell populations, effects of cryopreservation and off-target effects were evaluated. Next, diagnostic material of de novo AML patients was used to measure target gene (Wilms’ tumor 1 (WT1)) and reference gene (RPL13a, GAPD) expression. Expression analysis was performed in unfractionated bulk leukemic cells as well as blasts and rare subsets of leukemic cells, e.g. LSCs. FCM analyses were performed on a FACSVerse II (BD Biosciences) with set-up according to EuroFlow guidelines. Infinicyt™ (Cyto gens®) was used for data analysis and mean fluorescence intensities (MFI) values (with/without normalisation) were interpreted. P-values < 0.05 were considered significant.

Results: mRNA expression quantified by PrimeFlow™ significantly correlated with data obtained by RT-qPCR and remained detectable in rare (0.1%) cell populations. WT1 expression was shown to be statistically significantly higher in bulk leukemic cells of those patients characterized by WT1 overexpression, as defined by RT-qPCR, showing a mean 52% MFI upregulation by PrimeFlow™ compared to patients with normal WT1 expression, showing a 63% and 45% MFI upregulation, respectively, compared to patients with normal WT1 expression.

Discussion: For the first time, immunophenotypic and gene expression measurements can be performed simultaneously on rare leukaemic cells. The findings reported herein are in line with previous studies showing WT1 RNA overexpression in AML.
Summary/Conclusions: Key mRNA target expressions in AML, e.g. WT1 gene expression, could be evaluated using PrimeFlow™ RNA assay, including rare and heterogeneous cell populations herein, e.g. LSCs. This study demonstrates that PrimeFlow™ is a technique of interest for the discovery of novel LSC-specific targets.

E1115

POTENTIAL PREDISPORING GERMLINE MUTATIONS IN PATIENTS WITH CONCOMITANT MYELOID AND LYMPHOID MALIGNENCIES

A. Asmär1, M. Munk-Johansen2, T.C. El-Galaly3, H.E. Johnsen1, C. Westmore Yde1, D. El Fassi4, K. Grenbaek1

1Department of Haematology, Rigshospitalet, Copenhagen, 2Department of Hematology, University hospital of Aalborg, Aalborg, 3Center of Genomic Medicine, Rigshospitalet, Copenhagen, 4Department of Hematology, University Hospital Herlev and Gentofte, Herlev, Denmark

Background: Recent findings have suggested that mutations predisposing the development of either acute myeloid leukemia (AML) or chronic lymphocytic leukemia (CLL) may arise in pre-leukemic hematological stem cells. In addition, genes involved in epigenetic regulation, such as TET2, and RNA processing, such as SFB31, are mutated in both myeloid and lymphoid malignancies. This could indicate a possible genetic link between myeloid and lymphoid malignancies. Therapy related AML (t-AML) is a complication treatment with cytotoxic drugs such as alkylating agents and topoisomerase inhibitors. The susceptibility of developing t-AML has been associated with variation in DNA-repair pathways, drug metabolism and transport.

Aims: In this study, we aimed to investigate a possible common genetic origin of hematological cancers in patients with concomitant CML and de novo AML or myelodysplastic syndrome (MDS) and in patients with concomitant therapy-related AML (t-AML) and CLL.

Methods: The presence of concomitant lymphoid and myeloid malignancies in patients is rare, however we managed to include 3 patients with de novo AML and CLL, 1 patient with MDS and CLL, 1 patient with chronic myelomonocytic leukemia(CMML) and CML, and 2 patients with t-AML and CML. The patients' diagnoses were based on the evaluation of the morphological, immunohistochemistry, cytogenetics, and flow cytometry analysis in accordance to the WHO classification. For each patient mononuclear cells (MNCs) from blood or bone marrow were isolated using Ficoll gradient centrifugation and used for fluorescence activated cell sorting (FACS) of the malignant clones and the T-cells. Paired end exome sequencing (2x150) aiming for an average coverage of 50-100x was performed using either the HiSeq2500 or NextSeq500 platforms from Illumina. Raw sequencing data was processed using CASAVA-1.8.2. Mapping to the human genome (hg19/GRCh37 UCSC) was performed using CLC Biomedical Genomics Workbench (Qiagen) mcl software. Variants with a frequency of 5% or above were called.

Results: We identified possible pre-disposing germline mutations in all 7 patients by comparing variants between the myeloid malignant clone, CLL cells, and T cells, as well as using saliva to aid in characterizing the mutations as somatic or germline in the hematopoietic compartment. In all the patients except one with de novo AML and CML, we identified a potential damaging germline variant in a DNA-repair related gene, such as ATM (387dupA, D130fs*4), SMARCAL1 (2114C>T, T705I), HELQ (393_397delAGGTG, G132fs*16), SWI5 (652C>T, R218*), LIG1(2168A>G, Q761R) and PRKDC(802G>A, c.301Y). In the remaining patient with concomitant de novo AML and CML, we identified a potential damaging germline variant in an epi- genetic regulator believed to play a role in normal and malignant hematopoiesis, KDM2B(44deic, P159fs*). Furthermore, we identified the somatic mutational landscapes of the malignant clones using T-cells as germline tissue for the characterization of mutations in the hematopoietic compartment. In all the patients except one with de novo AML and CML, we identified a potential damaging germline variant in a DNA-repair related gene, such as ATM (387dupA, D130fs*4), SMARCAL1 (2114C>T, T705I), HELQ (393_397delAGGTG, G132fs*16), SWI5 (652C>T, R218*), LIG1(2168A>G, Q761R) and PRKDC(802G>A, c.301Y). In the remaining patient with concomitant de novo AML and CML, we identified a potential damaging germline variant in an epi-genetic regulator believed to play a role in normal and malignant hematopoiesis, KDM2B(44deic, P159fs*). Furthermore, we identified the somatic mutational landscapes of the malignant clones using T-cells as germline tissue for the characterization of mutations in the hematopoietic compartment.

Summary/Conclusions: Our results suggest a possible role of germline variations in the susceptibility to development of concomitant de novo hematological cancers as well as t-AML. However, further studies including more patients are needed to confirm this hypothesis.

E1116

THE MUTATIONAL LANDSCAPE OF DNMT3A MUTATIONS IN CLONAL HAEMATOPOIESIS OF INDETERMINATE POTENTIAL. CHIPPING AWAY AT THE PROBLEM

S. Chaundy1, T. Chevasseu1

1Brighton and Sussex Medical School, Brighton, United Kingdom

Background: Dysfunction of epigenetic modifiers contributes significantly to the pathogenesis of acute myeloid leukaemia (AML). One frequently mutated gene involved in epigenetic modification is DNMT3A (DNA methyltransferase-3-alpha). Approximately 22% of de novo AML and 36% of cytogenetically normal AML are found to have DNMT3A mutations and around 60% of these mutations affect the R882 codon. In particular, the R882H mutation has been associated with a poor prognosis and survival outcomes for patients. A large number of DNMT3A mutations are present in clonal cells in healthy individuals with no characteristics of haematological malignancy and is termed as clonal haematopoiesis of indeterminate potential (CHIP).

Summary/Conclusions: Key mRNA target expressions in AML, e.g. WT1 gene expression, could be evaluated using PrimeFlow™ RNA assay, including rare and heterogeneous cell populations herein, e.g. LSCs. This study demonstrates that PrimeFlow™ is a technique of interest for the discovery of novel LSC-specific targets.
Methods: We applied a data-mining algorithm to generate percentile charts for hematology analytes using laboratory data collected during the clinical care of patients. A total of 9,517,245 samples from 343,463 patients (72,614–337,011 samples per analyte) from 8 German tertiary care centers and 2 German laboratory service providers were examined. Percentile charts were calculated using an established statistical approach which extracts the proportion of samples from healthy individuals from the unfiltered input dataset containing both non-pathologic and pathologic samples. To evaluate the clinical benefit of hematology test result interpretation using percentile charts, accuracy and speed of pediatricians assessing eight different predefined clinical situations were measured in comparison to conventional test result representations.

Results: We created percentile charts for hematology analytes in girls and boys from birth to 18 years which can be used as common reference intervals. Results are provided for hemoglobin, hematocrit, red cell indices, red cell count, red cell distribution width, white cell count, and platelet count, example charts for hemoglobin, mean corpuscular volume, and platelet count are shown in the accompanying figure. A web application at www.pedref.org/hematology demonstrates hematology test result interpretation using percentile charts and z-scores with special consideration of pediatric dynamics. Comparison of pediatricians’ decision times when assessing different clinical scenarios using percentile charts and conventional representations shows more correct decisions (75.9% vs 68.4%, p<0.01) which are made in shorter time (2.7 s vs 3.8 s, p<0.01) when using percentile charts.

Summary/Conclusions: The created percentile charts enable the appropriate differential diagnosis of changes in hematology analytes due to disease and changes due to physiological development. Integration of suitable forms of result reporting using the provided percentile charts into clinical decision making improves assessment of the unique dynamics in pediatric hematology.

GROWTH FACTOR INDEPENDENCE 1 (GFI1) REGULATES THE AML SUPPORTING FUNCTION OF MESENCHYMAL STROMAL CELLS
Y. Al-Matary1,*, L. Botezatu 1, A. Thivakaran 1, R. Köster 1, J. Schütte 1, J. Göthert 1, U. Dührsen1, B. Opalka1, C. Khandanpour1
1University Hospital of Essen/ West centre of tumor, Essen, Germany

Background: Mesenchymal stromal cells (MSCs) harbor and support the function of normal hematopoietic stem cells. Less is known about their interaction with leukemic cells, e.g. in acute myeloid leukemia (AML). The prognosis of AML, a clonal malignant disease of the bone marrow (BM), is still poor with only 25% of patients living longer than 5 years.

Aims: In the current study, we investigated the interaction between MSCs and AML cells, and we also investigated the underlying molecular mechanism.

Methods: We used cell cultures using primary cells from human and mice and cell lines of MSCs and AML cells. Different Mouse models of human AML were used in our study to confirm the results obtained from human sample. MSCs were characterized by differentiation assay, flow cytometry and RT-PCR. Matrigel test was also applied in this study.

Results: MSCs from AML patients called AML-associated MSCs (AMSCs) or from murine models of human leukemia enhance significantly in vitro the growth of leukemic cells compared to AML cells growing without MSCs or in presence of MSCs from non-leukemic patients or mice. Among other, AMSCs increased entry of leukemic cells into the cell cycle, and at the same time protected the leukemia cells against exogenous toxic events such as chemotherapy or irradiation. The interaction between AMSCs and leukemia cells is dependent on cell-to-cell contact. In vivo, absolute and relative numbers of AMSCs and other stromal cells, i.e. endothelial cells and osteoblast lineage cells were highly expanded in the BM of mice modeling of human AML. AMSCs showed a higher efficiency of capillary tube formation in the matrigel assay than normal MSCs which gives an additional indication that AMSCs were polarized by leukemia cells towards a tumor-supporting state. On a molecular level, the polarization of MSCs towards an AML-supporting state depends on upregulated expression of the transcription factor Growth factor independence 1 (Gfi1). Loss of Gfi1 diminished the tumor-supporting state of AML-associated MSCs.

Summary/Conclusions: We conclude that leukemia cells polarize AMSCs towards a leukemia-supporting state in a Gfi1-dependent manner, which could open the way to new therapeutic approaches.
BASELINE LEUKOCYTE AND EOSINOPHIL COUNTS PREDICT OUTCOME IN RELAPSED OR REFRACTORY CLASSICAL HODGKIN LYMPHOMA PATIENTS TREATED WITH PD1 INHIBITION

I. Hude1,1, S. Sasse2, P.J. Broekelman1, B. von Tresckow2, J. Momotow2, A. Enger1, S. Borchmann2

1Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, Zagreb, Croatia, 2German Hodgkin Study Group (GHSG), First Department of Internal Medicine, University Hospital Cologne, Cologne, Germany

Background: Despite encouraging efficacy of anti-PD1 antibodies in relapsed or refractory (r/r) classical Hodgkin lymphoma (cHL), not all patients achieve a lasting response, with few complete remissions (CR) observed. Thus, identification of predictive biomarkers is important. Recently, two models using readily available differential blood count parameters have been suggested to predict outcome in melanoma patients treated with immune checkpoint inhibition.

Aims: In this study, we aimed to identify baseline differential blood count parameters associated with response and progression free survival (PFS) in r/r cHL patients treated with anti-PD1 antibody nivolumab.

Methods: We retrospectively investigated baseline differential blood count parameters and their association with response and progression free survival (PFS) in 30 r/r cHL patients treated with the anti-PD1 antibody nivolumab. All 30 patients had previously received multiple lines of treatment, including treatment with high dose chemotherapy followed by autologous stem cell transplant (ASCT) for r/r disease; the median number of prior treatment lines was 5 (2-11) and 21 patients received prior brentuximab vedotin. To investigate the association of baseline blood count parameters (white blood cell count (WBC), relative monocyte count (RMC), relative neutrophil count (RNC), relative lymphocyte count (RLC) and relative eosinophil count (REC)) with outcome after PD1 inhibition, we used the last differential blood count performed immediately prior to the first received dose of nivolumab.

Results: RMC, RNC and RLC did not have a prognostic impact on PFS, whereas higher WBC ≥ 7.78x10³/µl and lower REC<1.7% were associated with worse PFS in both univariate and multivariate analysis. We constructed a simple score to prognosticate PFS. By adding 1 point each for WBC ≥ 7.78x10³/µl and REC<1.7% to the score, we could clearly differentiate a low (score=0), intermediate (score=1) and high risk (score=2) group for disease progression (p<0.001). Only one PFS event occurred in the best prognostic group (n=10, median PFS (days): 365 [129-NA]) and 7 out of 9 patients in intermediate (median PFS (days): 197 [50-NA]). Evaluation of best response achieved according to the initial risk score showed a trend towards higher CR-rates in low risk group, but was not significant.

Figure 1.

Summary/Conclusions: Our simple prognostic model, mainly characterized by a normal to high REC, robustly discriminates three risk groups for PFS. Almost all patients in the low risk group achieved a durable remission without disease progression throughout the study period, despite often achieving just a partial response. In contrast, high-risk patients often progressed quickly despite initially achieving a partial or complete response. Further validation of this score which is easily available from routine clinical parameters in a larger cohort of patients and further investigation of its potential predictive impact is needed. Moreover, efforts to clearly understand a possible mechanistic role of eosinophils in cHL patients treated with PD1-inhibition are warranted.

THE PROGNOSTIC SIGNIFICANCE OF BETA-2 MICROGLOBULIN (B2M) LEVELS IN PATIENTS WITH HODGKIN LYMPHOMA (HL) TREATED WITH ABVD OR EQUIVALENT (ABVD) DEQ CHEMOTHERAPY OR COMBINED MODALITY THERAPY (CM) IN ELDERLY PATIENTS WITH HODGKIN LYMPHOMA

1Department of Hematology and Bone Marrow Transplantation, 21st Department of Internal Medicine, Hematology Unit, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece, 2Department of Clinical and Experimental Medicine, Section of Hematology, University of Verona, Verona, Italy, 3Second Propedeutic Department of Surgery, Laikon General Hospital, National and Kapodistrian University of Athens, 4Department of Haematology, Athens Medical Center, 5Hematology Section, First Propedeutic Department of Internal Medicine, Laikon General Hospital, National and Kapodistrian University of Athens, 6Euroclinic, Athens, Greece

Background: The prognosis of HL primarily depends on clinical stage (CS) as well as limited-stage risk classification schemes and the International Prognostic Score (IPS), both of which delineate further prognostic subgroups within CS. B2m is a well-established prognostic factor for several hematologic malignancies, but its role in HL is yet controversial. Between 1993 and 2016, several reports from other groups have yielded heterogenous results in small-sized patient series, with no clear consensus on the optimal cut-off for the evaluation of serum b2m in HL.

Aims: Our aim was to investigate the prognostic significance of serum b2m levels in HL.

Methods: We analyzed 864 patients with HL treated with ABVD/Deq CT/CMT (1990-2016) and selected solely based on the availability of pretreatment b2m levels. B2m [P1] levels (upper normal limit 2.4mg/L) were analyzed according to other baseline features and prognostic factors as well as according to the outcome. Freedom From Progression (FFP) was defined as time between treatment initiation and treatment failure (primary refractoriness, PR with switch to alternative CT or relapse); deaths of unrelated causes were censored. Overall Survival (OS) was measured from treatment initiation to death of any cause. ROC curves and sequential cut-offs (1.8-3.5 by 0.1 increments) were used to explore the potential impact of b2m on FFP and OS.

Results: The median follow-up for currently living patients was 88 months. Univariate Analysis: FFP was significantly inferior in patients with higher b2m at all tested cut-off points. At 2.4mg/L (normal versus elevated) the 10-year FFP was 81% vs 71% (p<0.003). However, the best cut-off was the observed median b2m value of this series, calculated at 2.1mg/L, with 10-year FFP of 84% vs 71% (p=0.0001). In early stages (IA/IIA) significant results were obtained at cut-offs between 1.8 and 2.1mg/L. The best cut-off was 1.9mg/L, a close approximation of the median b2m level of early stage patients, with 10-year FFP of 89% vs 78% (p=0.003). In advanced stages, none of the cut-offs yielded statistically significant results (borderline at 2.0mg/L, 10-year FFP 77% vs 67%, p=0.057). Multivariate Analysis: B2m levels remained significant for FFP after adjustment for IPS factors, ESR and B-symptoms at both 2.1mg/L and 2.4mg/L cut-offs (hazard ratio (HR) 1.78, p=0.001 and 1.41, p=0.04 respectively) in the whole series of 864 patients. In early stages, b2m was a significant predictor of FFP at the cut-offs of 1.9mg/L and 2.1mg/L (HR 2.00, p=0.01 and 1.83, p=0.02 respectively), but only borderline at the cut-off of 2.4mg/L (HR 1.65, p=0.07). In advanced stages, b2m emerged as an independent prognostic factor for FFP at the cut-off of 2.2mg/L (HR 1.59, p=0.046 despite the lack of significance in univariate analysis), but was not significant at the cut-off of 2.1mg/L. The optimal cut-off for the evaluation of serum b2m in HL may be stage-dependent and appear to lie between 1.9 and 2.2mg/L, thus performing better than a “normal versus high” evaluation (cut-off 2.4mg/L).

THE PREDICTIVE VALUE OF INTERIM PET-CT IN ELDERLY PATIENTS WITH HODGKIN LYMPHOMA

O.S. Bentur1, 1, D.J. Eldad2, E. Paran3, D. Lavie4, B. Nachmias4, N. Dally5, O. Gutwin6, Y. Hershounu1, N. Sardi1, C. Perry7, I. Avivi7

1Department of Hematology and Bone Marrow Transplantation, 21st Department of Internal Medicine, Hematology Unit, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece, 3Department of Clinical and Experimental Medicine, Section of Hematology, University of Verona, Verona, Italy, 4Second Propedeutic Department of Surgery, Laikon General Hospital, National and Kapodistrian University of Athens, 5Department of Haematology, Athens Medical Center, 6Hematology Section, First Propedeutic Department of Internal Medicine, Laikon General Hospital, National and Kapodistrian University of Athens, 7Euroclinic, Athens, Greece

Background: Despite encouraging efficacy of anti-PD1 antibodies in relapsed or refractory (r/r) classical Hodgkin lymphoma (cHL), not all patients achieve a partial or complete response. In contrast, high-risk patients often progressed quickly despite initially achieving a partial or complete response. Further validation of this score which is easily available from routine clinical parameters in a larger cohort of patients and further investigation of its potential predictive impact is needed.
Background: Hodgkin lymphoma (HL), a disease of mostly young patients, also peaks in the elderly. Despite the profound improvement in the clinical outcome of young patients, in the elderly, 5-year overall survival (OS) is estimated at only 40-55%. Interim PET-CT (iPET), known to be highly predictive for progression free survival (PFS) in young patients with HL, has not been sufficiently validated in elderly patients, nor have many other outcome predictors in HL of the elderly.

Aims: The objective of the present study was to evaluate the significance of iPET in elderly patients with HL.

Methods: All consecutive patients (age ≥60) diagnosed with HL between 1998-2016 were retrospectively reviewed in this multi-center study. Baseline characteristics as well as PET-CT results at diagnosis, interim analysis and end of treatment (EOT) were recorded and analyzed. PET-CT results were classified as no evidence of disease (NED), partial response (PR), stable disease (SD) and progressive disease (PD).

Results: Ninety-five patients from 5 centers were identified. Median age was 71 (range 60-89) years. Subtype was nodular sclerosis in 48% and mixed cellularity in 23%. Sixty three (69%) patients had advanced disease and mean international prognostic score (IPS) was 3.5±1.4. Fifty nine (63%) patients received first-line treatment with ABVD, in 13 (14%) chemotherapy was followed by involved field radiotherapy. At EOT, sixty seven (82%) patients achieved CR, 6% (7%) achieved PR, 10 (11%) were primary refractory and 2 (2%) died during treatment. Fifteen (16%) patients experienced relapse. Five year PFS and OS were 56% and 78%, respectively. ABVD treated patients had 5 year PFS and OS of 59% and 82% as opposed to 48% and 68% for all other regimens, but these differences were not statistically significant. Seventy two (76%) patients had undergone both iPET and EOT-PET. 50 patients had NED on iPET, 20 had PR, 1 SD and 1 PD. NED-EOT-PET was achieved in 47/50 (94%) patients who had NED iPET, 12/20 (60%) patients who had PR iPET and none of the patients with SD/PD iPET (p<0.01). In patients with either NED or PR on iPET, relapse occurred in 11 (15%) patients and 5 year PFS and OS were 82% and 95%, respectively. The 5 year PFS of these patients differed according to the depth of response on iPET - 69% vs 45%, (p=0.02, fig.1) in patients achieving NED vs PR, while 5 year OS did not reach statistical significance, 90% vs 71% (p=0.08). Restricted analysis, evaluating only 59 patients who were treated with ABVD, showed similar results with 94% of NED iPET vs 45% of PR iPET achieving NED on EOT-PET (p<0.01). Outcome differed according to the depth of response in iPET with 5 year PFS rates of 74% vs 34%, in patients achieving NED vs PR, respectively (p<0.01). 5 year OS rates were 92% vs 76%, in patients achieving NED vs PR (p=0.1).

Background: The management of patients with refractory or relapsed Hodgkin lymphoma (HL), especially after autologous stem cell transplantation (ASCT), remains controversial. Bendamustine has demonstrated efficacy in several lymphoproliferative disorders but limited data are available regarding the schedule in patients with HL, in particular its dosages and the possible combinations for a synergistic effect. Brentuximab Vedotin is a CD30-directed antibody-drug conjugate, currently approved for the treatment of relapsed or refractory HL.

Aims: The objective of this retrospective observational trial was to evaluate efficacy and safety of salvage cytotoxic regimens in patients with refractory and/or relapsed HL. Three different regimens were evaluated.

Methods: From May 2011 to December 2016, 32 consecutive patients (19 M/13 F) with a median age of 31.7 years (range, 16-73) received a salvage regimen after failure of ASCT. Patients were by chance assigned to one of these three arms: standard dose bendamustine (90mg/sqm) days 1 and 2 plus standard DHAP schedule (every 4 weeks) x 3 cycles (Arm A, n= 10 cases), brentuximab single agent 1.8mg/kg (every 3 weeks) x 4-8 cycles (Arm B, n= 11 cases), high dose bendamustine (120mg/sqm) days 1 and 2 plus brentuximab 1.8mg/kg (day 3) x 4-6 cycles (Arm C, n= 11 cases). Each cycle in arm C was repeated every 28 days and growth factor support was systematically administered, in association with antimicrobial prophylaxis. The treatment efficacy in each arm was evaluated according to Revised Response Criteria for Malignant Lymphoma by Cheson et al. Adverse events occurred were recorded and classified for type and grade using NCI-CTCAE criteria (v 4.0).

Results: In arm A, the overall response rate (ORR) was 40% (4/10 patients), with 4 (40%) complete remission (CR) and 6 (60%) progressive disease (PD). Hematological toxicity was grade 3 thrombocytopenia in 4 patients (40%) and bone marrow aplasia in 1 patient (10%); extra-hematological toxicity was gastrointestinal toxicity of grade 2 in 6 patients (60%) and grade 1 in 3 patients (30%), in arm B, ORR was 63.6% (7/11 patients), with 5 (45%) CR, 2 (18%) partial response (PR) and 4 (36%) PD. Hematological toxicity was grade 2 neutropenia in 4 patients (36%), extra-hematological toxicity was grade 3 neuropathy in 2 patients (18%). In arm C, ORR was 100% (11/11 patients), with 11 CR followed by SCT (second autologous transplant, 6 cases; and haploidentical transplant, 5 cases) with persistence of complete remission in all patients at a median follow-up of 33.4 months (range, 12-60). Hematological toxicity was grade 3 thrombocytopenia in 4 patients (36.3%); extra-hematological toxicities were increase of transaminase (grade 2) in 2 patients (27%), and cytomegalovirus (CMV) reactivation in 2 patients (18%), treated successfully with valganciclovir. Three patients had fever during infusion at first cycle, together with a skin rash, managed with corticosteroid injections, and a successful antihistamine plus corticosteroid prophylaxis in the next cycles of treatment.
Rome, 2Clinica di Ematologia, AOU Ospedali Riuniti Università Politecnica delle Marche, Ancona, 3associazione Onlus Gemme dormienti, 4Unità di ginecologia, Ospedale San Carlo di Nancy, Rome, Italy

Background: In the last decades, Hodgkin and Non-Hodgkin Lymphoma (HL- NHL) therapies have resulted in high cure rates and increased survival. However, up to 30% of patients (N=50) experienced late toxicities, such as, gonadal toxicity that can result in permanent sterility.

Aims: to evaluate different aspects of fertility (menstrual status, pregnancy, and menopause) in women with HL and NHL in reproductive age before and after chemotherapy.

Methods: By a phone interview we administered a questionnaire to the patients. The interview was composed of questions concerning reproduction (pregnancies, menses and abortion) and also menopausal status. The analyses were made using data collected in a cohort 109 women patients from two Italian hematologic centers. Statistical analysis was carried out in Graphpad® system, data were compared by the chi-square (P value <0.05) to consider to be statistically significant.

Results: the median age (in years) at the time of the treatment was 31 (range 16-49), 69/109 (63%) had HL and 40/109 (37%) NHL. 74/109 [EST] (64%) of the patients had a stage I-II. All HL patients were treated with ABVD, whereas the NHL patients were treated with R-CHOP (20%) or similar regimens (16%), respectively. Radiotherapy was delivered to 62/109 (57%) of the sample. Complete Remission (CR) was obtained by the 101/109 (93%) and only 16/101 (16%) relapsed. Considering the gynecologic history of the patients there were no statistically significant difference between the regularity of menses and the event of an abortion pre and post treatment. As for pregnancies, 35% of patients had children before therapy and 17% after. Among these 109 patients, 68/109 (62%) received gonadotropin-releasing hormone (GnRH) analogues and/or oral contraception, while 41 (38%) were not treated with hormonal therapy. Among the 68 patients who received hormonal therapy the regularity of menses recovered in 61/68 (90%) while in those of the control group a recover of menses was observed in 20/41 (48%). This difference was statistically significant (P<0.05). The same was observed as for early menopause. In this case excluding patients who had a natural menopause, a lower cases of early menopause was observed in those who received hormone therapy (8/65, 12%) versus control cases 33/40 (82%), respectively (P<0.05). Considering only the 81/109 (74%) patients who had regular menses after chemotherapy, 61/81 (75%) received hormonal therapy and 20/81 (25%) were not treated with hormonal therapy. Before treatment for lymphoma, 16% of patients belonging to the hormonal group had pregnancies versus 45% of the control group (P<0.05). Following therapy, pregnancies were observed in 23% of these receiving hormonal therapy vs 5% of the control group (P<0.05).

Summary/Conclusions: The use of hormonal therapy is fundamental not only to favor of pregnancies and motherhood but in particular to avoid the consequences of an irregular cycle or an early menopause with its symptoms and clinical implications.

25(OH) D SERUM LEVELS IN Hodgkin Lymphoma

A. Cuccaro1,*, E. Galli1, F. Visconti1, I. Zangrilli1, F. Corrente1, S. Bellesi1, E.1124

Background: Vitamin D has pleiotropic effects on cellular differentiation, proliferation, apoptosis and angiogenesis in addition to maintaining serum calcium and skeletal homeostasis. Several studies suggest that low serum 25(OH)D levels may be associated with inferior outcome in solid tumors as colorectal and breast cancer, and in Non-Hodgkin lymphomas [Drake et al, J Clin Oncol 2015; 33:1482]. 25(OH)Vitamin D levels have not been reported for Hodgkin Lymphoma (HL).

Aims: To evaluate 25(OH)D serum levels in patients newly diagnosed with NHL. The aim was to compare the efficacy and safety of the conventional chemotherapy plus irradiation versus the R-including treatment of patients with NHL.

Methods: Within a retrospective study, we collected the medical records of 24 consecutive adult patients with NLPHL, taken from the total of 484 patients with NHL who referred to our institution from 1 October 2001 to 31 July 2014. According to our institutional guidelines, the 12 patients diagnosed from 1st January 2001 to November 2007 received a treatment based on ABVD with/without involved-field radiotherapy (IFRT). Treatment was modulated according to the stage. The 9 patients with stages I and II received 4 courses of ABVD plus IFRT, while 3 patients in stages III or IV received 6 cycles of ABVD. The subsequent 12 patients (diagnosis from December 2007 to July 2014) received R (375mg/m2) along with or ABVD. The stage-adapted strategy of therapy was applied for these patients, as well. The 5 patients with early favourable disease according to the stage and of baseline EGFR2 risk factors, received R as single agent (once per week for four consecutive weeks) followed by R maintenance (MR) (once every three months for 2 years); the 2 patients with early unfavorable stage were treated with R (once per month on day 1) plus 4 cycles of ABVD, while the remaining 5 advanced stage patients received R (on day 1 and 15) plus ABVD for 6 cycles. The primary end-point was DFS rate, and secondary end-points were ORR and treatment-related toxicity evaluation.

E1125

NODULAR LYMPHOCYTE PREDOMINANT HODGKIN LYMPHOMA: A NEW RISK ADAPTED TREATMENT STRATEGY BASED ON RITUXIMAB

A. Cuccaro 1,*, E. Galil, F. Visconti, I. Zangrilli, F. Corrente, C. Santoni, A. Cuccaro 1

Background: Nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) is a rare variant of Hodgkin’s lymphoma (HL), that only accounts for 5% of all HL. Due to its rarity, consolidated and widely accepted guidelines of treatment still lack for this type of HL. Due to NLPHL cells expression of CD20, targeted therapy with Rituximab (R), a chimeric anti-CD20 monoclonal antibody, has been explored as a treatment option.

Aims: This study analyzed two different risk-adapted therapeutic strategies to cure patients newly diagnosed with NLPHL. The aim was to compare the efficacy and safety of the conventional chemotherapy plus irradiation versus the R-including treatment of patients with NLPHL.

Methods: Within a retrospective study, we collected the medical records of 24 consecutive adult patients with NLPHL, taken from the total of 484 patients with NHL who referred to our institution from 1 October 2001 to 31 July 2014. According to our institutional guidelines, the 12 patients diagnosed from 1 October 2001 to November 2007 received a treatment based on ABVD with/without involved-field radiotherapy (IFRT). Treatment was modulated according to the stage. The 9 patients with stages I and II received 4 courses of ABVD plus IFRT, while 3 patients in stages III or IV received 6 cycles of ABVD. The subsequent 12 patients (diagnosis from December 2007 to July 2014) received R (375mg/m2) alone or combined with ABVD. The stage-adapted strategy of therapy was applied for these patients, as well. The 5 patients with early favourable disease according to the stage and of baseline EGFR2 risk factors, received R as single agent (once per week for four consecutive weeks) followed by R maintenance (MR) (once every three months for 2 years); the 2 patients with early unfavorable stage were treated with R (once per month on day 1) plus 4 cycles of ABVD, while the remaining 5 advanced stage patients received R (on day 1 and 15) plus ABVD for 6 cycles. The primary end-point was DFS rate, and secondary end-points were ORR and treatment-related toxicity evaluation.

Results: At final restaging, 4 weeks after the cycle of treatment or completion of IFRT, 23/24 patients (95.8%) were in CR while one patient showed refractory disease and was addressed to rescue therapy with autologous hematopoietic stem cell transplantation.
stem cell transplantation (ASCT). Patients treated with R alone or R+ABVD had better DFS (p=0.04) than those treated with ABVD with/without IFRT. Specifically, the year Kaplan-Meier estimates for DFS were 100% for the R treated group versus 50% for those treated with ABVD with/without IFRT. Four patients in the latter group, showed insufficient response to the therapy: 1 refractory disease in the early stage group and 3 recurrent diseases in the advanced stage group were recorded. The median follow-up time of the entire cohort of patients was 4.3 years (range, 0.5-8.2 years). Over the study period, one patient died for infectious pneumonitis due to severe neutropenia following the last cycle of R-ABVD. Of the 9 patients treated with addition of IFRT, adverse events regarded mainly thyroid (4), bone (2), lung (1) and salivary glands (1). Nobody developed a secondary malignancy.

Summary/Conclusions: Our results confirm the value of R in NLPHL and show that R induction and maintenance combined with chemotherapy only in the presence of risk factors or in more advanced stages give excellent treatment results. Resistant radio-chemotherapy either in term of ORR and of DFS while sparing long term toxicity usually seen in patients affected by classical HL who receive chemo and irradiation.

E1126

CASE-BASED LEARNING IN CONTINUING EDUCATION: IMPROVING HEMATOLOGIST/ONCOLOGIST EVIDENCE-BASED DECISIONS FOR PREVENTING HODGKIN LYMPHOMA POST-TRANSPLANT RELAPSE

P. Repetto1,2, C. Moskowitz3
1Oncology, Medscape, Grovelille, 2Oncology, Memorial Sloan Kettering Cancer Center, New York, United States

Background: Several prognostic factors have been identified as associated with a higher rate of relapse after autologous stem cell transplantation (ASCT) for patients with Hodgkin lymphoma (HL). Due to the rarity of this disease, many hematologists/oncologists (hem/oncs), especially those in the community setting, lack experience in correctly identifying patients who may be at risk of post-transplant relapse. Proper risk assessment and understanding of treatment options in the pre- and post-transplant setting are critical to ensure optimal longer progression-free survival for qualified patients.

Aims: Underlying clinical practice gaps and educational needs were identified, and a study was conducted to determine whether an online, case-based educational intervention could improve knowledge, competence, and confidence of hem/oncs in managing patients with HL.

Methods: The educational format presented patient case scenarios (2) followed by a series of 4-5 questions that “tested” learner knowledge and competence before delivering the education focused on the optimal approach to the case using evidence-based medicine. Case questions assessed degree of patient risk for disease relapse or progression prior to ASCT and consolidation strategies, taking into consideration patients’ prior received therapies. To assess educational effectiveness, participants served as their own controls by responding to a series of questions again after (post-assessment) exposure to the content. For all questions combined, the McNemar’s chi-square test assessed differences from pre- to post-assessment. P values are shown as a measure of significance. P values <0.05 are statistically significant. Cramer’s V calculation determined the change in proportion of 184 participants who answered questions correctly from pre- to post-assessment and who qualified for the study.

Results: At post-assessment, there was a large effect to the education (V=0.442), indicating a sizable improvement in evidence-based choices and significant improvement in knowledge, competence, and confidence related to managing patients with HL, including: 138% relative improvement regarding the implications of type and number of prognostic factors on risk of HL relapse and benefit of consolidation brentuximab vedotin after ASCT (P<.001); 101% relative improvement in knowledge that a higher rate of relapse after ASCT is associated with a CR duration of less than 1 year, extranodal disease at relapse, and the presence of symptoms at relapse (P<.001); 5% relative improvement in knowledge regarding the efficacy of brentuximab vedotin in relapsed/refractory HL after ASCT (P<.001); Responses to a self-efficacy question indicated that 42% of hematologists became more confident in managing a patient on consolidation therapy for HL after participating in the education.

Summary/Conclusions: This study demonstrated the success of an online, case-based format using a predisposing pre/post-assessment was effective in improving the evidence-based practice patterns of hem/oncs in the management of patients with HL. Despite the marked improvement in knowledge, competence, and confidence, hematologist education needs specific to accurate risk assessment, treatment selection, and adverse effect monitoring remain.

The education gaps uncovered during this intervention and the evolving treatment landscape outside of the United States lay a foundation for future global education initiatives to bridge education gaps in HL.

E1127

QUANTITATIVE PET PARAMETERS PREDICTS OUTCOME IN PATIENTS WITH HODGKIN’S LYMPHOMA

E. Knetuyk1, O. Karpova1, L. Mykhalska1, O. Kindrakevych3, G. Pylypenko1, E. Lukjanec4, V. Duma4, V. Kozlov5, L. Batyuk1, O. Ryzhak1, N. Strembitska4, H. Chikalova4, M. Chupryna1, I. Kozlov6
1Onchoematology, National Cancer Institute, 2Radiology, 3Hematology, Clinical Hospital “Feofaniya”, Kiev, 4Hematology, Regional Oncology Center, Cherkassy, 5Hematology, Regional Clinical Hospital, 6Hematology, National Medical University, Odessa, Ukraine

Background: Positron emission tomography [18F] fluoroexoxyglucose (FDG-PET) has emerged as the standard response assessment after 1st line therapy for classical Hodgkin’s lymphoma (HL). Quantitative PET parameters are not well established as a predictive factor for disease progression in HL.

Aims: Thus, the aim of this study was to test the hypothesis that tumor burden characterized by mean standardized uptake value (SUVmean), maximum SUV (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) could be independent prognostic factors.

Methods: We analyzed the relation of absolute value PET parameters, negative predictive value (negative PET scan and no treatment failure, NPV) and positive predictive value (positive PET scan and treatment failure, PPV) with event-free survival (EFS) or overall survival (OS). Quantitative PET parameters of the baseline (PET-1), interim (PET-2) and end of treatment (PET-3) PET-CT scans were investigated in the retrospective study. MTV was computed by using the 41% maximum SUV thresholding method, and the optimal cut-off for survival prediction was determined.

Results: Thirty one patients with HL with a stage I-I–51.6%, III–IV–48.4% consecutively admitted from April 2009 to December 2016, by 5 Ukrainian hematological centers were included in the analysis. Patients were staged at baseline, after 2-4 cycles of chemotherapy with PET/CT and at the end of chemotherapy. All patients were treated with ABVD, BEACOPP-14/esc. All 31 patients achieved CR or PR and 67.7% had a negative PET-2, while 16.3% had a positive PET-2. Patients with negative PET-2 and positive PET-2 had CR rates of 64,5% and 12,1%, respectively, which yielded a PPV of 26% and NPV of 74%. ROC analysis revealed that PPV and NPV are an important markers associated with EFS in patients with HL (Se=100%; Sp=100%; AUC=1.0). 3-year EFS was 100% for NPV patients and 12% for PPV patients, which was statistically significant (p<0.001). AUC was 0.7 for PPV patients and 0.9 for NPV patients, respectively (p<0.01). Quantitative parameters at PET-1 and PET-2 were not statistically significant in predicting clinical outcome in this study. This may be due to the small sample size in our study. PET-3 was negative in 67,7% cases. ROC analysis showed that TLG at PET-3 is an important marker associated with reduced EFS in patients with HL (Se=75%; Sp=100%; AUC=0.97, p<0.0001). 3-year EFS was 80% and 25% in patients with MTV<4.75 and MTV>4.75, respectively (p=0.005). Also, ROC analysis revealed that TLG at PET-3 was associated with decrease EFS in patients with HL (Se=75%; Sp=100%; AUC=0.97, p<0.0001). Multivariate analysis confirmed TLG and TLG at PET-3 were the only significant variables for EFS with HRs of 1.07 [95% confidence interval(CI) 1.0–1.15, p=0.003] and 2.9 [95% (CI) 9.10–1.3, p=0.05], respectively. The PET-3 SUVmax and SUVmean were not statistically significant in predicting EFS.

Summary/Conclusions: Quantitative PET parameters may play a predictive role for identifying patients at high risk of treatment failure. These results should be evaluated prospectively in larger cohorts with longer follow-up.

BIOMARKER ANALYSIS OF PATIENTS WITH FOLLICULAR LYMPHOMA TREATED WITH IBRUTINIB IN THE PHASE 2 DAWN STUDY

1Hospices Civils de Lyon-Université de Lyon, Pierre-Bénite cedex, Lyon, France; 2The University of Washington/Fred Hutchinson Cancer Research Center, Seattle Cancer Care Alliance, Seattle, WA; 3Lymphoma Program, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA, United States; 4Haematology Department, Concord Hospital, University of Sydney, Sydney, NSW, Australia; 5Department of Hematology/Oncology, Johannes Gutenberg University, Langenbeckstr, Mainz, Germany; 6Division of Hematology/Oncology, University of Pittsburgh Medical Center and University of Pittsburgh Cancer Institute, Pittsburgh, PA, USA; 7University of Kansas Medical Center, Kansas City, KS, USA; 8Cedars-Sinai Medical Center, Los Angeles, CA, USA; 9Weill Cornell Medical College, New York, NY, USA; 10Hematology, Azienda Ospedaliero Universitaria Città della Salute e della Scienza di Torino, Turin, Italy; 11Alfred Hospital–Monash University, Melbourne, Australia, 12University of Manchester and the Christie NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom; 13Department of Hematology, Jagiellonian University, Kraków, Poland; 14Haematology and Oncology Clinics of Australia, Milton, QLD, Australia; 15Blokbin Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation; 16Instituto Biosanitario de Salamanca (IBSAL), Hospital Clínico Universitario, Salamanca, Spain; 17Janssen Research & Development, Raritan, NJ, United States; 18Janssen Research & Development, Leiden, Netherland, 19Lombardi Comprehensive Cancer Center, Georgetown University Hospital, Washington, DC, USA; 20Department of Lymphoma/Myeloma, University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: Ibrutinib, a first-in-class, oral, covalent inhibitor of Bruton’s tyrosine kinase, has demonstrated robust clinical activity and is approved in various B-cell non-Hodgkin’s lymphomas. To assess the efficacy and safety of ibrutinib in patients (pts) with follicular lymphoma (FL), the DAWN study (FLR2002-2) investigated single-agent ibrutinib in chemoimmunotherapy in patients (pts) with FL, small lymphocytic lymphoma (SLL), or marginal zone lymphoma (MZL). Aims: To determine the effect of ibrutinib on circulating T-cells, chemokines, and cytokines in ibrutinib-treated CIT-refractory FL pts.

Methods: The DAWN study was an open-label, multicenter, single-arm, phase 2 study of ibrutinib in pts with CIT-refractory (i.e., ≥3 prior lines of treatment and progressive disease [PD]) ≥12 months after last dose of a CIT regimen. All pts received ibrutinib (560 mg QD) on a 21-day cycle until PD or unacceptable toxicity. The primary end point was Independent Review Committee (IRC)-assessed overall response rate (ORR) (complete response [CR] + partial response [PR]). Flow cytometry assessed T-cell subsets in blood at baseline (C1D1) and at cycle 3 (C3D1) for 57 pts (14 responders and 43 nonresponders); cytokine and chemokine analyses were performed at C1D1 and at cycle 2 (C2D1) for 50 pts (21 responders and 29 nonresponders).

Results: Results from the DAWN study have been presented previously (Gopal A et al. ASH 2016). Briefly, 110 pts with a median age of 61.5 years and a median of 3 prior therapies were enrolled. Ibrutinib achieved an ORR of 20.9% (CR rate, 10.9%) and a median duration of response of 19.4 months. Flow cytometry analysis revealed significant downregulation of CD4+CD25+FoxP3+ at C3D1 in 14 responders (CR + PR, mean decrease 17 to 12.9% CD4+ FoxP3+ vs 20.9% at C1D1, p=0.0003). From a large panel of inflammation-related cytokines and chemokines, some of the most significant changes at C2D1 were the Th1 cytokines interferon (IFN)-γ and interleukin (IL)-12, both of which were increased in responders but decreased in nonresponders (p=0.0025 and p=0.035, respectively, Figure 1). Conversely, the chemokines IFN-α-induced protein 10 (IP-10) and monocyte-chemotactic protein 3 (MCP-3) were decreased in responders but increased in nonresponders (p=0.022 and p=0.016, respectively).

Summary/Conclusions: Here we show immunomodulatory effects of ibrutinib in pts with CIT-refractory FL, which may be related to response to therapy. In responders, pts at early time points, downregulation of Th1 cells was observed, along with increases in Th1-associated cytokines IFN-γ and IL-12. This shift in T-cell population may be linked to the antitumor response; in nonresponders, these cytokines were decreased but Th1 was not. Chemokine changes observed also indicate variation in chemotraction of T-cells and monocytes/macrophages. These data suggest that immunomodulatory effects of ibrutinib could play a role in its antitumor activity in FL, so combinations with other immune-oncology therapies may prove beneficial.

E1130

DYNAMO: THE CLINICAL ACTIVITY OF DUVELISIB IN PATIENTS WITH CIT-REFRACTORY SMALL LYMPHOCYTIC LYMPHOMA IN A PHASE 2 STUDY

P.L. Zinzani1, N. Wagner-Johnston2, C. Miller3, S. Tretreaul4, F. Passamonti5, S. Lunini6, H. Youssoufiouan7, J. Porter8, S. Prados9, J. Finn10

1Institute of Hematology Seràgnoli, University of Bologna, Bologna, Italy; 2Site- man Cancer Center, Washington University, St Louis, MO, United States; 3Florida Cancer Specialists - Tallahassee, Tallahassee, United States; 4University Hospital Ospedale di Circolo, Varese, Italy; 5Florida Cancer Specialist, Fort Myers, FL, Verastem Inc, Needham, MA, Tenessee Oncology, Nashville, United States

Background: Duvelisib is an oral, dual inhibitor of PI3K-δ,γ in development for the treatment of hematologic malignancies. DYNAMO is a Phase 2 study to evaluate the safety and efficacy of duvelisib in a double refractory iNHL population, which included 28 patients (pts) with small lymphocytic lymphoma (SLL) or lymphoplasmacytic lymphoma (PLL).

Aims: The primary objective was to evaluate the antitumor activity of duvelisib monotherapy in pts whose disease is refractory to rituximab and to either chemotherapy or RIT, with an additional objective to further characterize the safety duvelisib.

Methods: DYNAMO is an open-label, single-arm, safety, and efficacy study in patients (pts) with FL, small lymphocytic lymphoma (SLL), or marginal zone lymphoma (MZL), whose disease is double refractory to rituximab (monotherapy or in combination) and to chemotherapy or radioimmunotherapy. Pts received duvelisib 25mg BID in 28-day treatment cycles until disease progression, unacceptable toxicity, or overall toxicity. The primary endpoint was independent review committee (IRC)-assessed overall response rate (ORR) as assessed by an independent review committee (IRC) per revised IWG criteria. Secondary endpoints include duration of response (DoR), progression-free survival (PFS), overall survival (OS), time to response (TTR), adverse events (AEs), and changes in safety laboratory values. Pneumocystis jiroveci pneumonia (PJP) prophylaxis was mandated for all pts receiving duvelisib.

Results: 129 pts with iNHL were treated on study. Of these, 28 pts with SLL received duvelisib with a median duration of exposure of 9 mo. (range 6.5-12). Median age was 65 years; 68% were male. Most SLL pts had either relapsed or refractory disease at time of study entry. Median time from last anticancer therapy to first dose of duvelisib was 3 months. SLL pts received a median of 3 prior anticancer regimens (range: 1-18); 43% of pts received ≥4 prior anticancer regimens, 29% ≥6 regimens. The ORR for SLL pts received a median of 3 prior anticancer regimens, 29% of pts were not assessable. Per Investigator assessment, the ORR was 79% (including 1 CR). Median time to IRC response was 1.9 months (range 1.4-5.5). 93% of pts had a reduction in nodal target

Figure 1.
lesions. Among the 19 SLL pts with a response per IRC, the median DOR was 9.8 months. The median PFS among all SLL pts was 11.3 months, while the median OS was not reached. The estimated probability of survival at 12 months was 83.9%. Among all pts treated (n=129), AEs were mostly Gr 1-2. Most common ≥ Gr 3 AEs were transient cytopenias (neutropenia [23%], anemia [12%], and thrombocytopenia [10%]), and diarrhea (15%). 4 SLL pts had SAEs that led to discontinuation of duvelisib: NSCLC, neuroendocrine carcinoma of the skin, pseudomembranous colitis, and pneumonia. Two SLL pts has a fatal AE, 1 pneumonia and 1 viral infection.

Summary/Conclusions: In DYNAMO, duvelisib showed clinical activity in a double-refractory SLL population (68% ORR, median DOR 9.8 mo., 93% with a reduction in target lesions). Duvelisib was generally well tolerated, with a manageable safety profile with appropriate risk mitigation. Duvelisib monotherapy appears to have a favorable benefit-risk profile in double refractory SLL. Updated clinical data will be available at the time of presentation.

E1132
WALDENSTROM MACROGLOBULINEMIA: UK REAL WORLD EXPERIENCE
D. El-Sharkawi1, H. Renshaw1, M. Lunn2, D. Hughes3, A. Rismani1, S. D’Sa1
1Cancer Division, University College London Hospital (UCLH), 2Peripheral Nerve Service, National Hospital for Neurology and Neurosurgery, 3Haematology, UCL, London, United Kingdom

Background: There are few randomised controlled trials in Waldenström macroglobulinemia (WM) due to its rarity and indolent nature. As a result, there is no standard treatment approach and management is variable.

Aims: The aim of this retrospective study was to review “real world” management of WM in the UK and correlate this with survival outcomes.

Methods: All patients with a diagnosis of WM seen at ULCH between 01/07/2002 and 31/12/2016 were included. Patient characteristics, presenting features, lines of treatment, responses and overall outcome were recorded. IPSSWM where available, was calculated at time of first treatment. Survival was estimated using Kaplan-Meier analysis from time of first treatment and P values calculated using the log-rank test.

Figure 1. Results: A total of 211 patients were identified (116 M/ 95 F), median age 60 yrs (range 34-89). Presenting symptoms included anaemia, n=33; neuropathy, n=19; fatigue, n=18; hypertensive symptoms, n=13; lymphadenopathy, n=6; progression fromMGUS, n=5; B symptoms, n=5; other, n=28; unknown, n=55. Mutated MYD88 was seen in 59 of 72 cases analysed (82%). Of these 59 cases, 13 were CXCR4 mutated. IPSSWM was known in 150 cases of whom 64 were in low, 63 intermediate and 23 high risk groups. Median follow-up from first appointment was 64 months (range 0-394). The median number of lines of therapy was 2 (range 0-9). Dexamethasone, rituximab and cyclophosphamide (DRC) was given to 62 patients upfront, 52 had other cyclophosphamide containing regimens e.g. CHOP +/- rituximab, 29 had Chlorambucil-based regimen, 14 R-bendamustine, 15 fludarabine-based with a minority getting R- cladribine (5) or R-bortezomib (4), 9 pts had no treatment at all cut-off. Notably, DRC was given to 1 patient before 2009, 28% of patients between 2009 and 2013, and 41% from 2013. In the 149 cases with known responses to first line treatment, 11% achieved a CR (7 patients with R-CHOP, 4 DRC, 2 fludarabine containing regimen, and 3 patients other treatment), 63% PR/VGPR, 21% no response or PD and 5% stopped due to toxicity. For the 52 patients who had DRC chemotherapy, median PFS was 61 months. Of those patients who had at least 3 lines of chemotherapy (n=62), median time between 1st and 2nd line treatment was 27 months between 2nd and 3rd line. Transplants were performed on 28 patients after a median of 2 lines of chemotherapy. Median overall survival (OS) has not been reached in the 195 patients with available data. Stratifying by IPSSWM shows median OS for the low risk group has not been reached, 11 years for the intermediate risk and 9 years for the high risk group. P=0.29 (Figure). Patients had a significantly reduced OS if they developed Bing Neel syndrome or high grade transformation compared to other known complications of WM. Despite differences in chemotherapy strategies over the past two decades, there was no difference in outcome in patients treated before 2005, between 2005-2009, 2009-2013 and 2013 onwards. Of the 34 deceased patients, the cause of death was unknown in 3 cases, due to PD in 16 and other causes in 15 cases.

Summary/Conclusions: The management of patients with WM in this large case series reflects the variability of treatment given over time and also geographically. UCLH treats both a local and tertiary referral patient population, thus it is not completely typical. Survival data confirms the IPSSWM is likely to still differentiate patients into prognostic groups but the overall prognosis is better than when first published. With the advent of targeted therapies, it is imperative to perform randomised controlled trials and to collect data prospectively in order to elucidate the optimal management. To this end, a WM Biobank and Registry has been set up at our centre.

E1133
CLINICAL CHARACTERISTICS AND LONG-TERM RESULTS OF TREATMENT OF INDOLENT NON-HODGKIN’S LYMPHOMA ASSOCIATED WITH HEPATITIS C (IL + C)
1Russian National Research Medical University named after N.I. Pirogov, 2Research and Treatment Center for Haematology, 3National Research Center for Oncology named after N.N. Blochin, 4City Clinical Hospital named after C.P. Botkin, 5City Clinical Hospital named after V.M. Buyanov, 6City Clinical Hospital named after V.M. Buyanov, Moscow, Russian Federation

Background: According to the WHO classification (2008) hepatitis C virus is one of the causese of non-Hodgkin lymphoma. The incidence of chronic hepatitis C (HCV) in patients with indolent B-cell non-Hodgkin’s lymphoma (IL+C) is 15%. Diagnosis of hepatitis C related lymphoma (IL+C) is established in cases with abnormal liver function tests or the presence of proteins of hepatitis C virus. These proteins could be defined by immunohistochemistry (IHC).

Aims: The aim of this work was evaluation of the results of treatment of IL associated with hepatitis C in comparison with a control group of patients with IL without viral hepatitis markers.

Methods: The study included 107 patients with indolent lymphoma who were identified in the blood markers of hepatitis C.

Results: Histological types were follicular lymphoma - 74%, marginal zone lymphoma - 32%. The age of patients ranged from 28 to 82 years (median 50). Men / women ratio was 1: 1. Stage I + II were in 3%, III stage was in 24% of patients, IV stage was at 73% of patients. Primary extranodal lymphoma was diagnosed in 33% of patients. Extranodal lesions: splenic lesion - in 53% of patients, liver injury - 21% of the patients, the bone marrow - 62% of patients. LDH > 450 IU / l was at 76% cases, ALT >40 IU / l was at 82% of cases, albumin <35 g / l was at 31% of patients. 57 patients were treated with interferon and Ribavirin as a first-line treatment. Treatment lasted for 2 years after achieving the antitumor effect. 50 patients were treated with immunochemotherapy (R-CHOP, R-CVP) as a first-line treatment. Antiviral therapy was effective in 88% patients, immunochemotherapy was effective in 64% of patients. Median progression-free survival in patients with IL + C treated with antiviral treatment was 42 months, in patients with IL + C treated with immunochemotherapy - 19 months (p=0.00001). Five-year overall survival was 67% and 32%, respectively (p=0.0003). It was diagnosed disease relapses after immunochemotherapy in 39% of patients. All the patients in the second-line was received antiviral treatment. Twenty-seven patients were assigned to the ongoing antiviral therapy. 13 of 35 cases of patients. Medi- an progression-free survival in relapsed lymphoma was 31 months.

Summary/Conclusions: Antiviral therapy in first-line and relapse of disease surpasses all the indicators of efficiency of treatment IL + HCV. In this category of patients preferred option is to conduct anti-viral treatment.
(R every 8 weeks for 4 or 12 doses) still appears as an optional part of the therapy (NCCN V3.2016). Radioimmunotherapy with 90Ytrium-bromomab tiuxetan (90Y-IT) is available in our institution since 2006 and more than 100 patients have been treated with RIT since then. Here an institutional analysis focus in their use as consolidation is presented

**Aims:** To analyze the experience with 90Y-IT as a consolidation therapy in patients in CR after first-line therapy.

**Methods:** A retrospective analysis was performed including all the patients that have received RIT with 90Y-IT. Inclusion criteria were: patients 18 years or older with a grade 1-2a follicular lymphoma, RIT was received as a consolidation therapy in complete response (CR) after a first-line therapy. Demographic and follow-up data were included. International working group (IWG) criteria of response was used. Progression free survival (PFS) was calculated from the date of RIT to the date of a confirmed relapse according IWG criteria, overall survival (OS) was calculated from the FL diagnosis to the last contact.

**Results:** A total of 31 FL patients have received 90Y-IT been in CR after a first-line therapy and were included for the study. Mean age at diagnosis was 61.2 (29-86) years with a female predominance (19, 61.3% vs 12, 38.7%). 80.6% (26) with ECOC O-1 and 19.4 ECOC 2. A third of them (10, 32.3%) were diagnosed with low tumor burden (stage I-II), 2 (6.7%) of them presented extra nodal infiltration (subcutaneous and gut) and 12 (38.7%) showed bone marrow infiltration demonstrated by flow cytometer or biopsy. There were no patients with bulky disease. Stages: I: 7 (22.6%), II: 3 (9.7%), III: 9 (29.1%), IV: 12 (38.7%). As first-line therapy the patients received: Rx4: 11 (35.5%) cases, R-Cyclophosphamide vincristine prednisone (COPx4): 3 (9.7%) cases and 17 (54.8) R-cyclophosphamide doxorubicin, vincristine and prednisone (R-CHOPx4). The median follow-up was 58.0 (10-107) months. During this time only 5 (16.1%) of patients have relapsed and need another therapy. None of the patients that have received R-CHOP+90Y-IT have relapsed; the relapsed patients received Rx4 (4) and R-COP (1). The median PFS after 90Y-IT has not reached, the mean was 93.3 (71.7-94.9) months, see Fig 1. Four (12.9%) patients have died, none of them were relapsed and the mortality was due other causes. The median OS was not reached, the mean was 95.8 (85.6-106.1) months. As long-term events one 82 years old patient developed a colon cancer after 67 months of RIT; one 72 years old female a breast cancer after 17 months of RIT and one 71 years patient amgUS after 24 months of RIT, none of them related with mortality events.

**Summary/Conclusions:** The use of immunotherapy with rituximab or combined schedules with immunochemotherapy (R-COP and R-CHOP) followed by consolidation with 90Y-IT remains as a valid option for follicular lymphoma patients. After ~6 years of follow-up: 63.6% (Rx4+RIT), 66.7% (R-COP+RIT) of patients have died, none of them related with mortality events.

**Figure 1.**

**E1135**

ASSESSING RISK OVER TIME IN PATIENTS WITH SYMPTOMATIC WALDENSTRÖM MACROGLOBULINEMIA (WM). A STUDY ON 114 PATIENTS

**Background:** Contrast, with follicular lymphoma (J Clin Oncol 2015;33:2516) or other chronic hematological malignancies (Blood 2009; 114:1299; Blood 2016:128;902), few results attempted to decipher the evolution of pts with WM, a disorder associated with delayed response to therapy in some pts.

**Aims:** To assess the prognostic role during the clinical course of initial interna
tional prognostic index (IPSSWM), response and progression (according to 6th International Workshop guidelines).

**Methods:** We took advantage of our continuously updated clinical database for reviewing a series of 114 symptomatic WM pts treated in our 2 institutions between 1993 and 2016 (median age 70, male/female ratio=1.91, high, low/intermediate and unavailable IPSSWM in 57, 36 and 21 pts respectively). Response rate after 1st line therapy was 70%. Sixty-two, 37 and 19 pts received a 2nd a 3rd and 4 to 6 lines of therapy respectively according to the 2nd International Workshop guidelines. Monitoring of serum monoclonal immunoglobulin concentration (SMIC) throughout the evolution of the disease was available in 106 pts. Informed consent was obtained according to the protocol submitted to the Institution Review Board.

**Results:** Median survival after 1st line was estimated 79 months. It was estima
ted 69 and 65 months after 2nd line and 3rd line respectively. High IPSSWM (hiPSSWM vs low/intermediate) retained prognostic value for survival after 1st treatment initiation (SAFTI, p=0.005). However, plot of hazard function showed a decrease of hazard ratio over time with a departure from the proportionality hazard hypothesis (Grambsch and Therneau test: p=0.053). Consequently, Dxy concordance index obtained in multiple landmarks analyses decreased from 0.27 to 0.12, during the first 6 years of follow-up. In Cox model of SAFTI with time dependent covariate, onset of response (whatever cut-off in SMIC and combination schemes). Time to next treatment (TTNT) seems to be a clin-
ically meaningful endpoint that incorporates both symptom control and disease progression. It has been investigated in few retrospective studies focusing on retinoids in monotherapy both in limited-stage and advanced stage MF, but up to now no data are available concerning the use of retinoids in combination.

**Summary/Conclusions:** The prognostic value of initial IPSSWM decreased in part during the first 6 years of evolution. Onset of progression and 2nd treat
tment initiation provided additional prognostic information for predicting SAFTI. Therefore progression-free survival or time to next treatment may be satisfac
tory surrogate endpoint of SAFTI in WM. Further international collaborative studies are mandatory for this purpose. Assessing response in more advanced phase of the disease may require specific tools.

**E1136**

TIME TO NEXT TREATMENT ANALYSIS FOR EARLY AND ADVANCED STAGES OF MYCOSIS FUNGOIDES /SEZARY SYNDROME TREATED WITH BEXAROTENE AND PUVA IN COMBINATION

**Background:** Bexarotene is a syntetic retinoid effective in early and advanced stages of Mycosis Fungoides (MF)/Sezary Syndrome (SS) both in monotherapy and combination schemes. Time to next treatment (TTNT) seems to be a clin
cially meaningful endpoint that incorporates both symptom control and disease progression. It has been investigated in few retrospective studies focusing on retinoids in monotherapy both in limited-stage and advanced stage MF, but up to now no data are available concerning the use of retinoids in combination.

**Aims:** To evaluate TTNT together with the usual time-to-event measures (OS and EFS) in our series of 21 refractory and/or relapsed patients with MF treated with Bexarotene and PUVA combination as reported recently published (Rupoli et al, EJD 2016). The follow-up of these protocols was pro
longed up to February 2017.

**Methods:** We recruited patients with stages I-IV MF who had failed PUVA (early disease) or several systemic regimens (early and advanced disease). We designed “mini” and “standard” protocols in which Bexarotene dose and PUVA administration were individually titrated, and tailored during induction and main
tenance according to previous therapy, disease stage and toxicity. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.
Results: We enrolled 21 patients, 12 males and 9 females, with median age of 67 years (range, 30-77), of which 15 affected by early MF (13 with stage IB, 2 with stage IIA) and 7 by advanced disease (2 with stage IIB, 2 with stage IIIA, 1 with stage IIIB and 1 with stage IVA). Six patients had previously received PUVA therapy only, while fifteen patients had received other therapies. The protocol proved to be effective, well tolerated and able to induce an overall response of 85.6% at the end of induction phase (93.4% of early stage patients and 66.6% of advanced stage patients) and of 76.2% at the end of maintenance phase (86.7% of early stage patients and 14.2% of advanced stage patients). Median follow up for all patients was 85 months (6-118) with respectively 98 months (21-118) for early stages and 46 months (6-102) for advanced stages. For the entire cohort, median OS, PFS and TTNT were not reached; mean values of OS, PFS and TTNT were respectively, 105, 103 and 72 months and median EFS was 33 months. For the early stage MF cohort, the median OS, PFS and TTNT were not reached; mean values of OS, PFS and TTNT were respectively, 105, 103 and 79 months, and median EFS was 58 months. For advanced stage patients, median OS, PFS, EFS and TTNT were 32, 29, 18 and 39 months respectively.

Summary/Conclusions: Our combination treatment seems to have superior TTNT compared to data published in the literature for PUVA and bexarotene used in monotherapy. When considering early and advanced MF, 66% of our patients are estimated to be free from further treatment at 2 years, a higher percentage compared to the results of Hughes et al. (Blood, 2015) for patients treated with PUVA (54.2%) or bexarotene (36.8%) as single agents. Moreover, TTNT seems to be longer in our study than in the study by Hanel et al (AJH 2016) on patients treated by retinoids in monotherapy, respectively 79 vs 60 months (mean TTNT values) in the early stages and 39 vs 9 months (median TTNT values) in the advanced stages. We believe that our results strongly suggest a synergistic or additive effect between PUVA and bexarotene compared to either agent alone in the treatment of both limited-stage and advanced stage MF.

E1137
PERIPHERAL BLOOD INVOLVEMENT IN PATIENTS WITH ADVANCED STAGE FOLLICULAR LYMPHOMA: CLINICAL-BIOLoGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT
A. Rivas-Delgado1,*, L. Magnano 2, P. Mozas 1, I. Dlouhy 1, J. Rovira 1

Methods: We selected 304 patients in stage IV out of 654 patients diagnosed with FL between 1991 and 2014 in a single institution. Patients with a diffuse large B-cell lymphoma component, histological grade 3b and primary cutaneous FL were not included. Fifty-six (18%) had PB involvement (PB+ ) defined by the presence of circulating FL cells by morphology, further confirmed by immunophenotyping. The main clinical and biological characteristics, response to treatment and outcome were analyzed.

Results: Patients with PB+ more frequently had splenic involvement, anemia, elevated β2-microglobulin and LDH and high FLIPI score than those without PB involvement (PB- ) and differences were statistically significant. There were no differences concerning the proportion of patients undergoing a watchful wait approach (7% vs 9%), type of treatment, or overall response rate (93% vs 88%) and complete response rate. Overall, 149 patients had refractory disease or relapsed, including 34/52 (65%) PB+ and 115/225 (51%) PB-. The median follow-up was 7 years (range 0.7 - 22.2 years). The 5-year progression-free survival (PFS) of treated PB+ group was 28% (95% CI: 14-42%) compared with 48% in the PB- (95% CI: 41-65%) (p=0.013). However, when the analysis was restricted to patients receiving rituximab combination regimen, 5-year PFS was 45% (95% CI: 24-66%) vs 64% (95% CI: 54-74%) (p=NS). Ninety-six patients died during the follow-up (19 PB+ and 77 PB-), with a 5 -year overall survival (OS) of 68% (95% OR: 54-82%) in the PB+ group and of 81% (95% CI: 76-86%) in the PB- group (p=NS) (Figure). Finally, there was no difference in the risk of histological transformation or secondary malignancies.

Summary/Conclusions: Peripheral blood involvement in FL is associated with particular clinical features, higher tumor burden load and shorter PFS, although in the short-term it appears that has not impact on overall survival.

E1138
TREATMENT PATTERNS OF PATIENTS WITH FOLLICULAR LYMPHOMA IN A LARGE US-INSURED DATABASE FROM 2010 TO 2014
M. Mehra1,*, N. Monga1, B. Schenker2, R. Potluri3, L. Farsi1

Methods: Using the Optum integrated database, patients with FL were identified and included if 1) they were diagnosed with the International Classification of Diseases, Ninth Revision (ICD-9) codes 202.0 or 202.00 to 202.08 between January 2010 and December 2014; 2) their age was ≥ 18 years at the index date; and 4) they had continuous insurance coverage for 365 days prior to index date; and 4) they had continuous insurance coverage for 365 days prior to index date. All reporting was done using descriptive statistics.

Table 1.

Results: A total of 2569 patients with FL met the inclusion criteria and were included in the analysis. In this cohort, the mean age was 60 years; 51% were male; 72% were Caucasian, 5% African American, 2% Asian, and 20% other. The median duration of follow-up was 610 days. Across all LOTs, 1180 patients (46%) had at least one National Comprehensive Cancer Network (NCCN) guideline-recommended treatment for FL, and 153 patients (6%) had rituximab monotherapy only in their follow-up. Across all LOTs, rituximab monotherapy (RTX) was the most frequently used regimen (26%; average duration of therapy [DOT]: 96 days), followed by rituximab-cyclophosphamide-doxorubicin-vincristine-prednisolone (R-CHOP) or R-CHOP-containing regimens (19%; average DOT: 75 days) and bendamustine-rituximab (BR) (12%; average DOT: 128 days). These regimens represented 21%, 16%, and 14% of the first LOT, and 27%, 16%, and 11% of the second LOT, respectively. Across all LOTs, the use of other FL treatments was very low, including rituximab-cyclophosphamide-vincristine-
E1139
A PHASE 1 STUDY EVALUATING THE SAFETY AND PHARMACOKINETICS (PK) OF VENETOCLAX (VEN) IN JAPANESE PATIENTS (PTS) WITH NON-HODGKIN LYMPHOMA (NHL) AND MULTIPLE MYELOMA (MM)

1Department of Clinical Research and Department of Hematology and Cell Therapy, Aichi Cancer Center Hospital, Nagoa, Japan, 2Department of Hematology and Oncology, The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan, 3Department of Hematology and Rheumatology, Tohoku University Hospital, Sendai, Japan, 4Department of Hematology and Oncology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan, 5Department of Hematology, National Hospital Organization Nagoya Medical Center, Aichi, Japan, 6Department of Hematology, National Cancer Center Hospital, Tokyo, Japan, 7AbbVie GK, Tokyo, Japan, 8AbbVie Inc., North Chicago, IL, United States.

Background: The antiapoptotic protein BCL-2 is commonly overexpressed in hematologic malignancies. VEN is a potent, selective, orally bioavailable BCL-2 inhibitor that has demonstrated acceptable safety and antitumor activity in NHL and MM pts.

Aims: To evaluate the safety, PK profile, and preliminary antitumor activity of single-agent VEN in Japanese pts with NHL or MM.

Methods: Phase 1 open-label, dose-escalation study of VEN in Japanese pts with relapsed or refractory (R/R) NHL or MM (NCT02265731). Dose escalation followed a 3+3 design. After a 2-week ramp-up period with weekly dose escalation, VEN was administered daily at final doses of 300, 600, 900, or 1200mg on 21-day cycles until progression. All pts received tumor lysis syndrome (TLS) prophylaxis (allopurinol, hydration, hospitalization and monitoring) starting at least 72 hours before the first VEN dose and before each dose escalation. Adverse events (AEs) were assessed by NCI CTCAE v4.0. Dose-limiting toxicities (DLTs) were determined during the ramp-up period and during cycle 1. Responses were assessed by 2007 IWG (NHL) or 2006 IMWG (MM) criteria.

Results: As of January 19, 2017, 20 pts (50% male; median age 65 years [39–81]) have been enrolled: 3 pts in the 300-mg, 7 pts in the 600-mg, 7 pts in the 900-mg, and 3 pts in the 1200-mg VEN dose cohorts. Eighteen (90%) pts had NHL (stage III/IV; n=14), including 11 with follicular lymphoma (FL), 6 with diffuse large B-cell lymphoma (DLBCL), and 1 with concurrent FL+DLBCL; 2 (10%) pts had MM at diagnosis. Treatment-emergent AEs (all grades) in ≥20% pts included lymphopenia (45%), neutropenia (40%), and leukopenia (30%). One pt in the 900-mg dose cohort experienced grade 3 transient neutropenia. DLTs were defined from all pts. Of these, patients were followed with weekly blood counts for 12 weeks post-treatment. One DLBCl pt died while on study due to disease progression. No TLS events were reported. Steady-state VEN exposures were nearly dose proportional across 300-mg to 900-mg doses. At the 1200-mg dose, exposures to VEN increased less than dose proportionally, which is consistent with non-Japanese subjects. VEN exposures were comparable between Japanese and non-Japanese pts at the 300-mg dose. At higher doses, individual exposures were generally within the range observed in non-Japanese pts with R/R NHL or MM, with most common toxicities being hematologic. Individual exposures were generally within the range observed in non-Japanese pts but mean exposures were 30–100% higher. Overall, the OR rate was high, with nearly half the pts with NHL achieving an OR. Further evaluation of VEN in Japanese pts with hematologic malignancies is ongoing.

E1140
A SIMPLIFIED APPROACH IN THE ASSESSMENT OF T-CELL CLONALITY BY FLOW CYTOMETRY

M. Sarto1, E. Lau1, V. Lou1, Z. Timbo1, S. Wong3, S. Deo1, L. Pasalic1, D. Brown2, E. Tegg1, D. Goulet2

1Haematology, 2immunopathology, Weatmead Hospital, 3Faculty of medicine, Sydney University, Sydney, Australia.

Background: T-cell lymphoproliferative disorders are amongst the most challenging diagnoses in haematology. Flow cytometric T-cell receptor (TCR)-V(β)-R repertoire analysis (TCR-V(β)-R) is a sensitive method for detection of T-cell clonality; however, the assay is cumbersome owing to the required eight-part analyses that limit its clinical utility.

Aims: Here we describe a simplified flow cytometric method utilising a monoclonal antibody that targets the T-cell receptor β constant domain 1 (TRBC1). The cβ TCR is a pan T-cell antigen, expressed on >90% of T-cell lymphomas and all normal T-cells. A feature of the TCR is that the β-constant region comprises 2 functionally identical genes: TRBC1 and TRBC2. Each T-cell phenotype CD3+CD4+CD8+, CD3+CD4+CD8+, CD3+CD8+ and CD3+CD4+CD7- respectively were either positive or negative for Jovi-1. Patients with persistent lymphocytosis were also assessed for Jovi-1 expression. A comparison of Jovi-1 and TCR-V(β)-R was also performed to compare the two approaches.

Results: Jovi-1 expression within the CD4 and CD8 compartments of T-cells in normal donors was a median of 42.6% (range 33.7%–49%) and 36.4% (range 22.3%–48.5%) respectively. The T-cell line, Jurkat was exclusively positive for Jovi-1. Of the 9 patients with T-LGL, 7 patients shared a common T-cell phenotype CD3+CD8+CD4-. One patient was predominantly CD4+ and the other patient was dual negative for CD4 and CD8. Jovi-1 expression within the abnormal T-cell population of this group of patients was >90% restricted to one compartment; these findings were confirmed by TCR-V(β)-R analysis. Similar results were also obtained in each case of T-NHL and Sezary syndrome, more than 90% of T-cells from the population with an abnormal phenotype (CD3dim/CD4+CD8-, CD3dim/CD4+CD8+, CD3+CD4+CD8+, CD3+CD4+CD8+ and CD3+CD4+CD7- respectively) were either positive or negative for Jovi-1.

Conclusions: In summary we have demonstrated a novel approach in the assessment of T cell clonality by targeting T-cell receptor β constant domain 1 (TRBC1). The addition of Jovi-1 in routine practice could improve the clinical evaluation of abnormal T-cell populations by flow cytometry.

E1141
A HIGHER AMOUNT OF LILOTOMAB PRE-DOSE INCREASES THE ACTIVITY-ADJUSTED AUC AND HAS A PROTECTIVE EFFECT AGAINST MYELOPOIETIC SUPPRESSION OF LUTETIUM (177Lu)-LILOTOMAB SATETRAX - IN NON-HODGKIN INDOLENT NHL PATIENTS

1Radiumhospitalet, 2Oslo University Hospital, 3Nordic Nanovector, Oslo, Norway, 4Norrland University Hospital, Umeå, Sweden, 5University of Manchester, Manchester, United Kingdom.

Background: lutetium (177Lu)-lilotomab satetraX (Betalutin®) is a novel CD37-binding murine IgG3 antibody radionuclide conjugate (ARC), in a ready-to-use formulation currently in Phase I/II clinical development for the treatment of non-Hodgkin lymphoma (NHL). Previously, pharmacokinetic (PK) data have been reported from 2 treatment arms of the ongoing LYMRIT-37-01 study. In this abstract PK data from 4 treatment arms are presented for the first time.

Aims: This PK sub-study in iNHL patients (pts) was designed to determine the PK profile of 177Lu-lilotomab when administered after four different pre-dosing schedules.

Methods: Patients with relapsed incurable indolent NHL, with platelet counts ≥150 x10^9 and <25% bone marrow involvement were eligible for inclusion in the study. All pts received one or two doses of rituximab to deplete normal B cells. In addition, prior to 177Lu-lilotomab administration pts also received: - 40mg lilotomab prior to 10, 15 or 20 MBq/kg 177Lu-lilotomab; - no pre-dosing prior to 10 or 15 MBq/kg 177Lu-lilotomab; - 250 or 375mg/m^2 rituximab prior to 15 MBq/kg 177Lu-lilotomab; - 100mg/m^2 lilotomab prior to 20 or 20 MBq/kg 177Lu-lilotomab. PK samples were collected at 0 and 5 minutes, then after 1, 2, and 20 hours and at 2, 3, 4, 7, 11 and 21 days post-177Lu-lilotomab administration. The patients were followed with weekly blood counts for 12 weeks post-treatment.

Results: A total of 22 pts were enrolled into this PK sub-study, 19 with follicular lymphoma, 2 with mantle cell and 1 with marginal zone histologies. The number
of prior therapies ranged from 1 to 7. median body weight was 79 kg (range: 58-118kg). The administered activity across all treatment groups ranged from 746 to 1982 MBq. The table below shows the median of the median PK and haematology safety results for $^{177}$Lu-lilotomab by treatment group. The activity-adjusted AUC$_{\text{last}}$ of $^{177}$Lu-lilotomab increased with 100mg/m$^2$ of lilotomab compared to the other pre-dosing regimens (p<0.001 compared to 40mg lilotomab). The median volume of distribution and clearance were both reduced with 100mg/m$^2$ of lilotomab compared with the other pre-dosing regimens. However, activity adjusted Cmax was similar. Smaller percentage post-treatment reductions in platelet and neutrophil counts were observed in patients receiving 100mg/m$^2$ lilotomab. Most common grade 3/4 AEs were hematological and were transient and reversible.

#15 MBq/kg only. N=3 for each arm except with no pre-dosing n=2

Summary/Conclusions: A higher pre-dose of lilotomab increases the activity-adjusted AUC and decreases the volume of distribution and clearance rate of $^{177}$Lu-lilotomab in iNHL pts. Despite the increase in AUC the percentage reductions in neutrophil and platelet counts were smaller, indicating that a higher dose of lilotomab may have a protective effect against the myelosuppression associated with $^{177}$Lu-lilotomab. Further characterisation of 20 MBq/kg dose of $^{177}$Lu-lilotomab with 100mg/m$^2$ of lilotomab pre-dosing is ongoing and will be presented.

E1142

PHARMACOKINETICS AND TOLERABILITY OF OFATUMUMAB AND BENDAMUSTINE IN PATIENTS WITH INDOLENT B-CELL NON-HODGKIN’S LYMPHOMA

1Division of Hematology / Clinical Oncology, University of Alabama at Birmingham, Alabama, 2West Cancer Center, Tennessee, 3Houston Methodist Cancer Center, Houston, 4West Virginia University, Morgantown, 5Novartis Oncology, East Hanover, NJ, United States, 6Novartis Pharma AG, Basel, Switzerland, 7Cancer Therapy & Research Center, San Antonio, United States

Background: Anti-CD20 antibody rituximab (R)-based immunochemotherapy is the standard treatment for untreated or relapsed indolent B-cell non-Hodgkin lymphoma (iNHL). Due to the inevitable relapse of patients with iNHL, an unmet need remains for active and well-tolerated novel therapies. Bendamustine (BEN) is approved for the treatment of refractory iNHL, and the combination therapy BEN-R showed efficacy in the treatment of relapsed iNHL. Ofatumumab (OFA) is an anti-CD20 human monoclonal antibody (mAb) with high binding affinity and slower dissociation from a distinct membrane-proximal epitope on both small and large loops of CD20. OFA is indicated for the treatment of chronic lymphocytic leukemia (CLL) and is being investigated for the treatment of iNHL. The combination of OFA and BEN may provide additional clinical benefit in patients with iNHL and therefore the potential for drug-drug interaction was investigated.

Aims: The study aimed to evaluate the pharmacokinetics (PK) of OFA and BEN alone and in combination, along with the safety and tolerability assessments in patients with previously untreated or relapsed iNHL.

Methods: In this Phase I open-label, multicentre study, patients (aged ≥18 years) with previously untreated or relapsed iNHL were randomized 1:1 to Arm A (OFA + BEN) or Arm B (OFA alone) to receive at least four cycles and up to eight cycles of treatment (cycle length 28 days). All patients provided informed consent. Arm A patients received single-sequence treatment of BEN, then OFA (1000mg) on day 1 of weeks 2, 3, and 4 of cycle 1 and on day 1 of cycles 2-8. Patients in Arm B received OFA alone at same dosing schedule. Blood samples including all end-of-infusion (EOI) PK samples were collected for plasma concentration over time. The primary PK parameters C$_{\text{max}}$, AUC$_{\text{last}}$, AUC$_{\text{inf}}$ were derived using non-compartmental analysis. All adverse events (AEs) and severe AEs (SAEs) were recorded for safety assessments.

Results: Thirty two patients were randomized (15 in Arm A and 17 in Arm B), 3 patients in Arm A discontinued study treatment due to consent withdrawal (2 patients) and infusion related AE (1 patient). All 32 patients were included for safety and PK concentration analysis while 30 patients (15 in each arm) were included for PK parameters. Patient and disease characteristics were similar between treatment arms; the majority of patients from both arms did not receive prior NHL therapy. PK concentration profiles and PK parameters of OFA were comparable when administered alone or co-administered with BEN (Table 1). As compared to OFA alone, there was a decrease of 14% in C$_{\text{max}}$ and 15% in AUC$_{\text{last}}$ when OFA was co-administered with BEN, which was not considered relevant (Table 1). BEN PK concentration profiles and PK parameters were comparable with or without OFA co-administration (Table 1).

All patients reported AEs. The most frequent treatment-related AEs were infu-}

Summary/Conclusions: No relevant drug-drug interaction between OFA and BEN was observed in this study. OFA alone or in combination with BEN exhibited manageable safety profile in patients with iNHL.

ASSOCIATION OF INTERNATIONAL CONSENSUS GROUP FOR HEMATOLOGY (ICGH) SMEAR REVIEW RULES FOR AUTOMATED PLATTFORMS IN THE DETECTION OF MALARIA

J. Chu, A. Yang, S. Havysson, N. Ali1,2
1Haematology, National Health Laboratory Services, 2Molecular Medicine and Haematology, University of the Witwatersrand, Johannesburg, South Africa

Background: Peripheral blood smear review (SR) is a useful adjunct to the full blood count (FBC) and differential white cell count (DWCC), but is labor intensive and time consuming. For this reason, the international consensus group for hematology (ICGH) published guidelines to reduce SR rates in clinical laboratories using rules based on a combination of blood parameters and instrument suspect flags. These rules have reduced SR rates in many laboratories, but adjustment is often required to accommodate for local pathology/clinician preferences. As malaria is common in Johannesburg (JHB) (although not endemic), this study was undertaken to retrospectively evaluate the performance of modified ICGH SR rules for detection of malaria at the Chris Hani Baragwanath Academic Hospital Laboratory (CHBHAH) (part of the National Health Laboratory Service (NHLS) network) in JHB, South Africa.

Aims: To assess the performance of the CHBHAH NHLS SR rules in the detection of malaria.

Methods: Malaria test results (P. falciparum antigen & thick/thin SR) were extracted from the laboratory information system and corresponding FBCs assessed in those with parasitaemia. All ICGH rules were applied to patients with a FBC performed in the absence of parameter flags in only 5(7.9%) patients with a FBC performed and 64(88.9%) in those with a FBC and DWCC. The thrombocytopenia (platelets (Plt)<100x10^9/l) and anaemia (Hb<7g/dl) rules were the most common, triggering in 105(79.5%) and 24(15.7%) patients respectively. Common analyzer morphology flags included those querying the presence of atypical lymphocytes, immature granulocytes and blasts, but 1/2 of these triggered in the absence of a DWCC requested, while only the parameter related rules were applied to patients with only a FBC performed. Samples were processed using a Sysmex XE-5000 analyser (Sysmex, Kobe, Japan), and the rules violated for each FBC recorded. As a retrospective laboratory based study, informed consent was not obtained. However, the study was approved by the Human Research Ethics Committee of the University of the Witwatersrand.

Results: Of the 153 samples included, all had P. falciparum parasitaemia and 37 were collected from patients with severe malaria. A FBC with a DWCC was performed in 72/153 (47.1%) patients, and a FBC alone in 81/153 (52.9%). SR rules were triggered in 132 (86.3%) patients (68(64.0%) in those with only a FBC performed, and 64(85.9%) in those with a FBC and DWCC). The thrombocytopenia (platelets (Plt)<100x10^9/l) and anaemia (Hb<7g/dl) rules were the most common, triggering in 105(79.5%) and 24(15.7%) patients respectively.

Common analyzer morphology flags included those querying the presence of atypical lymphocytes, immature granulocytes and blasts, but 1/2 of these triggered in the absence of a DWCC requested, while only the parameter related rules were applied to patients with only a FBC performed. Samples were processed using a Sysmex XE-5000 analyser (Sysmex, Kobe, Japan), and the rules violated for each FBC recorded. As a retrospective laboratory based study, informed consent was not obtained. However, the study was approved by the Human Research Ethics Committee of the University of the Witwatersrand.

Summary/Conclusions: ICGH SR rules are FN in 13.7% of patients with malaria, machine FN largely in those with near-normal blood counts. Furthermore, SR failed to identify the parasites in a further 13.0% of cases (particularly those with very low parasitaemia). Elimination of a proportion of FN samples is thus not likely to be possible, and clinical vigilance for this condition is required. Reassuringly, SR rules were triggered in all the patients with severe malaria, and the parasites identified in 90.5% of these.

BONE MARROW ASPIRATION AND BIOPSY: EFFECTIVE DIAGNOSIS OF MALIGNANCIES IN NEUTROPENIC PATIENTS WITH HEMATOLOGICAL DISORDERS

C. H. Yau1, D-P. Wu2, J-D. Hu3, H. Huang4, M. Jiang5, J. Li6, M. Hou7
1Peking University People’s Hospital, Beijing, 2The First Affiliated Hospital of Soochow University, Suzhou, 3Fujian Medical University Union Hospital, Fuzhou, 4The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, 5Wuhan Union Hospital, Wuhan, China

Background: Candidemia is one of the most common nosocomial bloodstream infections and is associated with morbidity and mortality, especially amongst the immunocompromised population. Several articles focus on the epidemiology of candidemia, but most of them were from cancer patients, patients with hematological malignancies, patients receiving solid organ transplant, or patients receiving hematopoietic stem cell transplantation (HSCT). Only 3 retrospective studies from single center described the clinical and microbiological features of candidemia in neutropenic patients with hematological malignancies.

Aims: A prospective, multicenter, observational study was designed to investigate the incidence, risk factors and outcomes of candidemia in neutropenic patients with hematological diseases.

Methods: This study was conducted in 11 hematological centers in China over a five-month period. From October 20, 2014 to March 20, 2015, consecutive patients of any age who were included in this prospective study if they met the following criteria: (1) had hematological disease (2) experienced at least one episode of neutropenia during hospitalization.

Results: A total of 1139 consecutive cases were enrolled in this study. Out of 1139 neutropenic cases, 8 developed candidemia. The median time from neutropenia to diagnosis of candidemia was 18 days (range: 8-20 days). Among these 8 cases, 4 cases were from patients with acute myeloid leukemia (AML) and 4 cases were from patients with acute lymphoblastic leukemia (ALL). The cumulative incidence of candidemia in neutropenic patients with hematological diseases was 0.00% (95% confidence interval (CI): 0.00%, 0.00%) at 7 days, 0.26% (0.00, 0.65%) at 14 days, 2.24% (0.67, 3.81%) at 21 days and 2.24% (0.67, 3.81%) at 28 days after neutropenia, respectively. Among 8 cases with candidemia, 3 were from patients receiving HSCT, other 8 were from patients who had acute myeloid leukemia (AML) and receiving induction chemotherapy. The cumulative incidence of candidemia in patients with AML and receiving induction chemotherapy was also significantly higher than that in patients receiving HSCT and other patients (5.45% vs. 3.19% vs. 0.00%, P=0.023).

Methods: In a large volume of patients with neutropenia, modified ICGH SR rules for detection of malaria at the Chris Hani Baragwanath Academic Hospital Laboratory (CHBHAH) (part of the National Health Laboratory Service (NHLS) network) in JHB, South Africa. This study was approved by the Human Research Ethics Committee of the University of the Witwatersrand.

Summary/Conclusions: This study provided a description for the epidemiological study of candidemia in neutropenic patients with hematological diseases. This study defined the risk factors associated with candidemia in these patients, and confirmed that based on the risk factors, risk-stratification could identify the patients with a high-risk of candidemia.
Results: Out of 769 patients consecutively admitted in our ward, 85 had LI and 47 of them underwent BAL (total amount: 51 procedures). A causative agent of LI was detected in 33 cases (65%) allowing to modify the ongoing anti-microbial treatment in 25 of these ones (76%). Twelve cases of probable IPA, according to standard criteria, were diagnosed. Seven cases of LI fulfilling the radiologic criteria for IPA, though presenting only a positive Aspergillus PCR on BAL, were detected and treated as probable IPA. One life-threatening post-procedure complication was observed.

Summary/Conclusions: BAL seems a safe approach for an early diagnosis of LI in hematologic patients. The assessment of a broad diagnostic panel allowed the detection of a putative agent in 65% of cases. Assessment of Aspergillus by PCR on BAL proved useful for probable IPA diagnosis.

E1146 ESCAPE DRUG-RESISTANT INFECTIONS IN HEMATOLOGICAL MALIGNANCIES. DARE TO REVIEW! C. Gentille Sanchez1, K. Sun1, P. Teegavarapu1, Q. Qian1, P. Mamta2, S. Wong2, I. Ibrahim1, L. Rice3, S.R. Pingali1, S. Iyer2 1Houston Methodist Cancer Center, 2Houston Methodist Research Institute, 3Houston Methodist Department of Hematology, Houston Methodist Hospital, Houston, United States

Background: Patients with hematological cancers are at a high risk for increasingly resistant and severe infections. The Infectious Diseases Society of America has defined commonly resistant bacteria as ESKAPE (Enterococcus, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter, Pseudomonas aeruginosa, Enterobacter). As suggested in recent literature, other common and difficult-to-treat infections such as Clostridium difficile and Enterobacteriaceae organisms (E. coli, Proteus) can be added to this group and the acronym from ESKAPE to ESCAPE.

Aims: We performed a retrospective review of the rate of ESCAPE infections, resistance profile, and outcomes in patients with various hematological malignancies at the Houston Methodist Hospital from 2006 to 2015.

Methods: The patient data was obtained from METEOR (Methodist Environment for Translational Enhancement and Outcomes Research), a clinical data warehouse that contains records dating back to January 1, 2006, with over 3 million patients and over 10 million unique patient encounters. We queried for leukemias (AML, CML, ALL, CLL), amyloidosis and myelodysplastic syndrome (MDS) along with hospitalizations due to bacterial infections. Baseline demographics and overall outcomes were also obtained.

Table 1.

Results: Out of 6017 patients with Hematological Malignancies, 660 patients with 684 malignant diagnoses were found; 235 had MDS, 174 had AML, 105 had CLL, 77 had amyloidosis, 44 had CML, 39 had ALL, and 10 had an unspecified hematological cancer. Of 1132 infectious events, 62% were ESCAPE infections. The bacteria most frequently isolated were Enterococcus (23.4%), Staphylococcus aureus (18.5%) and Pseudomonas (16.9%). Bacteremia was the most predominant type of infection (41.9%) followed by urinary tract infections (38.2%). Patients with MDS (39.6%) and AML (25.3%) were mainly affected. A prevalent resistance to levofloxacin was detected in gram positives (22%). Proteus had the highest resistance rate (45.2%). Followed by Enterococcus (44.2%) and Pseudomonas (36.7%).

Summary/Conclusions: Hematological cancers with risk for neutropenia such as MDS and AML were the most affected by ESCAPE. Further statistical review of this data set will be presented at the EHA Meeting, Madrid 2017.
compared to Neulasta® (pegfilgrastim).

Background: Neutropenic sepsis remains a leading cause of morbidity and mortality in both haematopoietic malignancy and general oncology patients on cytotoxic chemotherapy, leading to increased healthcare costs. It is anticipated that this long term 13-week study will provide evidence of safety and proof of concept support advancement of ANF-Rho into Phase II clinical studies in chemotherapy-induced neutropenia and chronic idiopathic neutropenia in Europe, USA and India.

Results: No observed clinical signs seemed to be related to ANF-Rho administration. There were no related effects in body weight changes or food consumption. Observed ophthalmic effects were considered procedural related due to low incidence. No biologically meaningful findings were noted during the function observational battery assessment. Preliminary analysis showed a trend of increase in kidney weight in rats and a dose dependent decrease in kidney weight in primates. Genotoxicity studies found no signs of mutagenicity, clastogenicity or cytotoxicity.

Summary/Conclusions: The results from this preliminary toxicology studies are unremarkable and consistent with those of an earlier 28-day study. Results from the 28-day rat neutropenia dosage model found that the blood pharmacodynamics parameters of ANF-Rhino were significantly superior to PEG-filgrastim. Both PK and PD data demonstrate relatively predictable systemic exposure and activity following SC or IV dose levels in both rat and primate. It is anticipated that this long term 13-week study will provide evidence of safety and proof of concept support advancement of ANF-Rho into Phase II clinical studies in chemotherapy-induced neutropenia and chronic idiopathic neutropenia in Europe, USA and India.

E1150

USE OF MICAFUNGIN IN PROPHYLAXIS IN ONCO-HEMATOLOGY: RESULTS OF AN OBSERVATIONAL, MULTICENTER, PROSPECTIVE FRENCH STUDY (OLYMPE)

J. El-ekelih1,* , H. J. Dalle2,4, S. Ducastelle-Leprêtre4, J.-B. Quinou4, P. Ceballos5, R. Herbrechet6

1American Hospital, Beirut, Lebanon, 2Hôpital Robert Debré, Paris, 3Hôpitaux de Paris, Medical Affairs, Astellas France, Levallois-Perret, 4Centre Hospitalo-Universitaire, Montpellier, 5Centre Hospitalo-Universitaire, Strasbourg, France

Background: Antifungal prophylaxis is being used increasingly.

Aims: The therapeutic arsenal is extensive and requires a better understanding of micafungin use in oncology-hematology where most-at-risk patients of invasive fungal infections (IFI) are managed.

Methods: This observational study was conducted in 18 oncology-hematology units in adult patients and children treated with micafungin in prophylaxis with a 3-months follow-up period.

Results: 150 patients (95 adults, 55 children) were included and represent the analysis population. In total, 15 patients (10%) presented an IFI during micafungin treatment. Among them, 11 presented a probable or proven IFI. The rate of IFI was higher in children (15%, n=8) than in adults (7%, n=7) and seem not influenced by the type of hemopathy and if the patient was allo-transplanted or not: 14% (n=6) in allografted patients, 9% (n=4) in patients with AML or SMD and 7% (n=3) in other patients. Median time to infection was 24 days (1 to 68 days) and was longer in adults (25 days, 4 to 68 days) than in children (16.5 days, 1 to 68 days). Twelve patients (8 children and 4 adults) presented at least one clinical or radiological sign of suspected IFI. Fungus was identified in 8 patients (62%), mostly in blood cultures (50%, n=4); candidiasis in 4 patients, aspergillosis in 2 patients and infection related to Rhiisopus in 1 patient. Incidence rate of IFI (10%, 5 patients) was inferior to prophylaxis failure rate (23%, 34 patients). Prophylaxis failure rate takes in account patients who switched to empirical treatment besides patients who switched to preemptive or curative treatment. After the end of prophylaxis, 4 patients (3%, 3 adults and 1 child) presented a proven IFI. Median time to infection after the end of treatment was 10,5 days in adults (7 to 24 days) and 52 days in children. Mica- fungin was overall well tolerated: only 10 patients (7%, mostly children) presented grade 1 to 4 adverse events related to micafungin, including 5 patients (33% with grade 3 or 4 adverse events.

Summary/Conclusions: Effectiveness and safety profile of micafungin in prophylaxis are similar to what was observed in previous studies. Incidence IFI (10%) confirms the clinical effectiveness of micafungin in prophylaxis in high risk patients. The low rate of serious adverse events confirms micafungin safety profile, in children included.

E1115

OUTBREAK OF MULTI-DRUG RESISTANT PSEUDOMONAS AERUGINOSA (MPA) IN A HEMATOLOGY WARD (HW): MANAGEMENT AND INFECTION CONTROL MEASURES

D. Armenti1,* , E. Cerchiara1, O. Annibali2, M. Becilli3, E. Circhetta1, S. Ferraro1, A. Pagano1, A. Scardocci1, M. Tufani1, C. M. Tinndelli4, G. Avvisati1

1Haematology, North West London NHS Trust, 2Haematology, West Midlands University Hospitals NHS Trust, 3Renal Medicine, Imperial College Healthcare NHS Trust, 4Haematology, Hillingdon Hospital NHS Trust, London, United Kingdom

Background: Neutropenic sepsis remains a leading cause of morbidity and mortality in both haematopoietic malignancy and general oncology patients on cytotoxic chemotherapy, leading to increased healthcare costs. It is anticipated that this long term 13-week study will provide evidence of safety and proof of concept support advancement of ANF-Rho into Phase II clinical studies in chemotherapy-induced neutropenia and chronic idiopathic neutropenia in Europe, USA and India.

Results: No observed clinical signs seemed to be related to ANF-Rho administration. There were no related effects in body weight changes or food consumption. Observed ophthalmic effects were considered procedural related due to low incidence. No biologically meaningful findings were noted during the function observational battery assessment. Preliminary analysis showed a trend of increase in kidney weight in rats and a dose dependent decrease in kidney weight in primates. E1149

PRELIMINARY RESULTS FROM A LONG-TERM REPEATED DOSE TOXICITY AND TOXICOGENICITY STUDY OF ANF-RHO, A NOVEL ANTI-NEUTROPENIC FACTOR

J. Valentino1, H. Misra1, J. A. Newmark2

1Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, 2Toxiology, Toxikon, Bedford, United States

Background: ANF-Rho is a novel polyethylene glycol-modified granulocyte colony stimulating factor that has biological and biological properties that produce a prolonged pharmacokinetic and pharmacodynamic profile as compared to pegfilgrastim (Neulasta®). As such, it has potential applications in chemotherapy induced neutropenia and chronic idiopathic neutropenia. These discoveries require additional studies to better understand the therapeutic potential and risk associated with ANF-Rho administration.

Methods: The study design used 288 rats, divided into 5 dosage groups: control, 100, 300, 1000 (high) and 1000 (positive) µg/kg. A total of 58 monkeys were also divided into 5 dosage groups: control, 75, 250, 750 (high dose) and 750 (positive) µg/kg of ANF-Rho. Doses were administered by weekly subcutaneous injections on Day 1, 15, 22, 29, 36, 43, 50, 57, 64, 71, 78, 85 and 92 at a dose volume of 5 mL/kg. Genotoxicity assessments were evaluated using Salmonella typhimurium and Escherichia coli reverse mutation assay, rodent blood micronucleus assay and chromosomal aberration assay. Toxicology assessment included clinical observations, body weight change, food consumption, ophthalmic examination, function observational battery (motor activity, behavioral changes, coordination and sensory/motor reflex response), organ weight, biochemical and toxicokinetic analysis, immunogeneity, gross necropsy and histopathology.

Results: No observed clinical signs seemed to be related to ANF-Rho administration. There were no related effects in body weight changes or food consumption. Observed ophthalmic effects were considered procedural related due to low incidence. No biologically meaningful findings were noted during the function observational battery assessment. Preliminary analysis showed a trend of increase in kidney weight in rats and a dose dependent decrease in kidney weight in primates. Genotoxicity studies found no signs of mutagenicity, clastogenicity or cytotoxicity.

Summary/Conclusions: The results from this preliminary toxicology studies are unremarkable and consistent with those of an earlier 28-day study. Results from the 28-day rat neutropenia dosage model found that the blood pharmacodynamics parameters of ANF-Rhino were significantly superior to PEG-filgrastim. Both PK and PD data demonstrate relatively predictable systemic exposure and activity following SC or IV dose levels in both rat and primate. It is anticipated that this long term 13-week study will provide evidence of safety and proof of concept support advancement of ANF-Rho into Phase II clinical studies in chemotherapy-induced neutropenia and chronic idiopathic neutropenia in Europe, USA and India.
Background: *Pseudomonas Aeruginosa* (PA) is a gram negative, ubiquitous, opportunistic pathogen. Its intrinsic resistance to many antibiotics and the selective pressure exerted by empiric antimicrobial use, led to the emergence of *PA* in haematological patients with high mortality and morbidity rates among infected immunocompromised patients (pts). Considering our *PA* incidence of 9% in 2007/08, an outbreak developed at the HW of “Campus Bio-Medic” University Hospital of Rome, from 2008, despite the measures employed from the previous 2 years (health personnel sensitization, regular air and water filters changing, isolation precautions).

Aims: To describe the *PA* outbreak occurred between 2009 and 2013.

Methods: Our HW, opened in 2007, is composed by 7 rooms, each with a private WC: 2 single, 1 double and 4 single, positive pressure, each with a filtered air, dedicated to outpatients and transplant. Retrospectively, from 01/2009 to 04/2013 we hospitalized 415 adult pts; of these, 106, at high infectious risk (HIR) for severe and prolonged expected post-chemotherapy neutropenia, have been routinely screened at admission with microbiological samples (nasal, pharyngeal and rectal swabs) and additional tests when clinically indicated. Because, during this period, we observed a dramatic incidence of *PA* isolates, we fulfilled specific sequential measures, to assess potential reservoirs and breaks in infection control and to manage the outbreak, summarized by the following 4 phases: phase A: closing of HW from 29/04/2013 to 09/06/2013; phase B: serial pre and post-disinfection environmental sampling from each room: swabs from toilet, bed, toilet, shower, glass bottle, air extractor, etc.; phase C: room environmental disinfection and microbial decontamination with nebulized H₂O₂ solution added with silver cations; phase D: disposal of BAW, introducing the use of different bedpans and planning an environmental sampling and disinfection program.

Results: On 04/2013 we revised retrospective study data: 82 pts carried bacterial isolates; of these, 48 (59%) had *PA*, classified as colonisation in 13 pts (mainly detected on rectal swabs) and true infection in 35: 10 pneumonias (25%), 6 anorectal/perineal (17%), 5 urinary tract (14%), 14 bloodstream infections (40%). Ten pts died of *PA* related infection, with a mortality of 33% (10 on 19 pts) and case-fatality rate of 29% (10 on 35 pts). Phase B defined a prevalence of *PA* isolates in 6 out of 7 rooms in different sample types, with 4 *PA* isolates identified in 3 different BAW and 1 bedpan after washing cycle. After reviewing phase B data, we demonstrated colonization of 3 out of 6 PA and 3 out of 4 *PA* isolation sites. As a main corrective action, after 41 days we resumed admissions and approached phase D, resulting in a prompt and maintained decrease in isolates (Table 1).

<table>

</tbody>
</table>

Summary/Conclusions: We identified the contaminated water residue from BAW as the main source of *PA* spread in our HW, getting a full outbreak control by improving environmental measures. *Pseudomonas* contaminates and survives on many ecological niches, being continuously reintroduced in nosocomial settings. We experience the high value of environmental and personal hygiene measures on *PA* infections control.

**E1152**

MONITORING VORICONAZOLE PHARMACOGENOMICS AND PLASMA CONCENTRATIONS IN THE TREATMENT AND PREVENTION OF INVASIVE FUNGAL DISEASE FOR HEMATOLOGICAL PATIENTS A SINGLE CENTER EXPERIENCE

D. Guo¹, T. Xu¹, Z. Li¹, J. Yin¹, X. Tian¹, D. Guo¹, Y. Xu¹, X. Zhu¹, L. Miao¹, D. Guo¹, Y. Xu¹, L. Miao¹, T. Xu¹, X. Tian¹, Z. Li¹

¹The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, ²Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Voriconazole has been widely used in treatment and prevention invasive fungal disease for immunodeficiency hematological patients. And the voriconazole plasma drug levels were associated with its efficacy and toxicity. The hepatic cytochrome P450 isoenzyme 2C19 plays a important role in voriconazole metabolism. However if CYP2C19 genetic polymorphism can result in voriconazole metabolism and drug plasma level in setting of Asian patients. The hepatic cytochrome P450 isoenzyme 2C19 plays a important role in voriconazole metabolism.

Aims: To evaluate the effect of CYP2C19 polymorphism on the voriconazole (VCZ) plasma concentration of patients with hematological disease and the value of serial monitoring voriconazole plasma concentrations in the treatment and prevention of invasive fungal disease (IFD).

Methods: Between January to August 2016, 76 hematological patients who received voriconazole for the treatment or prevention of invasive fungal disease were enrolled in this study. The population CYP2C19 polymorphism of voriconazole were performed using PCR-Pyrosequencing. The trough plasma concentrations of voriconazole (C_{trough}) was determined using high-performance liquid chromatography (HPLC).

Results: Genotyping for CYP2C19 polymorphic isozyme variations showed that 32 subjects (43.42%) for the CYP2C19 wild-type, 43 (56.58%) for the CYP2C19*2/*2 patients. 45 subjects were identified as extensive metabolizers’ group for CYP2C19 wild-type phenotype. The trough plasma concentrations of voriconazole were determined in the treatment and prevention of IFD. The trough concentrations of voriconazole were determined in the treatment and prevention of IFD.

Methods: Our study was aimed for identification of bacteremia in oncohematological patients following intensive chemotherapy, and assessment of potential modifying role of herpesvirus infections.

Results: Retrospective review of positive bacterial isolates of blood between January 1991- December 2015. Prospective study the cases of bacteremia and sepsis in cohort of 64 patients with hematologic malignancies.

Background: Intensive cytostatic chemotherapy is a standard strategy for leukemia treatment. Meanwhile, such treatment causes negative effects, including lymphopenia, granulocytopenia and damage to tissue barriers associated with significant risks of infectious complications, especially, bacterial sepsis and viremia.

Aims: Our study was aimed for identification of bacteremia in oncohematological patients following intensive chemotherapy, and assessment of potential modifying role of herpesvirus infections.

Results: Based on the study 4923 blood samples it was shown that the frequency of detection of bacteria was 11.0%. The predominant Gram-negative bacteria was demonstrated among pathogens detected in the bloodstream. However, the ratio of detectable Gram-negative flora was found to be increased from 23.1% to 39.6% between 2002 and 2015 (p<0.05). Coagulase-negative staphylococci (CoNS) prevailed among Gram-positive microorganisms. In particular, S. epidermidis, whereas Enterobacteriaceae, especially, E. coli, dominated among the Gram-negative bacteria. It is shown that the development of bacteremia were significantly more frequently occurs on the background of the detection of Cytomegalovirus and the Epstein-Barr virus genomes. In recent years, there has been increase the frequency of micromycetes detection in the blood of patients with hematological malignancies. In present study, antibacterial therapy started with β-lactame antibiotics combined with fluoroquinolones, aminoglycosides, metronidazole. If required, the antimicrobial strategy was adjusted.

Summary/Conclusions: Our study was aimed for identification of bacteremia in oncohematological patients following intensive chemotherapy, and assessment of potential modifying role of herpesvirus infections.

GLYOSYLATED FERRITIN MEASURING SIGNIFICANCE FOR SECONDARY HEMOPOYETIC SYNDROME DIAGNOSTICS

V. Potapenko1, M. Pervakova1, S. Lapin2, A. Klimovich1, O. Mironova1, N. Petrova3, N. Onyshkaya1, N. Skorobogatova1, E. Karyagina1, E. Karyagina1, E. Pavlichenko1, N. Potikhonova1, T. Kultaba1, N. Medvedeva1, A. Afanasyev2 1Municipal clinical hospital №31, 2Academician I.P. Pavlov First St. Petersburg State Medical University, 3Municipal hospital №15, 4L. Mechnikov North-Western State Medical University, 5Russian Scientific Research Institute of Hema- tology and Transfusiology, 6Saint-Petersburg State University, Saint-Petersburg, Russian Federation

Background: Hemophagocytic syndrome (HPS) is a clinicopathologic condition characterized by systemic inflammatory reaction with cytopenia and tissue damage. The HFS may be primary (genetic associated) or secondary (SHPS), caused by different systemic disorders (immune, infectious, neoplastic). The overall clinical symptoms are similar to sepsis, so it could be difficult to differentiate among these entities. Ferritin levels are high in both cases, but the glycosylated/nonglycosylated ferritin fractions ratio is seems to be indicative.

Aims: The estimation of the ferritin fractions ratio and biochemical profile in patients with sepsis and SHPS.

Methods: The data from 64 patients were analyzed: 40 pts with diagnosed SHPS (median age 57, range 8-74 years) and 24 with lethal septic shock (median age 57.5, range 18-82 years). SHPS in patients with persistent fever refrac- tory to antibacterial therapy and/or prolonged cytopenia and/or organ (lungs, CNS) involvement was established after the other conditions had been excluded. Sepsis diagnostics was based on the confirmed infection site and systemic inflammation with multorgan failure. The following serum values were analyzed: alkaline phosphatase (AlPh), alanine aminotransferase (ALT), aspartate transaminase (AST), bilirubin, creatinine, INR, C-reactive protein (CRP), procalcitonin (PCT), total ferritin, and glycosylated ferritin percentage. Mann-Whitney U test and ROC-analysis were used for statistical analyses.

Results: No differences were found in sepsis and SHPS for ALT, AST, AlPh, LDH, and bilirubin levels. The difference of INR, CRP, PCT, creatinine levels was significant (p<0.01). The most substantial difference in SHPS and sepsis groups had serum concentrations of ferritin, triglycerides, level of ferritin glycosylation (p<0.01) (Table 1). According to ROC-analysis, the area under the curve for ferritin, triglycerides and percentage of ferritin glycosylation were 0.78, 0.82, and 0.92, respectively.

Table 1.  

Summary/Conclusions: The most difference between sepsis and SHPS was observed for triglycerides, ferritin and percentage of glycosylated ferritin. Per- 
centage of glycosylated ferritin fraction seems to be the most indicative, which may make it useful for SHPS diagnostics and its differentiation from sepsis.

E1155

SERUM HEPIDIN QUANTIFICATION IN INFRAWINTARY BOWEL DISEASES

V. Manolov1,2, V. Vasilev1, K. Tzatchev1, O. Georgiev2, D. Stefanova-Petrova2, R. Tzrantcheva2, V. Mitev3 1Dept. of Clinical laboratory and clinical immunology, 2Department of Propaedeutics of Internal diseases, 3Department of Medical chemistry and bio-chemistry, Medical University, Sofia, Sofia, Bulgaria

Background: Inflammatory bowel diseases (IBD) include different intestinal pathologies, most common among them are Colitis Ulcerosa (CU) and Crohn’s Disease (CD). Pathogenesis of IBD is still unclear, however they are multifactor diseases, with genetic and autoimmune compounds, in combination of envi- ronmental factors. One of IBD symptoms is iron deficiency anemia.

Aims: We aimed to search for connection between serum hepcidin quantifica- tion and anemia in IBD.

Methods: We included 64 patients with IBD - 29 with Colitis Ulcerosa (CU), and 35 with Crohn’s Disease (CD). They were diagnosed in University “Alek- sandrovskaya” hospital in Clinic of Gastroenterology. Their results were compared to age and gender matched healthy controls. Laboratory assessments were analyzed for included groups – iron, ferritin, CRP, IL-6 and hepcidin. AAS, nephelometric, ELISA and statistical methods were used during analyzes and obtained results interpretation.

Results: 53 from our patients had with iron deficiency anemia (IDA) and low hepcidin concentrations (5.9±1.1 µg/L) compared to control group (19.9±2.8 µg/L). 11 of induced anemia had cytoalbuminosis/cytopenia and 16 of chronic disease (ACD). Their hepcidin levels were increased (59.9±6.4 µg/L) in comparison to healthy controls (19.9±2.8 µg/L); P<0.001. In patients with ACD/IDA, quantified serum hepcidin correlates positively to increased IL-6 (r=0.756, P<0.005) and CRP concentrations (r=0.899, P<0.001).

Summary/Conclusions: Iron deficiency anemia in patients might be a key element in diagnosis and treatment of anemia in these patients. Serum hepcidin levels are useful marker for differential diagnosis between iron deficiency anemia and combination iron deficiency anemia/ane- mia of chronic disease.

E1156

MUTATIONS IN YARS2 CAUSE CONGENITAL SIDEROBLASTIC ANEMIA WITHOUT SHOWING EVIDENCES OF MYOPATHY AND LACTIC ACIDOSIS

B. Cadenas1, J. Fita1, S. Montesdeoca2, C. Pedro3, M. Sanchez1 1Iron Metabolism: Regulation and Diseases, Josep Carreras Leukaemia Research Institute (JIC), BADALONA, 2Hematology Service, Hospital del Mar, Barcelona, Spain

Background: Mutations in the gene YARS2 encoding mitochondrial tyrosyl-tRNA synthetase have previously been identified as a cause of MLASA2, a mitochondrial respiratory chain disorder presenting with myopathy, lactic acidosis and congenital sideroblastic anemia (OMIM #610697, ORPHA 2698). Up to date in the literature it has been reported 9 families with 11 affected indi- viduals with mutations in YARS2 gene and affected from MLASA2.

Aims: Here we report a new case with a different clinical presentation.

Methods: We have identified two novel variations in YARS2 gene using Next Generation Sequencing (NGS) panel containing 10 genes involved in congen- 

tal and acquired sideroblastic anemia.

Results: The proband is a young woman aged 24 where we have identified 2 novel variations in YARS2 gene. One pathogenic splicing mutation NM.001040436.2 c.[1104-1G>A], and a missense variation NM.001040436.2 c.608 G>T; NP_001035526.1: p. Ser203Ile located in the C-core catalytic domain of the mitochondrial tyrosyl-tRNA synthetase. None of these two vari- 
atations were previously reported in public databases (ExAC, NCBI SNP, Ensem- bli). Clinical data from the patient showed marked sideroblastic anemia (Hb 91 g/L, 32% ring sideroblasts), but not signs of muscle weakness or myopathy at any age. No lactate and pyruvate levels were elevated (2.9 mmol/L, normal range: 0.5 - 2.2 mmol/L; creatine kinase 23 U/I, normal range: 23-170 U/L), as could be 

expected due to previously reported cases in the literature. Functional assays are on-going to confirm pathogenicity of the novel missense variation.

Summary/Conclusions: Here, we reported a patient with mutation in YARS2 gene showing congenital sideroblastic anemia but presenting neither lactic aci- 
dosis nor myopathy. Therefore, patients with defect in YARS2 gene may pres- 

cent with a less severe clinical manifestations only involving congenital sidero- blastic anemia without other extra-hepatoepoietic defects. MLASA2 must be 

considered in patients presenting with only congenital sideroblastic anemia since early diagnosis and supportive therapy will be important to prevent complica- 

tions.

E1157

IRON CHELATION DATA OF CONGENITAL DSYSERYTHROPOIETIC ANEMIA PATIENTS: A SINGLE CENTER EXPERIENCE

M. Celin1, N. Kaikan1, T. Bayhan1, F. Gumruk1, S. Unal1 1Hacettepe University, Division Of Pediatric Hematology, Ankara, Turkey

Background: Congenital dyserythropoietic anemia (CDA) is a rare, genetically heterogenous disorder characterized with ineffective erythropoiesis, and con- 
genital malformations in certain types. Patients present with varying degrees of 

anemia, cytopenias, reticuloendothelial hyperplasia and some of the patients may have mild disorder whereas others may be transfusion dependent. The ineffective erythropoiesis and the transfu- 
sional iron load puts these patients at risk for iron overloading and there is very 

scarce data on the iron loading and chelation types in these patients.

Aims: We aimed to summarize the chelation results of our patients with CDA 

from a single center.

Methods: Of the 33 patients with CDA, 11 were initiated iron chelation treat- 
ment either for receiving more than 20 packed RBC transfusions previously or for having serum ferritin levels above 1000ng/ml.

474 | haematologica | 2017; 102(s2)
Results: Of these 11 patients, 7 were CDA type II. The median age of diagnosis was 12 months (3-144 months) and male to female ratio was 7/4. Median transfusion requirement per year at previous year prior to initiation of chelation was 12 times (0-17). All of the patients were on chronic transfusion programme at initiation of iron chelation except for 2 (one receives occasional transfusion, and the other patient was on chronic transfusion programme but became transfusion independent after splenectomy). The median age at last visit was 70 months (32m-40 years). The median value of serum ferritin at initiation of iron chelators was 822 ng/ml. All of the patients were initiated deferasirox for iron chelation at a median dose of 24mg/kg/day (10-40) and the median chelation follow-up duration was 27 months (2-54 months). Three of the patients were evaluated with cardiac and hepatic T2* assessment prior to and by the end of 1 year of chelation and none of the patients were found to have cardiac iron loading at chelation initiation, whereas 2 had severe and 1 had moderate LIC values. In the subsequent assessment under chelation of these 3 patients all still had cardiac T2* values above 20 ms, wheras 1 had mild and 2 had moderate LIC values. Serum ferritin levels at initiation and by the end of 1 year were compared and the difference was found statistically insignificant.

Summary/Conclusions: Patients with CDA are at risk for iron loading and they need to be screened for the iron loading periodically. The prompt chelation in these patients prevent organ failure risks at long term including cardiac failure, cirrhosis and endocrinopathies.

E1158

ORAL IRON CHELATION FOR TREATMENT OF HEREDITARY HEMOCROMATOSIS IN CHILDREN

M. Moraki1,*, E. Repousi1, D. Kyriakopoulou1, P. Delaporta1, A. Kattamis1
1Thalassemia Unit, First Department of Pediatrics, National and Kapodistrian University of Athens, ‘Aghia Sophia’ Children’s Hospital, Athens, Greece

Background: Hereditary hemochromatosis (HH) very rarely presents during childhood. The most common form of HH in children is Juvenile Hemochromatosis (JH), a rare genetic disorder inherited with an autosomal recessive manner, resulting from mutations in either the hemjouvin (HJV) (type 2A) or the hepcidin (HAMP) gene (type B). Early diagnosis and closely monitoring of iron overload indexes, namely, serum ferritin levels, transferrin saturation and tissue iron measurement by magnetic resonance imaging (MRI) are essential in order to prevent permanent organ damage and potentially life threatening complications (cirrhosis, diabetes mellitus, cardiac dysfunction, and hypogonadism). Therapeutic intervention in children with HH may be problematic, as erythropoiesis is invasive and may not be well tolerated in young children. Iron chelation therapy can be implemented as an alternative treatment to erythropoiesis.

Aims: The scope of this study was to evaluate the use of an oral iron chelation therapy in young children with HH.

Methods: 3 children (2 females and 1 male) were diagnosed with HH at the aged of 4, 6 and 8 years old, respectively, based on increased ferritin and transferrin saturation levels and abnormalities of iron overload indexes of hyperferrinemina. Genetic analysis were performed in all 3 patients and showed positive results in 2 of them, while on the 3rd no genetic changes could be identified. All patients were at pre-symptomatic stage of the disease and they were referred for evaluation after hyperferrinemina was discovered on a routine screening examination. Liver iron concentration (LIC) and cardiac iron content were evaluated by MRI (table 1). Iron chelation therapy with deferasirox (DFX) at low dose (of 10mg/kg/24h) was initiated, after evaluation was completed and permission from regulatory authorities obtained.

Table 1. Clinical characteristics of the patients.

Results: All 3 patients responded promptly to therapy and showed decreased levels of ferritin, LIC and cardiac iron concentration. Gastrointestinal disturbances were noted in 1 patient, which resolved with H2-blockers and with changing the treatment to 5d/wk (patient 2). Mild increase in serum creatinine (>33% from baseline but within normal range for her age) was observed in patient 3, which resolved with temporary cessation of the chelation therapy.

Summary/Conclusions: HJ is very rare disorder in children, most frequently due to JH. Timely initiation of treatment to prevent iron overload consequences is essential. Chelation therapy with deferasirox is efficacious with a manageable toxicity profile and it can be considered as an alternative therapeutic option to chronic erythropoiesis for the treatment of JH.

E1159

NEUTROPHIL HYPERSEGMENTATION IN ADULTS WITH IRON DEFICIENCY: A CASE-CONTROL STUDY

I. Erdogan Ozunali1,*, D. Keskin2, E. Durcan2, Y. Gunay2, S. Bilgin2, S. Berk1
1Hematology, Hospital de Sant Pau, Barcelona, Spain

Background: Neutrophil hypersegmentation (NH) has been accepted as a hallmark of the macrocytic anemias associated with the deficiency of cobalamin or folate. However, there are a small number of reports stating that NH might accompany iron deficiency anaemia. The aim of the present study was to determine the association of NH with iron deficiency (with or without anaemia).

Aims: The aim of the present study was to determine the association of NH with iron deficiency (with or without anaemia) in adults and also to compare neutrophil segmentation status in anaemia group before and after oral or parenteral iron treatment.

Methods: Fifty-six patients with iron deficiency and 20 age and sex matched controls were included in this prospective, single blind, case-control study between February-November 2016. Subjects were included if they were ≥ 18 years of age, and had normal serum vitamin B12 and folate levels, liver, thyroid and renal function tests. Pregnant women and patients with a history of blood transfusion within last 3 months and/or those with acute renal failure, anaemia of chronic disease, hypothyroidism, additional cytopenias and infection were excluded. Patients with iron deficiency were divided into 2 groups being with iron deficiency anaemia (IDA) and iron deficiency without anaemia (ID). Those with adequately normal haemoglobin were further evaluated prior and after iron replacement. Results of the study groups were compared to age and sex matched healthy controls. Blinded peripheral blood smear slides were evaluated by a haematologist by counting 200 neutrophils. Hypersegmentation was defined as reported by Bain et al.. Iron deficiency was diagnosed based on the findings of iron parameters including serum iron, total iron binding capacity, and ferritin. Anaemia was defined according to the WHO recommendation. Cohort characteristics were given in Table 1.

Table 1.

Results: Hypersegmentation was detected in 25 individuals with iron deficiency (45%) and 1 healthy control (5%). It was significantly more frequent in the IDA group (48.8%) than in the ID group (30.7%) [p<0.001]. After iron treatment 3 IDA patients’ peripheral blood smear were checked and with normalization of iron parameters and hemoglobin, hypersegmentation was undetectable. The study is still ongoing and rest of the IDA group are still on treatment, their peripheral blood smears are to be examined after iron treatment is over.

Figure 1.

Summary/Conclusions: Although the mechanism of neutrophil hypersegmentation in iron deficiency anaemia is not clear, it is thought that iron acts as a cofactor in folate metabolism and/or DNA synthesis in granulocytes. There are a limited number of studies dealing with NH associated with ID in the literature. However most of these studies were observational and did not include controls or were not blinded. Our study is the first to demonstrate the association of NH with iron deficiency anaemia in adults in the absence of megaloblastic anemia.

E1160

M-TOR INHIBITORS-ASSOCIATED MICROCYTIC ANEMIA AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION

R. Angel F.1,*, A. Monter1, A. Esquiro1, R. Martino1, I. Garcia-Cadenas1, J. Remacha1, S. Payan1, S. Brunet1, J. Sierra1
1Hematology, Hospital de Sant Pau, Barcelona, Spain
Background: Immunosuppression with mTOR inhibitors (sirolimus or everolimus) has been associated with development of microcytic anemia after solid organ transplantation. The prevalence reaches 27 to 57% in the case of kidney transplantation. This anemia has been attributed to hepcidin increase induced by the inhibition of mTOR protein.1,2

Aims: To evaluate the prevalence of microcytic anemia after allogeneic hematopoietic stem cell transplantation in patients receiving mTOR inhibitors.

Methods: 61 consecutive allogeneic stem cell reduced intensity conditioning (alloRIC) recipients were analyzed. In all cases, a non-related donor was used. Baseline disease was: 23 acute leukemia (37.7%), 12 non-Hodgkin lymphomas (19.7%), 10 myelodysplastic syndromes (16.4%), 7 Hodgkin lymphomas (11.4%), and 4 multiple myelomas (6.5%). 3 chronic lymphocytic leukemia (4.9%), and 2 myelofibrosis (3.2%). All of them received Fludarabine-based conditioning treatment and the combination sirolimus (mTOR inhibitor)-tacrolimus (calcineurin inhibitor) as GVHD prophylaxis. Drug doses were adjusted according to blood levels and renal function. Levels of Hb, MCV and iron parameters were performed at hematological evaluation after alloRIC. Microcytosis was considered when MCV was below 80 fl.

Results: At 6 months 56 out of 61 (92%) were alive. Anemia was observed in 30 (49%) of them, with only 8 cases (13.1%) showing Hb level below 100 g/l. Microcytic anemia was diagnosed in 2 of them (3.3%). One patient showed an iron deficiency anemia due to gastrointestinal bleeding (Hb 94 g/l, MCV 69 fl, serum ferritin 21 μg/l). However, the second one, a 61-year old male with an acute leukemia, had a microcytic anemia with iron parameter changes similar to those observed in kidney transplantation and associated with increased hepcidin, (see table). Anemia progressively improved with sirolimus tapering.

Table 1.

|---|

Summary/Conclusions: In contrast to kidney transplantation, microcytic anemia related to immunosuppression with mTOR inhibitors was seldom observed in alloRIC recipients. However, this association should be taken in account in this setting, as a rare cause of anemia. In case of microcytic anemia, the evaluation of iron parameters and hepcidin provides the diagnosis of this rare type of anemia.

E1162

ORAL IRON ELEVATES SERUM IRON AND CONSEQUENTLY CHANGES IRON DISTRIBUTION IN LIVER AND ERTHROCYTES

Y. Matsuo-Tezuka1,*, M. Noguchi-sasaki1, M. Kurasawa1, K. Yorozu1, Y. Shimokuma1, M. Hirata1

1Product Research Department, Chugai Pharmaceutical Co., Ltd., Kamakura, Japan

Background: For renal anemia patients, there are several therapeutic options including erythropoiesis-stimulating agents (ESAs), intravenous and oral iron suplementations. In terms of iron absorption, ESAs were known to activate iron absorption via down-regulation of hepcidin, a key mediator of iron metabolism, and consequent up-regulation of duodenal iron transporters divalent metal transporter 1 (DMT1) and ferroportin (FPN). On the other hand, our previous study, intravenous iron was demonstrated to deactivate absorption system via hepcidin elevation. However, iron absorption under oral iron supplementation have not fully evaluated yet.

Aims: In this study, we investigated the activity of iron absorption under oral iron supplementation in mice as well as under intravenous iron supplementation.

In this study, we also analyzed iron distribution under intravenous and oral iron supplementation.

Methods: To load iron orally, a diet including 200 ppm of iron was used as control and a diet including approximately 5000 ppm of ferric citrate was used as iron-rich diet. 6-week-old male C57BL/6NCrl mice were divided into 3 groups; control group, intravenous iron (IV iron) group, and oral iron (oral iron) group (n=5). Mice in IV iron group were fed a control diet from days 0 and intravenously administered 0.4mg/mouse of iron-dextran on days 9. Mice in Oral iron group were fed an iron-rich diet from days 0 and intravenously administered 0.4mg/mouse of dextran as vehicle on days 9. Mice in control group were fed a control diet from days 0 and intravenously administered 0.4mg/mouse of dextran on days 9. All mice were euthanized by exsanguination under anesthesia with isoflurane on days 14. For analyses of iron absorption, serum hepcidin and iron were measured and expression of duodenal DMT1 and FPN were evaluated immunohistochemically. For analyses of iron distribution, blue staining assay and hematological indices were used.

Results: Serum hepcidin levels in IV and Oral iron groups were significantly higher compared with control group. However, serum iron levels were elevated only in oral iron group. In immunohistochemical analyses, expression levels of duodenal DMT1 were not detected in all groups and expression levels of duodenal FPN in IV and Oral iron groups were significantly lower than control group. As for iron distribution in liver, iron was accumulated in reticuloendothelial cells in IV iron group, on the other hand, in Oral iron group iron was accumulated in parenchyma. In hematological analyses, although red blood cell and reticulocyte count were not significantly different among all groups, Ret-He and MCH in Oral iron group were higher than IV iron groups.

Summary/Conclusions: It was demonstrated in this study that serum iron levels were elevated in spite of high hepcidin levels and down-regulation of duodenal iron transporters under oral iron supplementation. Furthermore, iron was distributed in liver parenchyma and hemoglobin contents in each reticuloocyte and erythrocyte were up-regulated only under oral iron supplementation. We speculated that high serum iron lead to excess iron uptake into tissues and erythrocyte fraction. These data might provide an opportunity to rethink the importance of proper use of iron supplementations.
Background: Children with haemoglobinopathy and rare anaemias often require regular red cell transfusions at some stage of their lives. Iron overload is therefore inevitable and iron chelation is a key component of therapy for children in this group. However, its use has not been validated especially in children under two years of age. Deferasirox (Exjade®; Novartis Pharma AG, Basel, Switzerland) is an iron chelator that is conclusively proven to be effective and safe in transfusional anaemia such as haemoglobinopathies.

Aims: We aim to look at the efficacy and safety of Deferasirox in children with severe anaemias.

Methods: We present a case report of 6 children with severe anaemias treated with Deferasirox in a tertiary pediatric hematology centre in London, UK.

Results: Here we report 5 cases where Deferasirox has been used in young children with rare anaemias and sickle cell disease. Patients 1 and 2 presented within the first year of life with pancytopenia requiring regular transfusion and were diagnosed with Pearson syndrome. Deferasirox was started at the age of 30 months and 4 months respectively. Patients 3 and 4 presented with neonatal anaemia requiring regular transfusion and were diagnosed with Pyruvate Kinase deficiency. Deferasirox was started at 12 and 19 months consecutively. Patient 5 presented with pure red cell aplasia at the age of 3 months and was diagnosed with Diamond Blackfan anaemia. He was initially treated with steroid but became resistant at around 40 months of age. He was then started on regular transfusion and was started at deferanox at 4 years of age. Patient 6 was diagnosed at birth with sickle cell anaemia. He suffered from stroke at the age of 8 months and was started on chronic transfusion program. Deferasirox was started at around at the age of 1. He had a successful maternal haplo-identical bone marrow transplant at 2 years and 11 months of age. He was started on deferasirox after 8 months of follow up and was subsequently stopped.

Figure 1. Illustration of the transfusion process. The transfusion dose is expressed in mg/kg of the patient's body weight.

Summary/Conclusions: All of these children had stabilization or improvement of ferritin values after initiation of deferasirox as shown in figure 1. Deferasirox is licensed in Europe to be used in children with thalassaemia older than 6 years of age or older than 2 year of age when desferoxamine therapy is inappropriate or inadequate. Deferasirox is preferable in severe anaemias due to better side effect profile on the bone marrow compared to deferiprone; the use of which can cause agranulocytosis or neutropaenia. Furthermore, its oral administration improved compliance compared to desferrioxamine that required frequent i.v. administrations. Deferasirox was started at the age of 30 months and 4 months respectively. Patients 3 and 4 presented with neonatal anaemia requiring regular transfusion and were diagnosed with Pyruvate Kinase deficiency. Deferasirox was started at 12 and 19 months consecutively. Patient 5 presented with pure red cell aplasia at the age of 3 months and was diagnosed with Diamond Blackfan anaemia. He was initially treated with steroid but became resistant at around 40 months of age. He was then started on regular transfusion and was started at deferasirox at 4 years of age. Patient 6 was diagnosed at birth with sickle cell anaemia. He suffered from stroke at the age of 8 months and was started on chronic transfusion program. Deferasirox was started at around at the age of 1. He had a successful maternal haplo-identical bone marrow transplant at 2 years and 11 months of age. He was started on deferasirox after 8 months of follow up and was subsequently stopped.

E1165 AN INVESTIGATION ABOUT WEIGHT GAIN WITH TREATMENT OF IRON DEFICIENCY ANEMIA: CHANGES OF GHRELIN AND HEPCIDIN LEVELS WITH TREATMENT H. C. Kılınç1, B. Onec2,*, K. Onec1, E. Caliskan3, H. Ankaralı4 1Internal Medicine, 2Hematology, 3Medical Microbiology, 4Biostatistics, Duzce University Faculty of Medicine, Duzce, Turkey

Background: Iron deficiency anemia (IDA) is the most common hematological disease in infancy and childhood. Oral iron administration is a well-established, effective, and widely accepted treatment for anemia because of its efficacy, safety, and cost-effectiveness in children. Recent studies have shown that medications are not used regularly or discontinued due to weight gain during the treatment process.

Aims: We investigated ghrelin, known as appetite hormone and its relationship with hepcidin, the homeostatic regulator of intestinal iron absorption, in order to explain some symptoms of IDA and weight gain during iron treatment.

Methods: This observational study collected clinical and hematological data from 12 AIEOP (Associazione Italiana di Ematologia ed Oncologia Pediatrica) centers. Inclusion conditions for patient enrollment were age 3 months-12 years, diagnosis of IDA, exclusion criteria were all conditions interfering with iron absorption such as celiac disease, gastro-intestinal disorders and idopathic conditions. Local Physicians were free to prescribe any oral iron formulation, according to their standard practice. A calendar of laboratory test was suggested, including basal assessment of whole blood count, reticulocytes, iron status, and hepcidin, the homeostatic regulator of intestinal iron absorption.

Results: 112 (M 58) patients were enrolled. Ethnic distribution was: Caucasian 74, African 23, Asian 10, Other 5. The median age at diagnosis of IDA was 1.5 years, with a bimodal distribution with frequency peaks at ages 7 and 12-14 yrs. Eighty-eight percent of patients received single oral iron preparation, either ferrous fumarate 0.45mg/kg, 19 elemental iron (ferrous gluconate/sulfate) 2mg/kg, 12 liposomal iron 0.7-1.4mg/kg, and 15 other preparations. Eating habits were reported as normal in 48 patients, inadequate weaning in 21, meatfish restriction in 32, other in 11. Gastro-intestinal side effects were reported in 9/68 (13%) of the bis-glycinate iron group, in 3/19 (16%) of the elemental iron group, and in 0/12 of the liposomal iron group. Suspension of therapy due to side effects was needed only in 5 patients, 4 in the bis-glycinate and 1 in the elemental iron group, respectively. Final outcome was available for 77 patients; it was recorded as solved IDA, persistent IDA, or lost at follow up. Solved cases were 40/53 (75%) in the bis-glycinate iron group, 4/11 (36%) in the elemental iron group, and 8/13 (62%) in the liposomal iron group. Persistent cases were 8/53 (15%) in the bis-glycinate iron group, 6/15 (55%) in the elemental iron group, and 1/13 (8%) in the liposomal iron group. Lost at follow up were 5/53 (9%) in the bis-glycinate iron group, 11/1 (9%) in the elemental iron group and 4/31 (13%) in the liposomal iron group.

Summary/Conclusions: The collected data show that both bis-glycinate and liposomal iron formulations have a good efficacy/safety profile and offer a sustainable alternative to classic elemental iron preparations.
were examined once in the control group and twice in the patient group, before
and after treatment.

**Results:** When the patient and control groups were compared, there was no
significant difference in terms of age, sex, height, weight, BMI, waist and hip
circumference. The pretreatment plasma hepcidin and ghrelin levels of the
patient group were significantly lower than those of the control group (80±21
ng/ml vs 179 ng/ml, p <0.001 for hepcidin, 152±119 pg/ml vs 213±167 for
grelin, p=0.028). There was a significant increase in terms of weight (mean
1.15 kg, p <0.001), BMI (25.86 kg/m² vs 26.33 kg/m², p <0.001), waist and hip
circumference measurements (mean 0.81 cm in both, p <0.001) after treatment in
the patient group. After treatment, the levels of hepcidin was significantly
increased compared to the pre-treatment levels (80±21 ng/dl vs 92±13 ng/dl,
p=0.001). Although an increase in the plasma ghrelin levels was encountered
after treatment, it was not statistically significant (152±119 pg/ml vs 164±150
pg/ml, p=0.589). When correlations of individual increases in ghrelin levels
were examined, a weak positive correlation was found between increase in
grelin levels and weight gain.

**Summary/Conclusions:** In our study, ghrelin was significantly lower than the
control group in the IDA group, suggesting that it may be the cause of loss of
appetite. Ghrelin is also detected in neurons of hypothalamic arcuat nucleus, which
regulates appetite. The deficiency of iron may cause deficiencies in enzy-
matic activities of iron depended enzymes and it may disturb the function of
these neurons. But the increase with treatment did not reach statistical signif-
icance. This may be due to physiological suppression of levels by weight gain.

**E1166**

**SOMATIC MUTATION DYNAMICS IN HIGH-RISK MDS PATIENTS TREATED
WITH AZACITIDINE IDENTIFIED VIA SERIAL SAMPLING**

K. Polgarova1, K. Vargova1, V. Kulvati2, N. Dusilova2, L. Minark1, Z. Zemanova3,
A. Jonasova1, T. Stopka1,2

1Hematology Clinic, General Hospital, Prague, 2Biocev, Charles University, Vestec,
3Cyto genetic Center, General Hospital, Prague, Czech Republic

**Background:** Azacatidine (AZA) is a standard therapy for MDS patients with
higher risk of AML transformation and not eligible to undergo transplantation.
While AZA is well tolerated, the responses occurring in up to two thirds of patients
are not durable. Somatic mutations were previously associated with pathogen-
esis of MDS, some of them also with prognosis. Several studies suggested that
MDS patients as they progress may evolve new mutations and loose some of
the clonal architecture detected at preceding stages (Pelisaggi, Roy et al. 2016).
In addition, there exist gene mutations that are detected in patients sub-
sequently responding to hypomethylating agents (Bejar, Lord et al. 2014), which
implies that there exist variants-bearing clones that persist upon AZA as well
as those that do not.

**Aims:** To identify variants either persisting or not upon the AZA therapy we
tracked BM samples during AZA treatment. Next, we were interested in deci-
phering their relationship of the dynamics in somatic variants to clinical course
of the analyzed MDS patients.

**Methods:** Massive parallel sequencing with high accuracy utilized duplicate
libraries from myeloid cells and included the non-tumorous T-cell controls to
identify somatic mutations in the serial samples before and during AZA therapy.
The tool for detecting the dynamics of somatic mutations was the TruSight
Myeloid Panel that contains 54 gene regions with previously documented muta-
tion recurrence in 439 patients (Bejar, Stevenson et al. 2011). Indeed, 92% of
our MDS cohort bore at least one somatic mutation with mostly 4 mutations
per patient (range 1-9), which indicated that the MDS patients were already at
relatively progressed state (Papaemmanuil, Gerstung et al. 2013).

**Results:** Analysis of 38 patients treated with AZA (reaching median OS 24
months (Mo) with 60% hematopoiesis improvement) revealed 125 somatic vari-
ants with VAF over 5%. Adverse effects of variants in cooperating regulators of
dNA damage and cell cycle were confirmed: TP53 (OS on AZA 14.8 Mo),
CDK24 (12.3 Mo), EZH2 (11 Mo). Besides the stable variant’s allele frequency
(50%<VAF <200%) there existed four additional VAF profiles. Stable variants’
dynamics precluded putative AZA-resistant clones associated with shorter sur-
vival (19 Mo). In contrast, the patients bearing variants with decreasing VAF,
which supposedly were inhibited by AZA, lived longer (31 Mo). Interestingly,
small group of highly dynamic variants upon AZA therapy formed a subgroup
with longer-lasting complete remissions.

**Summary/Conclusions:** Our work support the importance of catalogization
of somatic variants to delineate pathogenesis of MDS with a focus on molecular
AZA responsiveness. Several types of variant dynamics during the AZA therapy
were noted by using the massive parallel sequencing approach of the duplicate
libraries per MDS BM samples also utilizing non-tumorous controls and serial
sampling. Stable dynamics was found in variants previously recorded by COS-
MIC and targeting the adverse outcome genes such as TP53, BCORL1,
ASXL1, and EZH2 as well as their combinations with TET2 that may potentially
mediate clonal selection of additional variants mediating progression during
AZA therapy.

**E1167**

**WHOLE GENOME MBD-SEQ REVEALS DIFFERENT CPG METHYLATION
PATTERNS IN AZACITIDINE-TREATED JUVENILE MYELOMONOCYTIC
LEUKEMIA (JMML) PATIENTS**

P.P. Leoncini1,*, P. Vitullo1, F. Di Florio1, V. Tocco1, M.P. Cefalo1, A. Pitisci1,
K. Girardi1, C. Niemeyer2, F. Locatelli1, A. Bertain1

1Oncohaematology, Bambino Gesù Children Hospital, Roma, Italy, 2Pediatrics-
Oncohematology, University of Freiburg, Freiburg, Germany

**Background:** Juvenile Myelomonocytic Leukemia (JMML) is a rare and aggres-
seve leukemia of early childhood. Allogeneic hematopoietic stem cell transplant
(HSCT) is the only available curative treatment, but, since disease recurrence is
responsible for treatment failure in at least one third of transplanted patients,
developing alternative therapeutic approaches is desirable. Abrerrant DNA methyl-
ylation is a key molecular feature of JMML, suggesting an important role of epi-
genetic events in the pathophysiology of the disease. Azacitidine (AZA), a mole-
cule that inhibits DNA methylation in human cells, is under investigation in
JMML.

**Aims:** Here we report, for the first time, a global evaluation of DNA methylation
status of CD34+ cells deriving from JMML patients before and after AZA treat-
ment and compared the results with those of healthy controls. Identifying dif-
ferentially methylated CpG islands linked to various genes will help us describe
an epigenetic aberrant paradigm possibly involving transcriptional and translational regulation in JMML.

**Methods:** CD34+ cells isolated from 3 JMML patients samples collected at diagnosis (t0) and after the third cycle of AZA (t1) were evaluated together with those of 3 healthy donors (HD). JMML patients have been treated with AZA on a compassionate use basis after obtaining signed informed consent. DNA samples were processed and 10 fragment libraries were prepared. MBD-seq, bioinformatics and statistical analysis were performed by Genomnria srl (Bresso, Italy).

**Results:** First, we compared 10 JMML cells with HD cells, finding 987 different transcriptional units corresponding to 714 coding and 273 non-coding sequences. We also compared DNA methylation between t0 and HD cells. In this comparison, 644 unique transcriptional units, including 468 coding and 176 non-coding sequences, were found. Hypermethylation in JMML samples compared to HD was detected, but, unexpectedly, t0 vs t1 methylation analysis did not show any significant result, suggesting a likely unspecific patient-related pharmacological effect. Notably, 453 coding and 165 non-coding differentially methylated regions are shared between t0 vs HD and t1 vs HD sets. More in detail, 261 and 15 coding regions and 107 and 10 non-coding regions were uniquely found in t0 vs HD and t1 vs HD sets, respectively. However, 439 coding and 161 non-coding genomic regions preserve their hypermethylated status, probably due to a mechanism of resistance to AZA treatment. Among non-coding elements, we found different RNA species, such as microRNAs, splicing RNAs, lincRNAs/antisense transcripts (AS) and other unknown RNAs. Retrotransposons, belonging to LINEs and SINEs families, were also screened. We identified 13 sequences with a significant differential methylation profile in both t0 and t1 vs HD. Again, a comparison between t0 and t1 groups did not show any significant difference. Eleven hypermethylated common LINEs were evident between t0 vs HD and t1 vs HD sets. Two retrotransposons with opposite methylation patterns were found in t0 vs HD and t1 vs HD sets; while in the first comparison they included LINEs, in the second one they are 1 hypermethylated LINE and 1 hypomethylated SINE.

**Summary/Conclusions:** In conclusion, the whole genome MBD-seq performed for the first time on JMML CD34+ bone marrow derived cells, showed a broad genomic hypermethylation both in pre- and post-AZA samples compared to HD, suggesting a patient-specific AZA-effect. Transcription and translation processes of coding and non-coding genes could be deregulated in multiple ways, due to heterogeneity of sequences involved in CpG islands hypermethylation. Moreover, due to their known ability to insert random mutations in the genome, retrotransposons should be candidate for further studies in JMML pathogenesis.

**RESPONSE MONITORING IN MDS WITH DEL(5Q) USING DIFFERENT FLOW CYTOMETRIC (FCM)-SCORES IN COMPARISON TO CYTOGENETICS AN ELNET IMDS-FLOW EXPERIENCE**

U. Oelschlaegel1,2, T.M. Wessels1, B. Mohr1, D. Subira3, U. Johansson4, G. Ehnlinger1, M. Bornhäuser1, A.A. van de Loosdrecht2, U. Platzecker1
1Medical Clinic and Polyclinic I, MK1-L06, University Hospital of Tu Dresden, Dresden, Germany, 2Department of Hematology, VU University Medical Center, Amsterdam, Netherlands, 3Department of Hematology, Hospital Universitario de Guadalajara, Guadalajara, Spain, 4Department of Hematology, University Hospitals NHS Foundation Trust., Bristol, United Kingdom

**Background:** Flow cytometry (FCM) is one part of integrated MDS diagnostics. Different well established FCM-scores are applied, as FCSS (Wells et al. 2003), Ogata-score (Ogata et al. 2012), new iFS (Cremers et al. 2017), and del(5q)-FCM-score (Oelschlaegel et al. 2015).

**Aims:** The aim of this prospective study was to test, which of the mentioned FCM-scores fits best for response monitoring in del(5q) MDS in comparison to cytogenetics.

**Methods:** Overall, 245 FCM investigations were performed in 61 patients with MDS and del(5q) (IPSS-R very low/low: n=26, int: n=13, high/very high n=22) including 42 patients with isolated del(5q) or one additional cytogenetic abnormality. The majority of analyses were performed in patients receiving lenalidomide or azacitidine (n=29 and n=22 patients), or in patients receiving chemotherapy and/or allogeneic transplantation or growth factors (n=10). Standardized FCM (lyse-stain-wash) and cytogenetics/FISH procedures were performed according to ELN guidelines at the TU of Dresden, VUMC of Amsterdam, UH of Guadalajara and UH of Bristol. Cytogenetics/FISH analysis was considered the gold standard. All the applied FCM-score were propagated by the ELN in MDS working group. Additionally, hematomatological improvement of the erythroid lineage (HI-E) was evaluated (Cheson et al. 2006).

**Results:** The del(5q)-FCM-score reflected best the disappearance / presence of the cytogenetic abnormality del(5q) with a sensitivity of 98% and a specificity of 82%. This was confirmed if only MDS with del(5q) or only MDS treated with Lenalidomide were evaluated separately (sensitivity: 98% and 100%; specificity: 85% and 75%). The use of the Ogata-score considering almost only abnormalities of the myeloid progenitors, ended up with a slightly lower sensitivity (86%) and specificity (81%). The new iFS analyzing progenitor cells, granulo-, mono-, and erythropoiesis showed a comparably high specificity (83%) but a slightly impaired sensitivity (72%). FCSS, analyzing dyspoiesis of multiple cell lineages, showed a response in less than the half of all investigations being in cytogenetic CR (sensitivity: 41%), but revealed a high specificity (91%). The analysis of HI-E was high sensitive (81%) but not as specific (62%). Next, we investigated the potential prognostic impact of response monitoring using various FCM-scores compared to cytogenetics. Considering all del(5q) MDS patients as well as only those patients with del(5q) as a single abnormality, cytogenetics and all tested FCM-scores showed a significantly longer OS for MDS responding to therapy. The highest prognostic impact was detected in the iFS-score (p=0.0019) and Ogata-score (p=0.0092), respectively. Evaluating only MDS treated with lenalidomide, response monitoring using FCSS separated best the OS curves (p=0.0080). Finally, we combined the evaluation of HI-E with cytogenetics or the FCM-scores. This resulted in an even better OS for MDS fulfilling two response criteria vs one or none. The iFS-score was the best prognostic impact for the combination of HI-E plus the new iFS (p=0.0010).

**Summary/Conclusions:** Flow cytometry might serve as a rapid tool for response monitoring during treatment with disease-modifying drugs. All established FCM-scores allowed for an at least similar correctness of response prediction. The prognostic impact of the various FCM-scores seems to be even higher than that of cytogenetic response evaluation in this MDS subgroup. One reason might be, that most of the FCM-scores reflect not only the genetic background of the MDS but dyspoietic alterations in various cell lineages of the hematopoietic system.

**EVALUATION OF MUTATIONS AT RELAPSE IN MYELODYSPLASTIC SYNDROME PATIENTS RECEIVING ALLOGENEIC STEM CELL TRANSPLANTATION**

M. Cabrero1, J.M. Hernandez-Sanchez2, J.M. Caballero1, C. Chillon1, M. Martin-Izquierdo1, M. Abaigar1, A. Redondo1, F. Lopez-Cadenas1, E. Perez-Lopez1, L. Lopez-Corrall1, R. Benito1, C. Robledo1, M. del Rey1, M. Gonzalez1, C. del Cañizo1, D. Caballero1, J.M. Hernandez-Rivas1, M. Diaz Campelo1, 1Hematology Department, Hospital Universitario de Salamanca-IBSAL, Salamanca, Spain

**Background:** Allogeneic transplant (AlloSCT) is the only curative therapy for myelodysplastic syndromes (MDS). Unfortunately, relapse is the main cause of treatment failure. Evaluation of genetic mutations both at diagnosis and
before AlloSCT is a potent prognostic tool. However, mutational profile at relapse after AlloSCT has not been widely explored.

**Aims:** In this study, we evaluate mutational profile at post-AlloSCT relapse in MDS patients to determine if pre-AlloSCT mutations are still present at relapse, so we could eventually monitor them as minimal residual disease (MRD) after AlloSCT.

**Methods:** From a retrospective cohort of 115 patients, we selected those who relapsed post-AlloSCT (19/115, 16.5%) with available material at relapse (18 patients). We performed an in-house target-capture panel, sequencing across selected exons of 117 cancer-related genes previously related to MDS in pre-AlloSCT samples to identify genetic mutations and we checked the presence of those mutations in samples at relapse. Six patients were discarded because lack of pre-AlloSCT mutations, so we selected 12 patients for the sequential study. DNA was amplified with FastStart High Fidelity PCR System using exon-specific primers for each mutation. The indexed paired-end library was prepared with Nextera XT DNA Sample Preparation Kit (Illumina) The median coverage per base achieved was 4570 reads (range 857-53,474). In a second step, we explore the possibility of evaluating mutations in both CD34 positive and the rest of bone marrow cells, to check if we could increase the sensitivity of the detection.

**Results:** Median age of relapsed patients was 60 (45-70). Diagnosis were RAEB1 (n=4), RAEB2 (4), dysplasia associated AML (2) and RCMD (2). They relapse post-AlloSCT after a median of 2.5 months (1-7), and 4 of them are alive at last follow up after a median of 22 months (9-33). Patients had a median of 2.5 mutations (range 1-4), TET2 mutations were detected in 4 (33%) of patients; U2AF1, EZH2, SRSF2, KAS, JAK2 and RUNX1 in 2 (17%), and NRAS, TP53, ET6, PHF6, SMC1A, ZR52, BCR, DNM3 and SFB1 mutations in 1 (8%) (Table 1). In 10 out of 12 evaluated patients, we found the same genetic mutations at relapse compared with pre-AlloSCT sample (Table 1). In addition, mutational pattern was similar for all patients except for one in which dominant mutation at relapse was SRSF2 present in 14% of cells pre-Allo and in 3% at relapse) instead of ET6V (51% pre-AlloSCT and 0.6% at relapse). In 2 patients, pre-AlloSCT mutations were not detected at relapse (Patient 8: BCR and RUNX1. Patient 11: SRSF2, TET2 and RUNX1). In a second step, we searched for mutations in CD34+ cells to check its sensitivity to detect genetic alterations. We selected CD34 positive cells in one patient with KRAS and IDH2 mutations pre-AlloSCT. KRAS and IDH2 were present in 40% and 45% of CD34+ positive cells and in 37% and 48% of the bone marrow (CD34 depleted) compartment respectively in pre-AlloSCT samples. In relapse samples, mutations were present in similar percentage in CD34 positive cells compared to CD34 depleted bone marrow (KRAS 0.63% and 2.23%, IDH2 1.6% and 1.45% respectively).

**Table 1. Mutations before and after the AlloSCT in relapsed patients**

**Summary/Conclusions:** Post-AlloSCT relapsing MDS show same genetic mutations found in pre-AlloSCT evaluation, so they would potentially be used to confirm clonality and probably MRD assessment after AlloSCT in the near future. CD34 selection does not provide additional sensitivity to whole bone marrow cellularity sample.

**RIGOSERTIB COMBINED WITH AZACITIDINE EPIDEMIOGENICALLY MODULATES CHROMATIN AND HEMATOPOIETIC STEM CELL POPULATIONS IN THE MYELODYSPLASTIC SYNDROME (MDS) PATHWAY**

D. Beauvais1,*, B. Céline1,2, O. Nibourel2,3, C. Preudhomme2,3

1Department of Adult Hematology, CHRU University Hospital of Lille, 2UMR-S 1172, Institute for Cancer Research of Lille, 3Biology and pathology center, Laboratory of Hematology, CHRU University Hospital of Lille, Lille, France

**Background:** Unexplained cytopenias (UC) are common problems during hospitalisation, particularly in elderly patients. If there is no evident cause, myelodysplastic syndrome (MDS) is frequently suggested and a bone marrow aspiration is performed. Next-generation sequencing (NGS) reveals MDS-assoociated somatic mutations but therapeutic significance is discussed. In our centre, NGS was systematically realized in the context of unexplained cytopenias.

**Aims:** The objective of this study was to explore results of NGS in practical routine in the context of UC and to precise if some groups of patients could more specifically benefit of NGS.

**Methods:** All patients in our centre with analysis of NGS performed in blood or in bone marrow in a context of UC were included. Exclusion criteria were: patients under 18 years, monocytes >1000/mm3, excess of blasts, history of hematological malignancy disorder. Patients were included in group “positive NGS” if at least one significant mutation (no SNP) was found on 25 genes selected: TP53, TET2, ZRSR2, KRAS, TP53, U2AF1, EZH2, SRSF2, JAK2, IDH1, Idh2, KIT, KRAS, MPL, NPM1, NRAS, PHF6, PTEN11, RIT1, RUNX1, STBP1, SF3B1, SRSF2, TET2, TP53, U2AF, WT1, ZRSR2). Clinical and biological criteria were reported from local database. All patients gave consent.

**E1171**

**UNEXPLAINED CYTOPENIAS IN HOSPITAL: INDICATIONS AND BENEFITS OF NEXT-GENERATION SEQUENCING**

D. Beauvais1,*, B. Céline1,2, O. Nibourel2,3, C. Preudhomme2,3

1Department of Adult Hematology, CHRU University Hospital of Lille, 2UMR-S 1172, Institute for Cancer Research of Lille, 3Biology and pathology center, Laboratory of Hematology, CHRU University Hospital of Lille, Lille, France

**Background:** Unexplained cytopenias (UC) are common problems during hospitalisation, particularly in elderly patients. If there is no evident cause, myelodysplastic syndrome (MDS) is frequently suggested and a bone marrow aspiration is performed. Next-generation sequencing (NGS) reveals MDS-associated somatic mutations but therapeutic significance is discussed.

**Aims:** The objective of this study was to explore results of NGS in practical routine in the context of UC and to precise if some groups of patients could more specifically benefit of NGS.

**Methods:** All patients in our centre with analysis of NGS performed in blood or in bone marrow in a context of UC were included. Exclusion criteria were: patients under 18 years, monocytes >1000/mm3, excess of blasts, history of hematological malignancy disorder. Patients were included in group “positive NGS” if at least one significant mutation (no SNP) was found on 25 genes selected: TP53, TET2, ZRSR2, KRAS, TP53, U2AF1, EZH2, SRSF2, JAK2, IDH1, Idh2, KIT, KRAS, MPL, NPM1, NRAS, PHF6, PTEN11, RIT1, RUNX1, STBP1, SF3B1, SRSF2, TET2, TP53, U2AF, WT1, ZRSR2). Clinical and biological criteria were reported from local database. All patients gave consent.
Results: 156 patients were included between January 2014 and December 2015 with a mean age of 68 years (65.8-70.3) and 47.4% of men. 127 patients (81.4%) had a bone marrow analysis. 53 patients (34.0%) were reported in the group “positive NGS” and 103 patients (66.0%) in the group “negative NGS”. In univariate analysis, significant variable associated with “positive NGS” were age (<p=0.1), negative history of auto-immune disease (<p=0.002), hemoglobin <12g/dL (<p=0.017), platelets >150000/mm³ (<p=0.015), >10% dysplastic cells in erythroid (<p=0.012) and granulocytic lineage (<p=0.034). Trend test on dysplastic lineage number was significant (<p=0.006). Normal karyotype (78.1%) was comparable in the two groups (<p=0.35). Cirothosis and/or portal hypertension were comparable in the two groups (14.1%, p=0.092) as well as mean serum creatinine (p=0.24). In multivariate analysis, age >70 years (p=0.0011) and platelets >150000/mm³ (p=0.0213) remained significantly associated to positive NGS (Table 1). In “positive NGS” group, 1 (58.5%), 2 (32.1%), 3 (7.5%) or 4 (1.9%) mutation(s) were found per patient. Most frequent mutations were TET2 (25.9%), DNMT3A (17.3%), SF3B1 (12.3%), SRSF2 (8.6%), U2AF1 (4.9%), TP53 (3.7%) and ZRSR2 (3.7%). Other mutations were TET2 (25.9%), DNMT3A (17.3%), SF3B1 (12.3%), ASXL1 (12.3%), SRSF2 (8.6%), U2AF1 (4.9%), TP53 (3.7%) and ZRSR2 (3.7%).

Results: SKM1-R cells did not express UCK1, SRSF2, U2AF1 or ZRSR2. Corresponding proteins were also not expressed. A reduction of apoptosis was observed in UCK1-silenced SKM-1 S after azacitidine 0.1 μM treatment: 35.7±0.37% Annexin V-positive cells versus 25.2±0.35% (P=0.031) in non-silenced control SKM1-S cultures. We observed a reduction of apoptosis induced by UCK2-silencing after azacitidine 0.1 μM treatment too: 31.3%±0.85% Annexin V-positive cells versus 21.3%±0.35% (P=0.054). Hypomethylation induced by in vitro azacitidine treatment was also hampered by reduction of expression of UCK1 and UCK2. Quite surprisingly gene expression of UCK1, UCK2, hENT1, hCNT3, RRM1 and RRM2 in primary cells did not predict different clinical response to azacitidine. Reduced expression of UCK1 and UCK2 did not find any differences between responder and non-responder patients.

Summary/Conclusions: We demonstrated that UCK1, UCK2, hENT1, hCNT3, RRM1 and RRM2 and the corresponding proteins are absent in azacitidine-resistant cell line SKM1-R suggesting to be the determinant of the induced resistance to azacitidine. Reduced expression of UCK1 and UCK2 significantly decreased azacitidine effects. Prospective evaluation of the predictive role of cellular expression of genes involved in azacitidine metabolism is ongoing in a larger cohort of MDS patients.

E1174 FAMILIAL TIN2 N-TERMINAL LOSS OF FUNCTION MUTATION IN TELOMERE SYNDROME
D. Di Giacomo1,∗, V. Nofrini1, T. Iannotti1, M. Quintini1, F. Pellanera1, G. Barba1, C. Matteucci1, S. Ballanti1, R. Piazza2, C. Mecucci1
1Haematology and Bone Marrow Transplantation Unit, University of Perugia, Perugia, 2Medicine and Surgery, University of Milano-Bicocca, Milan, Italy

Background: the shelterin complex protects telomeres from being processed by the DNA damage repair machinery and regulates telomere access and function (Frank 2015). TIN2F2 (14q12) is encoding for TIN2, the central component of the complex (TRF1,TRF2 and TPP1), thus contributing to telomere length regulation and structural integrity (Frank 2015). About thirty TIN2 mutations are known in Dyskeratosis Congenita (DC) (Savage 2008) and other telomere related phenotypes, i.e. aplastic anemia (AA), idiopathic pulmonary fibrosis, liver cirrhosis, myelodysplastic syndromes (MDS) and acute myeloid leukemia (Armanios 2012). All mutations were missense and heterogeneous, clustering in exon 6 encoding for a highly conserved segment at the C-terminus (aa 280–291) (Frank 2015).

Aims: Precise diagnosis in AA/MDS with clinical features of telomere syndrome.

Methods: AA was diagnosed in a 69-year-old man, with a multisystem disorder, i.e. psoriasis, nail dystrophy, severe osteoporosis, chronic hepatopathy, mild chronic kidney failure and hypertension, suggesting a telomere syndrome. Karyotype was normal. Patient was unresponsive to immune-suppressive therapy. DNA from peripheral blood and hair bulbs was analysed for TERT, TERC and quantitated by western blotting in both cell lines. Evaluation of expression of TERT (TRF1,TRF2 and TPP1), thus contributing to telomere length regulation and structural integrity (Frank 2015). About thirty TIN2 mutations are known in Dyskeratosis Congenita (DC) (Savage 2008) and other telomere related phenotypes, i.e. aplastic anemia (AA), idiopathic pulmonary fibrosis, liver cirrhosis, myelodysplastic syndromes (MDS) and acute myeloid leukemia (Armanios 2012). All mutations were missense and heterogeneous, clustering in exon 6 encoding for a highly conserved segment at the C-terminus (aa 280–291) (Frank 2015).
PLASMA GALECTIN-9 LEVELS IN MYELODYSPLASTIC SYNDROMES

Summary/Conclusions: A new TIMF2 germline variation at exon 2, c.254A>G p.H85A, was identified in the proband and in two brothers. Screening on 200 healthy donors was negative. Significantly short telomeres were found in proband (p=0.0161) and brothers (p=0.0082 and p<0.0001), compared to age and sex matched controls. The proband had a normal SNPs profile and WES identified an additional somatic variation in TLR1 gene (c. 1859G>A p.R620Q). Co-immunoprecipitation experiments showed that the new TIMF2 mutation reduced TIM2 binding with TRF2 in vitro.

Methods: 1) We evaluated Tim-3 expression on CD45-gating blasts of bone marrow mononuclear cells (BMMCs) in 20 patients with MDS and AML transformed from MDS (AL-MDS), 12 healthy controls, and 4 MDS cell lines using flow cytometry (FCM). 2) To investigate Tim-3 induction, MDS cell line F-36P cells were co-cultured with the culture supernatant of human stromal cells and the MDS-related cytokine transforming growth factor-β1 (TGF-β1) and/or anti-Tim-3 blocking antibody. 5) Finally, we analyzed gal-9 concentrations in culture supernatants of MDS cells and in plasma obtained from patients with MDS (n=51) and AL-MDS (n=19), and healthy donors (n=10).

Results: 1) Tim-3 expression was observed on monocytes and CD45-gating blasts in MDS BMMCs and in all 4 MDS cell lines. In AL-MDS patients, Tim-3 expression levels on blasts were markedly higher than in controls and MDS patients in F-36P cells (p<0.0001). 3) To elucidate the functions of Tim-3 on MDS cells, F-36P cells were divided into Tim-3+ and Tim-3− fractions with FACS sorting and their differential gene expression was determined with oligonucleotide microarray analysis. 4) To investigate the proliferative potential of Tim-3 signaling, intracellular Ki-67 expression in F-36P cells was evaluated using FCM when co-cultured with/without anti-Tim-3 blocking antibody. 5) Finally, we analyzed gal-9 concentrations in culture supernatants of MDS cells and in plasma obtained from patients with MDS (n=51) and AL-MDS (n=19), and healthy donors (n=10).

Conclusion: A new TIMF2 germline variation at exon 2, c.254A>G p.H85A, was identified in the proband and in two brothers. Screening on 200 healthy donors was negative. Significantly short telomeres were found in proband (p=0.0161) and brothers (p=0.0082 and p<0.0001), compared to age and sex matched controls. The proband had a normal SNPs profile and WES identified an additional somatic variation in TLR1 gene (c. 1859G>A p.R620Q). Co-immunoprecipitation experiments showed that the new TIMF2 mutation reduced TIM2 binding with TRF2 in vitro.
Methods: Besides azacitidine and decitabine, three other agents (SGI-1027, zebularine, and gencitabine) are known as having hypomethylating effect. In vitro activities of the 5 HMA's on HMA resistant cell lines (MOLM/AZA-1 and MOLM/DEC-5) were tested by cell viability assay using luminescent-based CellTiter-Glo system. Protein and mRNA levels of DNMT enzymes (DNMT1, 3A, and 3B) were assayed before and after treatment of each HMA. Protopoietal degragation and activation of p-Akt were also determined to see the correlation with changes of DNMT's.

Results: Although azacitidine and decitabine could suppress DNMT1 and DNMT3A in MOLM-13, the agents could not suppress DNMT enzymes in resistant cell lines. Inhibition of protopoeitical degradation by bortezomib induced accumulation of DNMT enzymes in MOLM-13, whereas it did not accumulate the enzymes in MOLM/AZA-1 and MOLM/DEC-5. Phosphorylated Akt (p-Akt) was dramatically overexpressed in MOLM/AZA-1 and MOLM/DEC-5. SGI-1027 showed the lowest IC_{50} values for MOLM/AZA-1 and MOLM/DEC-5, and it suppressed the protein levels of all three DNMT enzymes. SGI-1027 could also decrease the level of p-Akt. GDC-0941, a PI3K inhibitor, suppressed DNMT1 and DNMT3A as well as p-Akt, but it could not decrease DNMT3B in MOLM/AZA-1 and MOLM/DEC-5. Cell viability assay showed the synergistic effects of combination of GDC-0941 and Nanomycin A, a specific DNMT3B inhibitor, in MOLM/AZA-1 and MOLM/DEC-5.

Summary/Conclusions: DNMT levels of MOLM/AZA-1 and MOLM/DEC-5 were not dependent on protopoeitical degradation. DNMT1 and DNMT3A might be regulated via PI3K-Akt pathway, while regulation of DNMT3B might be different from DNMT1 and DNMT3A. SGI-1027 appears to exert inhibitory effects on MOLM/AZA-1 and MOLM/DEC-5 by inhibition of both p-Akt and DNMT3B.

Background: Myelodysplastic syndromes (MDS) are a group of heterogeneous clonal stem cell disorders leading to ineffective hematopoiesis. Anemia is a frequent cytopenia in MDS and the majority of patients requires red blood cell (RBC) transfusion resulting in the development of iron overload (IO). Deferasirox (DFX) became a standard treatment of IO in MDS and seems to have positive effects on hematopoiesis with a reduced need of RBC transfusion.

Aims: Decipher the mechanisms of the potential improvement of erythropoiesis with DFX.

Methods: We report our in vitro data about the proliferation, cell cycle, apoptosis, erythroid differentiation, and cell signaling pathways concerning CD34+ hematopoietic stem progenitor cells from low risk MDS samples in a 2-step erythroid differentiation liquid culture with low dose DFX and iron overload.

Results: We observed a higher proliferation rate for cultures with 3µM DFX versus the control condition (p=0.038). In contrast, no increased proliferation was found with DFX=5µM and with other chelators used in the clinic. The higher proliferation rate with DFX 3µM was due to the combination of decreased apoptotic cells at day 10 (D10) (p=0.03) and D14 (p=0.007) and increased cycling cells at D10 (p=0.0001). Regarding clonogenic assays, there were more CFU-E colonies with DFX 3µM (p=0.04). Despite the low concentration of DFX, cells exposed to DFX 3µM had a lower intracellular iron concentration measured by ICP-MS than control cells (p=0.019). Nevertheless, this decreased iron amount was not sufficient to activate cellular iron regulation by Iron Regulatory Proteins suggesting the absence of a direct effect of low dose DFX on iron homeostasis. Moreover, low dose DFX decreased intracellular and mitochondrial reactive oxygen species (ROS) at D14 (p=0.048 and p=0.03) and decreased the level of malonaldehyde (p=0.048), a product of lipid peroxidation. Then, we have investigated which signaling pathways were sensitive to DFX 3µM. We found an increased nuclear translocation of NFκB detected by both CM (p=0.03) and luciferase reporter assay (p=0.03). NFκB activation was absent in the knock-down (KD) of mitochondrial TRX (siTRX2) condition. Moreover, in non-iron overloaded medium condition, the level of ROS was not increased, and DFX in the TRX1 KD condition was not associated with NFκB activation. These results suggest that NFκB activation in this model is linked to TRX1 and regulated by an extremely fine control of ROS levels with a likely threshold effect.

Summary/Conclusions: Our study describes the pro-proliferative effects of low dose of DFX on erythroid progenitors in low risk MDS patients. These results provide a biological rationale for a clinical trial which will propose low dose of DFX in MDS patients, refractory to erythropoiesis stimulating agents.
**Myelodysplastic syndromes - Clinical**

E1179 EVALUATING ERYTHROBLAST PAS POSITIVITY IN THE DIAGNOSTIC APPROACH OF MYELODYSPLASTIC SYNDROME

E. Travaglini,1 M. G. Della Porta1, L. Malcovati1, M. Cazzola1
1IRCCS Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy

**Aims:** The aims of our study were to evaluate the diagnostic significance of erythroblast PAS positivity in MDS and to investigate a possible correlation between levels of PAS positivity and other morphological and clinical features.

**Methods:** We retrospectively examined the results of the cytochemical PAS staining for glycogen in BM smears from 165 patients with MDS, 116 patients with non-clonal cytopenia and 49 healthy subjects. We developed a PAS score by counting 100 nucleated cells for the erythroid lineage and classifying them into four categories according to their degree of PAS reactivity: grade 0 (no PAS positivity), grade 1 (rare PAS positivity), grade 2 (low PAS positivity), grade 3 (medium PAS positivity), and grade 4 (high PAS positivity). We also classified patients into three categories according to the degree of PAS positivity in BM smears: grade 0 (no PAS positivity), grade 1 (rare PAS positivity), and grade 2 (low PAS positivity).

**Results:** PAS positive erythroblasts were observed in 104 (63%) MDS patients, 46 (40%) patients with non-clonal cytopenia, and 12 (24%) non-erythroid cells, with a significant difference between MDS and non-erythroid cells (p=0.0001) or non-clonal cytopenias (p=0.0001), but not between healthy controls and non-clonal cytopenias (p=0.09). In MDS, both positivity rates (median 2%, range 0-33) and scores (median 2, range 0-53) were significantly higher than those in normal and pathological controls (p=0.0001 and p=0.0004 for rate, p=0.0001 and p=0.0002 for score, respectively), without significant difference in relation to excess blasts or multilineage dysplasia. MDS patients with >4% ring sideroblasts (RS) showed lower PAS positivity rates and scores than MDS patients with ≤4% RS (p=0.0332 and p=0.0412, respectively). In MDS-RS, erythroblast PAS positivity was not influenced by SF3B1 mutation status.

**Discussion:** The combination of both PAS positivity and percentage of BM blasts, percentage of BM erythroblasts, dyserythropoiesis grading, or Hb levels, whereas an inverse correlation was noticed between PAS score values and intranuclear bridging (r=-0.23, p=0.0395). A ROC curve analysis allowed us to identify a PAS score value ≥1 (AUC=0.697, p=0.0034) as optimal cutoff to discriminate MDS patients from non-erythroid cytopenias.

**Summary/Conclusions:** The weight of both PAS positivity rate and score in the identification of BM dysplasia was lower than that of ring sideroblasts and macroblastosis, but higher than that of defective hemoglobinisation, nuclear lobulation, basophilic fraying, pyknosis, and intranuclear bridging. Integrating conventional parameters and PAS results significantly improved the sensitivity of our morphological scoring system.

**E1180**

A PHASE 3 RANDOMIZED PLACEBO (PBO)-CONTROLLED DOUBLE-BLIND TRIAL OF DARBEPOETIN ALFA IN LOW OR INTERMEDIATE-1 (INT-1) RISK MYELODYSPLASTIC SYNDROMES (MDS)

**Aims:** To evaluate darbepoetin alfa (DAR) in IPSS low/int-1 risk MDS (RBC:7400-9800/μl and Hb:10-12 g/dL) with a focus on transfusion burden, with no previous treatment with ESAs or biologic response modifiers, and with serum EPO<500 mU/mL.

**Methods:** Patients with MDS per WHO 2008 criteria with IPSS low/int-1 risk, anemia [hemoglobin (Hb)<10 g/dL], low transfusion burden, no previous treatment with ESAs or biologic response modifiers, and serum EPO<500 mU/mL were randomized 2:1 to 24 weeks (wk) SC DAR 500 μg or PBO every 3 wk (Q3W), stratified by IPSS, then 48 wk open label (OL) DAR; follow-up is ongoing.

**Summary/Conclusions:** In this phase 3, randomized, double-blind, PBO-controlled trial in anemic IPSS low/int-1 risk MDS patients, 24 wk of darbepoetin alfa Q3W significantly reduced transfusions and increased Hi-E rates with no new safety signals. Most patients met criteria to change to Q2W dosing during the 48-wk OL period, suggesting that Q2W dosing may offer more benefit. The true clinical benefit of darbepoetin alfa may have been underestimated due to the nature of IWG 2006 Hi-E criteria and trial design (Hb measured Q3W, dosing rules).

**E1181**

PRELIMINARY ANALYSIS OF EFFICACY AND SAFETY OF SINTRA-REV CLINICAL TRIAL, LENALIDOMIDE VS PLACEBO PHASE 3 STUDY IN LOW/INT-1 MDS PATIENTS WITH DEL(5Q) AND TRANSFUSION INDEPENDENCY

**Aims:** To evaluate darbepoetin alfa (DAR) in IPSS low/int-1 risk MDS (RBC:7400-9800/μl and Hb:10-12 g/dL) with a focus on transfusion burden, with no previous treatment with ESAs or biologic response modifiers, and with serum EPO<500 mU/mL.

**Methods:** Patients with MDS per WHO 2008 criteria with IPSS low/int-1 risk, anemia [hemoglobin (Hb)<10 g/dL], low transfusion burden, no previous treatment with ESAs or biologic response modifiers, and serum EPO<500 mU/mL were randomized 2:1 to 24 weeks (wk) SC DAR 500 μg or PBO every 3 wk (Q3W), stratified by IPSS, then 48 wk open label (OL) DAR; follow-up is ongoing.

**Summary/Conclusions:** In this phase 3, randomized, double-blind, PBO-controlled trial in anemic IPSS low/int-1 risk MDS patients, 24 wk of darbepoetin alfa Q3W significantly reduced transfusions and increased Hi-E rates with no new safety signals. Most patients met criteria to change to Q2W dosing during the 48-wk OL period, suggesting that Q2W dosing may offer more benefit. The true clinical benefit of darbepoetin alfa may have been underestimated due to the nature of IWG 2006 Hi-E criteria and trial design (Hb measured Q3W, dosing rules).
Background: Lenalidomide (LEN) is the first choice of treatment in low risk MDS patients with isolated del(5q) (MDS-del(5q)) and transfusion dependency (TD). Most of the low risk MDS-del(5q) patients diagnosed with anaemia and independent of transfusions developed TD or needed treatment for symptomatic anaemia early after diagnosis (median of 20 months, abstract 3180 ASH, 2016). LEN directly targets the del(5q) clone improving anaemia, quality of life and survival in these subset of patients. For these reasons, the use of LEN in patients with del(5q), anaemia and not TD seems to be very attractive. However, data about the use of LEN in MDS 5q- patients and transfusion independency (TI) are scanty, some retrospective studies suggest a benefit with the early use of LEN in this setting, but there is not already available any prospective and randomized study to confirm this likely advantage.

Aims: Our aims were to analyze efficacy and safety at week 12 of treatment with LEN vs Placebo in this setting of low risk MDS del(5q) patients with anaemia and not in TD at diagnosis.

Methods: From 2010 to 2017, 47 patients have been included in the Sintra-Revl trial, a phase III, multicenter, randomized and double blind study with LEN (5mg/day) vs placebo [2:1 randomization] in Low – Int-1 risk (IPSS) MDS del(5q) patients with anaemia but TI. Preliminary results of efficacy (according to the IWG 2006 criteria for erythroid [Hi-ER] and cytogenetic response [CyR]) and safety has been analyzed at week 12. Progression disease (DP) in the trial was defined as the development of TD.

Table 1.

<td>35 (0-5)</td>
</tr>
</tbody>
</table>

Results: Main clinical characteristics are summarized in table 1. 85% were females, median age was 72 years (37-89) and most of patients (95%) had del(5q) as the only cytogenetic abnormality. Among 47 patients, only 38 were evaluable at week 12 (6 out of 38 discontinued the study: 3 due to DP, 1 due to toxicity and 1 for unknown reasons), 7 patients are currently receiving the first 12 weeks of treatment and 2 patients were excluded (screening failures). Regarding efficacy (w12), data from 36 patients were available. Hi-ER was observed in 14/38 patients (39%), minor Hi-ER (Hb increased<1.5g/dL) in 4/36 (11%), stable disease in 15/36 (42%) and PD (transfusion dependency) in 3 (8%). CyR was available in 30 patients: complete CyR was obtained in 12 (40%), partial CyR in 6 (20%) and no CyR in 12 (40%) patients. Safety information in 38 patients demonstrated that most patients (87%) developed any adverse events (AE) while only 42% of these were relevant (G3-4). Most G3-4 AE were hematological (neutropenia 38%) being non-hematological only in 4%. Seven serious AE were reported in 5 patients: vestibular neuritis, congestive heart failure, polyarthitis, arterial hypertensive crisis, carpal arthritis, respiratory infection and chronic obstructive pulmonary disease exacerbation. All SAE were not related with the drug of the study (LEN/Placebo).

Summary/Conclusions: In this study we confirm a high rate of erythroid and cytogenetic responses early after treatment with an adequate safety profile in the first 12 weeks of treatment with LEN or placebo.

E1182

MYELODYSPLASIA-RELATED MORTALITY REMAINS THE MAIN CAUSE OF DEATH ALONG DIFFERENT GROUPS OF RISKS: AN ANALYSIS FROM MDS ARGENTINEAN STUDY GROUP

A. L. Basquiera1, A. Enrico2,*, J. Arbelbide1, E. Nucifora1, M. Iastrebner3, MDS ARGENTINEAN STUDY GROUP

1Hematology, Hospital Italiano de Buenos Aires, Ciudad Autónoma de Buenos Aires (CABA), 2Hospital Italiano de La Plata, La Plata, 3Sagrado Corazon, 4Hematology, Hospital Durand, Ciudad Autónoma de Buenos Aires (CABA), 5Hospital Nacional Prof A Posadas, Buenos Aires, 6Hospital Durand, Ciudad Autónoma de Buenos Aires (CABA), 7Hematology, Hospital Nacional Prof A Posadas, Buenos Aires, 8Hospital Curie, 9Instituto de Medicina Experimental (IME-CONICET), Ciudad Autónoma de Buenos Aires (CABA), Argentina, 10Laboratorio de Genetica Hematologica, Instituto de Medicina Experimental (IME-CONICET), Ciudad Autónoma de Buenos Aires (CABA), Argentina

Background: Myelodysplastic syndrome (MDS) are the most frequent hematological malignancy in elderly patients. The impact of MDS burden on overall mortality remains controversial, moreover, after the incorporation of hypomelinating agents in the therapeutic armamentarium.

Aims: We aimed to analyze overall mortality and causes of death in our population of patients with MDS.

Methods: A retrospective analysis of patients with MDS reported to Argentinian MDS registry and a previous study from Academia Nacional de Medicina. Causes of death were classified in: acute myeloid leukemia (AML), infections, bleeding, solid tumor, cardiovascular, transplant related mortality (MRT), others and unknown. AML, infections and bleeding were considered as MDS-related mortality. Causes of death were analyzed using cumulative competitive events curves with Gray test and Fine-Gray for proportional hazard regression was used for the multivariate analysis.

Results: From 1981 to 2016, 1040 patients with MDS were recorded; 717 out of 1040 (69%) were diagnosed after 2006. Median age of patients was 70 years (range: 14-95 years) with 588 (56%) being males. MDS was primary in 974 patients (94%). Median follow-up of 25 months (range: 1-170 months) for the surviving patients. The cumulative incidence of overall mortality was 20% at 12 months (95%CI 1-22), 37% at 24 months (95%CI 3-40) and 59% at 60 months (95%CI 5-63). The incidence of overall mortality did not significantly differ along the follow-up of diagnosis (p=0.291) neither according to age group. Multivariate analysis for cumulative incidence of overall mortality found Charlsion index (HR 1.38; p<0.001), sex (HR 1.45; p=0.014) and IPSS-R (HR 2.79; p=0.001) as prognostic variables. The main cause of death was AML accounting for 9% at 12 months (95%CI 7-11), 16% at 24 months (14-19) and 25% at 60 months (95%CI 22-26) of mortality by all patients. Infection-mortality and bleeding-mortality were the second and the third cause of death respectively. MDS-related mortality was 16% at 12 months (95%CI 13-18), 29% at 24 months (95%CI 26-32) and 44% at 60 months (95%CI 40-48); this incidence was not different by year of diagnosis. MDS-related mortality remained the main cause of death in all IPSS-R groups and in all Charlsion index categories. Multivariate analysis for cumulative incidence of MDS-mortality found Charlsion index (HR 1.29; p=0.02), IPSS-R (HR 2.88; p<0.001) and sex (HR 1.47;p=0.03) as independent variable. Age (p=0.034) and IPSS-R (p<0.001) were associated with AML-related mortality. A total of 56 patients underwent allogeneic transplant; cumulative incidence of MRT for all cohort was 5.5% at 12 months (95%CI 0.2-1.2) and 14% at 24 months (95%CI 0.8-2.4). Only male sex was associated with a higher cumulative incidence of mortality by solid tumor (p=0.001) and a Charlsion index ≥2 was associated with higher cumulative incidence of cardiovascular mortality (p=0.021).

Summary/Conclusions: In this large cohort of patient with MDS we demonstrate that MDS-related causes are the leading cause of death along all IPSS-R groups. The absence of difference in mortality along the years of diagnosis highlights the necessity of better treatments for these patients.

E1183

PROSPECTIVE STUDY OF FLOW CYTOMETRY OF BONE MARROW IN 105 CONSECUTIVE PATIENTS WITH CYTOPENIA AND SUSPICION OF MYELODYSPLASTIC SYNDROME: STRONG CORRELATION WITH RISK OF AML-EVOLUTION AND SURVIVAL

F. Marco De Lucas1,*, Z. Diez Gallarreta1, B. Blázquez1, P. Iusij1, B. Dávila1, C. Barrenetxea1, A. Blanco1, B. Barreña2, S. Herráez1, I. Capel3, I. Leal1, J. Uriarte1, C. Alonso Caballero1, J.I. Rodriguez1, J.A. Márquez1, 1Hematología, 2genética, Hospital Universitario Basurto, 3facultad De Medicina Upv, Bilbao, Spain

Background: Diagnosis of myelodysplastic syndromes (MDS) remains a challenge, specially in patients with scant displastic morphology features and/or in the absence of cytogenetic changes. Multiparametric flow cytometry (MFC) findings have been recognized as a co-criterion for the diagnosis of MDS and have also demonstrated prognostic value in some studies. Nevertheless, this diagnostic tool is not fully implemented for the study of MDS in many centers and data from real life out of investigational studies are few.

Aims: To prospectively assess the value of MFC in the diagnosis of MDS in our center and correlate its findings to the clinical outcome of patients in terms of overall survival, transfusional needings, risk of hospitalization and evolution to acute leukemia.

Methods: We studied bone marrow samples from 105 consecutive patients submitted to our hospital between January 2013 and April 2015 because of one or more cyopenia and suspicion of MDS. Cytomorphology of every sample
was evaluated by at least two morphology experts and a consensus diagnostic of MDS-suspected or MDS-excluded was emitted. MDS was performed applying at least five-colour staining and a numerical score was calculated for every patient following criteria defined by Ogata et al (Blood. 2006 Aug 1; 108(3):1037-44), with a score ≥2 suggesting MDS. Conventional karyotype and FISH employing probes to detect usual 5q-, 7q-, 8q-, 20q- and del[T(5;17)] by FISH was also performed.

Results: Median age of the patients was 73.7 y/o. Patients presented with anaemia in 88 cases (84%), neutropenia in 36 (34%) and thrombopenia in 49 (47%). Cytomorphology was reported as MDS-confirmed (60 pts), MDS-excluded (22) or MDS-suspected (23). MDS subtypes were Multilineage Dysplasia (23), Unilineage Dysplasia with Ring Sideroblasts (9), del(5q) Syndrome (3) and Unclassified (2). 4 pts being diagnosed of CML. MFC score was MDS-suggestive in 56 cases, MDS-not suggestive (36) and in 13 cases its use was precluded because of morphology findings. Considering cytomorphology as gold standard, the agreement between MFC and MDS-suspected or MDS-excluded by morphology MFC score sensitivity was 77%, specificity 88%, with positive and negative predictive values of 96% and 56% respectively. Furthermore, MFC-score showed a significant correlation with single morphologic findings of granulocytic (p<0.001), erythroid (p=0.001) and megakaryocytic dysplasia (p=0.002), and a trend to significant association with del(7q) by FISH (p=0.089). In the subset of patients with MDS-suspected but not confirmed by morphology, the presence of a MFC score ≥2 was significantly associated with a poorer overall survival (log-rank p=0.012), with all MFC score ≥2 patients alive after a median follow-up of 35 months. There was also a trend to statistical association between MFC score ≥2 and overall survival in the whole series of patients (log rank p=0.053). Interestingly, there was a striking difference in risk of evolution to AML according to MFC findings (log rank=0.013), with a 100% of patients free from this complication in the group of patients with MFC score <2.

Summary/Conclusions: MFC analysis of the bone marrow provides useful information in the diagnosis of MDS which can be specially helpful in the subset of patients with inconclusive morphological findings, showing a strong correlation in this group of patients with clinical outcome in terms of risk of evolution to AML and overall survival.

E1184

ECONOMIC IMPACT AND HEALTHCARE UTILIZATION IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell1, A. Galaznik1, E. Farrell2, M. Blazer2, H.-C. Shih2, A. Raju2, A. Ogbonnaya2, M. Eaddy2, R. Fram1, D. Faller1

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda, Palm Harbor, United States

Background: Therapy for patients with HR-MDS includes systemic chemotheraphy, stem cell transplant (SCT), and supportive care aimed at improving symptoms associated with MDS-related disruption of normal hematopoiesis. However, the economic impact of these interventions over time for HR-MDS patients has not been fully examined.

Aims: We evaluated the costs and healthcare utilization (HCU) of US HR-MDS patients treated during routine care.

Methods: Newly diagnosed adult HR-MDS patients who initiated first-line therapy were identified from Optum, a large US claims database, between 1/1/08 and 10/31/15. HR status was based on ICD coding: ≥1 inpatient claim or ≥2 outpatient claims with ≥1 HR-MDS ICD-9/10 code (ICD-9 code: 240.73; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date. Exclusion criteria included: lack of continuous enrollment in medical/pharmacy benefits in the 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or SCT during baseline period, MDS-related or non-MDS-related medical service costs incurred after follow-up were evaluated. MDS-related HCU and costs were medical claims with a primary diagnosis of MDS or MDS-related treatment (ie, MDS chemotherapy as defined by NCCN MDS Guidelines v2.2017 or MDS-directed supportive care which included hydroxyurea, erythrocyte- and colony-stimulating-growth factors and erythrocyte transfusions) and pharmacy claims for MDS treatment. Proportions of patients with MDS-related costs incurred were calculated as per-patient-per-month (PPP) costs adjusted to 2015 US dollars and reported as mean (standard deviation [SD]). Patients were a capped payment plan were excluded from the cost analysis. Patients were followed until death, withdrawal from plan or end of study (12/31/2015).

Results: 209 treated HR-MDS patients were identified. During the follow-up period, 69.4% of patients had ≥1 inpatient admission, but more patients had an MDS-related than non-MDS-related admission (Table 1). 56.9% of patients had MDS-related and 11% non-MDS-related HCU costs incurred during follow-up were evaluated. MDS-related HCU and costs were medical claims with a primary diagnosis of MDS or MDS-related treatment (ie, MDS chemotherapy as defined by NCCN MDS Guidelines v2.2017 or MDS-directed supportive care which included hydroxyurea, erythrocyte- and colony-stimulating-growth factors and erythrocyte transfusions) and pharmacy claims for MDS treatment. Proportions of patients with MDS-related costs incurred were calculated as per-patient-per-month (PPP) costs adjusted to 2015 US dollars and reported as mean (standard deviation [SD]). Patients were a capped payment plan were excluded from the cost analysis. Patients were followed until death, withdrawal from plan or end of study (12/31/2015).

Results: 209 treated HR-MDS patients were identified. During the follow-up period, 69.4% of patients had ≥1 inpatient admission, but more patients had an MDS-related than non-MDS-related admission (Table 1). 56.9% of patients had MDS-related and 11% non-MDS-related HCU costs incurred during follow-up were evaluated. MDS-related HCU and costs were medical claims with a primary diagnosis of MDS or MDS-related treatment (ie, MDS chemotherapy as defined by NCCN MDS Guidelines v2.2017 or MDS-directed supportive care which included hydroxyurea, erythrocyte- and colony-stimulating-growth factors and erythrocyte transfusions) and pharmacy claims for MDS treatment. Proportions of patients with MDS-related costs incurred were calculated as per-patient-per-month (PPP) costs adjusted to 2015 US dollars and reported as mean (standard deviation [SD]). Patients were a capped payment plan were excluded from the cost analysis. Patients were followed until death, withdrawal from plan or end of study (12/31/2015).

Method: Intravenous immunoglobulin (IVIG) is an effective treatment for bicytonopathies associated to circulating T-cell clones in myelodysplastic syndromes (MDS).

E1185

INTRAVENOUS IMMUNOGLOBULIN IS AN EFFECTIVE TREATMENT FOR CYTOPENIAS ASSOCIATED TO CIRCULATING T-CELL CLONES IN MYELODYSPLASTIC SYNDROMES

M. Eaddy2, R. Odchim-Rieissig2, S. C. Navada2, L. R. Silverman2

1Hematology, ASST Spedali Civili di Brescia, Brescia, Italy, 2Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States

Background: Myelodysplastic syndrome (MDS) can be associated with immunologic disorders, including autoimmune cytopenias and Coombs positive or negative (C+) hemolytic anemia. Abnormally expanded T-cells can be detected in these patients, possibly contributing to both bone marrow insufficiency and immune-related cytopenia in a series of 20 consecutive patients with MDS at a single institution.

Aims: To explore the role of intravenous immunoglobulin (IVIG) as a treatment for immune-related cytopenia in a series of 20 consecutive patients with MDS at a single institution.

Methods: T-cell clonal expansion in the peripheral blood (PB) was documented by flow cytometry and PCR. Eighteen patients had a confirmed MDS (16 IPSS lower-risk, LR). Two suspected MDS were designated as idiopathic cytopenia of uncertain significance (ICUS). Reasons for IVIG treatment were chronic hemolysis refractory to corticosteroids (16: 12 LR, 1 higher-risk (HR), 1 ICUS) or pancytopenia (2 LR and 1 HR refractory to standard therapy, 1 ICUS) associated to a T-cell clonal proliferation in the PB. Hematological response was assessed by IWG criteria 2006. Hemolysis response (HLR) included normal indirect bilirubin and haptoglobin.

Results: Clinical characteristics are shown in the Table. All patients had a chronic T-cell clone. The T-cell clone was characterized by flow cytometry: 6 had a CD3+ T-cell and 3 had a CD3+/CD16+CD56+ NK-cell expansion. Associated immunologic disorders were: ITP (4), neutrophil dermatosis (3), inflammatory bowel disease.
(3), seronegative arthritis (2), connectivitis (2). One patient with hypoplastic MDS had LGL liver involvement. Combs test was positive in 4/16 hemolysis cases. From Jan-10 to Jan-17, IVIG was administered at a dose of 500mg/kg once per week, in cycles of 1 to 4 weeks. The ORR was 75% (15/20); all patients showed an erythroid hematological improvement (HI) (100%), Platelets and neutrophil HI was seen in 50% and 80% of responsive cases, respectively. HLR occurred in 13/16 (81%; 4 CR and 9 PR). Median number of cycles and duration of treatment was 11 and 12 months (mo), respectively. The HLR-CR was stable in 7 patients; 4 relapsed from HLR but subsequently responded by shortening the intervals between administrations of IVIG; 2 were secondary refractory. Eventually, 6 responders became refractory to IVIG. Response was more durable with continuous rather than sporadic dosing. Median time to response was 1 mo. Median duration of response was 39 mo. Corticosteroids were discontinued in 5/10 patients and reduced in 5/10. Adverse events were: 1 palpitations (G1); 1 hypertension (G1). Responders had lower platelet counts (p=0.05), but no other clinical differences compared to non-responders. However, the 5-year OS rate was higher in the responders to IVIG: 53% compared to 30% (p=0.08).

|Table 1.|  

Summary/Conclusions: Treatment with IVIG of C± hemolytic anemia and pancytopenia associated with T-cell immune-clones and MDS was safe and yielded high rates of durable response on all lineages and on hemolysis. Transfusion independency and reduction/discontinuation of corticosteroids for chronic hemolysis make this drug a valuable option not only in LR but also in HR patients, although a confirmation on larger cohorts is needed. IVIG at intermediate-high dose suppresses proliferation of T-cells and induces immune-regulation. Given the relative rarity of T-cell clones in MDS, further investigational studies are underway to define their pathogenetic role and the mechanism of action of IVIG in this specific subset of patients.

**Results:** A new risk classification was developed, namely, the fatig (FA)-IPSS(h). Whereas use of the standard IPSS in more advanced disease discriminates between two risk categories for untreated patients, the new fatigue FA-IPSS(h) classification was able to distinguish three survival risk levels in patients with distinct survival outcomes. Overall survival rates at 6 months, 1 year, and 2 years were markedly different among the three groups. To illustrate, one year survival was 80.3% (95% CI, 73.4-87.8), 60.5% (95% CI, 52.3-70.0) and 37.6% (95% CI, 23.9-59.1) for patients classified into Risk-1, Risk-2 and Risk-3 respectively. Median OS in DFCI data by FA-IPSS(h) risk was similar to that of the development cohort for each of the three risk groups, indicating good external calibration. Patterns of OS through 2 years were also distinct between risk groups as in the development cohort of untreated patients, with one exception: 2-year OS was similar for FA-IPSS(h)-risk 3 and risk 2. Predictive accuracy of this new index was higher than the IPSS alone in both the development cohort (C-statistic, 0.61 vs 0.57) and as well as in the independent cohort including pre-treated patients (C-statistic, 0.58 vs 0.54).

Summary/Conclusions: The FA-IPSS(h) is an additional prognostic tool that might enhance clinicians’ ability to provide more personalized treatment strategies both in untreated and pretreated advanced MDS patients. This analysis offers a model for integration of PROs in prognostic systems for patients with other cancers and advanced illnesses.

E1187 PROGNOSTIC AND THERAPEUTIC IMPLICATIONS OF SIGNIFICANT MARROW FIBROSIS IN COMBINATION WITH P53 OVER-EXPRESSION IN PATIENTS WITH MEYODYSPLASTIC SYNDROME: A SINGLE CENTRE STUDY E. Groarke1,*, S. Maung1, K. Ewins1, M. Jeffers2, B. MacDonagh1, J. McHugh1, R. Desmond1, H. Enright1

**Methods:** We conducted a retrospective study utilizing a hospital database of 247 patients with MDS diagnosed in a single center between 2000 and 2014. Of these patients, 200 had bone marrow trephine samples adequate for reticulin stain analysis, which was completed using the European consensus on grading bone marrow fibrosis (grades 0-3). P53 expression was examined using immunohistochemistry staining in accordance to the modified quick scoring system. We then looked for an association between degree of marrow fibrosis and p53 expression. In patients with significant marrow fibrosis and p53 expression we examined overall survival and response to treatment with azacitidine.
Results: Overall, no significant correlation was seen between expression of p53 and degree of fibrosis (p=0.25). However, degree of fibrosis predicted for overall survival in patients with p53 expression (median overall survival of 4 months in patients with both p53 over expression and significant fibrosis compared with median overall survival of 18 months in patients with p53 over expression without fibrosis, p<0.001). In patients who received azacitadine, those with baseline significant fibrosis and p53 expression had a significantly increased overall survival compared with those who did not receive azacitadine (4 month versus 1 month, p=0.002). Azacitadine treatment was not associated with increased survival in patients with p53 expression without fibrosis but these patients did have an overall increased survival compared to those with fibrosis (median survival 12 vs 37 months).

Summary/Conclusions: This study confirms that significant marrow fibrosis adversely affects overall survival in patients with MDS, including those with p53 over expression. Patients who received azacitadine had a significant increase in median survival. Although the numbers of patients who received azacitadine were small, this data suggests that patients with fibrosis may benefit from the use of azacitadine and larger, and randomized studies should be considered to study this further.

FACS PURIFICATION OF BLAST CELLS IN MDS IMPROVES THE FISH DETECTION RATE FOR DEL(5Q) AND DEL(20Q), BUT NOT FOR DEL(7Q) OR T8
M. Pereira1,2,*, G. Marques3, J. Lima3, R. Reis3, A. Coelho3, L. Jorge3, S. Pedroso4, L. Ribeiro1, A. Palva4, F. Rodrigues4
1Clinical and Transplantation, Coimbra University Hospital Centre, 2Clinical Laboratory, University of Coimbra, 3Clinical Pathology Department, 4Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Prognostication in Myelodysplastic Syndromes (MDS) using validated scores includes the detection of chromosomal aberrations by conventional karyotyping. When the latter is unavailable or unsuccessful, fluorescence in-situ hybridization (FISH) panels can be used. Although panels vary by laboratory, some of the most commonly used probes include the search for monosomy 5 or del(5q), monosomy 7 or del(7q), del(20q) and trisomy 8 (T8). In our lab, FISH was historically performed on purified samples of blast cells using FACS (Full Sample); since 2015, we have primarily performed the analysis on Fluorescence Activated Cell Sorting (FACS) separated blast cells.

Aims: In this study, we aim to analyze the benefit of using purified samples of blast cells for FISH analysis in MDS, when compared to full mixed cellularity samples.

Methods: We reviewed all cases analyzed in our laboratory between January 1st 2011 and February 28th 2017 in which a FISH panel was performed due to a suspicion of myelodysplasia, using probes for del(5q), del(7q), del(20q) and T8. The proportion of patients positive for the test, as well as the proportion of positive cells within a positive sample, were compared.

Results: We obtained valid results for 328 samples during the relevant time-frame. 39.6% of which were collected from female patients. FISH was performed after FACS in one third of samples (35.1%, n=115), starting in 2015. Considering the overall cohort, nearly a quarter of samples (23.8%) had at least one aberration in the four probes tested in this study. This proportion of aberrations was significantly higher in FACS compared to full samples (33.0% compared to full samples patients (18.8%, p<0.004). Del(5q) was present in 5.6% of the cohort; however, positivity was fold higher in FACS patients, compared to full samples patients (12.3% vs 1.6%, p<0.001). Considering the percentage of positive cells in each sample, it doubled from 38.7±29.9% in the full sample to 71.8±28.1% after FACS, p<0.001. Del(7q) was similarly present in 5.7% of the cohort; however, in contrast, there were no relevant differences between FACS patients, 4.2% of whom had del(7q), and full sample patients (8.1%, p=NS). There were, however, differences in the percentage of positive cells within the sample, doubling from 32.1±11.2% in the full sample to 77.6±17.8% after FACS, p<0.001. Del(20q) was similarly present in 7.0% of the overall tested cohort; the asymmetry in results was marked, with a 36-fold higher proportion of positive findings after FACS (18.7%) compared to full samples (0.5%, p<0.001). The percentage of positive cells doubled from 15% in the single positive test in the full sample cohort, to an average of 35.5±22.2% after FACS. Finally, T8 was found in 10.3% of all samples; it was undetected in 7.0% of the overall tested cohort; the asymmetry in results was marked, with a 10.2-fold increase in both FACS and full samples, p=NS. The percentage of positive cells once again doubled from 25.5±14.7% in the full sample to 53.3±28.1% after FACS (p=0.0008).

Summary/Conclusions: We found that one quarter of all patients who underwent a FISH panel work up for a suspected diagnosis of MDS presented with aberrations in at least one of the four selected probes, a proportion which was significantly lower (one fifth) when a full sample was analyzed, and significantly higher (one third) in FACS purified blast cells. Although the purification of the sample through FACS doubled the percentage of positive cells within each sample for all four probes, the likelihood of obtaining a positive result for del(7q) and T8 in the cohort was unaffected by the methodology used. In contrast, the use of a sorted sample greatly increased the proportion of positive findings in del(5q) and, especially, in del(20q), the two probes for which the basal positivity in full samples was lowest. The clinical value of this increased rate of detection of del(5q) and del(20q) remains unclear, since their prognostic utility has only been established for levels detectable by conventional karyotyping of a full sample.

E1189
COUNTING BONE MARROW BLASTS AS A PERCENTAGE OF NON-EERYTHROID CELLS PROVIDES SUPERIOR RISK STRATIFICATION FOR MDS PATIENTS WITH ERYTHROID PREDOMINANCE
A. Sun1,2,*, Y. Yu1, T. Zhang1, Q. Wang1, D. Liu2, S. Chen1, D. Wu1,2
1The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Patients with erythroid predominance (≥50% erythroblasts, MDS-erythroid) compose a significant proportion of patients with MDS. The erythroid/myeloid subtype was divided from the AML category into MDS-erythroid by the 2016 WHO classification of myeloid neoplasms. At that time, there was no consensus on a more appropriate way of enumerating bone marrow (BM) blasts from TNCs or NECs in MDS-erythroid patients.

Aims: To clarify these questions, 1283 MDS patients were retrospectively analyzed in our center.

Methods: MDS-erythroid was observed in 27.0% of patients (346/1283), and these patients had similar clinicopathological features and overall survival, with 39% cases of MDS with <50% ENCs.

Results: By calculating the percentage of BM blasts from NECs, 73 of 200 patients (36.5%) with MDS-erythroid who were diagnosed within WHO subtypes without excess blasts (EB) were moved into higher-risk categories and showed shorter OS than those who remained in the initial categories (P<0.041). Recalculating the International Prognostic Scoring System-Revised (IPSS-R) by enumerating blasts from NECs, 40 of 168 (23.8%) MDS-erythroid patients with relatively lower risk were re-classified as higher-risk and had significantly poorer survival than those who remained in the lower-risk category (P=0.030). This was especially true for the intermediate risk group that was stratified by IPSS-R (unchanged patients vs shifted patients, P=0.007). However, the impact of enumerating BM blasts from NECs on classification and prognostication was not evident in all MDS patients.

Summary/Conclusions: In conclusion, our results suggested that enumerating the percentage of BM blasts from NECs significantly improved the prognostic assessment of MDS-erythroid, especially for patients within the intermediate risk group stratified by IPSS-R.

E1190
SUCCESSFUL TREATMENT WITH DANAZOL FOR MYELODYSPLASTIC SYNDROMES AND APLASTIC ANEMIA REFRACTORY OR INELIGIBLE TO STANDARD THERAPY
F. Schiopkati1,2,*, A. M. Pelizzari1, E. Borlenghi1, M. D’Adda1, E. Cerqui1, D. Marocolo1, G. Ross1
1Hematology, ASST Spedali Civili di Brescia, Brescia, Italy

Background: The discovery of danazol potential activity on telomere elongation in bone marrow failure has renewed interest in this drug. The treatment of cytopenia in myelodysplastic syndromes (MDS) and aplastic anemia (AA) patients who fail or are ineligible to standard therapies is an unmet medical need; however only dated reports on danazol use in this setting are available.

Aims: We report the results of treatment with danazol in patients with MDS and AA at a single institution.

Methods: From Jun-11 to May-15, danazol was administered to 31 consecutive patients (20 MDS and 11 AA). Criteria for treatment were non-severe AA (8), severe AA ineligible/refractory to immunosuppressive therapy or allogeneic transplantation (3), transfusion dependent (TD) lower risk MDS refractory to prior therapy (12), MDS with isolated thrombocytopenia (<50x109/L) (6) or with bone marrow hypoplasia and bicytopenia (3). Diagnosis was defined by WHO 2008 for MDS and according to Camitta (Blood 1975) for AA; response was assessed by IWG 2006 criteria.

Results: The characteristics of the patients are shown in the Table. All MDS patients had low-risk disease according to IPSS and IPSS-R, except 2 and 3 patients respectively. Nineteen patients (12 MDS, 7 AA) received danazol at full dose (600mg daily). A 400mg daily dose was given to 12 patients, due to toxicity (4 MDS, 4 AA) or comorbidities (4 MDS). Median duration of treatment
was 19 months (mo) (1-66) in AA and 6 mo (1-60) in MDS. ORR was 73% and 50%, respectively. Age and hemoglobin levels impacted on response in AA. Hematological improvement was seen on all lines in 92% of cases, with a median to a best response of 3-5 mo on platelets and neutrophils and of 8-12 mo on hemoglobin. Interestingly, duration of response in MDS patients was significantly longer with a danazol dose of 600mg than with 400mg (p<0.001). Conversely, dosing did not impact on response to danazol in AA patients. Grade 2-3 toxicity was significantly higher in AA patients (p<0.05), 60% pretreated with IST. Adverse events included: hepatotoxicity (3 G1, 1 G2, 3 G3), muscle pain/CKP elevation (3 G1, 2 G2), transient renal impairment (1 G1), hypotension (1 G1). Responders to danazol had a better survival in terms of OS and EFS in both groups (Figure 1).

Results: 209 newly diagnosed HR-MDS patients initiating 1LT MDS-Tx were identified; mean age was 73 years (standard deviation [SD]: 10.1) and 61.2% were male. In the 12 months prior to diagnosis, 27.3% of patients used MDS-directed supportive care (ie, colony stimulating-, erythrocyte-, or thrombopoietic growth factors; RBC or PLT transfusions; or hydroxyurea). 1LT with hypomethylating agents (HMAs) predominated in 89.5% of patients (azacitidine, 68.9% and decitabine, 20.6%); 8.6% of patients received an immunomodulator monotherapy; and 8.6% of patients underwent SCT during follow-up. Of the 169 treated HR-MDS patients with ≥60 days of follow-up on 1LT, 51% achieved transfection independence. For all treated HR-MDS patients, median PFS and 2-year failure rates were 12.5 months (95% confidence interval [CI]: 9.1, 14.9) and 27.0%, respectively. OS rate at 2 years was 59.1%. Patients who achieved transfection independence had a higher rate of 2-year OS (65.2% vs 53.8%) and PFS (36.3% vs 25.7%), but neither were statistically significant.

Table 1.

| Table 1. PFS and OS Outcomes in Treated HR-MDS Patients in Routine Care |
|------------------|------------------|------------------|
| OS (2 years)     | EFS (2 years)    |
| 25.7%            | 9.8%             |

Summary/Conclusions: Survival outcomes in routine clinical care were higher than reported in clinical trials, specifically in HR-MDS trials with azacitidine.

E1191

SURVIVAL OUTCOMES IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell1, A. Galaznik1, E. Farrell2, M. Blazer2, H.-C. Shih2, A. Raju2, A. Ogbonnaya2, M. Eaddy3, R. Fram4, D. Faller5

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda, Palm Harbor, United States

Background: MDS is composed of multiple and rare hematological stem-cell disorders, resulting in cytopenias and disease-related complications and deaths. There are no robust trial data comparing the available treatment options for HR-MDS patients; and of the approved drugs, only azacitidine has demonstrated a statistically significant, but modest clinical impact on overall survival (OS).

Aims: We evaluated first-line treatment (1LT) choice and survival outcomes in a US cohort of HR-MDS patients engaged in routine care.

Methods: Newly diagnosed HR-MDS patients who were ≥18 years old and who had initiated 1LT were retrospectively identified from Optum, a large US claims database, between 1/1/2008 and 10/31/2015. HR status was based on [Garcia-Manero, Blood 2016 128:114] and included: MDS-specific treatment (MDS-Tx) (NCCN MDS Guidelines of any chemotherapy or stem-cell transplant (SCT) during the baseline period. Exclusion criteria included: absence of continuous care for 12 months ≥1 HR-MDS ICD-9/10 code. The first MDS claim served as the index diagnosis of the patient’s HR-MDS. The index date was defined as the date of the first MDS diagnosis claim. All claims were evaluated using unadjusted Kaplan-Meier analyses.

Figure 1.

Summary/Conclusions: Danazol was proved both effective and safe as treatment of cytopenia in MDS and AA patients refractory or ineligible to standard therapies. The daily dose of 600mg was more effective for MDS patients, whereas a lower dose of 400mg may have a better risk/benefit ratio in AA. Younger AA patients with less severe anemia were more likely to respond. Danazol use is particularly attractive in thrombocytopenic patients, where responses were rapid, but delayed responses may be expected also on anemia by using danazol for prolonged periods, when tolerated. Response to danazol is also potentially associated to a survival advantage, although these data should be confirmed by larger prospective studies.

E1192

DOSE-CONFIRMATION PK/PD STUDY OF ORAL ASTX727, A COMBINATION OF ORAL DECITABINE WITH A CYTIDINE DEAMINASE INHIBITOR (CDAI) E7727, IN SUBJECTS WITH MYELODYSPLASTIC SYNDROMES (MDS)

1UT MD Anderson Cancer Center, Houston, 2Roswell Park Memorial Institute, Buffalo, 3Cornell University Medical Center, New York, United States, 4Hospital Maisonneuve-Rosemont, Montreal, 5Sunnybrook Medical Center, Toronto, Canada, 6University of Chicago, Chicago, 7Dana Farber Cancer Institute, Boston, United States, 8Princess Margaret Cancer Center, Toronto, Canada, 9Hackensack University Medical Center, Hackensack, 10Massachusetts General Hospital, Boston, 11Medical College of Wisconsin, Milwaukee, 12Astex Pharmaceuticals Inc., Pleasonton, 13Vanderbilt University Medical Center, Nashville, United States

Background: We have previously shown that ASTX727, a combination of oral decitabine and the oral CDAI E7727, emulates the pharmacokinetics of a one hour intravenous decitabine infusion (IV-DAC) in a dose-escalation phase 1 study. (Garcia-Manero. Blood 2016 128:114)

Aims: To confirm pharmacokinetic (PK) and pharmacodynamic (PD) comparability of 20mg/m² IV-DAC administered D1-5 of a 28 day cycle with an entire cycle of ASTX727 given at the selected dose from phase 1 (35mg decitabine and 100mg of E7727).

Methods: Adult patients with Int-1/Int-2 or HR MDS or Chronic Myelomonocytic Leukemia (CMML) were enrolled in a randomized close-over Phase 2 study. Patients were randomized 1:1 to receive in the first 28 day cycle, either 5 days of IV-DAC or 5 days of ASTX727, followed by a cross-over to the other in Cycle
2. Cycles 3 forward were with ASTX727. PD were assessed with LINE-1 methylation on bone marrow cells at baseline and cycles 3, 6, 12 and 18 in cycles 1 and 2. Full PK assessments of ASTX727 were performed on Days 1, 2, and 5 with sparse sampling on Days 3 and 4 and on Day 1 of IV-DAC. Modeling of 5 day exposures of ASTX727 and IV-DAC was created for each patient. Safety and clinical response were assessed on all patients.

Results: In total, 50 patients were randomized, 16 had matched PK and 46 had matched PD sample sets for the first 2 cycles. No significant differences were seen when comparing the randomized sequences for any parameters, so all assessments comparing ASTX727 and IV-DAC were performed independent of sequence. The geometric mean maximum decitabine was 9.9% for ASTX727 vs IV-DAC (95% CI: 1.3-4.1), IPSS-R score ≥4,5 (HR: 5.7, p<0.0005, 95% CI: 2.4-12.4) and MDS patients treated with azacitidine (especially AML patients) were at higher risk of infection than the first 2 AZA cycles. All important predictive factors should be assessed before therapy. Patients possessing factors predictive for infection require special approach and predictive infection model should be developed in further analysis.

Summary/Conclusions: Patients treated with azacitidine (especially AML patients) were at higher risk of infection than the first 2 AZA cycles. All important predictive factors should be assessed before therapy. Patients possessing factors predictive for infection require special approach and predictive infection model should be developed in further analysis.

E1194
OVERALL SURVIVAL, INITIAL TREATMENT AND TREATMENT DURATION OF PATIENTS WITH MYELODYSPLASTIC SYNDROME, A DETAILED POPULATION BASED STUDY
H. Rozema1,2, R. Kibbelaa2, N. Veeger2, E. Van Roo1,2, M. Hoogenboom2
1Pharmacotherapy, 2Epidemiology & -Economics, University of Groningen, Groningen, 2Medical Centre Leeuwarden, Leeuwarden, Netherlands

Background: Population-based studies on myelodysplastic syndrome (MDS) containing detailed clinical information of patient characteristics, treatment and follow-up of the disease are scarce. Since 2005, all patients diagnosed with hematological malignancies in Friesland, a province in the Netherlands, are prospectively registered and followed by their clinicians in a population-based registry, the HemoBase. The registry provides representative population-based data on diagnosis, treatment and outcomes in an era where low-intensity treatment such as hypomethylating agents have become available for the elderly.

Aims: The objectives of this study were to determine the overall survival (OS) of patients with MDS and the effect of the variables gender, age, comorbidities, IPSS, IPSS-R score and MDS subtype according to WHO 2016 classification. Furthermore, the leukemia free survival (LFS), the initial treatment and the duration of first-line treatment were analyzed.

Methods: An observational, population-based study was performed using the HemoBase registry. The bone marrow biopsies and aspirates of all MDS patients diagnosed between 01-01-2005 and 31-12-2013 were independently and blindly reviewed by both the hematologist and hematologist-pathologist and classified according to WHO 2016. Treatment categories were defined as intensive chemotherapy (IC) either combined or not combined with allogeneic stem cell transplantation, the hypomethylating agent azacytidine, the immunomodulatory agent lenalidomide, hydroxyurea or best supportive care (BSC) (blood transfusions, erythropoiesis-stimulating agents). Approval was obtained from the Medical Ethics Review Committee from Medical Centre Leeuwarden. Statistical analyses were performed with SPSS 19; survival analyses were presented using Kaplan-Meier estimates.

Results: 217 patients (72.4% male, 66.8% >70 years old, median age 75 years, 27.2% Charlson Comorbidity Index (CCI) score ≥3 at diagnosis) were included with a median follow-up duration of 70.2 months. 15.7% of the population had an IPSS score of ≥1.5 and 12.4% of the population had an IPSS-R score of ≥4.5. In 41.5% no cytogenetic information was available. MDS-RR, MDS-5q/MDS, MDS-EB, MDS-U and CMMML were diagnosed in 11.5%, 14.7%, 36.4%, 27.2% and 10.1% of the population respectively. 18.4% showed progression towards acute myeloid leukemia (AML), IC, azacitidine, lenalidomide, hydroxyurea and BSC were the initial treatment in 5.1%, 13.8%, 1.4%, 9.7% and 64.6% of the patients respectively. Within 12 months 78.1% of all treated patients terminated their first-line therapy because of death (20.0%), refractory to treatment (18.3%) or disease progression (16.7%). A second treatment was initiated in 10.1% of patients. The median LFS was 18.2 months (95% CI: 12.6-23.8). The median OS of MDS patients in Friesland was 22.5 months (95% CI: 15.2-29.7). Univariate analysis showed an association between lower OS and male gender (HR for women: 0.54, p=0.008, 95% CI: 0.34-0.85), age >80 years (HR: 2.7, p<0.0005, 95% CI: 1.6-4.6), CCI score ≥3 (HR: 2.0, p<0.001, 95% CI: 1.3-3.0), IPSS score ≥1.5 (HR: 2.3, p=0.004, 95% CI: 1.3-4.1), IPSS-R score ≥4.5 (HR: 5.7, p<0.0005, 95% CI: 2.4-2.4) and MDS subtype MDS-EB (HR: 1.8, p=0.016, 95% CI: 1.1-2.9).

Summary/Conclusions: This study provided complete and representative population-based data on overall survival and treatment of patients with MDS. Disease progression and MDS subtype according to WHO 2016 classification were significant comorbidities in this population, a third of the patients received treatment in addition to BSC.

E1195
DANAZOL TREATMENT FOR THROMBOCYTOPENIA IN LOWER-RISK MYELODYSPLASTIC SYNDROMES: A REAL LIFE EXPERIENCE
Vivali E, Ravani1,2
1Hematology Unit, ASST Grande Ospedale Metropolitano Niguarda, Milano, 2Hematology Unit, ASST Cremona, Cremona, Italy

Background: Severe thrombocytopenia is an uncommon event in lower-risk MDS patients, but it may significantly affect the prognosis. In fact, when it occurs during the first-line treatment (AZA), severe thrombocytopenia and significant bleeding events may significantly affect quality of life. A pharmacologic approach is nowadays available yet for this unmet need in Europe. Eztrombopag seems to be a very interesting product, but its efficacy and safety still need to be better demonstrated. Even romiplostim could be
suitable, but, at present, its safety is questioned in MDS patients. Furthermore, in clinical practice, danazol, an attenuated androgen, has been reported to have some ability to increase the platelet count in this context (Wattel 1994; Chan 2002).

Aims: To assess efficacy and toxicity of danazol employed to improve severe thrombocytopenia in lower-risk MDS setting.

Methods: We retrospectively reviewed twenty-four patients affected by MDS and treated with danazol for thrombocytopenia. The initial dose was 600mg/day for all patients. The IWG criteria of response (Cheson 2006) were adopted. The outcome was observed every 3 months till 12th month. The overall response rate and the average platelet count or each time of observation were described. Progression free survival was estimated with the Kaplan-Meier product limit method, followed by the logrank test and by the Cox proportional-hazard regression.

Results: Of the 24 patients, 3 patients had a therapy-related MDS. At the starting time of danazol therapy, the IPSS was "low" in 9, "int-1" in 13 and "int-2" in 2 cases respectively; the IPSS-R was "very low" in 2, "low" in 11, "intermediate" in 7 and "high" or "very high" in 4 cases. At baseline in 14 patients the platelet count was lower than 20x10^3/μL, the average was 10x10^3/μL and the maximum value was 38x10^3/μL. The median dose was 600mg (range 200-600) also maintained at least up to 3 months (range 400-600). At 6 and 12 months the median dose therapy was 400mg (range 400-600 and 200-600 respectively). The response rate was 79.1% (19 responders on 24 treated). The average count increased as shown in Figure 1, over 60x10^3/μL after 6 months from the beginning of therapy and so maintained after one year. Only 3 patients lost the response at 187, 600 and 633 days respectively. The median survival was not reached in the presented series, and the probability to maintain the response is over 75% after two years from the beginning therapy in the responder patients (Figure 2). Adverse events recorded were as follows: moderate (grade 3) (with subsequently drug suspension); severe (grade 3) but reversible renal failure in 1 case (the drug was stopped); moderate (grade 1 and 2) increasing of serum creatinine in 6 case (with reduction of danazol to 400mg/day in 2 of these); reversible cutaneous rush in 3 cases; amenorrhoea in 1 case (the only fertile woman in the series); weight loss and loss of appetite in 1 case, weight gain in 1 case.

Figure 1. AVERAGE MINIMUM AND MAXIMUM PLATELET COUNT (x10^3/μL)

Figure 2. Progression free survival

Summary/Conclusions: This series confirms the efficacy of danazol to improve platelet count in the most of patients with severe thrombocytopenia due to lower-risk MDS. In all patients with increased platelet count, the response was clinically significant. The median dose of 600mg should be maintained for at least 3 months to properly assess the effectiveness of therapy and then adjusted according to response and toxicity. The response may not be immediate, but seem to be reachable after 3-6 months of treatment. A responsive patients have short probability to loss the response, that may last for very long time. The toxicity profile of this drug is low. The mechanism of action of danazol in MDS patients remains unclear. Waiting for more information on the efficacy and safety of eltrombopag from the clinical trials in progress, danazol may be a good therapeutic option for these patients.

E1196

TREATMENT PATTERNS IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC PLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell1,*, A. Galaznik1, E. Farrell2, M. Blazer2, H.-C. Shih2, A. Raju2, A. Ogbonnaya3, M. Eaddy2, R. Fram1, D. Faller1

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, 2Xcenda, Palm Harbor, United States

Background: Treatment of patients with HR-MDS includes hypomethylating agents (HMAs) (azacitidine and decitabine), high-intensity induction chemotherapy (IC), and stem cell transplant (SCT). Given the rarity of disease, information available on how these treatments are applied in practice is limited.

Aims: We evaluated the treatment patterns of HR-MDS patients engaged in routine care within the US.

Methods: Newly diagnosed HR-MDS patients who were ≥18 years old were retrospectively identified from Optum, a large US claims database between 1/1/2008 and 10/31/2015. HR status was based on ICD coding ≥1 inpatient claim or ≥2 outpatient claims with an HR-MDS ICD-9/10 code (ICD-9 code: 238.73; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date. Exclusion criteria included: absence of continuous enrollment in medical and pharmacy benefits for 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or SCT during the baseline period. First-line therapy (1LT) was defined as an MDS-specific treatment (as defined by NCCN MDS Guidelines v2.2017)1 initiated on or after the index date. Patients were followed until death, end of continuous enrollment, or end of study (12/31/2015). For patients with progression to acute myeloid leukemia (AML), treatment pattern evaluation stopped at AML diagnosis.

Summary: 335 newly diagnosed HR-MDS patients were identified; 209 (62.4%) were treated with 1LT with treatment initiated within 1 month of diagnosis (median: 17 days, interquartile range [IQR]: 9, 35). A higher proportion of untreated patients (n=126) was ≥75 years of age (71.4% vs 53.1%) and had certain comorbidities at baseline (congestive heart failure, 23.0% vs 16.3%; renal disease, 24.6% vs 16.3%; diabetes 31.0% vs 23.4%, diabetes with end organ failure, 16.7% vs 8.1%) than treated patients. For treated patients, 1LT with azacitidine predominated in 68.9% of patients (n=144), followed by decitabine in 20.6% of patients (n=43), and immunomodulators (lenalidomide or thalidomide) in 8.7% of patients (n=19). The median duration was 4.5 months (IQR: 2.6, 9.5) for azacitidine and 4.8 months (IQR: 2.1, 11.6) for decitabine. A greater proportion of decitabine-treated patients...
received supportive care with colony-stimulating factors (CSFs) (39.5% vs 28.5%) and either erythropoietin or platelet transfusions (69.8% vs 57.6%) during 1LT vs azacitidine-treated patients. Second-line therapy (2LT) was administered to 30 (14.4%) patients; the HMAs again predominated in 63.3% of patients (n=19). Of patients not receiving 2LT, 65 (31.7%) progressed to AML, 47 (22.9%) had <30 days of follow-up due to proximity to end of study (38 [80.9%] of these were on 1LT at end of study). 33 (16.1%) continued to receive some supportive care and, 21 (10.2%) died.

Summary/Conclusions: Most HR-MDS patients treated in routine care are treated according to guidelines, with the HMA, azacitidine, predominating. Underlying comorbidities and older age may influence whether or not to treat HR-MDS patients with 1LT. For treated HR-MDS patients, duration of 1LT did not differ with azacitidine and decitabine. However, use of certain MDS-related supportive care treatments varied by choice of HMA, with more decitabine-treated patients receiving CSFs and transfusions. Further research is needed to determine how these factors influence both clinical outcomes in a HR-MDS population.

E1197

APPRECI8: A PIPELINE FOR PRECISE VARIANT CALLING INTEGRATING 8 TOOLS
S. Sandmann1, 2, M. Karimi2, A. de Graaf3, B. van der Reijden3, E. Hellström-Lindberg2, J. Jansen1, M. Dugas3
1Institute of Medical Informatics, University of Münster, Münster, Germany, 2Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden, 3Laboratory Hematology, RadboudUMC, Nijmegen, Netherlands

Background: For the use of next-generation sequencing in clinical routine same platform, on a different platform and expert-based review. To perform several steps of filtration, including a final automatic characterization of all reported calls as artifacts, likely polymorphisms and likely mutations. To consider variant calling results in clinical routine, it does not seem appropriate to rely on the output of a single tool only. Instead, combining the output of several tools and applying a set of filters as it is done by our appreci8 pipeline leads to results with both high sensitivity and PPV. Nonetheless, variant calling results should, especially at alleleic frequencies below 20%, always be viewed with criticism.

Methods: We developed appreci8, a variant calling pipeline combining the output of eight open-source variant calling tools: GATK HaplotypeCaller, Platypus, VarScan2, LoFreq, FreeBayes, SVNver, SAMtools and VarDict. The pipeline performs several steps of filtration, including a final automatic characterization of all reported calls as artifacts, likely polymorphisms and likely mutations. To train our pipeline, we analyzed two data sets covering data of 54 myelodysplastic syndrome (MDS) patients, sequenced on Illumina HiSeq, and 112 MDS patients, sequenced on Illumina MiSeq. Subsequently, two independent test sets were analyzed. The first test set covered 237 MDS patients, sequenced on Illumina MiSeq. The second test set covered 89 MDS patients, sequenced on Roche 454. In all cases the same target region consisting of 19 genes (42,322bp) was analyzed. Validation was performed by re-sequencing on the same platform, on a different platform and expert-based review.

Results: When analyzing the training sets with only one of the eight variant calling tools and considering all variants -pathogenic as well as polymorphisms-, sensitivity ranges between 0.85 and 1.00 in case of set 1 and 0.47 and 0.99 in case of set 2. Although FreeBayes features highest sensitivity regarding both sets, it consistently features lowest PPV as well (set 1: 0.03, set 2: 0.02). Combining the output of all variant calling tools leads to perfect sensitivity, while PPV is 0.03 for set 1 and 0.02 for set 2. Application of our appreci8 pipeline leads to a minor decrease in sensitivity (set 1 and set 2: 0.98), while PPV is significantly increased (set 1: 0.99, set 2: 0.94). The PPV of the appreci8 output for both training sets is higher compared to each of the individual tools. Analysis of the independent test set 1 leads to comparable results. Sensitivity of the individual tools ranges between 0.82 and 0.99, while PPV ranges between 0.02 and 0.91. Combining the output of all variant calling tools leads to sensitivity of 1.00 and PPV of 0.02. However, application of appreci8 leads to variant calling results with sensitivity of 0.98 and PPV of 0.99. To test the robustness of our approach, we analyzed Roche 454 data, although the pipeline was exclusively trained on Illumina data. Regarding the individual tools sensitivity ranges between 0.91 and 0.99, while PPV ranges between 0.07 and 0.68. By combining the output of all variant calling tools, sensitivity increases to 0.99, while PPV is 0.05. Application of appreci8 leads to sensitivity of 0.98 and PPV of 0.76.

Summary/Conclusions: To consider variant calling results in clinical routine, it does not seem appropriate to rely on the output of a single tool only. Instead, combining the output of several tools and applying a set of filters as it is done by our appreci8 pipeline leads to results with both high sensitivity and PPV. Nonetheless, variant calling results should, especially at alleleic frequencies below 20%, always be viewed with criticism.

E1198

COMPARISON OF ADMINISTRATION OF HYPOMETHYLATING AGENTS (HMA) AND ALLOGENEIC SCT IN ELDERLY PATIENTS WITH ADVANCED MDS
J. Cermak1, 2, A. Vitek1, J. Maaloul-Soukupova1, M. Markova-Štastna1, P. Celkovský1
1Clinical Hematology, Institute of Hematology and Blood Transfusion, Praha, Czech Republic

Background: Hypomethylating agents (HMA) have been introduced as a promising agent in the treatment of elderly patients with advanced myelodysplastic syndromes (MDS) leading to a response in approximately 50% of patients. However, most of the patients relapse and estimated years survival is below 10%. Stem cell transplantation (SCT) still represents the only curative treatment even in elderly patients with advanced MDS and it is connected with long-term survival in 35-40% despite relatively high risk of transplant related mortality (25-30%).

Aims: The aim of the study was a retrospective analysis of results of the treatment of 59 elderly patients (50 years of age or older) with MDS RAEB-2 or with acute myelogenous leukemia with multilineage dysplasia with less than 30% of bone marrow blasts (MDS RAEB-T according to the FAB classification) who received either HMA or underwent allogeneic SCT.

Methods: In the HMA group, 34 out of total 38 patients received azacytidine (Vidaza®) in the dose of 75mg/m2x7 every 28 days and 4 patients were treated with decitabine (Dacogen®) in the dose of 20mg/m2x5 every 28 days. Median number of cycles administered was 10.4 (range 3-31). An age and diagnosis matched transplanted group consisted of 21 patients, 9 patients were transplanted upfront, 12 patients were pretreated either with combination chemotherapy (10 patients) or with HMA (2 patients) and achieved CR prior to SCT. Ten patients received myeloablative conditioning and 11 patients were transplanted after reduced conditioning regimen.

Results: A hematologic response to HMA (CR, PR, hematologic improvement) was observed in 22 out of 38 patients in HMA group (57.9%), CR was achieved in 10 patients (31.8%). In SCT group, engraftment was reached in 20 out of 21 patients, 11 patients died after SCT (6 on complications related to SCT, 5 patients relapsed). No difference was observed between the groups in 2 years estimated overall survival (OS), (42% for SCT vs 36% for HMA), a significant difference in favour of SCT was present in estimated 3 years and 5 years OS (42% and 38% for SCT vs 9% and 4% in HMA group, P=0.001). Median OS was 18.7 months in HMA treated group compared to 42.6 months in SCT group (P=0.02). In a recent analysis performed at 48 months after starting the treatment, 2 patients treated with HMA (5.3%) and 9 patients treated with SCT (42.8%) were alive, 23 patients in HMA group and 6 patients in SCT group relapsed. No significant differences in results and adverse effects of treatment were observed between patients aged 50-60 years and those older than 60 years in both HMA and SCT groups.

Summary/Conclusions: Our results confirm previous observations showing that despite a promising effect of HMA resulting in hematologic response in more than 50% of elderly patients with advanced MDS, allogeneic SCT still represents the only potentially curative treatment connected with long-term survival in a significant number of patients even in elderly MDS patients.
**A MULTICENTER, OPEN-LABEL, PHASE I CLINICAL STUDY: SAFETY, EFFICACY, AND PHARMACOKINETICS OF ORAL RIGOSERTIB IN JAPANESE PATIENTS WITH RECURRENT/RELAPSED OR REFRACTORY MYELODYSPLASIC SYNDROMES**

K. Ishizawa12, K. Usuki3, K. Ando4, Y. Ueda2, T. Kiguchi6, N. Uiko7, Y. Onishi2, H. Idia

1Hematology and Cell Therapy, Yamagata University Faculty of Medicine, Yamagata, 2Department of Hematology and Rheumatology, Tohoku University Hospital, Sendai, 3Department of Hematology and Oncology, NTT Medical Center Tokyo, Tokyo, 4Department of Hematology and Oncology, Tokai University School of Medicine, Isehara, 5Department of Hematology/Oncology, Kurashiki Central Hospital, Kurashiki, 6Department of Hematology, Chugoku Central Hospital, Fukuyama, 7Department of Palliative Care Medicine, Saga Medical Center Koseikan, Saga, 8Department of Hematology, National Hospital Organization Kyushu Cancer Center, Fukuoka, 9Department of Hematology, National Hospital Organization Nagoya Medical Center, Nagoya, Japan

**Background:** Rigosertib, a novel phosphoinositide 3 kinase pathway inhibitor, induces G2/M arrest leading to the apoptosis of cancer cells and myeloblasts and is safe for and well tolerated by pts with low, intermediate-1, intermediate-2, or high-risk myelodysplastic syndromes (MDS).

**Aims:** The aims of the study were to assess the safety, efficacy, and pharmacokinetics of oral rigosertib and to determine the recommended dose (RD) for a Phase II clinical study in Japanese pts with recurrent/relapsed or refractory MDS.

**Methods:** We conducted a multicenter, open-label, Phase I clinical study of oral rigosertib. The key eligibility criteria were as follows: recurrent/relapsed or refractory MDS; age: ≥ 20 or older; ECOG PS of 0 to 2; and no major organ dysfunctions. Rigosertib (280 and 560mg BID) was administered orally in one 21-day cycle (up to cycle 6) that consisted of the 14-day, twice-daily, oral administration term, followed by 7-day monitoring. The primary endpoint was dose-limiting toxicity (DLT). The secondary endpoints were 1) safety as assessed with adverse events (AEs) and laboratory results, 2) efficacy as assessed with the International Working Group 2006 criteria, and 3) pharmacokinetics.

**Results:** Between March 2013 and November 2014, 6 male and 3 female pts (median age: 70; range 52-80) were enrolled. ECOG PS was 0 in 7 pts and was 1 in 2 pts, and 3 and 6 pts were eventually assigned to the 280 and 560mg BID arm, respectively. According to the FAB classification, 4, 2, 2, and 1 pts were categorized to RAEB, RARS, RA, and RAEB-1, respectively. The prognostic factor according to IPSS was Int-1 risk in 4 pts (1 and 3 pts in the 280 and 560mg BID arms, respectively) and was Int-2 in 5 pts (2 and 3 pts in the 280 and 560mg BID arms, respectively). DLT occurred in 1 pt in the 280mg BID arm and in 2 pts in the 560mg BID arm: the former consisted of type 2 diabetes and grade 4 delirium, and the latter grade 5 urinary tract infection and grade 3 prolonged QT interval. Therefore, the RD for a Phase II clinical study in Japanese pts was determined to be 560mg BID. On day 11 of treatment, 1 pt in the 560mg BID arm died of grade 5 urinary infection whose relationship with the investigational drug was rated to “Definite”. The presumed cause of death was septic shock due to urinary tract infection. The patient died at the mean counts of leukocytes, neutrophils, lymphocytes, and reticulocytes in the 280mg BID arm did not decrease along with increases in the number of cycles delivered but decreased slightly in the 560mg BID arm. Any changes of note were not found in other hematological items. One case of grade 3 neutropenia developed in the 280mg BID arm, and 1 case each of grade 3 laboratory abnormalities—increased alanine aminotransferase, increased aspartate aminotransferase, prolonged QT interval, neutropenia, and decreased hemoglobin—occurred in the 560 BID arm. The hematological remission rate was 11.1% (1 marrow CR, 1/9 pts), and the hematological improvement rate was 11.1% (1 HI-P: 1/9 pts). Among the PK parameters, inter-individual variability was observed in the $C_{\text{max}}$ and AUC. However, changes suggesting the accumulation of rigosertib during repeated oral administration (e.g., consistent increases in the $C_{\text{max}}$ and AUC) were not found.

**Summary/Conclusions:** The present chemotherapeutic regimen of oral rigosertib was well tolerated. Our study indicates that the RD for a Phase II clinical study is 560mg BID in Japanese patients with recurrent/relapsed or refractory MDS.
Aims: We used a custom target pulldown (TPD) approach on a large cohort of MM samples at diagnosis, with homogeneous treatment and long follow-up, to further our understanding of the landscape of driver lesions in MM and how this can be used to improve prognostication and disease classification.

Methods: We used a custom-designed SureSelect pulldown strategy (Agilent Biotechnologies) to target 246 genes implicated in MM or cancer in general; 2538 single nucleotide polymorphisms; the immunoglobulin heavy chain (IGH) locus. We sequenced unmatched DNA from CD138-purified plasma cells from 418 patients with a median follow-up of 5.4 years using Illumina Hiseq2000 machines. We applied algorithms developed in-house to detect driver genomic events, filtering out potential artifacts and germline variants. We then ranked each mutation on its likelihood of being oncogenic.

Results: We identified 197 driver events including gene mutations, aneuploidies and IGH translocations (IGH-Tx), median of 6 per patient. Gene mutations where found in >99% of patients. At least one oncogenic mutation of a known driver gene previously identified (KRAS, NRAS, TP53, FAMM6C, BRAF, DSS3, TPAS2, PHOX2, RPP4) was found in 64%, with a long tail of infrequently mutated genes with uncertain significance. Karyotypic class was assigned in 80% of patients, with 9% of hyperdiploid cases also showing an IGH-Tx (mostly t(4;14)). IGH-Tx and aneuploidies dominated the MM genomic landscape, KRAS and NRAS being the only point mutations present in the 15 most frequent driver events. Multivariate analysis by sparse Cox regression highlighted only four driver events with significant prognostic impact for both progression-free (PFS) and overall survival (OS): t(4;14) (HR 1.88, CI 1.25-2.84), amp(1q) (HR 2.83, CI 1.92-3.59), del(17p) (HR 2.55, CI 1.66-3.92), and rare mutations of ATP13A4 (HR 0.08, CI 0.01-0.65, mutated in 1.4% of patients). We found a significantly worse prognosis for increasing numbers of driver lesions in each patient (median OS 8.2 vs 3.5 years for <5 and >8 driver events, respectively). This was only partially explained by instances of additive effect or interactions between variables, which were very informative but not frequent. To better investigate these findings in the context of the genomic landscape of each case, we applied Bayesian clustering algorithms. The large number of driver events screened led to the identification of three groups: in the largest group, some hyperdiploid and IGH-Tx cases clustered together, suggesting that secondary mutations and CNAs required for tumor progression are often shared between these two subgroups. We then identified two clusters both characterized by significantly lower number of mutations, but with opposing features. One was enriched for IGH-Tx, had the highest number of CNAs overall, showed higher prevalence of amp(1q), del(13), del(17p). TP53 mutations, and had a shorter median OS of 5.3 years. The other was mostly composed of hyperdiploid cases and showed fewest CNAs and mutations, with a good prognosis (median OS not reached).

Summary/Conclusions: We report on the first attempt towards the use of extended tumor genotype for a genomic classification of MM using innovative clustering algorithms. Despite the heterogeneity of the disease, we could identify disease subgroups with a distinct spectrum and number of driver events carrying different prognosis, supporting the introduction of genomics in the clinical approach to MM.

3Haematology, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Assessment of gene mutations by next generation sequencing is now standard in patients with haematological malignancy. However, larger chromosomal aberrations (e.g. exon, gene and chromosome level gains and losses) also serve as critical prognostic indicators that guide therapeutic decision making. These larger gene mutations are typically assessed using a separate methodology such as conventional cytogenetics/FISH.

Aims: We aimed to develop and clinically validate a novel method for assessing genome-wide copy number changes using an existing hybridization-based targeted sequencing panel in order to provide further critical prognostic information for patients with MM without the need for a separate assay.

Methods: A custom Agilent SureSelect capture panel targeting 313 genes of relevance in myeloid and lymphoid malignancies was sequenced on an Illumina NextSeq (paired end 75bp reads) to a mean depth of 700X. An in-house bioinformatics pipeline was created to analyse probe counts from on-target and off-target events, which also introduced biases into the raw data. We used a novel read count ratio approach, and normalisation to a pooled reference comprising 10 normal sample variants, to generate the final output. An interactive web-based graphical user interface was developed to visualise both large-scale and exon level amplification and deletions.

Results: We validated the approach on 45 samples from patients with multiple myeloma (predominantly advanced disease) with known copy number status as determined by conventional cytogenetics, FISH and MLPA. Our novel method detected numerous copy number changes that were outside the targeted region (through genome-wide mapping and analysis of off-target reads) such as del(1p) in 12 patients, gain(1q) in 15 patients and MYC amplification in 5 patients. Moreover our method was able to intergrade and resolve the redundancy of changes on del(1p) including isolated deletions of FAMM6C, CDKN2C and FAP1. Of 25 patients with a TP53 mutation, 20 had concomitant del(17p) detected by our assay, while 1 case had a del(17p) without mutation; both monoallelic and biallelic TP53 aberration was associated with poor survival. Other findings in this cohort include frequent DIS3 mutations in patients receiving lenalidomide 13 and a higher mutation load of copy number changes such as the high level amplification of KRAS in 1 case.

Summary/Conclusions: We have developed and demonstrated utility of a reliable workflow for genome-wide copy number assessment that can be implemented using existing targeted short read sequencing data, greatly extending the ability of this technology beyond the identification of mutations for patients with haematological malignancy. In the context of myeloma this can be used to report clinically relevant changes including deletions of 1p and 17p, and gains of 1q and 8q, as well as novel numerical chromosome aberrations.

80% power to detect gene expression changes and genomic variants associ-
ated in >2% of the study population. WES data identified the main cytogenetic
groups, somatic variants, and significantly mutated genes. 28 significantly
mutated genes were present in newly diagnosed samples (17 genes in >2% of
samples). The main recurrent mutations included KRAS and NRAS, and neg-
ative regulators of the NF-kB pathway; however, novel genes were also iden-
tified. Our mutational patterns, proportions, and sites between translocation
subgroups were found and will be presented. In addition, we detected recurrent
copy number abnormalities and examined the interaction with mutations and
fusion gene expression from RNASeq. Preliminary analysis with an integrative
model developed with machine learning methods/approaches using CN, SNV, and
structural variants predicted a subset of high-risk patients. Unsupervised
molecular classification is in progress to integrate genomic data and define
subgroups, which will be presented.

Summary/Conclusions: We have established the largest repository of mole-
cular profiling data in MM associated with clinical outcomes. Integrated analyses
are enabling generation of clinically meaningful disease segments associated with
differing risk that will inform development of clinical tests. ThempP intends to
build a global network by expanding collaboration with global MM centers to

NOVEL COMPOUND, OSSL_325096, INDUCES APOPTOSIS IN MULTIPLE
MYELOMA CELLS THROUGH VCP INHIBITION
N. Nishimura1,*, M.O. Radwan2, M. Amano1, S. Endo1, S. Ueno1, N. Ueno1,
H. Tatetsu1, H. Hata4, Y. Okamoto2, M. Matsuoka1, M. Otsuka2, Y. Okuno1

School of Pharmacy, Kumamoto University, Kumamoto, Japan, 3Department
of Chemistry of Natural Compounds, National Research Center, Cairo, Egypt,
4Graduate School of Health Sciences, Kumamoto University, Kumamoto, Japan

Background: VCP (p97) is an ER-associated protein that belongs to the AAA
ATPase family. It has a variety of cellular functions including ER-associated
protein degradation, autophagy, and aggresome formation. Recent studies have
elicited emerging roles of VCP and its potential as a therapeutic target
in several cancer subtypes including multiple myeloma (MM).

Aims: We screened approximately 2,000 small molecular compounds to find
out novel small compounds that suppress growth of MM cell lines, and found
that OSSL_325096 has strong anti-proliferative activity on MM cell lines (IC50
100-500nM). In this study, we evaluated anti-MM activity of OSSL_325096
through VCP inhibition, in an ATP-competitive manner.

Methods: OSSL_325096 were purchased from Princeton BioMolecular
Research, Inc. (Princeton, NJ, USA). His-tagged human VCP (hVCP) cDNA
was cloned and utilized to generate hVCP protein in vitro as previously
described (Chou et al., PNAS, 2011, vol. 108(12): 4834-4839) to evaluate
the VCP inhibition by OSSL_325096. For in vivo analysis, MM xenograft model
mice were intraperitoneally administered with vehicle or 50mg/kg of
OSSL_325096 twice a week.

Results: OSSL_325096 inhibited proliferation of MM cell lines, including one
bortezomib-resistant cell line (Figure 1). OSSL_325096 induces apoptosis in
these MM cell lines and primary MM cells purified from patients but not in PBM-
Cs from healthy donors. OSSL_325096 treatment leads to accumulation of
poly-ubiquitinated proteins, cleavage of caspase-3, and up-regulation of
CHOP in MM cell lines (Figure 2), suggesting this compound induces caspase-medi-
atated apoptosis and ER-stress in MM cells. OSSL_325096 has a chemical struc-
ture similar to several known VCP inhibitors. Therefore, to evaluate the role of
VCP in MM cell lines, we next performed knockdown of VCP. Knock-down of
VCP induced apoptosis in MM cell lines, accompanied with accumulation of
poly-ubiquitinated protein. In-silico protein-drug binding simulation suggests
possible binding of OSSL_325096 to the ATP binding site in VCP’s D2 domain.
Indeed, in the cell-free ATPase assay, OSSL_325096 showed dose-dependent
inhibition of VCP’s ATPase activity (Figure 3). The IC50 of OSSL_325096 on
ATPase activity was 7-10µM, while IC50 of cell survival in MM cells was 0.1-
0.8µM, suggesting that OSSL_325096 may have other anti-myeloma function
in addition to VCP inhibition. RNA-sequencing of MM cells treated with
OSSL_325096 revealed that several pathways including mTRC1 signaling,
TNFα signaling, and unfolded protein response were activated by OSSL_325096.
Finally, OSSL_325096 was administered to xenograft mice with MM cell tumors
and inhibited the tumor growth in vivo (Figure 4).

Figure 1.

Summary/Conclusions: The present data suggest that OSSL_325096 may be
novel anti-myeloma drug candidate partially through its direct inhibition activ-
ity of VCP.

France
Results: Using only the expressed lincRNAs, we developed a risk prediction signature from SMM patients. The estimation of EFS at 4 years was 55% (95% CI, 45.1% to 63.1%) and 32.6% (95% CI, 25.1% to 42.2%) and OS at 4 years was 93.2% (95% CI, 88.9% to 97.6%) and 71.1% (95% CI, 62.9% to 80.3%) in our patients having a low or high risk score, respectively. We then combined lincRNA signature with known expression signatures and improved the risk prediction for known expression signatures dramatically. We validated our results on independent large cohort with newly diagnosed MM RNAseq data. When applied to patient cohort selected by other risk categorization including minimal residual disease status (MRD), cytogenetic risk status (del17p, t(4;14) and t(14;16)) and International Staging System (ISS), lincRNA signature was able to further identify patients with significant differential survival outcomes.

Summary/Conclusions: In summary, we report that lincRNAs have an independent effect on survival outcome in MM and provides rationale for its use in risk stratification as well as to understand biological impact. Combined prediction with other risk features improve the prediction power and helps to create better classification in MM.

E1207 DYNAMIC IMMUNOHISTOCHEMICAL EVALUATION OF MARROW MICROENVIRONMENT MODIFICATIONS IN PATIENTS WITH SMOLDERING MYELOMA
A. Mussetti1, A. Pellegrinelli2, N. Cieri3, M. Pennisi4, G. Garzoni5, F. Dominoni2, A. Cabras2, P. Corradini2, V. Montefusco1
1Hematology and Adult Bone Marrow Transplantation, 2Department of Pathology and Laboratory Medicine, Fondazione IRCCS Istituto Nazionale Tumori, 3Università degli Studi di Milano, Milano, Italy, 4Department of Oncology and Hemato-oncology, Università degli Studi di Milano, Milano, Italy.

Background: In most cases, multiple myeloma (MM) is preceded by an asymptomatic state known as monoclonal gammapathy of unknown significance (MGUS) or smoldering multiple myeloma (SMM). The mechanisms of progression from SMM to MM are not well understood. Despite an increasing evidence of an immune system dysregulation in the setting of MM characterized by a loss of immunogenicity (PDL1, PDL2, PD1, LAG3, IDO), loss of antigenicity and sympathetic markers expression was not significantly higher compared to healthy donors. Patients whose BM aspirates were collected from healthy volunteers undergoing BM harv...
Background: Bone marrow stromal cells (BMSCs) interact with multiple myeloma (MM) cells in the bone marrow, and also create a permissive microenvironment for MM cell growth and survival. Recent evidence indicated that MM cell-BMSC communication is mediated by extracellular vesicles (EVs) plays an important role in the MM microenvironment.

Aims: In this study, we investigated the biological property of EVs and miRNAs in EVs derived from BMSCs, aiming to establish the emerging strategies to target MM microenvironment to prevent tumor growth and spread.

Methods: Bone marrow samples were obtained from MM patients (age 56 to 82, n=20) and monoclonal gammopathy of undetermined significance (MGUS) patients (age 44 to 82, n=13) in accordance with the Declaration of Helsinki and using protocols approved by the research Ethics Committee of Tokyo Medical University (IRB No. 2648), and BMSCs derived from MM patients (MM-BMSCs) and MGUS patients (MGUS-BMSCs) were isolated by the classical adherance method. EVs were isolated from conditioned medium of BMSCs using an Exoquick-TC (SBI). The size of EVs was confirmed using a NanoSight LM10 (Malvern). The RNA from cells and EVs was profiled for 381 miRNAs using a TaqMan low-density array (ABI). For functional analysis of candidate miRNAs, the miRNA mimics (Ambion) were transfected into BMSCs using HiPerFect (Qiagen). Cell viability of miRNA-overexpressed BMSCs were determined using WST-8 (Dojindo), and Apoptosis rates were determined using Caspase-Glo assays (Promega). To assess the effect of the inhibition of EV secretion, BMSCs were treated with 10 µM GW4869 (nSMase2 inhibitor, Sigma) for 48h.

Results: MM-BMSCs and MGUS-BMSCs had a fibroblast-like morphology in culture, and were homogeneously CD73+, CD90+, CD105+, CD34-, and CD45-. The expression levels of mRNA and protein of PBK was observed in 8/8 MM-BMSCs and 4/4 MGUS-BMSCs. The size of EVs was approximately 50 nm. We found high expression of miR-10a in the EVs derived from MM-BMSCs, the expression of intracellular miR-10a was low in MM-BMSCs. We therefore hypothesized that low expression of cellular miR-10a might be important for survival of MM-BMSCs; As a result, miR-10a was packaged into EVs, and they were released to the extracellular space. To test the hypothesis, miR-10a mimic was transfected into MM-BMSCs and MGUS-BMSCs. The overexpression of miR-10a inhibited cell proliferation and induced apoptosis of MM-BMSCs, while the cell proliferation and apoptosis of MGUS-BMSCs were not affected by the overexpression of miR-10a. We also found that inhibition of EV release with GW4869 promote the accumulation of intracellular miR-10a in MM-BMSCs, and EV-release inhibitor also can inhibited cell proliferation and induced apoptosis of MM-BMSCs.

Summary/Conclusions: Our findings indicate that expression of PBKG/G was associated with myeloma cell proliferation, while PBKA/A was likely linked to tumor suppression. Increased phosphorylation of Thr 9 on PBK might contribute to proliferation in cells with PBKG/G. These results provide a novel insight into the mechanisms underlying myeloma cell growth and PBK3779620 genotype is a potential stratification and therapeutic target for plasma cell dyscrasias.

1Division of Hematology, Department of Internal Medicine, 2Department of Biochemistry, 3Department of Tumor Immunology, Aichi Medical University, Nagakute, Japan

Background: Elevated expression of PDZ binding kinase (PBK), which encodes a serine/threonine kinase, has been reported to be associated with a poor prognosis in a variety of cancers. The public gene expression profiling data also showed that higher expression of PBK was related with a poor prognosis in myeloma. However, the molecular mechanisms of PBK expression have never been investigated in myeloma.

Aims: The aim of this study was to elucidate PBK gene functions associated with myeloma cell growth in vitro and in vivo.

Methods: Eight human myeloma cell lines including ANBL-6, 8226, OPM2, and KMS-11 were used in this study. The expression levels of mRNA and protein of PBK were detected by real-time RT-PCR and western blotting, respectively. The inhibition of PBK expression was accomplished using the dye terminator method. Knockout of PBK was performed using CRISPR-Cas 9 system. A single guide RNA sequence for PBK was in exon 5 and PBK expression was completely disrupted (Fig. 1). Transfection of the plasmid expressing PBK into cells was performed using with the Amaxa Nucleofector system. Cell viability and proliferation were examined by the MTT and colony formation assay. The KMS-11 cells were subcutaneously injected to mice and tumor volumes were observed every 3 to 4 days.

Results: High expression of mRNA and protein of PBK was observed in 8/8 myeloma cell lines. Genome sequencing revealed the rs3779620 polymorphism in the 5’ region of PBK. The exon 5, in which the A to G transition results in the N107S substitution. A/A, A/G and G/G were found in 88, 0 and 12%, respectively. Of note, PBK inhibition by CRISPR-mediated knockout enhanced cell proliferation in ANBL-6, 8226, and OPM2 cells, all of which carry PBKA/A. Surprisingly, in the KMS-11 cells carrying PBKG/G, PBK inhibition by CRISPR-mediated knockout suppressed cell growth in vitro and in xenograft mice (Fig. 2). Moreover, exogenous expression of PBKG/G augmented cell proliferation in the PBK-deficient OPM2 cells, which carry PBKA/A originally. Furthermore, Thr 9 phosphorylation on PBK was increased in cells expressing PBKG/G compared with those cells expressing PBKA/A.

Figure 1.

Summary/Conclusions: Our findings indicate that expression of PBKG/G was associated with myeloma cell proliferation, while PBKA/A was likely linked to tumor suppression. Increased phosphorylation of Thr 9 on PBK might contribute to proliferation in cells with PBKG/G. These results provide a novel insight into the mechanisms underlying myeloma cell growth and PBK3779620 genotype is a potential stratification and therapeutic target for plasma cell dyscrasias.

E1210

SINGLE-NUCLEOTIDE POLYMORPHISM IN THE PBK GENE IS CLOSELY ASSOCIATED WITH MYELOMA CELL PROLIFERATION

I. Hanamura1,*, A. Ota2, S. Karnan2, M. Wahiduzzaman2, S. Mizuno1, K. Uchino1, J. Kato1, K. Hashimoto1, A. Ota2, S. Mizuno1, K. Uchino1, E. Menu1, K. Vanderkerken1, J. Moreaux2, E. De Bruyne1

Background: Elevated expression of PDZ binding kinase (PBK), which encodes a serine/threonine kinase, has been reported to be associated with a poor prognosis in a variety of cancers. The public gene expression profiling data also showed that higher expression of PBK was related with a poor prognosis in myeloma. However, the molecular mechanisms of PBK expression have never been investigated in myeloma.

Aims: The aim of this study was to elucidate PBK gene functions associated with myeloma cell growth in vitro and in vivo.

Methods: Eight human myeloma cell lines including ANBL-6, 8226, OPM2, and KMS-11 were used in this study. The expression levels of mRNA and protein of PBK were detected by real-time RT-PCR and western blotting, respectively. The inhibition of PBK expression was accomplished using the dye terminator method. Knockout of PBK was performed using CRISPR-Cas 9 system. A single guide RNA sequence for PBK was in exon 5 and PBK expression was completely disrupted (Fig. 1). Transfection of the plasmid expressing PBK into cells was performed using with the Amaxa Nucleofector system. Cell viability and proliferation were examined by the MTT and colony formation assay. The KMS-11 cells were subcutaneously injected to mice and tumor volumes were observed every 3 to 4 days.

Results: High expression of mRNA and protein of PBK was observed in 8/8 myeloma cell lines. Genome sequencing revealed the rs3779620 polymorphism in the 5’ region of PBK. The exon 5, in which the A to G transition results in the N107S substitution. A/A, A/G and G/G were found in 88, 0 and 12%, respectively. Of note, PBK inhibition by CRISPR-mediated knockout enhanced cell proliferation in ANBL-6, 8226, and OPM2 cells, all of which carry PBKA/A. Surprisingly, in the KMS-11 cells carrying PBKG/G, PBK inhibition by CRISPR-mediated knockout suppressed cell growth in vitro and in xenograft mice (Fig. 2). Moreover, exogenous expression of PBKG/G augmented cell proliferation in the PBK-deficient OPM2 cells, which carry PBKA/A originally. Furthermore, Thr 9 phosphorylation on PBK was increased in cells expressing PBKG/G compared with those cells expressing PBKA/A.

Figure 1.

Summary/Conclusions: Our findings indicate that expression of PBKG/G was associated with myeloma cell proliferation, while PBKA/A was likely linked to tumor suppression. Increased phosphorylation of Thr 9 on PBK might contribute to proliferation in cells with PBKG/G. These results provide a novel insight into the mechanisms underlying myeloma cell growth and PBK3779620 genotype is a potential stratification and therapeutic target for plasma cell dyscrasias.
Results: Here we report that high expression levels of both G9a and GLP are associated with a worse disease outcome in newly diagnosed MM patients. Moreover, gene set enrichment analysis of patients with high G9a/GLP expression levels displayed a significant enrichment of genes involved in pathways associated with MM disease progression, including the Ras pathway, NF-kB canonical pathway, IRF4 multiple myeloma program and mRNA splicing. Next, we performed specific G9a/GLP inhibitors BIX01294 and UNC1998 significantly and potently reduced MM cell viability in vitro. Moreover, both inhibitors also induce cell cycle arrest and apoptosis. When comparing between both inhibitors, BIX01294 was found to be the most potent in inducing apoptosis. Mechanistic studies for BIX01294 furthermore indicated that BIX01294 treatment resulted in a significant increase in the expression of LC3B puncta and an increase in LC3II and beclin-1 protein levels. In addition, we found that BIX01294 sensitizes MM cells to the prostate specific inhibitor bortezomib and the Bcl-2 inhibitor ABT199. Lastly, therapeutic treatment of 5TMG1 inoculated mice with BIX01294 resulted in a clear cell depletion, as evidenced by a clear decrease in tumor burden and a significant increase in the overall survival of BIX01294 treated mice compared to vehicle treated mice.

Summary/Conclusions: Altogether, our results demonstrate for the first time the importance of the histone methyltransferases G9a/GLP in MM pathogenesis. Further, specific targeting of G9a/GLP induces MM cell apoptosis, enhances MM sensitivity to ABT-199 and bortezomib and significantly delays tumor progression in the murine 5TMG1 model. Thus, G9a/GLP targeting represents a promising strategy to improve treatment of MM.

E1214

CYTOTOXIC LYMPHOCYTES IN NEWLY DIAGNOSED MYELOMA HAVE REVERSIBLE FUNCTIONAL AND PHENOTYPIC ABNORMALITIES THAT MAY OFFER THERAPEUTIC OPPORTUNITIES

F. Seymour1,*, J. Caveneigh1, J. Gribben1

1Haematology-Oncology, Barts Cancer Institute, London, United Kingdom

Background: A bi-directional interaction exists between malignant cells and those of the immune microenvironment. This dynamic relationship results in gradual loss of clonal control associated with loss of cytotoxic lymphocyte (CTL) response. Mechanisms of immune escape are variably included the induction of tumor immune evasion, notably the PD-1/PDL-1 axis. Multiple myeloma is a disease characterised by a pre-malignant phase which can evolve into periods of asymptomatic and symptomatic disease. One possible mechanism for disease progression is progressive loss of immunological control. The malignant plasma cell has multiple potentially immune modifying effects including the expression of PDL1 and induction of a pro-tumour micro-environment. The role of CTLs is less well understood.

Aims: To undertake deep immune profiling of the CTL landscape in myeloma in order to establish whether features of immune dysregulation are present and to identify potential therapeutic opportunities.

Methods: Cryopreserved bone marrow from 16 patients with newly diagnosed and untreated myeloma and 9 controls were assessed using a 36 parameter mass cytometry panel. The panel was designed to assess 9 immune checkpoint regulators, 5 cytokines, and markers of proliferation and degranulation across multiple lymphocyte subsets. Samples were stimulated with CD3 and CD28 to assess functional capacity. Dimensional reduction and clustering algorithmic analysis was used alongside traditional data analysis techniques to identify functional subpopulations characterised by expression of multiple markers.

Results: The cytokine profile in newly diagnosed myeloma is shifted towards a pro-tumour microenvironment with particularly marked elevation of TGFb throughout resting CTLs (36.4% v. 66.2%, p<0.0001). IFNg production is reduced in the resting myeloma effector population (0.33% v. 1.8%, p=0.0099). Stimulation restores the cytokine profile to match that of controls. Myeloma CTLs retain the capacity to proliferate and produce the constituents for cytotoxic granule formation, however elevated PD1 expression alongside other markers of exhaustion and enhanced NKG2D expression clusters towards the activated phenotype is occurring. Strongly PD1 expressing populations in myeloma are larger (26% v. 47%, p=0.0198) and TIM3 expression is increased (34% v. 56%, p=0.0241). Populations of CTLs from myeloma up-regulate expression of the TCR co-stimulation molecules CD40L (74% total CD8), NKG2D (45% total CD8) and OX40 (33% total CD8) following stimulation.

Summary/Conclusions: Clear differences can be identified in the functional and phenotypic features of CTLs in myeloma compared to those of controls. The partial nature of these defects and the fact that reversibility can be demonstrated suggests that these cells have not yet reached the stage of irreversible exhaust. Taken together this data suggests that targeting immune checkpoint regulators at an early disease stage, in order to optimise immunological function and reverse partial defects, is a viable therapeutic strategy to explore. PD1, PD1L, CTLA4 and TIM are all potential immune checkpoint targets. In addition the expression of the cibgain CP-31398, which binds to the novel PML-RARA receptor, indicates a novel therapeutic strategy.

Summary: CP-31398 sensitizes MM cells to apoptosis, enhances MM sensitivity to ABT-199 and bortezomib and significantly delays tumor progression in the murine 5TMG1 model. Thus, CP-31398 targeting represents a promising strategy to improve treatment of MM.
Results: Only N educated by SMM- and MM-MSC (both from patients at diagnosis, relapsed and refractory) significantly up-regulated Arg1, NOS2 and TNFα and exhibited suppressive effect with a reduction of T cell proliferation (p<0.001). By co-culturing educated-N with Human Brain Microvascular Endothelial Cells (HBMEC), we observed increased both tube length and number of branch points only in conditions where HBMEC were incubated with MM-MSC or MM-MSC+MM-MSC-educated N (p<0.05). Adding Bortezomib, Lenalidomide or Pomalidomide during co-culture of PBMC with MM-MSC, isolated N showed a significant reduction of pro-angiogenic activity but did not lose immunosuppressive ability. To examine if PC play a role in MSC “activation”, before forming co-cultures with PBMC, we pre-treated HS-5 or HC-MSC with MM cell lines. PC pre-treatment drives a healthy MSC to activate N in immunosuppressive, and pro-angiogenic cells. Implating mixtures of fluorescently labeled MM cells and healthy- or MM-MSC into zebrafish, animals coinjected with PC and MM-MSC showed enhanced tumor colonization and growth compared with those injected with PC and healthy MSC.

Summary: To conclude, tumor microenvironment transformation frommUS to MM is associated with progressive activation of MSC that have a pro-tumoral activity. Indeed SMM- and MM-MSC polarize N in immunosuppressive and pro-angiogenic N (N2) in vitro. In addition, MM-MSC facilitate MM growth in vivo confirming their central role in tumor progression.

E1215 LONG TERM CR MULTIPLE MYELOMA PATIENTS STUDIED WITH NEXT GENERATION FLOW SHOW PREDOMINANTLY CURED VSmgUS-LIKE MINIMAL RESIDUAL DISEASE PATTERNS: A STUDY OF THE GTMM-TUSCAN GROUP FOR MULTIPLE MYELOMA
G. Papini1, C. Zuanelli Brambilla 1, B. Mecacci 1, G. Buda 3, R. Caporale 4, A. Bosi5,2, M. Petrinì5,2, M. Bocchì5,2
1Hematology Unit, University of Siena, Siena, 2Hematology, Azienda Ospedaliera Universitaria Careggi, Firenze, 3Hematology, University of Pisa, Pisa, 4Azienda Ospedaliera Universitaria Careggi, Firenze, Italy

Background: CR is a prerequisite for long term responses, progression free survivals, and ultimately overall survivals and cure. In the era of novel agents, many MM patients can achieve stringent CR (sCR), i.e. disease disappearance at serological, immunostiochemical level plus negativity of free light chains (FLC). On the other hand most of these patients still will relapse and minimal residual disease (MRD) detection will play a crucial role in the very next future. Recently, two colours tubes panel developed by the EuroFlow Consortium can detect MRD with an increased sensitivity and can be applied as standardized method to study multiple myeloma (MM) patients.

Aims: While many studies have looked at MRD status sequentially and soon after autologous or allogeneic stem cell transplantation with flow or molecular techniques, little is known about long term remission patients (>5-10 years) and in particular if more sensitive techniques such as NGS or NGS can still detect residual disease in those patients. Aim of the study was to analyse patients with MM in >VGPR with next generation flow at >2 and >5 years of lasting remission.

Methods: Clinical assessment definition of CR status included serum and urine immunofixation, free light chain determination, imaging study with CT-PE, bone marrow biopsy. BM-MSC (n=30/26), were studied with NGS at two GTMM centers between February 2016 and February 2017. 28/56 (50%) patients were in sCR at the moment of the study at a median of 40 months after therapy (range 3-140). 28/56 (50%) patients were in VGPR at study analysis according to new IWG response criteria. N= 12, 25 and 44 patients had a remission disease >5 years, >2 years, and <5 years, respectively. Two tube assay incorporated 8 antibodies each: CD38, CD56 β2-Microglobulin, CD19, α-Kappa Anti-Lambda CD45 CD138, and CD38, CD28, CD27, CD119, CD81, CD45 and CD138 (OneFlow™ PCST and PCD, BD Biosciences) and were utilized to detect MRD level with a lyse-wash-and-stain strategy, immunofomation of flow cytometry (FACSanto II, BD Biosciences). Accurate identification of BM plasma cells (PCs) and discrimination between phenotypically aberrant (aPC) and normal PC (nPC) were carried out after acquisition and analysis of >2 x 106 cells (Diva 8, BD Biosciences).

Results: MRD+ status was detected in 23/56 (41%) of the patients. 4/12 (33%) were MRD positive at >5 years remission (2 sCR, 2 VGPR) (median 96 months range 72 – 186 months); 20/44 (45%) were positive at >5 years of remission (3 CR, 17 VGPR)(median 9.5 range 3 – 46 months). 9/25 (36%) were MRD+ and >2 years of remission (2 sCR, 7 VGPR) (median 46 months range 24 – 186 months). As expected being in sCR was correlated with a low MRD rate (1/12 patients after >5 years). Interestingly looking at long lasting remission, i.e. >5 years, the 4/14 patients that resulted MRD+ displayed anmgUS-like --plasmacell immunophenotype (prevalence of normal plasmacells vs aberrant monoclonal) with a Pcn/Pctot ratio of 48%, 95%, 35%, 30%. CTPET was positive in 22/56 patients. All patients with sCR displayed a negative MRD+ status.

Summary/Conclusions: In conclusion NGS showed that MM patients with long remission status can be considered disease free/cured with a high sensitivity method. MM patients that display anmgUS-like phenotype after achieving a CR can have long lasting remissions meaning disease control. Patients in sustained CR after 2 years can have high percentage of MRD negativity. Larger studies are warranted to identify patients who need treatment consolidation or continuous treatment based on MRD+ status vs others who could stay treatment free with social and economical benefits.

E1216 THE NOTCH PATHWAY IN THE INTERPLAY BETWEEN MYELOMA CELLS AND ENDOTHELIUM IN THE BONE MARROW NICH E M.T. Palano1,*, N. Palatonova 2, I. Saltarella 3, S. Garavelli 1, M. Colombo 1, F. Baccianti 1, A. Neri2, R. Ria3, R. Chiaramonte 1
1Scienze della Salute, 2Oncologia ed emato-oncologia, Università degli Studi di Milano, 3Medicina interna e Oncologia clinica, Università di Bari, Bari, Italy

Background: Angiogenesis is a hallmark of tumors, and it is a peculiar caracteristic in bone marrow (BM) of multiple myeloma (MM) patients. MM is a still recusrable disease that strongly depends on interactions with BM microenvironment. Endothelium of MM patients displays malignant behavior as compared to a healthy counterpart (1). MM displays a dysregulation of the Notch pathway due to Jagged ligands and Notch receptors overexpression. This condition brings to the generation of homocytic and heterocytic interaction loops that sustain MM cells. However, Notch signalling might change with BM resident cells, including osteoclast and BM stromal cells (BMSCs), although its role in the crosstalk of MM and endothelium is still to be clarified.

Aims: The aim of this study is to investigate Notch role in MM crosstalk with endothelium exploiting 2D assays and 3D organoid systems to mimic tumor microenvironment (TME).

Methods: The Notch ligands, Jagged1 and 2, were silenced in the MM cell line RPMI8226 (RPMI8226JAG1/2) using an inducible lentiviral vector carrying two short hairpin RNAs targeting Jagged1 and 2. To mimic the endothelial compartment, bone marrow-derived normal endothelial cells (HPAECs) were used and for the stromal compartment, the GFP+HSS cell line. Matrigeld and wound healing assays were set up to investigate Notch role in modulating the angiogenic potential of MM cells co-cultured with HPAECs and HPAECs motility in response to MM-derived soluble factors. To develop a TME-like system, a decellularized extracellular matrix (dECM) was used as a physiologic scaffold for organoid generation. dECM was produced by treating murine fibroblast NIH3T3 with ascorbic acid and was loaded with cells for organoids generation. We evaluated apoptosis of MM cells in single culture and co-culture with BMSCs or HPAECs by flow cytometry.

Results: Matrigel assay of HPAEC co-cultured with MM cells showed that direct contact increased angiogenic potential of HPAEC to form a grid of tubes; this effect is significantly reduced when HPAECs are co-cultured with RPMI8226JAG1/2 cells, indicating a key role of Notch signaling in endothelial stimulation. Wound healing assay demonstrated that Notch signaling affects MM cell mobility, since it is reduced when Jagged1 is over-expressed. Concerning the 3D-organoid generation, our results indicate that the handcrafted dECM was a suitable scaffold. Moreover, apoptosis assays indicated that MM cells displayed an increased survival when cultured in the presence of BMSCs, that consistently with their recognized protective role; no significant difference in MM cell apoptosis was observed in the presence of endothelial cells. On the contrary, we have observed that endothelial cells were protected by MM cells suggesting that MM cells improve angiogenesis by preventing endothelial cells apoptosis.

Summary/Conclusions: These results indicate a novel role for Notch pathway in MM-EC crosstalk suggesting that the Notch pathway activation in MM cells can increase their proangiogenic potential. 3D-organoid mimics BM microenvironment and may be used as a novel tool to recapitulate the interactions of BM and tumor cells beyond the animal models.

E1217 MIR-101-3P REGULATES BONE MARROW STROMAL-INDUCED DRUG RESISTANCE IN MULTIPLE MYELOMA CELLS BY TARGETING SURVIVIN AND MODULATING CELL-CELL ADHESION
J. Abdil1,*, Y. Chen1, N. Rastgoo1, H. Chang1
1University Health Network, Toronto, Canada, 2LabHematology, University Health Network, Toronto, Canada

Background: In multiple myeloma (MM), bone marrow stromal cells (BMSCs) protect MM cells against cell death by direct or indirect interaction. This phenotype can partly explain de novo or acquired drug resistance in MM. Findings of relevant studies indicate activation of some oncogenic or survival pathways including PI3K/mTOR, Ras/ MAPK, NFκB and Wnt. However, the potential regulatory mechanisms and druggable targets have not been clearly elucidated.

haematologica | 2017; 102(s2) | 499

Madrid, Spain, June 22 – 25, 2017
AIMS: To understand the role of stromal induced drug resistance and to identify new therapeutic targets in myeloma

METHODS: GFP-tagged human myeloma cell lines, 8226, U266 and MM1.s, were co-cultured with MM patient-derived BMMSCs or HS.5 cells with or without BTZ for 24 h. MM cells in monocytes were used as controls. Co-cultures were then applied to magnetic cell separation to isolate MM cells for downstream analyses including western blotting and mRNA or miRNA qPCR arrays. Furthermore, percent apoptosis of gated GFP+ cells was determined using FACS. In other experiments, MM cells were exposed to BMMSCs pre-treated with Brefeldin-A (BFA) or separated with a transwell (TW) insert. For functional analysis, miR-101-3p was overexpressed using lentiviral transduction and survival analyses were then performed using FACS in presence or absence of BTZ. GFP fluorescence-based adhesion, cytotoxicity and annexin-V/PI apoptosis were applied.

RESULTS: qPCR arrays showed that BMMSCs up- or down-regulated several miRNAs and mRNAs in MM cells. Survivin (BIRC5) was confirmed to be consistent with previous reports, and mRNA and protein levels were downregulated in contrast, miR-101-3p was confirmed to be significantly downregulated by stroma in MM cells. Moreover, suppression of miR-101-3p or upregulation of survivin was reversed partially when BMMSCs were pre-treated with BFA but highly significantly when they were separated from MM cells with a TW insert. The same results were observed in in vitro analyses FACS analysis indicating that direct cell-cell adhesion was more effective in BMMSC-induced modulations in MM cells. Next we identified that survivin was a direct target of miR-101-3p, overexpression of miR-101-3p suppressed survivin mRNA/protein. As indicator of involvement in stroma-mediated drug resistance, survivin and miR-101-3p inhibition of the bone marrow microenvironment in a xenograft model was used to demonstrate the impact of miR-101-3p on overall survival. Furthermore, miR-101-3p overexpression or silencing of survivin increased BTZ-induced apoptosis in MM cells in the absence or presence of BMMSCs significantly overcame stroma-mediated drug resistance. To test whether miR-101-3p could also regulate adhesion of MM cells to BMMSCs, we found that adhesion was significantly reduced in the presence of the miRNA compared to HS.5 and primary MM BMMSCs compared to scrambled control. This finding suggests that miRNA-101-3p regulates cell adhesion-mediated drug resistance (CAMDR) by modulation of MM-BMSC adhesion.

Summary/Conclusions: Our results identify a mechanism whereby BMMSCs induce drug resistance in MM cells by upregulating survivin and downregulating miRNA-101-3p which directly targets survivin. Overexpression of miRNA-101-3p or silencing of survivin sensitizes MM cells to BTZ significantly overcoming stroma-induced drug resistance. These findings disclose a role of survivin-miRNA-101-3p axis in regulation of BMMSC-induced BTZ resistance in MM cells, thus provide a rationale to further investigate the anti-myeloma activity of miR-101-3p in combination with BTZ as a potential therapeutic strategy in MM.

ARQ-197, A SMALL-MOLECULE INHIBITOR OF C-MET, REDUCES TUMOUR BURDEN AND PREVENTS TUMOUR-ASSOCIATED BONE DISEASE IN A MURINE MODEL OF MYELOMA

A. Chantry1,*, E. Holly1, M. Fisher1, D. Jenny1, L. Michelle1, L. Darren1
1Oncology and Metabolism, University of Sheffield, Sheffield, United Kingdom

Background: The receptor tyrosine kinase c-Met, its ligand HGF, and their signalling pathway, have all been implicated in the pathogenesis of myeloma. The receptor tyrosine kinase c-Met, its ligand HGF, and their signalling pathway, have all been implicated in the pathogenesis of myeloma. For example, cell adhesion-mediated drug resistance (CAMDR) is a hallmark of myeloma cell survival and is poor. Therefore, targeting these molecules or their pathway in such patients remains incurable in most cases. This is mainly attributed to the large genetic and heterologous malignancies, such as multiple myeloma (MM). A complex interplay between cytokines, adhesion molecules, cell receptors and their ligands provides the MM plasma cells with survival signals and contribute to therapy resistance.

Aims: To unravel the role of the bone marrow mesenchymal stem/stromal cells (BMMSCs) in MM cell growth, progression and drug resistance.

Methods: Hypothesizing that the interaction between MM cells and the BMMSCs is bidirectional, we have compared BMMSCs from healthy individuals, mUS, and MM patients and used our “humanized” bone marrow-like model to characterize the molecular impact of MM cells on BMMSCs. Finally, we have validated targets by generating HS-5 knock-out lines using CRISPR/Cas9 targeting.

Results: Analyzing the BMMSCs of healthy individuals,mUS, and MM patients, as well as BMMSCs impacted by MM in our humanized bone marrow-like model, allowed us to confirm established disease biomarkers (e.g. IL-

THE PAN-PIM KINASE INHIBITOR, PIM447, POTENTLY SYNERGESYS WITH POMALIDOMIDE PLUS DEXAMETHASONE IN PRECLINICAL IN VITRO AND IN VIVO MODELS OF MULTIPLE MYELOMA

F. Accardi1,5, A. L. Horenstein2, F. Aversa1,5, F. Malavasi2, N. Giuliani1,3,5 E.M. Algarín1,2, M. Martín-Sánchez1, M.-V. Mateos2, M. Garayoa1,2, E.M. Ocio1,2
1Centro de Investigación del Cáncer (CIC-IBMC), 2Complejo Asistencial Universitario de Salamanca-IBSAL, Salamanca, Spain

Background: PIM kinases are a family of serine/threonine kinases recently proposed as therapeutic targets in myeloma. Recent work from our group has shown the dual antimyeloma and bone-protective effects of the pan-PIM kinase inhibitor, PIM447, and its in vitro synergism with current standards of care. Since myeloma remains an incurable disease, the preclinical evaluation of new drug combinations is of utmost importance, in order to support the development of future clinical trials. In this scenario, effective all-oral combinations are particularly attractive.

Aims: The aim of the present work has been the evaluation of the efficacy and mechanism of action of the all-oral triple combination PIM447 + pomalidomide + dexamethasone in preclinical in vitro and in vivo models of multiple myeloma.

Methods: in vitro cytotoxicity of PIM447, pomalidomide and dexamethasone alone or in double and triple combinations was evaluated on myeloma cell lines. The combination index (CI) was calculated with CalcuCyts software based on results from MTT assay. Effects on apoptosis and cell cycle were evaluated by flow cytometry. Glucose uptake was analyzed by incubation with 2-NBDG. The mechanism of action was explored by analysis of different protein levels by western blot. Finally, a plasmacytoma model in CB17-SCID mice was employed for in vivo studies.

Results: Triple combination PIM447 + pomalidomide + dexamethasone showed a strong synergism (CI<1.0) in MM1S and RPMI-8226 cell lines. The efficacy of this combination was promoted by its induction of apoptosis and cell cycle arrest at G0/G1 phase. Accordingly, cleavage of caspase 3 and PARP, as well as reduction of cyclin D2 was observed by western blot. In addition, triple combination inhibited mTORC1 as shown by decreased levels of p-4E-BP1 and p-P85a. Moreover, treatment with PIM447 + pomalidomide + dexamethasone remarkably reduced the levels of the glucose metabolism-associated enzyme hexokinase II and also reduced glucose uptake by cells. Finally, the efficacy of this combination was confirmed in a plasmacytoma model in CB17-SCID mice, where it clearly reduced tumor growth as compared to single and double treatments.

Summary/Conclusions: Our preclinical data suggest that myeloma patients could benefit from treatment with the triple combination PIM447 + pomalidomide + dexamethasone and would support future clinical trials with this combination.

E1224

TRIM33 IS A POTENTIAL TUMOR SUPPRESSOR IN MULTIPLE MYELOMA

C.K. Johnston1,*, L.J. Crawford1, K.I. Mills1, A.E. Irvine1
1Centre for Cancer Research and Cell Biology, Queen’s University Belfast, Belfast, United Kingdom

Background: Myeloma (MM) continues to be an incurable plasma cell neoplasm, regardless of recent therapeutic advances. The success of proteasome inhibitors in MM validates the ubiquitin proteasome system (UPS) as a therapeutic target. Using a UPS-specific microarray (PIQOR) we identified aberrant expression of an E3 ligase TRIM33 (tripartite motif containing protein 33) in MM. TRIM33 has previously been identified as a tumor suppressor in chronic myeloidneuomo-lentric lymphoma and hepatocellular carcinoma.

Aims: The aim of this study was to examine TRIM33 expression and to investigate its role as a potential tumor suppressor in MM.

Methods: Western blotting and qPCR were used to analyse TRIM33 expression at basal level and following knockdown in four MM cell lines representing a range of MM translocations; JJN3 t(14;16), U266 t(11;14), KMS-18 t(4;14), OPM-2 t(4;14). TRIM33 knockdown was performed using shRNA/pLKO lentiviral plasmids. CellTiter-Glo6 was used to determine cell viability following knockdown of TRIM33. In vivo, the TRIM33 expression and correlation with survival in subsets of newly diagnosed MM patients; GSE19784 (N=320) and GSE2658 (N=551), qPCR was used to validate the changes in expression of the TRIM33 gene signature.

Results: Compared to normal bone marrow, lower expression of TRIM33 was observed at both gene and protein level (p=0.03) in the t(4;14) cell lines, KMS-18 and OPM-2. Conversely, expression was found to be high in the non t(4;14) cell lines, JJN3 (p=0.001) and U266 (p=0.015). Knockdown of TRIM33 expression did not alter cell viability in the t(4;14) cell lines. However, cell viability was found to be increased in JJN3 (p=0.004) and U266 (p<0.005). Analysis of a publicly available dataset, GSE19784, showed lower levels of TRIM33 present in patients with a t(4;14) compared to other MM subtypes, particularly (6;14) (p=0.004) and hyperdiploid cluster (p=0.03). Low TRIM33 expression has also been associated with poor overall survival (GSE2658; p=0.0034). Forty-seven genes associated with TRIM33 expression and correlation with survival in subsets of newly diagnosed MM patients; GSE19784 (N=320) and GSE2658 (N=551), qPCR was used to validate the changes in expression of the TRIM33 gene signature.

Conclusion: Western blotting and qPCR analyses revealed TRIM33 expression at basal level and following knockdown in four MM cell lines representing a range of MM translocations; JJN3 t(14;16), U266 t(11;14), KMS-18 t(4;14), OPM-2 t(4;14). TRIM33 knockdown was performed using shRNA/pLKO lentiviral plasmids. CellTiter-Glo was used to determine cell viability following knockdown of TRIM33. In vivo, the TRIM33 expression and correlation with survival in subsets of newly diagnosed MM patients; GSE19784 (N=320) and GSE2658 (N=551), qPCR was used to validate the changes in expression of the TRIM33 gene signature.
enhancer of the TRIM33 signature that potently decreased the viability of the OPM2 cell line. This study suggests that enhancing the TRIM33 gene signature could potentiate the tumor suppressive effect of TRIM33 and identify novel therapies for this subset of MM.

E1225
LONG NON-CODING RNAS EXPRESSION HETEROGENEITY AND FUNCTIONAL INVOLVEMENT IN MULTIPLE MYELOMA: A PERSPECTIVE FOR A POTENTIAL THERAPEUTIC TARGET
A. Carrasco1,*, T. Exponda1, C. Meydan2, M. Kulis3, F. Ordonez1, V. Segura4, L. Garate1, D. Alignan5, B. Paiva6, J. San Miguel6, J.L. Martin-Subero3, A. Melnick2, F. Prössper6, X. Agirre1

Aims: To characterize the IncRNA transcriptome of MM and its heterogeneity, and determine whether altered IncRNAs have a functional involvement in this disease.

Methods: Paired-end strand-specific RNA sequencing (ssRNA-seq) was performed in 38 purified plasma cell (PC) samples from MM patients, as well as in 5 tison PCs (TPCs) and in 3 bone marrow PCs (BMPCs) of healthy donors as controls. We also performed ssRNA-seq of populations from B cell differentiation (Naive, Germinal Center, Memory and PC) to study the heterogeneity of IncRNAs expression we performed sample level enrichment analysis (SLEA), in which each individual IncRNA was compared to BMPCs. To determine the epigenetic regulation of IncRNAs we used whole-genome bisulfite sequencing (WGBS) and CHIP-seq. shRNA-mediated knockdown using 2 different shRNAs and MTS (cell proliferation) and annexin V (cell death) assays were utilized to study the functional effect of IncRNA overexpression.

Results: We identified 40,552 novel IncRNAs in MM samples that were present in at least 3 of the 38 patients. Principal component analysis demonstrated that TPCs and BMPCs cluster separately, suggesting that, in spite of being the same cell type, their transcriptomes are very different. We observed that the expression of IncRNAs was more heterogeneous than that of coding genes. More importantly, SLEA showed 11,067 IncRNAs that were overexpressed and 5,601 underexpressed in >40% of patients. Thus, the number of deregulated genes analyzed by SLEA was much larger than the 70 IncRNAs that appeared as deregulated when all MM were compared to BMPCs, demonstrating the relevance of studying the heterogeneity in this disease. To determine the function of heterogeneously altered IncRNAs in the biology of MM cells we focused on the study of LINC-SMIL0 (Specific Myeloma Iniheric Lon non-coding RNA), a IncRNA that is It is overexpressed in ~40% of MM patients and not in different stages of B-cell differentiation. DNA methylation analysis demonstrated that CpGs located upstream of LINC-SMIL0 showed a significant hypomethylation inmGLs, that was even more pronounced in MM samples. We also have observed a gain of active chronatin modifications in the promoter region of LINC-SMIL0 in MM patient samples. These data suggest that epigenetic modifications, namely DNA hypomethylation and the gain of active histone modifications, may be the cause of LINC-SMIL0 overexpression in MM. Knockdown of LINC-SMIL0 in 3 different cell lines (MM.1S, MM.1R and KMS-11) resulted in reduced proliferation and induction of apoptosis, indicating this IncRNA is essential for the survival of MM cells.

Summary/Conclusions: All together, these data demonstrate that alteration of IncRNAs is an important and unexplored feature of MM. Moreover, overexpression of LINC-SMIL0 is required for the survival of MM cells and could represent a potential therapeutic target for the treatment of this disease.

E1226
ROLE OF EPHA3 IN MULTIPLE MYELOMA: A PERSPECTIVE FOR A NOVEL TARGET THERAPY?
F. La Rocca1,*, I. Airoldi2, E. Di Carlo3, P. Marotta4, G. Falco5, V. Simeon6, A. Melnick2, F. Prössper6, X. Agirre1

Aims: To evaluate the expression of this molecule in primary bone marrow plasma cells (BMPCs) from MM patients and MM cell lines compared to healthy controls (HCs). In addition, using a “loss of function” approach by mRNA silencing and an anti-EphA3 monoclonal antibody (EphA3mAb), we studied in vitro plasma cells (PCs) viability and movement. Finally, we analysed the in vivo effects of EphA3mAb in a MM mouse xenograft model.

Methods: EphA3 mRNA and protein where investigated in 15 MM BMPCs, 11 MM cell lines and 10 HCs by qRT-PCR and flow cytometry. The effects of EphA3 targeting by lentiviral RNA silencing (shRNA) and anti-EphA3mAb on PC trafficking and viability were studied by adhesion assay on fibronectin and on bone marrow stromal cells (BMSCs), invasion assays and proliferation MTS assay, respectively. Gene expression profiling (GEP) was performed in shEphA3 and control cells. Furthermore, the effects of EphA3mAb were analysed in a MM xenograft model by measuring tumor size and by assessing angiogenesis, proliferation and apoptosis rate on tumor biopsies using immunohistochemistry (anti-CD31, anti-kit6 and TUNEL assay, respectively). Statistical significance was determined by the t-test or One-way ANOVA analysis.

Results: EphA3 was found overexpressed in primary MM BMPCs and MM cell lines when compared with HCs (figure 1A-B). The EphA3 loss of function by siRNA and by EphA3mAb significantly inhibited in vitro the ability of MM PCs to adhere to fibronectin, to BMSCs and to invade (figure 1C-E), without affecting cell proliferation and viability (data not shown). GEP showed that knockdown of EphA3 modulated some molecules that regulate adhesion, migration and invasion processes. Importantly, the treatment with EphA3mAb in vivo significantly reduced tumor size and inhibited angiogenesis, as revealed by decrease of CD31+ vessels at immunohistochemistry (data not shown).

Pathology and Molecular Medicine, Chiari, 4Department of Stem Cell and Development, Istituto di Ricerche Genetico Gaetano Salvatore Biogenni, Ariano Irpino, 5Department of Biology, University of Naples “Federico II”, Napoli, 6Laboratory of Pre-clinical and Translational Research, 7Department of Onco-Hematology, IRCCS, Referral Cancer Center of Basilicata (CROB), Rionero in Vulture, 2Laboratorio di Oncologia, IRCCS - G. Gaslini Institute, Genova, 3Department of Medicine and Sciences of Aging, CESI-Met Aging Research Center and Division of Anatomic

Figure 1.
Summary/Conclusions: Our findings suggest that EphA3 is a novel regulator of MM PC trafficking, in part via effects on adhesion and invasion; its targeting using EphA3mAb inhibits tumor growth, possibly by reducing angiogenesis, though other possible mechanisms of tumor death cannot be excluded. These data, together with the favourable clinical properties of a humanized EphA3mAb reported in a phase I trial on acute myeloid leukemia and myelodysplastic syndrome (Swords et al. 2016), support EphA3 targeting as a new potential therapeutic opportunity for MM that would warrant to be further investigated.

E1227

PROGNOSTIC SIGNIFICANCE OF AMP1Q21 IN MULTIPLE MYELOMA

T. Abramova1,*, T. Obukhova1, L. Mendeleva1, O. Pokrovskaya1, E. Gribanova1, M. Nareiko1, L. Grebenyuk1, O. Votyakova2, M. Solovei1, M. Ff7/1q21, I. Nakastsev1, A. Grachev1, M. Kanaeva1, A. Danilina1, S. Kulkov1, M. Rusinov1, V. Savchenko1

1Hematology Research Center, 2N.Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: Multiple Myeloma (MM) is a genetically heterogeneous and complex disease with widely diverging survival times from months to years. Amplification of locus 1q21 (amp1q21) is among the most commonly reported genetic abnormalities in MM, but its prognostic value remains unclarified.

Aims: To define the frequency of amp1q21 in MM and its correlation with other chromosomal abnormalities, clinical course and prognosis.

Methods: In 134 patients (pts) with newly diagnosed MM from December, 2009 to March, 2016, 67 male and 67 female, median age 70 years (30-81), we performed FISH with locus-specific and centromere DNA probes (XL 1p32/1q21, XL IGH pl, XL t(11;14), XL t(4;14), XL t(14;16), XL t(14;20), XL t(6;14), XL cMYC BA, XL 5p15/9q22/15q22, XL P53 (MetaSystems), D13S25 (CytoCell). Induction therapy with bortezomib-based courses was initiated for 131 pts, 3 pts with smoldering MM remained under observation. Response was evaluated according to the IMWG criteria for 127 pts, because 4 pts died in induction. 48 pts were underwent ASCT. The median follow-up of group was 19.3 months (3.2 – 77.4). Progression was diagnosed in 69 pts, 12 in those of FISH-analysis was performed also in disease progression.

Results: Chromosomal aberrations were revealed in 133 of 134 (99%) pts. T(14q32) was detected in 42.5% (57/134), hyperdiploidy in 57.5% (77/134), hypodiploidy in 2.1% (3/134) pts. In 11.2% (15/134) a concurrent t(1g1q14) and a trisomy were found. The IgH translocations t(11;14), t(4;14), t(14;16), t(14;20), t(6;14) were observed at a frequency of 16.4%, 12.7%, 3.2%, 2.2%, 0.7% respectively, chromosomal partner is not found in 6.7%. Del(13q) was detected in 40.3% (54/134), del(17p) in 12.7% (17/134), tCMYC/Bq24 in 17.2% (23/134), Amp1q21 was detected in 39.6% (53/134). We identified 3 copies of 1q21 in 30% (40/134) and>3 copies 1q21 in 21 (39.6%) pts. Cases with Amp1q21 had a high incidence of del(13q) (OR=2.71 (1.32-5.55); p=0.006) and as higher LDH values (OR=2.27 (1.09-4.72); p=0.027). From 12 pts investigated in progression amp1q21 was found in 9 pts (75%); in 2 cases amp1q21 was not found at diagnosis and was revealed in disease progression only; in 7 cases - amp1q21 was detected at diagnosis and in progression, and its copy number did not change. The difference in response after induction between pts with or without amp1q21 was not statistically significant: CR – 11.8% versus 14.5%; VGPR – 39.2% versus 27.6%; PR – 37.2% versus 27.6%; therapy resistant 11.8% versus 30.3% (p=0.07). Pts with amp1q21 had significantly worse 5-year overall survival (OS) (43.5% vs 79.4%; p=0.07). According to copy number of 1q21 the 5-year OS pts carrying 3 or >3 copies of 1q21 were 67.3% and 20.9% (p=0.0016) (Figure 1). On multivariate analysis 3 copies of amp1q21 (HR=4.29, p=0.0094), tCMYC/Bq24 (HR=6.51, p=0.0082), del(17p) (HR=3.46, p=0.007) were found to be an independent adverse predictors of shorter OS.

Amplification of 1q21 can appear in the course of MM, therefore FISH-analysis of locus 1q21 should be performed at diagnosis, as well as in disease progression.

E1228

ADAPTIVE IMMUNE RESPONSE IN PLASMA CELL DYSCRASIAS: IMMUNE PROFILING AND DETERMINATION OF CIRCULATING B CELL LEVELS AS A SURROGATE ASSAY FOR BONE MARROW TESTING

S. Drain1,*, P. Eglen1, I. Deighan2, P. Elder3, T. Bjourson1, F. McNicholl3, M. Bowers4, C. Morris5, D. Alexander1

1Stratified Medicine, C-tric, Ulster University, 2Clinical Biochemistry, 3Haematology Department, Altnagelvin Hospital, Derry, 4Haematology Department, Ulster Hospital, Belfast, United Kingdom

Background: Immune paresis is commonly identified in patients with plasma cell dyscrasias (PCD). Often, in newly presenting multiple myeloma (MM), it is associated with intractable infections for which the patient first seeks medical help. Furthermore, recent evidence suggests the importance of assessing levels of bone marrow (BM) derived B cells for risk stratification of the MM patients as reduced levels of B-cells in the BM have been associated with poorer outcomes and reduced progression free survival1. This cellular measure of adaptive immune function (ie: B cell enumeration) is, however, seldom analysed in the peripheral blood (PB) of patients with PCD.

Aims: This study was designed to examine measures of the adaptive immune response in PCD patients, by measuring relative and absolute numbers of T, B cell subset, NK and NKT cells at different stages of PCD, and to determine if the PB B-cell component can act as a surrogate marker for B cell enumeration in MM.

Methods: PB and BM lymphocyte subset analysis was performed on samples obtained from a range of PCD patients (n=70) using directly conjugated monoclonal antibodies (MAB) and multicolour flow cytometry, carried out on a FACSAria III cell sorter (BD, Oxford, UK). Serum protein electrophoresis was performed to identify and quantify paraproteins, and uninvolved Ig levels were quantified in the monoclonal protein (MP) using immunoturbidimetry. sFLC were performed using the Freelite assay on the SPAplus instrument (Binding Site, Birmingham, UK).

Results: Data is presented on 102 PB samples obtained from 70 PCD patients at different stages of disease, including monoclonal gammopathy of undetermined significance (MGUS), smoldering myeloma (SMM), and MM at diagnosis (MMD), throughout treatment (MMT) and at relapse (MRR). Quantification of circulating lymphocyte subsets showed reduced, absolute, numbers of B cells (56/102), T cells (19/102), Tc1 cells (32/102), CTLs (17/102), NK cells (32/102) and NKT cells (72/102). Furthermore, these reduced B cell levels were more frequently seen in the MMD and MMT groups (50% of samples) compared with the other PCD groups (10-25% of samples). Lymphocyte subset analysis was also performed on paired PB and BM samples from 14 patients with MM and a significant, positive, correlation was seen between relative numbers of B cells in both PB and BM (r<0.0001, r=0.94). No clearcut correlations were found between reductions in uninvolved Ig or sFLC levels, and numbers of cells involved in the adaptive immune response.

Summary/Conclusions: The results presented here are further evidence of immune paresis in PCD with specific effects seen at the cellular level. The highest frequency of reduction was in B lymphocytes and NKT cells, and uninvolved Ig levels were quantified in the monoclonal protein (MP) using immunoturbidimetry. sFLC were performed using the Freelite assay on the SPAplus instrument (Binding Site, Birmingham, UK).

NOVEL MONOCLONAL ANTIBODY THERAPY TARGETING CD26 IN MULTIPLE MYELOMA

H. Nishida1,*, H. Suzuki1, M. Hayashi1, M. Sakamoto1, T. Yamada1

1Pathology, Keio University, School of Medicine, Tokyo, Japan

Background: Bone disease is a hallmark of multiple myeloma (MM) and targeting osteoclasts (OCs) to alleviate bone destruction is a component of the standard care for MM. CD26 is a 110-kDa cell surface glycoprotein with DPP IV enzyme activity and has well-defined roles in T-cell activation and several tumor developments, including malignant lymphoma. However, little is known about the role of CD26 in regulating bone remodeling.

Aims: In this study, we examine the CD26 expression in human normal OCs and OCs of MM patients. We explore the function of CD26 in osteoclastogenesis (OCG) and investigate the effects of humanized anti-CD26 monoclonal antibody (CD26mAb) on human OCG. We further define the molecular targets of CD26 in signaling cascade in OCG and explore the therapeutic potential of CD26mAb for treating MM.
Methods: Human BM-MNCs derived from normal human subjects or MM patients were cultured with M-CSF plus sRANKL with or without CD26mAb for OC formation for TRAP staining and functional assay. To assess the mechanisms of action of CD26mAb on OC, RANK signaling proteins were examined by immunoblotting.

Results: CD26 is expressed on normal human OCs and is intensely expressed on activated OCs in MM, M-CSC and sRANKL induced humoral OC differentiation, in association with CD26 expression on monocyte-macrophage lineage cells. CD26 expression was accompanied by increased phosphorylation of MK2/3 and p38MAPK, which is crucial for human OC differentiation with its downstream activation of microphthalmia-associated transcription factor (mz/mt) plays an important role in OC function. CD26 decreased the number of multinucleated Ocs (>3 nuclei) by TRAP/CD26 staining and down-regulated the secretion of TRAP-5b and type 1 collagen. It decreased the size of Ocs and the number of nuclei per OC, with significantly defective bone resorption activity. It was revealed that in the presence of CD26mAb, which is able to down-regulate IDO expression in the CD26/CD138 positive plasma cells. MK2/3 and p38MAPK phosphorylation pathway was specifically, rapidly inactivated and subsequently, its downstream miRf phosphorylation was persistently inhibited. Thus, OC maturation with its bone resorption was impaired by suppressing the expression of TRAP and OC fusion proteins. In contrast, MK2/3-p38MAPK-miRf was not phosphorylated at all in immature Ocs after RANKL stimulation, regardless of the absence or presence of CD26mAb. These results suggest that CD26mAb blocked RANKL induced p38MAPK phosphorylation in OC precursor cells, but not in Ocs. The activation of other MAPKs including ERK and SAPK/JNK, or NF-kB was rapidly induced in response to RANKL both in OC precursor cells and mature OCs. Although the absence of CD26/CD138 in Ocs did not directly affect mature OC functions. Next, although CD26mAb did not demonstrate direct inhibition of proliferation of MM cells, to further investigate the role of CD26 in MM cells in the BM, co-cultures of MM cells with 11 MM cell lines with CD26-stained Ocs were performed. We examined the expression of CD26 in MM cells. Although CD26 expression was only slightly detected in any of MM cell lines in mono-culture, CD26 expression level was upregulated in all MM cell lines, co-cultured with Ocs by flow cytometry and immunohistochemistry. CD26 protein level in these cell lines was also increased by immunoblotting or ELISA. To further explore the CD26 expression in the BM of MM patients, we performed qRT-PCR of CD26 mRNA. In several MM cell lines (HMCLs), CD26/CD138 positive plasma cells were detected around CD26 positive Ocs and certain endothelial vascular cells in several cases. Anti-myeloma efficacy of CD26mAb on MM cells, co-cultured with Ocs was also observed.

Summary/Conclusions: Our data imply that the blockade of CD26 signaling with CD26mAb impairs the development of human functional OCs. Targeting CD26 in both Ocs and MM cells with CD26mAb may be a promising novel therapeutic strategy in MM-associated bone disease and MM progression.

KYNURENINE INHIBITS T-CELLS THROUGH THE ARYL HYDROCARBON RECEPTOR AT IDO-POSITIVE TUMOR MICROENVIRONMENT
M. Dimopoulos1,2, M. T. Bagnati3,1, E. Kastritis1, N. Mavriyannou1, C. Liascos1, E. Terpos1,2, N. Natali3,2,1, National and Kapodistrian University of Athens, Athens, Greece

Background: Due to the immunoglobulin production, multiple myeloma (MM) plasma cells are dependent on the unfolded protein response process (UPR), which controls protein production and ensures its proper translation and folding. A study by Michallet et al (2011) showed that knockdown of one of the three well-known arms of the UPR, PERK (protein kinase R (PKR)-like ER kinase) in MM cells resulted in autophagic cell death. This outcome indicated the importance of PERK activation for the replication of MM cells but also its ability to impede the apoptotic effect. In this study we used a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK enzyme activity in its inactive DFG conformation at the ATP-binding pocket of the enzyme, displaying ≥385 fold selectivity over c-kit, Aurora B, BRK and many other kinases.

Aims: In this study we aimed to use a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK/enzyme activity in its inactive DFG conformation at the ATP-binding region, while displaying ≥385 fold selectivity over c-kit, Aurora B, BRK and many other kinases.

Methods: We initially screened 25 CD138+ MM patients and 6 human myeloma cell lines (HMCLs) for PERK mRNA expression. Our results showed that PERK mRNA is highly expressed in almost all patients (5-10 fold higher than the mean PERK expression of HMCLs).

Results: To test the effect of GSK2606414 on the proliferation of MM cells, 4 HMCLs were treated with different doses of GSK2606414 at two time points (24 and 48 hours). Treatment of cells with 3-30μM GSK2606414 resulted in a dose-dependent inhibition of cell proliferation in all HMCLs ranging for 20-95% reduction of proliferative activity, thus, indicating the dependency of these cells on PERK pathway. Treatment with 20μM GSK2606414 resulted in 40% and 30% reduced cell proliferation in H929 and L363 respectively compared to bortezomib-treated cells (87% and 42% respectively). In addition, the effect of GSK2606414 in combination with bortezomib in the proliferation of H929 and L363 cells was examined. As seen in the apoptosis assay, pre-treatment with GSK2606414 followed by bortezomib reduced cell proliferation in 40% and 30% while treated cells proliferation in 40% and 30% reduced cell proliferation in H929 and L363 respectively compared to bortezomib-treated only treated cells. Under ER stress conditions, the activation of ATF6 and PERK/eIF2α results in the induction of ATF4 translation and results in the upregulation of CHOP. To determine the gene target effects of GSK2606414, ATF4 and CHOP mRNA expression levels were determined in H929 cell line after 24 hour of treatment. Treatment with GSK2606414 alone did not alter the expression levels of CHOP but reduced more than 50% the expression levels of ATF4. When combined with bortezomib CHOP and ATF4 levels were reduced 20% and 60% respectively while treatment with bortezomib alone reduced CHOP levels by 70% and 90% respectively. Changes in RNA expression of 84 UPR-related genes were analyzed in H929 cells. Specifically H929 cells were pre-treated with GSK2606414 and then subjected to ER stress conditions by treatment with tunicamycin (TM). After 24 hours of treatment, 50 genes were found to be transcriptionally regulated by ≥5-fold with the greatest regulation being observed in TM-induced (1, PPARD, PPP1R15A, etc.) and clinical stage of MM. We found that there was a positive correlation between the expression of AhR and the proportion of plasma cells in BM (r=0.76, P=0.04) and clinical stage of MM. The mean expression of AhR in T-cells from stage 2 and stage 3 were 7.3% (3-11.16) and 19.5% (11.3-26.6), respectively.

Summary/Conclusions: KYNURENINE produced by IDO, induce inhibitory signal in T-cells through the AhR. Anti-PD-1 and anti-CTLA-4 therapies, which block directly the inhibitory signal in T-cells, have been getting some clinical benefits against such as melanoma and Hodgkin lymphoma. Therefore, the AhR in T-cells might be a target for IDO-positive hematological malignancies.

ENVIRONMENTAL CONTROL OF PLASMA CELL FITNESS IN MULTIPLE MYELOMA: MALIGNANT CO-OPTATION OF ARGININE AS NOVEL IMMUNO-METABOLIC CHECKPOINT

A. Romano1,2, J. M. Garcia Manteiga3, V. Simeoni4, L. Parrinello5, L. Canziani1, E. Milani1, M. Ghizzinni1, D. Tibilu6, G. Giallongo2, P. La Cava2, F. Cremaschi1, C. Conticelli1, P. Musto6, F. Cicero7, D. Di Raimondo8, S. Cenci9

1Division of Genetics and Cell Biology, San Raffaele Scientific Institute, Milano, 2Division of Oncology and Hematology Policlinico e Vittorio Emanuele di Catania, 3Center for Translational genomics and Bioinformatics, San Raffaele Scientific Institute, Milano, 4Laboratory of Pre-clinical and Translational Research IRCCS, CROB Referral Cancer Center of Basilicata, Rionero in Vultura (Pz), 5Division of Genetics and Cell Biology, Azienda Ospedaliera Policlinico e Vittorio Emanuele di Catania, 6Department of Oncology-Metabolism, San Raffaele Scientific Institute, Milano, Italy

Background: The bone marrow (BM) environment plays a crucial role in the incurable plasma cell (PC) malignancy multiple myeloma (MM). Our previous work showed that activating autocrine signaling through arginine-derived NO (1) and cysteine-derived GSH (2) in MM might sustain PC fitness and could potentially act as a therapeutic target in MM. Here we are investigating whether modulating the environment of normal BM might have impact on the fitness of MM PCs.

Aims: To test the hypothesis that the metabolic microenvironment is key for MM PC fitness, we investigated the effects of arginine deprivation on MM cells in vitro and the downstream effects of arginine depletion on PC fitness in vivo. We further investigated the impact of arginine deprivation on the efficiency of CAR T-cell therapy in MM. We also assessed whether arginine deprivation could trivially improve the immunologist's diagnostic tools (biochemical or functional).

Methods: Using a panel of MM cell lines and patient derived MM BM cells, we investigated the effects of arginine deprivation on cell proliferation, survival, migration, invasion, and the expression of PC stemness markers.

Results: Compared to MM cells in Dulbecco's Modified Eagle Medium (DMEM) containing 2 mM arginine (2 mM Arg), myeloma cells cultured in low arginine (0.4 mM) medium had lower doubling times, increased ATP availability and immunoglobulin production. Conversely, stable lentiviral p62 silencing significantly reduced Blimp-1 and ATP, and led to complete extinction of MM cell lines within 10 days of culture. Bioinformatic analysis of MMRF-Encompass trial data showed a positive correlation between p62 and Blimp-1 expression levels detected by RNA-sequencing (RNAseq) available from the open-access, public clinical and molecular database, the CoMMpass Researcher Gateway (https://research.themmrf.org, v IAI8, n=649).

Summary/Conclusions: Taken together, our findings disclose a novel environmental circuit co-opted by MM cancer, whereby immunosuppressive HDNs sustain MM cell proliferation through arginine depletion to increase p62 and Blimp-1 via the GCN2/CHOP pathway.

ESTIMATED GLOMERULAR FILTRATION RATE (eGFR) CALCULATED BY CKD-EPI EQUATION COMBINED WITH THE INTERNATIONAL STAGING SYSTEM PROVIDES A POWERFUL PROGNOSTIC MODEL FOR EARLY MORTALITY IN MYELOMA PATIENTS

E. Katodritou1,2, V. Palaska1, E. Giannopoulou1, S. Papadaki1, A. Geroftis1, N. Karampatzakis1, K. Keramidioti1, E. Verrou1, K. Kokoviadou2, I. Batsis3, A. Romanos2, K. Keramidioti1, E. Verrou1, K. Kokoviadou2, I. Batsis3, J. M. Garcia Manteiga3, V. Simeoni4, L. Parrinello5, L. Canziani1, J. M. Garcia Manteiga3

1Hematology Department, Theagenion Cancer Hospital, 2Hematology Department, Papageorgiou General Hospital, 3Hematology Department and Bone Marrow Transplantation Unit, G. Papanikolaou General Hospital, THESSALONIKI, 4Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, ATHENS, Greece

Background: During the last decades, the introduction of autologous transplant and novel agents has improved early mortality rates (EM, henceforth defined as death within one year after diagnosis) in Multiple Myeloma (MM). However, the incidence of EM remains high. Data relating to prognostic factors for EM in MM are limited.

Aims: The aim of this study was to explore for possible prognostic factors for EM, which could be a useful tool for planning treatment strategy in MM.

Methods: We have studied the medical records of 479 patients with MM (MF: 258/221, median age: 68 years, range 29-88, IgG: 269, IgA: 123, light chain: 72, non-secretory: 15), diagnosed and treated in our Department between January 2001 and January 2016; 86 patients (18%) had EM. Comparisons of patients’ characteristics between the EM group and the rest of the patients, were performed with χ2, one-way ANOVA and Mann Whitney U test. Prognostic factors for EM and overall survival (OS) were studied by using logistic regression and cox regression analysis, respectively; OS was plotted by Kaplan-Meier; p<0.05 was considered as statistically significant.

Results: Patients with EM were more often men with a higher median age; hemoglobin, platelets and albumin were lower whereas β2 microglobulin, lactate dehydrogenase (LDH) and calcium were higher in the EM group compared to the rest of MM patients (p<0.05). The percentage of patients with abnormal estimated Glomerular filtration (eGFR) calculated by chronic kidney disease epidemiology collaboration (CKD-EPI) creatinine equation (<40ml/min/1.73m2) was higher in the EM group compared with the rest of the patients (60% vs 17%, p<0.001). In accordance with the International Staging System (ISS), advanced MM stage (i.e ISS3) was observed more often in the EM group compared to the rest (65% vs 31%, p<0.001). High risk cytogenetics including t(4;14), t(14;16) and del17p were present in 48% of patients in the EM group vs 21% of the patients (p<0.001). The percentage of patients with abnormal eGFR included: infections 26%, relapsed/refractory disease: 26%, other causes: 6%. Univariate logistic regression analysis demonstrated that ISS, revised ISS (R-ISS), abnormal LDH, hemoglobin <10g/dl, high risk cytogenetics, and CKD-EPI <40ml/min/1.73m2 were independent prognostic factors for EM. In the multivariate analysis ISS and abnormal eGFR were the only independent prognostic factors for EM. When we incorporated ISS and eGFR in a single prognostic model (CKD-EPI/ISS) we identified 3 distinct prognostic groups: 1) low risk group including patients with ISS1 and CKD-EPI b40ml/min/1.73m2, 2) high risk group including patients with ISS3 and CKD-EPI <40ml/min/1.73m2 and 3) intermediate risk group including patients that did not fit in either low or high risk group. The incidence of EM in each group was 8.1% 39% and 15.3%, respectively (OR: 2.8, 95% CI:1.9-4.1, p<0.001). Multivariate cox regression analysis of prognostic factors for OS in the whole population demonstrated that CKD-EPI/ISS model was the strongest independent prognostic factor for OS (HR: 0.38, 95% CI: 0.3-0.4, p<0.001).

Summary/Conclusions: Based on our data, the combination of eGFR estimated by CKD-EPI with ISS (CKD-EPI/ISS) represents a powerful independent prognostic model for EM and OS, in the era of novel agents. The markers constituting ISS and eGFR are cheap and available for most of MM patients, therefore the CKD-EPI/ISS prognostic model will be easy to implement. Nevertheless, the establishment of CKD-EPI/ISS model requires further validation.

ACTIVATED AND EXPANDED NATURAL KILLER CELLS FROM MULTIPLE MYELOMA PATIENTS DESTROY TUMOR DRUG RESISTANT CELLS AND CLONOCENIC TUMOR CELLS

A. Leivas1,2, J. Papad1,2, L. Fernandez1, A. Perez-Martinez2, J. J. Lahuruta2, J. Martinez-Lopez1,2

1Hematological Malignancies Clinical Research Unit, Spanish National Cancer Research Center, 2Hematology, Hospital Universitario 12 de Octubre, 3Pediatrìatics, Hospital Universitario La Paz, Madrid, Spain

Background: Multiple myeloma (MM) remains an incurable disease. Novel therapeutic strategies targeting drug resistant cells (DRC) and clonogenic tumor cells (CTC) are needed. Our group has conducted a phase I clinical trial with activated and expanded autologous NK cells (NKAES) in patients with refractory MM with a relevant clinical effect. Likewise, it has been possible to discriminate DRCS in MM by side population (SP) detection.

Aims: The aim of this study was to characterize DRC and to check the activity of NKAES against these DRCs and CTCs while preserving the hematopoietic progenitor cell.

Methods: Flow cytometry of the side population was performed by Dye Cycle Violet efflux detection to characterize DRC of MM cell lines and bone marrow samples from MM patients. The side population was purified by sorting and characterized by RNAseq. NK cells from MM patients' peripheral blood were collected and cocultured in the genetically modified K562-mb15-CD48 cells in order to obtain NKAES. The activity of NKAES against SP was evaluated by time lapse microscopy and the activity against CTCs was evaluated by methylcellulose assay. In vitro safety against CD34 + progenitors was evaluated by time-resolved fluorescence cytotoxicity with europium-TDA and cul- turation with methylcellulose to check the activity of the NKAES against hematopoietic progenitor cells.

Results: SP cells from both cell lines and samples from different stages of MM showed overexpression of stemness markers. Patient NKAES were shown to have much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAES from MM were able to detect and destroy the MM tumor cells with much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAES from MM were able to detect and destroy the MM tumor cells with much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAES from MM were able to detect and destroy the MM tumor cells with much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAES from MM were able to detect and destroy the MM tumor cells with much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAES from MM were able to detect and destroy the MM tumor cells with much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAES from MM were able to detect and destroy the MM tumor cells with much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient.
destroy drug resistant MM cells and clonogenic tumor cells with high efficiency, preserving CD34+ hematopoietic cells, and thus constitute an effective and safe therapy against MM.

E1235
UNMASKING THE RETROTRANSPOS-ONEREGULATED POLYGENETIC EXPRESSION OF THE RETROVIRAL S RANKL PROMOTER IN MULTIPLE MYELOMA CELLS

S. Papamichos1, Laboratory of General Biology, Aristotle University of Thessaloniki Medical School, Thessaloniki, Greece.

Background: Growing evidence suggest that production of soluble receptor activator of nuclear factor-kappa B ligand (sRANKL) directly by myeloma cells is causally related to generalized bone loss in multiple myeloma (MM). Notably, sRANKL may be produced either by proteolytic cleavage of membrane-bound RANKL or by alternative splicing of TNFSF11 gene (TNFSF11 variant 2, sRANKL mRNA). Recent analysis argues against proteolytic processing of the membrane-bound form being the main mechanism of sRANKL production by myeloma cells. Accumulative data indicate that sRANKL mRNA presents a restricted transcriptional pattern, namely expressed predominantly in malignant cell types. Accordingly, sRANKL mRNA overexpression in primary MM and human MM cell lines has been validated in three independent studies. Furthermore it was recently demonstrated that sRANKL mRNA proximal promoter and first exon are of retroviral origin, residing within a large genomic cluster of transposable elements (TEs).

Aims: To unmask the TE-transcribed and epigenetic apparatus impelling the expression of sRANKL mRNA in a cell type- and cell context-specific manner.

Methods: RepeatMasker software was used to reveal the presence of integrated TEs in the genomic segment comprising TNFSF11 RNA-Seq data, generated by the GTEX project across 51 normal human tissues, were analyzed via GTEX Portal. TNFSF11 mRNA-Seq data from 4 bone marrow samples and 8 white blood cells samples, generated from the PRJEB4337 and PRJNA182351 BioProjects, were analyzed via the NCBI portal. TNFSF11 transcription factor (TF) ChIP-seq data were downloaded from the UCSC Genome Browser Database. Data on TNFSF11 proximal promoter methylation status in 63 cell lines were downloaded from the HAIB Methyl450 ENCODE track.

Results: RNA-Seq data from 51 normal human tissues show that sRANKL mRNA is expressed exclusively in the testis, which is in accordance with the retroviral origin of the transcript. Data analysis from the PRJEB4337 and PRJNA182351 BioProjects further validates the null expression of sRANKL mRNA in normal human bone marrow and white blood cells. Methylation status of sRANKL mRNA promoter in 5 lymphoblastoid cell lines (LCLs) signifies that the retroviral promoter remains heavily methylated in these cell types. TNFSF11 TF ChIP-seq data show that 5 of 161 TFs can bind to the TE-derived sRANKL mRNA promoter region. Four of the five TFs (EBF1, PAX5, IKZF1, and PU.1) bind to this genomic segment exclusively in LCLs, signifying a cell-type specific transcriptional regulation. Notably, all 4 TFs are known to play a major role in normal and/or malignant lymphopoiesis. Furthermore, IKZF1 and PU.1 represent direct targets of immunomodulatory drugs (IMiDs) for down-regulation.

Summary/Conclusions: Transcription of sRANKL mRNA is driven by a retroviral promoter which remains heavily methylated, thereby inactive, in normal lymphocytes. Epigenetic derepression of this promoter during the course of myeloma development may be facilitated by the (over)expression of sRANKL mRNA by myeloma cells represents a plausible scenario. Should the IKZF1 and the PU.1 TFs act as enhancers of sRANKL mRNA expression, directly contributing to upregulation of sRANKL production in MM, it is a tantalizing hypothesis that warrants further investigation because this type of transcriptional boost could be coordinated following treatment with Lenalidomide, that Lenalidomide treatment downregulates the amount of sRANKL in the serum of patients with MM through inhibiting PU.1 expression (Breitkreutz et al., Leukemia 2008) is in accordance with the above and further raises the interest on the mechanisms promoting the anti-osteoclastogenic properties of IMiDs.

ADENOSINE IN THE MYELOMA BONE MARROW NICHE: IMMUNE MODULATION AND PROGRESSION/PROGRESSION DISEASE PROGRESSION

A. Horenstein1,2, A. Chimenti1, V. Quaroni1, F. Costa1, D. Toscani2, F. Morandi3, D. Marimpietro4, N. Giuliani5, F. Malavasi1, 2Medical Sciences, University of Turin, 2CERMS, A.O.U. Città della Salute e della Scienza, Turin, 3Myeloma Unit, Department of Clinical and Experimental Medicine, University of Parma, Parma, 4Laboratory of Oncology, Istituto Giannina Gaslini, Genova, Italy.

Background: The tumor microenvironment is rich in extracellular mono- and di-nucleotides (ATP, NAD) which are metabolized by cell surface ectoenzymes to produce adenosine (Ado), a nucleoside involved in the control of inflammation and immune responses. Multiple myeloma (MM), a plasma cell malignancy that develops within the bone marrow (BM) niche, overexpresses CD38, a molecule with complex functions. As a nucleotide-metabolizing ectoenzyme, CD38 catalyzes the initial disassembly of NAD (to cADPR and ADPR), which is followed by adenosinergic activity, provided that CD38 is operating in the presence of other ectoenzymes (CD203a and CD73).

Aims: To demonstrate that adenosinergic pathways contribute to customize homeostasis in MM.

Methods: Evaluation of the expression of adenosinergic enzymes was assessed by immunohistochemical and flow cytometric analysis on cell lines, and primary myeloma cells and BM biopsies from patients with MM or with asymptomatic monoclonal gammopathy (MGUS). Furthermore, immunohistochemical and flow cytometric analysis on cell lines, and primary myeloma cells and BM biopsies from patients with MM or with asymptomatic MGUS. Having investigated the adenosinergic activity of BM cell populations, we undertook to test this in a single center study.

Summary/Conclusions: We confirm the clinical value of a simple, rapid, two-tubes FC quantification of the proportion of pathologic plasma cells in the evaluation of the risk and kinetics of disease evolution immgUS and SMM. It’s use allows identification of patients which require more frequent follow-up.

E1238
PATHOLOGICAL PLASMACYTES, ASSESSED BY 8-COLOR FLOW CYTOMETRY, PREDICTS RISK OF PROGRESSION IN MONOCLOCAL GAMMOPATHY OF UNKNOWN SIGNIFICANCE AND SMOURDLING MULTIPLE MYELOMA

C. Ferretti1, C. Lemmo1, C. Zaraftzian1, M.O. Chandesris2, L. Frenzel2, R. Delaur2, F. Suarez2, O. Hermine2, E. Macintyre1, V. Asnafi3, 1Laboratory Onco Hematology, 2Clinical Hematology, Necker Enfants Malades Hospital and Descartes University, Paris, France

Background: mgUS and SM are defined by the presence of a monoclonal immunoglobulin and bone marrow infiltration by plasmacytoses, with no associated symptoms of Multiple Myeloma (MM). The risk of development of symptomatic MM justifies identification of the factors associated with an increased risk of evolution. Flow cytometric quantification of the ratio of bone marrow pathological/plasmascytoses (PP/PT) has been reported to be predictive in the context (Pérez-Persona E. et al. Blood 2017: 130:256–259).

Aims: We undertook to test this in a single center study.

Methods: All patients undergoing bone marrow evaluation following identifying of a monoclonal peak (at diagnosis or during follow-up) during a 7.5-year period with a diagnosis of mgUS (n=154) or SMM (n=56) and at least 6 months follow-up were analysed by 8-color FC (including 11 antibodies) from fresh whole bone marrow. PP/PT ≥95% were considered high risk. Disease evolution was indicated by a necessity to treat.

Results: The 210 PP/PT ratios were on average 77% (10-100). Amongst the 154mgUS patients, 24 had a ratio >95%, of which 8 (33%) evolved, compared to 9/130 (7%) with a ratio below 95%. Only 2 of these 8mgUS demonstrated other high risk factors (a non-IgG monoclonal peak or a peak at >15g/L). Amongst SMM patients, 22/30 (73%) patients with a high ratio evolved, of which 9 (41%) had a non-IgG peak, compared to 10/26 (38%) evolution in MM with low PP/PT ratios. The risk of evolution to active MM was significantly higher in patients with a PP/PT >95%, both in themgUS (p=0.0001) and overall (p=0.0004) groups. There was a discordance between PP/PT ratio and disease evolution in 11% (17/154) mgUS patients and 23% (48/210) of the overall group but no other FC markers associated with an increased risk of evolution could be identified.

Summary/Conclusions: We confirm the clinical value of a simple, rapid, two-tubes FC quantification of the proportion of pathologic plasma cells in the evaluation of the risk and kinetics of disease evolution immgUS and SMM. It’s use allows identification of patients which require more frequent follow-up.
TREATMENT OPTIMIZATION FOR MULTIPLE MYELOMA: SCHEDULE-DEPENDENT SYNERGISTIC CYTOTOXICITY OF POMALIDOMIDE AND CARFILZOMIB ON AN IN VITRO AND EX-VIVO MODEL

E. Borsí1,2, M. Martello1,2, B. Santacroce1,2, V. Solli1,2, R. Termini1,2, E. Zamagni2, P. Taccletti2, L. Pantani2, S. Rocchi2, M. Cavo2, C. Tarenghi2

1Fondazione Umberto Veronesi (FUV), Milano, 2Department of Experimental Diagnostic and Specialty Medicine - DIMES, Institute of Hematology “L. e A. Seràgnoli” - University of Bologna, Bologna, Italy

Background: In recent years significant progress has been made in the understanding of Multiple Myeloma (MM) biology. These advances have translated into the development of new drugs and a different approach to treatment, which has ultimately translated into an unprecedented rate of complete remissions. Immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs) form the backbone of modern MM treatment, but new and more targeted treatments are under development and are being tested in the context of clinical trials. Pomalidomide (POM) is a third-generation IMiD with immunomodulatory, antiangiogenic, and direct anti-MM activities, and greater in vivo potency than its sister Lenalidomide. Carfilzomib (CAR) is a second-generation irreversible PI that is structurally and mechanistically distinct from Bortezomib. Preclinical study suggested that the timing and dosing schedules of IMiDs in combination with PIs treatment is critical, proposing a first evidence that established treatment regimens need to be carefully re-evaluated to maximize the anti-tumor effects.

Aims: In this study we tried to optimize the anti-MM therapy using the new class of agents of IMiDs and new generation PIs, by evaluating a possible synergistic effect between POM and CAR.

Methods: For the purpose of this study we used five bona fide MM cell lines (MM1.S, OPM-2, NCI-H929, KMS12.8M and U266), a human bone marrow stromal cell (HS-5) cells and primary samples from newly diagnosed MM patients. Apoptosis analysis was done up to 48h after administration of the first drug. For each drug, three different concentrations were used: low dose, intermediate dose and high dose. Since the BM microenvironment is a complex and active system, with potential contributions of both physical adhesion and soluble factors, we used three experimental conditions to differentiate these interactions: 1) MM cells cultured in complete medium, 2) MM cells suspended in medium conditioned in the prior presence of BMSCs, or 3) MM cells co-cultured with BMSCs in a transwell system.

Results: Using the median effect method of Chou Talalay, we evaluated the combination indices for simultaneous and sequential treatment schedules, and we found that the schedule of administration is important to maximize the synergistic effects. Indeed, schedule-dependent synergistic cytotoxicity was demonstrated for the combination of IMiDs and PIs and a maximal apoptosis consistently observed in IMiDs pre-exposure schedule. The superiority of this schedule was maintained throughout BM microenvironment models. Our data overall suggest that the administration of IMiDs before PIs can improve efficacy. Clinical trials are needed to investigate the most effective schedule, which could be to start the administration of IMiDs a day before PIs to increase cells killing.

Summary/Conclusions: Schedule-dependent synergistic cytotoxicity was demonstrated for the combination of CAR and POM and a maximal apoptosis consistently observed in POM pre-exposure schedule. The superiority of this schedule was maintained throughout BM microenvironment models using low dosage of both drugs. Whilst the clinical efficacy of CAR and POM combinations has been demonstrated, the synergistic cytotoxicity may be further exploited by using optimized schedule. Utilizing such a schedule with IMiDs pre-treatment may improve the depth and duration of response of MM patients both as upfront therapy and in the relapsed/refractory setting.

Myeloma and other monoclonal gammopathies - Clinical

ASSESSMENT OF THE IMPACT OF POST-AUTOLOGOUS STEM CELL TRANSPLANT MAINTENANCE THERAPY ON SURVIVAL OUTCOMES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA IN THE COMMUNITY-BASED CONNECT MM REGISTRY

1Mount Sinai Hospital, New York, 2Indiana University Simon Cancer Center, Indianapolis, 3Cedars-Sinai Medical Center, Los Angeles, 4MD Anderson Cancer Center, Houston, 5US Oncology Research, Maryland Oncology Hematology, Columbia, 6Providence Cancer Institute, Southfield, 7Duke University Medical Center, Durham, 8Steeplechase Cancer Center, Somerville, 9University of South Carolina, Columbia, 10Wake Forest University School of Medicine, Winston-Salem, 11Celgene Corporation, Summit, 12US Oncology Research, Rocky Mountain Cancer Centers, Denver, United States

Background: Randomized phase 3 clinical trials have shown that maintenance therapy after autologous stem cell transplant (ASCT) can extend time to progression, progression-free survival (PFS) and overall survival (OS) for patients (pts) with newly diagnosed multiple myeloma (NDMM) (Sonneveld, J Clin Oncol 2012; McCarthy, N Engl J Med, 2012; Attal, N Engl J Med, 2012; Palumbo, N Engl J Med, 2014; Attal, ASCO, 2016). Connect MM is a largely community-based, US prospective observational cohort study designed to characterize diagnosis, treatment patterns and outcomes in pts with NDMM in clinical practice.

Aims: The Connect MM registry was used to assess impact of maintenance therapy on survival outcomes in pts with NDMM receiving ASCT.

Methods: Adult pts with NDMM were eligible to enroll in the registry within 60 days of diagnosis. Pts were enrolled in 2 sequential cohorts and were treated at the clinician’s discretion as per standard of care. Cohort 1 pts receiving induction and ASCT were included in the analysis and characterized into 4 maintenance regimen subgroups: no maintenance, lenalidomide (LEN)-based maintenance, bortezomib (BORT)-based maintenance, and LEN+BORT maintenance. Duration was from 100 days post-ASCT (no maintenance group) or start of maintenance until progressive disease, death, disconnection, or data cutoff of January 7, 2016. End points were PFS, second PFS, OS, and safety. An exploratory analysis of the impact of baseline characteristics on survival outcomes was performed.

Table 1.

Results: A total of 1493 pts were enrolled in Cohort 1 from Sep 2009 to Dec 2011; 1450 were treated, 81% (n=1173) in a community setting. Of those, 432 (29%) met analysis criteria. Median follow-up was 39.3 months. Median age was 60 y (range, 24-78); 60% were men; and 86% were white. A total of 165 pts did not receive maintenance. Of 267 pts receiving maintenance, 213 (80%) received LEN-based maintenance; 30 (11%) received BORT-based maintenance; and 16 (6%) received LEN+BORT maintenance. Of the maintenance groups, only data from LEN maintenance is presented; small sample sizes in the other maintenance groups limited interpretation. The median treatment duration was 32.5 months for pts who received LEN maintenance and 26.1 months for those who did not receive maintenance. Median PFS was significantly longer for pts who received LEN maintenance vs no maintenance (50.3 months vs 30.8 months; hazard ratio [HR]=0.62 [95% CI: 0.46, 0.82]; P=0.008; Table). OS was also significantly improved for pts who received LEN maintenance vs no maintenance (HR=0.54 [95% CI: 0.36, 0.83]; P=0.005). Second PFS (PFS for second-line treatment) was similar for both LEN and no maintenance groups. Exploratory analyses showed generally similar PFS and OS improvements across subgroups (age, ECOG status, International Staging System stage, risk group, and induction regimen). No new safety signals were observed.

Summary/Conclusions: In this observational study, post-ASCT LEN maintenance therapy significantly improved PFS and OS compared to no maintenance. These improvements appeared to be independent of induction regimen. Preliminary analysis of second PFS suggests no adverse impact of maintenance treatment on the efficacy of second-line therapy. These data, from a largely community-based setting, support results from randomized phase 3 trials.
IMPACT OF METFORMIN USE IN THE OUTCOMES OF MULTIPLE MYELOMA PATIENTS POST STEM CELL TRANSPLANT

N. Duma 1,*, J. Vera-Aguilera 1, J. Paludo 1, Y. Wang 1, T. Anagnostou 1
1Division of Hematology, Mayo Clinic, Rochester, United States

Background: Metformin, a biguanide, is commonly prescribed in the management of type 2 diabetes, as it reduces insulin resistance, promotes weight loss and has been associated with lower cancer incidence. However, there is a lack of studies investigating the effect of metformin on multiple myeloma (MM).

Aims: The purpose of this study was to investigate the association of metformin use with overall survival (OS) and progression-free survival (PFS) in patients with MM, and to explore potential mechanisms responsible for any observed associations.

Methods: All patients who underwent stem cell transplantation (SCT) at Mayo Clinic Rochester between 2007 and 2012 were included. Metformin use was based on chart review. Kaplan-Meier method and Cox regression were used for time-to-event and multivariate analysis.

Results: Of 130 patients, 59% were males and median age at SCT was 67 (49-93) years. Median duration of metformin use from diagnosis was 22.8 months. Patients who used metformin had significantly longer OS (31.3 months vs 16.6 months, 95% CI: 10.4-52.2, p=0.02). A trend toward better OS was noted in the Metformin group (27.6 months vs 16.6 months, 95% CI: 11.4-52.2, p=0.03). Median OS was not reached for patients who continued metformin use beyond SCT. A trend toward better OS was also noted in the Metformin group (20.2 vs 13.4, p=0.05).

Summary/Conclusions: Metformin use was associated with better OS and PFS in patients with MM. Larger studies are needed to better understand the clinical effect of metformin on MM.
and Nuclear Medicine, looking for focal bone lesions, bone marrow pattern and incidental findings. Details of the patients’ demographics, myeloma diagnosis and treatment were collected from the medical records.

**Results:** Of the 33 patients, 24 were male. The median age was 64 years (range=43-86 years). One patient had a solitary plasmacytoma, the other 32 had myeloma (21 IgG, 3 IgA, 2 non-secretory, 4 light chain disease). Of these, 22 had ISS stage 1 disease, with a median paraprotein at diagnosis of 17 (range 0.52-6). 21 patients had a bone marrow plasma cell burden of 10-60%, 10 patients >60% and 2 were unknown. Sixteen patients were diagnosed with smouldering myeloma and a ‘watch and wait’ policy was adopted. Eleven patients were treated with chemotherapy. 4 were entered into a clinical trial, one was offered palliative care and one was referred to our centre for autograft. WBMRI identified a focal lesion of disease in 30% of patients compared with 36% by PET-CT. This was not a statistically significant difference (p=0.18). In addition there was no statistically significant difference between PET-CT & MRI in detecting <3 or >3 lesions (p=0.075 and p=0.083 respectively). The apparent difference in sensitivities at vertebral L5 (using diffusion weighted imaging) was measured. This showed a strong correlation with the degree of bone marrow infiltration by plasma cells (r=0.64). An ADC of <600mm²/s had a negative predictive value of 93% for a bone marrow plasma cell infiltrate of >60%. There was also a significant difference (p=0.012) in the ADC between those with and without smouldering myeloma and those with symptomatic disease. It was noted that 9 scans resulted in incidental findings including pneumonia, adrenal lesions and one case of colocal cancer.

**Summary/Conclusions:** We have shown no difference in PET-CT and WBMRI detecting a myeloma defining focal bone lesion, or providing prognostic estimation of both bone disease. Using MRI, a measure of the ADC at vertebral L5 has been shown to be a semi-quantitative parameter that correlates with bone marrow plasma cell infiltration and distinguished between those with smouldering and symptomatic disease. In addition it is noted that whole body imaging has led to incidental findings of further pathology, including an unrelated malignancy, which may lead to useful clinical information or to further investigations and imaging which may not be needed.

**E1243**

**PERSISTENCE OF MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY CAN HINDER RECOVERY OF ORGAN DAMAGE IN PATIENTS WITH AL AMYLOIDOSIS (UCORE, AUGUST 2017)**

P. Milanil,1,2 M. Massla,1 M. Bassset,1 F. Russo1, P. Bert2, A. Foll2, O. Annibali1, G. Palladini1, G. Merlini1

1Department of Molecular Medicine, Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy, 2Institut d’Investigacions Biomèdiques August Pi i Sunyer, Hospital Clinic, Barcelona, Spain

**Background:** In multiple myeloma, Minimal Residual Disease (MRD) demonstrated by multiparameter flow cytometry (MFC) identifies subjects with significant chance of survival above those who attain complete response (CR). The role of MRD in AL amyloidosis has not been assessed so far.

**Aims:** In the present study, we assessed the MRD by MFC in patients with AL amyloidosis who attained CR.

**Methods:** CR was defined as per current criteria (negative serum and urine immunofixation and light chain ratio) and treatment response in those who attain complete response (CR). More than 2 lines of therapy were required to achieve CR in 7 subjects. Median time to CR was 10 months (range: 3-82). Five patients (62%) had achieved cardiac response and 9 (50%) renal response at the time of CR. The median time from CR to MRD was 30 months (range: 6-148), this was not different in the MRD positive vs negative patients (p-value NS). Sixteen patients (49%) had cardiac involvement at diagnosis. More than 2 lines of therapy were required to achieve CR in 7 subjects. Median time to CR was 10 months (range: 6-148), this was not different in the MRD positive vs negative patients (p-value NS). Sixteen patients (49%) had cardiac involvement at diagnosis.

**Results:** In ASPIRE, grade ≥2 PN rate was low (8.0% [KRd] vs 8.0% [Rd]; Table). Pain subscale scores were similar between arms. Median PFS was longer with KRd vs Rd for patients with grade 2 PN at baseline. In ENDEAVOR, grade ≥2 PN rate during the study (prespecified key secondary endpoint) was significantly lower with Kd vs Vd (6.0% vs 32.0%, Table). Patients had significantly improved pain and neurotoxicity subscale scores with Kd vs Vd. PFS improved with Kd vs Vd in patients with baseline history of grade ≥2 PN (Table 1).

**Summary/Conclusions:** In ENDEAVOR, the rate of PN was significantly lower with Kd then with Vd: In ASPIRE, PN rate was similar for KRd and Rd. Improved pain and neurotoxicity subscale scores with K could be attributed to better disease control and/or lower PN rates.

**E1245**

**EARLY RELAPSE FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN MYELOMA IS A POOR PROGNOSTIC MARKER FOR OVERALL SURVIVAL AND IS DIFFICULT TO PREDICT AT DIAGNOSIS OR DURING INDUCTION TREATMENT**

I. Walker1,2, A. Coady2, I. El-Najjar3, K. Wilson4, K. Cuthill1,3, W. Ingram4,

1Department of Haematology, King’s College Hospital Foundation Trust, 2Guy’s, King’s and St Thomas’ School of Medical Education, King’s College London, 3Department of Haematology, Guy’s and St Thomas’ NHS Foundation Trust, London, 4Department of Haematology, University Hospital Wales, Cardiff, United Kingdom

**Background:** High dose chemotherapy followed by autologous stem cell transplant (ASCT) remains the gold standard treatment in myeloma for young patients with AL amyloidosis who attained CR.

A validation study in a larger cohort is ongoing. The possible impact of MRD should be considered in trials aiming at increasing organ response rate in patients in CR.
patients at induction. A number of factors have been shown to correlate with overall survival (OS) and progression free survival (PFS), including depth of remission prior to ASCT, initial ISS stage and high risk cytogenetics. Emerging evidence has demonstrated that early relapse following ASCT is associated with reduced OS, and is not correlated with depth of pre-transplant response.

Aims: To characterise myeloma patients who relapsed within 12 months of ASCT; through baseline characteristics and transplant engraftment, and assess the impact of this early relapse on OS and PFS.

Methods: We performed a multicentre retrospective analysis of patients who underwent ASCT at 3 centres between 01/2009 – 02/2016 (London) and 06/2006 – 03/2013 (Cardiff). Baseline characteristics were reviewed and ASCT engraftment was assessed by; time to neutrophils 5 x 10⁹ and platelets >20 x 10⁹. Post-transplant PFS & OS was calculated by time (months) from diagnosis to progression or death.

Results: 443 myeloma patients were identified, median age was 57 (r 31-73), 56% were male. 41% of patients were ISS stage 1, 34% stage 2, 25% stage 3. Cytogenetic data was available for 139 patients. 1st-line therapy prior to transplant was a B-cell monoclonal antibody drug (IMD) based (THAL/LEN) for 318/443 patients & 72/443 were proteasome inhibitor (PI) based (BORT/CARF). In addition, 11 patients received combination PI and IMIDs. Median time from start of therapy to ASCT was 10 months (r 3-109m), 67 patients progressed within 12m of ASCT (early progression). No statistical difference was found between <12m or >12m relapse for; age, gender, 1st line therapy, ISS stage, Hb, LDH, Ca or cytogentic, confirming that this group is difficult to predict at baseline. Median OS from time of diagnosis was 103 months (95% CI 101 -137), median OS from start of ASCT was not reached, however 5-year OS was 68%. Patients with progressive disease within 12 months of ASCT, has significantly reduced median OS compared with those diagnosed 31 months (95% CI 21- 39) compared to non-progressive patients (median OS:103m 95% CI 89-117) p=0.0005. Median OS from ASCT was reduced in early progression median OS:18m (95% CI 14-22m) vs progression >12 months median OS:89 months (95% CI 79-98m) p<0.0005. 1st line therapy did not influence likelihood of PFS<12months, with no statistical difference between patients who received PIms, IMIDs or both 1st line (p=0.484). A significant difference was observed in median time to platelet engraftment between the 2 centres. Increased time for platelets to reach >20 x 10⁹ was associated with reduced OS from ASCT for each centre HR 1.4 & 1.20 (p=0.046 & 0.03) for Cardiff or London centres respectively (Cox's Method).

Summary/Conclusions: Early relapse following ASCT is a significant predictor of inferior OS in myeloma and difficult to predict from standard baseline characteristics. From our analysis; 1st line treatment prior to ASCT did not influence OS or PFS. There was an association between slow platelet engraftment following ASCT and PFS and OS. Possible explanations include: residual occult disease, toxicity of chemotherapy or patient stromal factors which facilitate disease resistance and impair normal haematopoiesis. All of these factors have been shown to drive relapse. RCTs are required to standardise bone marrow response assessment post ASCT, quantify remission status (using laboratory and imaging techniques) and definitively predict early relapse. Additionally, these studies will investigate further biological or genetic mechanisms driving early relapse to help identify novel therapeutic approaches in this extremely poor prognosis group.

E1246

PATIENT-REPORTED OUTCOMES (PROS) WITH IBRUTINIB: SUBSTUDY OF INNOVATE FOR WALDENSTRÖM MACROGLOBULINEMIA (WM)

1Haematology, Concord Repatriation General Hospital, Concord, Australia, 2National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, 3Azienda Ospedaliero-Niguarda Ca' Granda Hospital, Milan, Italy, 4Coroado Blood Cancer Institute, Denver, 5Winship Cancer Institute of Emory University, Atlanta, United States, 6Royal Victoria Hospital at McGill University Health Centre, Montreal, Canada, 7Hospital Universitario de Salamanca, Salamanca, Spain, 8Dana-Farber Cancer Institute, Boston, United States, 9Hospital Pitié-Salpêtrière APHP, UPMC Université, Paris, France, 10Pharmacy, LLC, and AbbVie Company, Sunnyvale, United States, 11University of Ulm, Ulm, Germany.

Background: Anemia and fatigue are frequent indications for WM treatment. To date, patient-reported outcomes (PROs) have not been used to quantify benefit of ibritinib (IBI). In Ibrutinib (ibr) is a first-in-class, once-daily inhibitor of BTK, is indicated in the EU for the treatment of WM after ≥1 prior therapy or >12m relapse for: age, gender, 1st line therapy, ISS stage, Hb, LDH, Ca or cytogentic, confirming that this group is difficult to predict at baseline. Median OS from time of diagnosis was 103 months (95% CI 101 -137), median OS from start of ASCT was not reached, however 5-year OS was 68%. Patients with progressive disease within 12 months of ASCT, has significantly reduced median OS compared with those diagnosed 31 months (95% CI 21- 39) compared to non-progressive patients (median OS:103m 95% CI 89-117) p=0.0005. Median OS from ASCT was reduced in early progression median OS:18m (95% CI 14-22m) vs progression >12 months median OS:89 months (95% CI 79-98m) p<0.0005. 1st line therapy did not influence likelihood of PFS<12months, with no statistical difference between patients who received PIms, IMIDs or both 1st line (p=0.484). A significant difference was observed in median time to platelet engraftment between the 2 centres. Increased time for platelets to reach >20 x 10⁹ was associated with reduced OS from ASCT for each centre HR 1.4 & 1.20 (p=0.046 & 0.03) for Cardiff or London centres respectively (Cox’s Method).

Summary/Conclusions: Early relapse following ASCT is a significant predictor of inferior OS in myeloma and difficult to predict from standard baseline characteristics. From our analysis; 1st line treatment prior to ASCT did not influence OS or PFS. There was an association between slow platelet engraftment following ASCT and PFS and OS. Possible explanations include: residual occult disease, toxicity of chemotherapy or patient stromal factors which facilitate disease resistance and impair normal haematopoiesis. All of these factors have been shown to drive relapse. RCTs are required to standardise bone marrow response assessment post ASCT, quantify remission status (using laboratory and imaging techniques) and definitively predict early relapse. Additionally, these studies will investigate further biological or genetic mechanisms driving early relapse to help identify novel therapeutic approaches in this extremely poor prognosis group.

Background: Cardio-vascular (CV) toxicities in patients (pts) with multiple myeloma (MM) may derive from comorbidities, MM itself and its treatment. Carfilzomib, an irreversible proteasome inhibitor, is approved as single agent or in combination with dexamethasone or lenalidomide-dexamethasone for relapsed MM.

Aims: We conducted an integrated analysis of CV adverse events (AE) in newly diagnosed, transplant-ineligible MM patients treated with Carfilzomib in 3 phase III studies (IST-CAR-506, IST-CAR-501, IST-CAR-601).

Methods: All pts were treated with 9, 28-day induction cycles with carfilzomib, cyclophosphamide (300mg/m² on days 1,8,15) and dexamethasone (40mg weekly) (CCyd), followed by carfilzomib maintenance until progression or intol-

Papanikolaou General Hospital, Thessaloniki, Greece

Background: The all-oral combination of ixazomib, lenalidomide and dexamethasone (IRd) has been recently approved as a novel standard of care for relapsed/refractory multiple myeloma (RRMM).

Methods: This was a retrospective, non-interventional study, which recorded IRd treatment data from patients with RRMM who participated in the name-patient program of ixazomib in Greece. The primary endpoint was the evaluation of overall response rate (ORR) according to the International Myeloma Working Group criteria. Secondary endpoints included: treatment duration; time to response; duration of response; percentage of patients who experienced adverse events (AEs), needed dose modification or treatment discontinuation; evaluation of PFS and TTP.

Results: Forty-one patients were included in the present study. Of those, 35 (85%) were treated with POM + LoDEX, while 6 (15%) were treated with POM + LoDEX + Daratumumab. Aims: The aim of this study was to evaluate the efficacy and safety of IRd in the “Real World” (RW) practice, where data are very limited.

Aims: To present updated safety and efficacy analyses only from cohort A, in which pts received POM + LoDEX immediately after relapsing or being refractory to second-line LEN-based therapy.

Methods: Pts aged ≥18 years had documented MM, measurable disease, 2 prior lines of treatment, and PD after ≥2 cycles of second-line LEN-based treatment. Pts received 28-day cycles of POM 4mg/daily on days 1-21 + LoDEX 40mg/daily on days 1-7 (pts ≥75 years) or on days 1, 8, 15 and 22 (in pts ≤75 years) until PD or until a maximum of 24 cycles or in absence of thrombocytopenia. The primary endpoint was overall response rate (ORR; ≥ partial response [PR]) assessed by modified IMWG criteria. Key secondary endpoints included time to response (TTR), progression-free survival (PFS), secondary primary malignancies (SPMs), and biomarkers. All pts provided informed consent.

Results: Of 51 enrolled pts in cohort A, 39 (76.5%) discontinued treatment, mostly due to PD. Median age was 68.0 years, and 92.2% had an Eastern Cooperative Oncology Group performance status of ≥1. A total of 45 pts (88.2%) were refractory to their last treatment with LEN, and 37 (72.5%) had prior treatment with pomalidomide. Median duration of prior LEN-containing therapy was 24.6 months. With a median follow-up of 13.6 months, ORR was 29.4%, with 1 (2.0%) complete response, 5 (9.8%) very good partial responses, and 9 (17.6%) PRs. Minimal response (MR) was reached in 15.7% of pts. Median TTR was 1.9 months and 66% of pts had ongoing response at 1 year. Median PFS was 13.8 months. The 2-year PFS rate was 48.0% for the intent to treat population, 69.4% for pts with ≥ MR, and 69.1% for pts with ≥ PR. In addition, pts with ≥ MR had similar treatment durations as those achieving ≥ PR (10.5 vs 11.5 months; Table). Common grade 3/4 adverse events (AEs) included anemia (25.5%), neutropenia (11.8%), and infections (19.6%; including pneumonia [9.8%]. No pts experienced SPMs. In the immune subset analysis, the proportions of CD3+ and CD3+/CD8+ T cells after treatment were significantly higher vs baseline (72.6% vs 67.8% and 36.9% vs 32.1%, respectively, P<0.05).

Pts with response also had significantly elevated proportions of these T-cell populations, but pts with no response did not. Relative changes from baseline for CD3+ and CD3+/CD8+ T-cell populations were significantly greater in pts with response vs those with no response (10.4 vs -0.8 and 4.2 vs -3.5, respectively; P<0.05).

Table 1.

Summary/Conclusions: This update confirms the safety and efficacy of POM + LoDEX following second-line LEN-based treatment failure in pts with RRMM. Hematologic AE rates improved, and median PFS was longer with third-line use than previously reported with POM + LoDEX use in later treatment lines. In addition, achieving disease control of ≥ MR led to similar PFS rates as reaching ≥ PR.

Table 1.

Summary/Conclusions: Among newly diagnosed MM pts treated with carfilzomib, cyclophosphamide and dexamethasone, at least 1 CV risk factor at enrolment had a 4-fold increased risk (odds ratio: 4.12; p=0.012) and grade 3-5 CV-AEs occurred in 15% of patients, the most common being heart failure (4%), hypertension and dyspnea were the most common. Pts ≥75 years of any grade (58% vs 36%; p=0.002) and grade 3-5 CV-AEs (34% vs 15%, p=0.01) major cardiac events of any grade were more frequent in older patients (29%) than in younger ones (6%; p<0.001). Patients with at least 1 CV risk factor at enrolment had a 4-fold increased risk (odds ratio: 3.79; p<0.001) of developing a CV-AE during treatment as compared to patients with no CV risk factors; in detail, baseline hypertension (odds ratio: 4.12; p=0.012) and peripheral vascular disease (odds ratio: 3.75; p=0.002) conferred the highest risk of developing CV-AE.

Figure 1.
5.7% (2/35) and 2.9% (1/35) had received 2 and 3 prior treatment lines, respectively. Overall, 82.9% (29/35) of patients had been exposed to pro- some inhibitors prior to IRd (77.1% to bortezomib and 8.6% to carfilzomib) and 48.6% (17/35) to IMiDs [31.4% (11/35) to thalidomide and 22.9% (8/35) to lenalidomide]. Autologous transplantation had been given in 42.9% (15/35) of patients. Median treatment duration was 7.1 months. Among 34 patients with available data, 3 (8.8%) patients discontinuation. The ORR (PR) or better was 67.6% (10/15) and 96.6% (15/15) for patients who received unilateral and bilateral treatment, respectively. Median time to best response was 1.6 months. Treatment interruptions due to AEs were recorded for 11.4% (4/35) of patients, while 20.0% (7/35) of patients discontinued treatment. Reasons for treatment discontinuation were AEs for 3 patients (an event of treatment-related death, shock, and pancreatitis), disease progression in 2 patients, and, on the administrative reason (patient could no longer visit the site) in 1. Among the 35 patients analyzed, 17.1% (6/35) had experienced disease progression or death; the 6-month PFS rate was 90.5% and the 6-month TTP rate was 93.2%. Regarding AEs of interest, 31.4% (11/35) of patients experienced peripheral neuropathy, 54.3% (19/35) had resolution, and 45.4% (5/11) did not resolve (three patients, three out of four, and two out of three, respectively) at the end of follow-up. In addition, 31.4% (11/35) of patients developed gastrointestinal AEs, 11.4% (4/35) experienced pneumonia, 9.4% (3/32) hypertension, 5.7% (2/35) cataract and herpes zoster, and 2.9% (1/35) deep vein thrombosis; no cardiovascular, renal, or psychiatric events were recorded, while osteonecrosis of the jaw developed in 5.7% (2/35) of the patients.

Summary/Conclusions: This study showed that the IRd regimen produces an ORR of near 68% and a clinical benefit in almost all patients with RRMM who are treated in RW practice. IRd acts rapidly and has an acceptable toxicity profile with no cardiac events.

Orsola, Malpighi, Bologna, Italy, 6University Hospital Ostrava and Faculty of Medicine Ostrava, Ostrava, Czech Republic, 7University Medical Center Utrecht, Utrecht, Netherlands, 8National and Kapodistrian University of Athens, Athens, Greece, 9Centre Hospitalier Universitaire de Liége, Liege, Belgium, 10Aarhus University Hospital, Aarhus, Denmark, 11Uddェvellia Sjukhus, Uddevalla, Sweden, 12St Olavs Hospital, Trondheim University Trondheim, Trondheim, Norway, 13Midland Cancer Network, Leicester, United Kingdom, 14Coloane International, Boudry, Switzerland, 15Department of Internal Medicine III, Charité Campus Benjamin Franklin, Berlin, Germany

Background: EU PASS is an observational, non-interventional study designed to evaluate the safety of lenalidomide (LEN) and other agents in the treatment of patients with RRMM in a real-world setting.

Aims: To assess the incidence of adverse events (AEs) of special interest (ie, neutropenia, thrombocytopenia, venous thromboembolism [VTE], neuropathy, and second primary malignancies [SPMs]).

Methods: In this EU PASS study, patients receiving LEN treatment were enrolled at the investigator’s discretion into the LEN cohort (LEN + dexamethasone, the approved combination for the treatment of RRMM); patients who received ≥1 prior therapy initiating a non–LEN-based treatment were enrolled into a background cohort (all other treatments, including novel agents). Thromboprophylaxis was administered in accordance with local standard practice. Parameters were graded according to the National Cancer Institute-Common Terminology Criteria for AEs, v3.0. SPMs were defined using MedDRA terms, SPM assessments were to be conducted using available ECOG scores, 2895 (96.0%) had an ECOG score ≤2. The median number of prior therapies was 1 (range 1-6); the proportion of patients with only 1 prior treatment was lower in the LEN (44.2%) vs BORT (70.8%) and THAL (56.2%) cohorts. Overall, 1843 patients (50.8%) had grade 3/4 AEs (Table). All grade neuropathy occurred in 9.8%, 28.2%, and 17.7% of patients in the LEN, BORT, and THAL cohorts, respectively. Treatment discontinuation rates due to AEs were similar in each cohort (LEN: 22.4%, BORT: 20.1%, and THAL: 21.2%). Rates of treatment-emergent AEs, 7 and 10 days to dose reductions were also similar across cohorts, occurring in 23.9% of patients in the LEN cohort, 21.2% in BORT, and 17.5% in THAL. Data on long-term responders will be presented at this meeting.

Table 1

Summary/Conclusions: LEN was generally well tolerated and the safety results were similar to published data. As expected, the occurrence of neutropenia, TCP, and VTEs were higher in patients in the LEN cohort, whereas neuropathy was more frequently reported in patients in the BORT cohort. VTEs were low in all cohorts. The occurrence of SPMs was generally low and comparable between cohorts.
Results: During the development process, a number of similarities and discrepancies between centers as well as evidence gaps were identified. Intense discussion and literature searches resulted in a concise, harmonized clinical pathway, released by all 14 Centers of Excellence. This is freely available on the website ccc-netzwerk.de and provides a very decisive insight according to the current state of knowledge on the CCC-level (e.g. on the diagnostic algorithm, Fig. 1). The clinical pathway is well suited for informing patients and physicians about the most up-to-date, comprehensive medical treatment standards as well as innovative procedures. Furthermore, this project initiated the idea of developing a national evidence-based clinical practice guideline for MM in the frame of the German Guideline Program in Oncology.

E1252
WT1 HETEROCLITIC EPITOME IMMUNIZATION FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH-RISK MULTIPLE MYELOMA (MM)
G. Koehne1,*, S. Devlin1, D. Chung1, H. Landau1, N. Kordel1, S. Mailankody1, H. Hassoun2, A. Lesokhin1, N. Lendvai1, S. Giralt1, O. Landgren1
1Memorial Sloan Kettering Cancer Center, New York, United States

Background: The Wilms tumor 1 (WT1) protein is a tumor-associated antigen that is a target for anticancer immunotherapy. We had previously demonstrated overexpression of WT1 in multiple myeloma (MM) cells by IHC, as well as formation of a WT1 peptide fragment (RMFFNAPYL-HLA-A*0201 complex) on the engagement interface between malignant plasma cells and T-cells in HLA-A*0201 MM pts using the high-affinity fully human lgG1 mAb ESX1. We report initial results from MM pts immunized with the WT1 heteroclitic peptide mixture galinpepimut-S (GPS) after autoSCT.

Aims: To determine the safety and potential efficacy of the WT1 heteroclitic peptide immunizer GPS administered in patients with multiple myeloma following autologous stem cell transplantation.

Methods: 16 MM pts underwent autoSCT with melphalan conditioning followed by (flb) lenalidomide maintenance starting 3 months (mos) post-SCT. 13/16 pts presented with high-risk (HR) cytogenetics [t(4;14), t(14;16), del(17p, 1q21)/del(17p, 1q21) gain and/or del(13q)]. GPS was administered with montanide s.c. starting 2 ws post-SCT and 2 q2 ws thereafter x 6 initial doses flb boosters q4 wks x 6 additional doses. GM-CSF was given on days -2 and 0 of each cycle. GPS consisted of 4 peptides: WT1-A1: YMFNPAPYL (247-L); RSDLERVHNMHQRNMTKL 331-L; PGCNKRYFKLHSLQHMSRHTG, and 1220-L; SGQAY*MFPNAPYLPSCLES. 2 of the 4 peptides were mutated at a single residue (*) to induce stronger HLA-binding/reduce tolerance. WT1-specific immune responses (IRs) were assessed by intracellular IFN-g analyses post-challenge with PBMC’s pulsed with a ‘total pool’ of overlapping 15mers along the entire WT1 protein; or each of the 4 WT1 peptides in GPS; or the non-mutated (native) WT1 peptides corresponding to the 2 heteroclitic sequences.

Results: 16 pts underwent auto SCT followed by WT1 heteroclitic peptide immunization; median follow-up of 16 mos (range: 3-51 mos) for survivors; median age: 61.6 y. Overall survival (OS) and progression-free survival (PFS) (95% CI) at 18 mos: 0.88 (0.73-0.99) and 0.62 (0.42-0.97) respectively. Current median PFS: 23.6 mos (15.2- not reached). No ≥G2 systemic side effects were observed, however, all pts developed local nodularity at the site of injections which resolved over 2 – 6 wks. Both CD8+ and CD4+ IRs could be detected at various levels and were induced not only against the heteroclitic peptides (within GPS), but also against the corresponding native WT1 peptide sequences as well as the ‘total pool’ of WT1-derived overlapping peptides.

Summary/Conclusions: Administration of the novel WT1 heteroclitic peptide immunizer GPS post-SCT demonstrates favorable safety profile along with an encouraging mPFS of currently 23.6 mos in this high-risk MM population. This novel immuno-therapy is easy to administer and has been specifically designed to elicit responses across most common HLA Class I and II alleles. Based on these results, a larger phase II trial is being planned to optimally integrate post-transplant immunotherapeutic strategies to meaningfully delay or reduce risk of relapse in this challenging clinical setting.
Background: Multiple myeloma (MM) represents the second most common hematological malignancy characterized by the proliferation of monoclonal plasma cells (PC) in the bone marrow. The natural history of active MM patients may be complicated in significant fraction by the occurrence of infections that can be related both to the development of therapy induced neutropenia (mainly due to high dose chemotherapy used in the setting of autologous stem cell transplantation or in salvage regimen) or to MM induced secondary immunodeficiency.

Aims: The aim of this study was to analyse the frequency, the type and the major risks factors of severe infections in our cohort of patients affected by MM and to understand the impact of these events on MM patient overall survival (OS).

Methods: A cohort of 341 patients affected by MM (104 with smouldering MM and 237 with symptomatic MM) followed from 1996 to 2016 was retrospectively studied for the presence of severe infections (si, defined by the need of hospitalization) during the natural history of the disease. Infections were classified as “not neutropenia related” or “neutropenia related” according to the Absolute Neutrophil Count > or <1,000/ml respectively. International Staging System (ISS) and Durie-Salmon (DS) were used for MM patients staging.

Results: In our cohort of patients, si were significantly associated to active MM (28.69% of symptomatic patients vs 3.85% of asymptomatic patients; p=0.0001, c²=26.318). Among the 138 infective events occurred in 91 active MM patients, 38 (26%) were neutropenia related while remnant 100 not (72%). Furthermore, almost 44% of these events (61/138) developed during induction therapy, with 12 out of 61 (20%) being present at time of the diagnosis. Considering that majority of si was not neutropenia related and that these infective events involved most of active MM patients who developed si (68/91, 75%), our aim was to identify MM patient characteristics associated to the development of not neutropenia related si. Our results prove evidence that major features presented at the time of the diagnosis significantly associated to si were DS stage III (p=0.0004, c²=12.14), ISS stage III (p=0.0001, c²=21.11), age >70 years (p=0.0195, c²=5.455), bone marrow plasma cells >60% (p=0.034, c²=4.50), acute renal failure (p=0.0003, c²=13.010) or MM presenting with at least three of CRAB criteria (p=0.0123, c²=6.26). For what concern the impact of si on the natural history of the disease, patients who experienced infective event presented a reduced OS towards other patients (p=0.0001). Among infected patients no significant differences were reported referring to the number of infections (>1 or =1, p=0.11), while patients who developed exclusively neutropenia related infective events showed better OS towards patients who experienced not neutropenia related infections (p=0.0011).

Summary/Conclusions: Severe infections represent an underestimated comorbidity in MM, characterizing all phases of the disease and not only refractory/relapsed patients receiving multiple lines of therapy. Considering that severe infections impact OS mostly in the setting of not neutropenia related infective events and immunoglobulin replacement therapy by recombinant phylaxis may possibly have a protective role in high risk old patients characterized by ISS and DS stage III, bone marrow PC >60% and aggressive disease at the time of diagnosis.

E1255
EVALUATION OF CARDIOVASCULAR EVENTS ASSOCIATED WITH DIFFERENT TREATMENT MODALITIES OF MULTIPLE MYELOMA IN THE REAL-WORLD SETTING IN THE UNITED STATES

D. Lenihan1, R. Potluri2, H. Kanakamedala2, A. Dasgupta2, C. Chen1,2,5,1

1Vanderbilt University Medical Center, Nashville, 2SmartAnalyst Inc., New York, 3Bristol-Myers Squibb, Lawrenceville, United States

Background: Multiple myeloma (MM) is a disease of the elderly. The prevalence of cardiovascular (CV) comorbidities in the MM population is high. Past research suggests that MM is associated with a range of cardiac risks, and emerging evidence shows that both proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) can have important CV sequelae. The improved efficacy of PI plus IMiD combination therapy (PI+IMiD) has resulted in its widespread adoption, which suggests that CV events may become a prominent concern in patients receiving PI+IMiD as contemporary treatment for MM.

Aims: To assess the risk of developing CV events in patients receiving anti-MM treatment and to test if a specific treatment modality was associated with higher risk of a CV event.

Methods: Patients with ≥1 inpatient claim or ≥2 outpatient claims with a primary diagnosis code for MM who were treated with PI and/or IMiD drugs between Jul 2012 and Sep 2014 were identified in a large US claims database. The first claim for a PI or IMiD drug in this period was defined as the index date, which was preceded by 180-d continuous eligibility with no anti-MM treatment (baseline). Patients were divided into three cohorts based on the anti-MM treatment received: PI, IMiD, PI+IMiD. CV events of interest included cardiac arrhythmia, cardiac failure, venous thromboembolism (VTE), myocardial infarction, ischemic heart disease, angina, stroke and coronary atherosclerosis, and were measured during anti-MM treatment. Kaplan–Meier methods were used to estimate the occurrence rate of a CV event, and multivariate Cox regression models were developed to identify prognostic factors of each CV event among patients treated with anti-MM therapies.

Results: 4288 patients met the eligibility criteria for inclusion in the study (57% male, median age 66 y, 41% with Charlson Comorbidity Index ≥2, mean duration of treatment 192 d; Table). 42% (n=1779) were treated with PIs, 38% (n=1624) with IMiDs and 20% (n=865) with PI+IMiDs. Patients receiving PI+IMiD were significantly younger and generally had lower prevalence of CV comorbidities than those receiving PI or IMiD (Table). Compared with patients on PI, the risk of developing VTE was 46% greater in patients on PI+IMiD (HR: 1.46; 95% CI: 1.09, 1.96). Compared with those on IMiD, the risk of developing cardiac failure and cardiac arrhythmia was 33% and 18% greater in patients on PI+IMiD (HR: 1.33; 95% CI: 1.03, 1.72; HR: 1.18; 95% CI: 1.00, 1.40). After 6 months of treatment, the rates of VTE were 8%, 10%, and 11% for patients on a PI, those on an IMiD and those on PI+IMiD, respectively. The corresponding rates for cardiac failure were 18%, 11% and 11% for PI, IMiD and PI+IMiD cohorts, and 21%, 16% and 22% for cardiac arrhythmia.

Summary/Conclusions: PI+IMiDs may be associated with incremental occurrence of specific CV events during treatment, and may result in specific CV events earlier during therapy than PIs or IMiDs alone. These highlight a need for treatments that do not exacerbate CV risks and are appropriate for patients with pre-existing CV conditions. The lower prevalence of baseline CV comorbidities and lower mean age in patients on PI+IMiDs suggest that prevalence of a CV comorbidity and age influences treatment choice. Further analysis may be necessary to better understand the impact of baseline CV comorbidities on choice of MM treatment.

E1256
LENALIDOMIDE PLUS HIGH-DOSE VERSUS LOW-DOSE DEXMETHASONE FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA: A SYSTEMATIC REVIEW

K. Kupas1,2, I. Kaspar1, V. Baeccker4, K. Weise3
1Bristol-Myers Squibb, Munich, 2Ecker + Ecker GmbH, Hamburg, 3University of Tubingen, Tubingen, Germany

Background: Lenalidomide in combination with dexamethasone is approved globally for the treatment of multiple myeloma (MM). Although older pivotal regimens used lenalidomide combined with dexamethasone (LD), more recent studies have used lenalidomide plus low-dose dexamethasone (LD) for relapsed/refractory MM (RMM), as the LD regimen demonstrated better survival with lower toxicity for the treatment of newly diagnosed MM.
Methods: We searched MEDLINE, EMBASE and Cochrane databases and key clinical trial registries for studies including adults with RRMM who had received ≥1 prior therapy and had a symptomatic relapse on their last treatment. Eligible studies evaluated LD (lenalidomide: 25mg on Day 1–21 of each cycle; dexamethasone: 160mg/cycle, not pulsed) or LD (Cycles 1–4: 480mg/cycle; Cycle 5+: 160mg/cycle, pulsed). Only those trials with designs and baseline patient characteristics approximately aligning with those of ELOQUENT-2 were eligible to ensure comparability. Studies with a follow-up of ≥16–25 months were evaluated separately from studies with a follow-up of >30 months; these observation periods approximate those of ELOQUENT-2.

Results: From an initial bibliographic search yielding 5155 non-duplicate results and 619 registry results, 7 studies (8 publications) met the inclusion criteria (4 LD studies, 3 LD studies). Data for overall survival and tolerability from 1153 patients in the LD group and 353 patients in the LD group were analyzed. The median patient age was 63–68 years. Most patients were white, male and had an ECOG score of 0 or 1. LD was not associated with loss of efficacy in terms of overall survival; however, >30 months of follow-up, the hazard ratio for LD vs vs LD was 1.04 (95% CI 0.85–1.28). Tolerability was similar for LD vs vs LD; after 16–25 months of follow-up, LD was associated with a statistically significantly increased risk of Grade 3/4 adverse events (AEs; relative risk [RR]: 1.10 [95% CI 1.01–1.19]). However, after >30 months of follow-up, LD was not associated with an increased risk of AEs (RR: 1.00 [95% CI 0.99–1.01], RR: 1.03 [95% CI 0.95–1.12]) or serious AEs (RR: 1.08 [95% CI 0.97–1.20]; RR for AEs leading to discontinuation was 1.16 [95% CI 0.87–1.54].

Summary/Conclusions: Overall survival and safety are not significantly affected by different dosing of dexamethasone in combination with lenalidomide; thus, there is no evidence that use of LD versus LD can be recommended in this patient population. Further studies may provide additional evidence to inform clinicians and revision of international guidelines for dexamethasone dosing in RRMM.

Study funded by Bristol-Myers Squibb.
IMPACT OF IMMUNOPARESIS IN PATIENTS WITH LIGHT CHAIN AMYLoidosis

L.G. Rodríguez-Lobato1,2,*, I. Fernández de Larrea1, M.T. Cibeira1, N. Tovar1, J.I. Aróstegui2, L. Rosillo1, M. Elena3, J. Yagüe2, J. Bladé1
1Department of Haematology, 2Department of Immunology, 3Department of Biochemistry, Hospital Clinic, Barcelona, Spain

Background: The presence of immunoparesis (IP) at diagnosis in several plasma cell disorders is a risk factor for progression, associated with an unfavorable outcome with reduced progression-free survival (PFS) and overall survival (OS). However, its impact in light chain (AL) amyloidosis has been evaluated only in few series, and when present it was associated with worst response and survival.

Aims: The aim of this study was to investigate the prognostic impact of IP in patients with newly diagnosed AL amyloidosis at a single institution.

Methods: We reviewed the clinical records of patients with AL amyloidosis diagnosed from January 2008 to December 2016. Sixty-nine patients (32F/37M; median age at diagnosis 62) with available immunoglobulin (Ig) measurements were the final study population. Initial baseline demographics, clinical and laboratory data, treatment and follow-up were collected. Median follow-up was 30.2 months. IP was defined as suppression of all uninvolved Ig below the lower reference value. PFS and OS were calculated from the date of diagnosis.

Results: Forty-three patients (62.3%) were transplant ineligible while 26 (37.7%) underwent an autologous stem cell transplantation (ASCT). The distribution of the monoclonal protein type by immunofixation at diagnosis was as follows: light chains only (46.4%), IgG (39.1%), IgA (10.2%) and IgM (4.3%). The predominant light chain isotype was lambda (79.7%). A very good partial response (VGPR) or better was achieved in 53.6% of patients. Three-year OS rate was 64.3%. IP was observed in 27.5% of the patients at diagnosis. Patients with IP had a higher bone marrow plasma cells (BMPC) infiltration (29 ± 10% vs. 21.7% vs. 22.1%; P=0.08). IP was more frequent in those who received an ASCT (34.3% vs. 21.7% vs. 22.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (57.9% vs. 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (57.9% vs. 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (57.9% vs. 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (57.9% vs. 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (57.9% vs. 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (57.9% vs. 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (57.9% vs. 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (57.9% vs. 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (57.9% vs. 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (57.9% vs. 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (57.9% vs. 42.1%; P=0.03).

Regard its prognostic value, IP did not influence survival in the whole series. In the ASCT group, the presence of IP resulted in a significantly shorter PFS (median: 30.3 months vs. NR; P=0.011; Figure 1A) and OS (62.5 months vs. NR; P=0.014). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B) and OS (27.6 months vs. NR; P=0.074). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B) and OS (27.6 months vs. NR; P=0.074). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B) and OS (27.6 months vs. NR; P=0.074). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B) and OS (27.6 months vs. NR; P=0.074). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B) and OS (27.6 months vs. NR; P=0.074). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B) and OS (27.6 months vs. NR; P=0.074). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B) and OS (27.6 months vs. NR; P=0.074). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B) and OS (27.6 months vs. NR; P=0.074). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B) and OS (27.6 months vs. NR; P=0.074). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B) and OS (27.6 months vs. NR; P=0.074). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B) and OS (27.6 months vs. NR; P=0.074).

Summary/Conclusions: The presence of IP has a negative impact on survival, especially in the sub-group of patients in early stages of the disease. The presence of IP at diagnosis could be an additional powerful discriminatory prognostic indicator in the group of patients without advanced stage of the Mayo risk stratification system of 2012.
Background: Polyclonal antibodies against the conformational epitopes between the heavy and light chains (HLC) of immunoglobulin (lg) have been recently introduced as diagnostic tool in multiple myeloma (MM) and other monoclonal gammopathies. They separately identify the two different light chain types of each Ig, allowing the quantification of the monoclonal component. HLC and HLC ratios may be particularly useful for monitoring the presence of monoclonal component in oligo-secretory MM or when it migrates in the β range, as frequently observed in IgA MM. The International Myeloma Working Group (IMWG) has published in 2016 new consensus criteria for assessing response and minimal residual disease (MRD) in MM, outlining the potential role of HLC assay in this setting and the need of its further investigation, particularly in patients achieving complete response (CR) and failure to maintain the response. Aims: We conducted a single center, prospective study of HLC ratio, in comparison with free light chain (FLC) ratio, for the evaluation of MRD and its prognostic role in MM patients achieving CR after first line treatments including novel agents.

Methods: Twenty-five consecutive patients were evaluated. Mean age was 63 years (range 43-92), fourteen patients were males. Ig isotype was IgG or IgA in 14 and 11 patients, respectively, with 20 patients showing kappa and 5 lambda light chains. According to International Staging System, seven patients had stage 1, ten stage 2 and eight stage 3. Fourteen patients not eligible to autologous stem cell transplantation (AuSCT) received a bortezomib-based treatment, mainly constituted by bortezomib, melphalan and prednisone combination (VMP), while eleven patients underwent AuSCT after induction therapy with bortezomib, thalidomide and dexamethasone (VTD). With a median follow-up of 52 months (range 21-92), overall survival (OS) of the entire cohort was 61 months (95% CI 52-80) and progression-free survival (PFS) was 26 months (95% CI 12-38). IgGk/IgGl and IgAk/IgAλ were analyzed on serum samples at diagnosis and at the time of immunofixation negative CR (according to 2006 IMWG criteria), using Hylevite and Freellite commercial kits, respectively, on a SPAplus analyzer (Binding Site); IgGk/IgGlA and IgAk/IgAλ and k/λ ratios were then calculated. Results: At CR time, we found seven (28%) samples still showing abnormal HLC ratio and fourteen samples (56%) with abnormal FLC ratio. Discrepancies between the two assays occurred in 11 patients. FLC assay normalization in CR was significantly associated with better PFS (43 months, 95% CI 14-85) with respect to patients with persistent abnormal FLC ratio (12 months, 95% CI 5-35, p=0.049). In contrast, normalization of HLC ratio had no impact on PFS (26 months, 95% CI 10-38, vs 20 months, 95% CI 10-34, p=0.51), even selecting IgA MM. Notably, in 9 patients, the negative effect of abnormal FLC ratio at CR on PFS was not mitigated by concomitant normalization of HLC ratio (19 months, 95% CI 4-35, p=0.022). Neither FLC, nor HLC affected OS. There were no differences between patients who received AuSCT and those who did not.

Summary/Conclusions: To the best of our knowledge, this is the first study to analyze HLC ratios exclusively in MM patients in CR. While our preliminary data confirm the prognostic usefulness of FLC in this setting, currently they do not support a role for HLC as putative biomarker of MRD.

Background: Emerging resistance to modern antimyeloma agents such as proteasome inhibitors (Pis) and immunomodulatory drugs (ImDs) remains the main clinical problem in managing multiple myeloma (MM). Daratumumab, a first-in-class anti-CD38 monoclonal antibody, has been recently approved in Europe as a monotherapy for patients (pts) with relapsed and refractory multiple myeloma (RRMM), whose prior therapy included a PI and an IMiD and whose disease had progressed during this time; based on the SIRIUS clinical trial outcome (Lonial et al. Lancet 2016). Nevertheless to optimize daratumumab use in clinical practice, more data on its “real life” activity and safety are still required.

Aims: This observational study of the Polish Myeloma Group (PMG) was aimed to prospectively evaluate the efficacy and toxicity of daratumumab monotherapy in RRMM pts who met the SIRIUS criteria. Daratumumab compassionate use named DaraCUP.

Methods: Patients were eligible for DaraCUP if they met all the following criteria a) confirmed diagnosis of RRMM, b) relapse after a minimum of 3 prior lines of therapy including: PI and IMiD or were double refractory (CR and PR) c) had a ECOG performance status score 2 or lower. Data on treatment outcomes and complications were anonymously collected using electronic CRFs. The IMWG response criteria were applied.

Results: In total 30 patients were qualified to DaraCUP in Poland and all were enrolled to the PMG observational study. At the time of writing this report, 26 pts (87%) had received at least 1 dose of daratumumab and were included in the safety analysis, while 22 pts (73%) had received at least 2 cycles of daratumumab and were included in the preliminary efficacy analysis. Baseline pts characteristics are reported in Table 1. Pts were heavily pretreated, with a median of 4 prior lines of therapy (range, 2-10). Ten pts (38.5%) were double refractory to both PI and IMiD while 15 pts (58%) were refractory to the last line of previous therapy. Median time since initial diagnosis to start of treatment with daratumumab was 3.9 years (range, 1.4-12.2 years). At the time of analysis, the median follow-up time within the study was 5.1 months (range, 0-8 months) and median daratumumab treatment duration was 4.4 months (range, 0-8 months). Sixteen pts (61.5%) remain on treatment, while ten pts (36.5%) discontinued therapy as a result of disease progression (n=7) and adverse events (AEs) (n=3). Overall response rate (PR or better) was 31.8% including one (4.5%) CR and two (9%) VGPR (Table 1). Stable disease was reported in 11 (50%) pts. The median PFS and OS had not been reached. During the time of observation three deaths were recorded due to disease progression. Regarding daratumumab toxicity, grade 3 or 4 non-haematological toxicities occurred in 8 pts (30.7%) and included: infusion-related reactions (n=2), pneumonia (n=2), other infections (n=2), mandible inflammation (n=1), dyspnoea (n=1). The most common haematological toxicities were grade two anemia (n=30.7%) and neutropenia (n=23.1%), while thrombocytopenia occurred in 3 pts; 11.5%. Grade 3 or 4 anaemia and neutropenia were found in 3 (11.5%) and 2 (7.7%) pts, respectively. Updated results will be presented at the meeting.

Table 1.

Summary/Conclusions: In this first real-world analysis we confirm that daratumumab monotherapy is able to induce response in one third of highly pretreated and double refractory RRMM patients. Regarding safety, in contrast to the SIRIUS trial where no treatment discontinuations due to AEs occurred, 3/26 pts (11%) treated with daratumumab in clinical practice had their therapy interrupted due to complications.

E1263
REAL-WORLD TREATMENT PATTERNS AND PATIENTS CHARACTERISTICS IN MULTIPLE MYELOMA ACROSS EUROPE

A. Fassnacht1, A. Zomas1, E. Papakostas1, T. Do1, M. Russo2, R. D’Ambrosio1, G. Schneidewind1, 1EUCAN Medical Affairs, 2Global Market Access, Takeda, CH-8152 Glattpark-Oppikon (Zurich), Switzerland
Background: Multiple myeloma (MM) is the second most common haematological malignancy after non-Hodgkin lymphoma, accounting for 13% of all blood malignancies and 1% of all cancers 1. The medical management of multiple myeloma has changed over the years and is influenced by multiple factors (e.g., evidence from clinical trials, drug approval status, level of drug reimbursement, guidelines), which vary across Europe. Information describing how patients are managed in the real world is needed.

Aims: The aim of this analysis was to investigate real-world treatment patterns and patient characteristics in MM across Europe.

Methods: Physicians in Europe were requested to answer a series of questions on patient characteristics and treatment regimens of the last eight patients that they had treated during the months prior to answering a questionnaire, according to their patients’ medical charts. The questionnaire was conducted between January and June 2016. Data on 2564 patients with MM were available and are presented here. Countries were grouped into regions according to similar health care systems: Spain, Portugal, Italy and Israel (Southern Region, SR, n=1099); Austria, Netherlands, Belgium, Norway, Sweden, Switzerland and Finland (Central and Northern Region, CNR, n=776); Croatia, Estonia, Hungary, Latvia, Lithuania, Poland, Serbia, Slovakia (Eastern Region, ER, n=689). Analyses were descriptive.

Results: Patient characteristics were generally similar across regions, with the majority being <75 years old (69-76%), receiving frontline therapy at study inclusion (57-58%), and being eligible for autologous stem cell transplant (ASCT) (53-59%). The median time from MM diagnosis to the time that the physician answered the questionnaire was higher in ER (19.5 months) than other regions (9.7-11 months) (Table). The majority of frontline regimens contained bortezomib, although this was lower in CNR (61%) than in other regions (66-70%). The median duration of frontline therapy was longer in ER (4.5 months) than other regions (3.2 months). This difference was mainly driven by ASCT eligible patients having longer duration of therapy in ER (4.5 months) than other regions (2.8 months). The number of bortezomib injections in frontline therapy, however, was higher in SR and CNR (both 24) than in ER (18). The majority of second line regimens contained lenalidomide (57-64%) in all regions except ER, where bortezomib-based regimens were most frequent (38%). The median duration of second line therapy was shorter in SR and CNR than in ER (Table). Moreover, for second line therapy, ASCT eligible patients had shorter duration of therapy in ER and SR (3.2 months) than in CNR regions (4.5 months). The majority of later-line (3+) regimens were based on therapies that did not include bortezomib, lenalidomide or pomalidomide for all regions (57-67%) with the exception of SR where pomalidomide (29.4%), lenalidomide (12%), and bortezomib (14%) were the preferred options. In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems. Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

Summary/Conclusions: This study shows that the prevalence of frailty syndrome is high and has a profound impact in early death. It is also independently associated with a worse prognosis. Frailty should be considered as part of the clinical assessment when treating elderly patients with myeloma.

E1265

PROGNOSIS OF AL AMYLOIDOSIS WITH KIDNEY INJURY

A. Talbot1, 2, X. Beleifant2

1Immulogy, hospital Saint Louis, Paris, 2Nephrology, chiag, montreuil, France

Background: AL amyloidosis is a rare disease related to excessive and uncon- trolled secretion of monoclonal light chains. The consequence of this prolifer- ation is an alteration of the affected organs due to deposition of free light chains. Despite therapeutic advances in recent years based, among others, on the finding of French studies, the prognosis of this disease remains poor in particul- ar for patients with cardiac disease. Kidney involvement is also frequently observed, especially in the form of a classical nephrotic syndrome, but at present the prognosis of chronic renal failure in this context is unknown.

Aims: The study was interested in the prognosis of AL amyloidosis associated with endstage renal disease on dialysis in the era of treatment with bortezomib.

Methods: A total of 133 patients (61 from Ile-de-France region register and 72 from reference center) were analyzed. The median survival was 66.7 months compared to 70.6 months for patients without dialysis (p=0.65). Within the group

E1264

FRAILTY AND MORTALITY IN ELDERLY PATIENTS WITH MULTIPLE MYELOMA

N. Schutz1, 2, M. Smitienskay1, D. Fantl1, V. Otero1

1Medicina Interna - Hematología, Hospital Italiano de Buenos Aires, CABA, Argentina

Background: Worldwide, life expectancy continues to rise. The treatment of elderly people with cancer poses special challenges that should be better addressed. Frailty is a geriatric syndrome associated with functional reserve, impairment in multiple physiological systems, and reduced ability to regain physiological homeostasis.

Aims: To evaluate the impact of the level of frailty on early death and overall survival of elderly patients with multiple myeloma.

Methods: Retrospective study of more than 150 patients older than 65 years with a recent diagnosis of multiple myeloma from January 2006 to December 2012. Patients were treated with IMiDs, alkylating or bortezomib based chemotherapy based on physician preference blind to the geriatric assessment. A check list for frailty burden measurement was used based on Edmonton frailty score and included: cognitive impairment, depressive disorder, polyphar- macy, urinary incontinence, functional impairment, gait disturbance or falls, low weight or weight loss and previous hospitalization. Level of frailty was scored as the sum of each area involved. Record of all the variables were obtained from a retrospective review of the centralized and computerized medical files of the hematologic unit of the reference center, using predefined standardized cri- teria. Patients were classified as fit (0-1 frailty criteria), vulnerable (2-3 criteria) or frail (≥ 4 criteria). OS and PFS were estimated using the Kaplan Meier method using Sta4a13 program Group differences according to frailty were investigated using the Cox proportional hazard model accounting for ISS, age, Charlson comorbidity index and treatment.

Results: From the 150 patients evaluated, 124 patients were included in the study. The median age was 77 years (range 65-98). Thirty one percent of the patients were older than 80 years, 51% were female. The median Charlson Comorbidity index was 2 (range 0-7), 28% had renal failure and 40% of the patients were?'t.e presented with Myeloma ISS 3. Sixty five percent of patients met at least one frailty criteria and 31% of patients were considered frail. The most common findings were polypharmacy, gait and functional impairment. Most patients were treated with IMiDs (47%); alkylating agents (33%) or bortezomib (14%) based chemotherapy. There was no difference in treatment according to frailty group (p=0.38). The median overall survival time was 75 months (95% CI 53-110), 39 months (95% CI 19-64) and 17 months (95% CI 5-37) for fit, vulnerable and frail patients respectively (log rank p 0.0002). Frailty was specially associated with early death (OR 8.2 (95% CI 1.9-34) p=0.0007). In the multivariate analysis a higher risk of death was observed related to age (HR 1.07 (95% CI 1.02-1.12) p 0.002), number of frailty criteria (HR 1.13 (95% CI 1.02-1.13) p 0.05) and ISS (HR 2.6 (95% CI 1.8-3.8) p 0.001). The frailty criteria independently associated with death were incontinence polypharmacy and previous hospital admissions. Frailty was specially associated with early death (OR 6.2 (95% CI 1.9-34) p=0.0007).

Summary/Conclusions: This study shows that the prevalence of frailty syndrome is high and has a profound impact in early death. It is also independently associated with a worse prognosis. Frailty should be considered as part of the clinical assessment when treating elderly patients with myeloma.
of patients on dialysis, there is no significant difference between those receiving or not bortezomib. Median survival before 2008 was 54.82 months and rose to 82.30 months for patients treated after this date (p=0.95). Age (HR: 0.2819, CI 0.1375 to 0.5782), heart disease (HR: 0.3746, CI 0.1724 to 0.8141) and serum albumin (HR: 2.50 CI: 1.077 to 5.803) were identified as prognostic factors. Transplantation is a viable treatment option for good responders.

### Summary/Conclusions

Prognostic analysis of AL amyloidosis in dialysis could identify the patient who may benefit the most dialysis. This results need to be matched by sex and age with non-dialysis and dialysis for another cause.

---

**REAL-WORLD DATA ON THE TREATMENT OF RELAPSED/REFRACTORY MYELOMA WITH LENALIDOMIDE AND DEXAMETHASONE IN 2ND LINE (LEGEND STUDY): THE PROGNOSTIC SIGNIFICANCE OF BIOCHEMICAL VS. CLINICAL RELAPSE**

1Department of Hematology, Theagianon Cancer Hospital, THESSALONIKI; 2Department of Paediatric Internal Medicine, National and Kapodistrian University of Athens, Laikon Hospital; 3Department of Hematology and Bone Marrow Transplantation Unit, Evangelismos General Hospital, ATHENS; 4Department of Transfusion Medicine, University of Larissa, LARISSA; 5Department of Hematology, University of Thessalia Medical School, PATRAS; 6Department of Hematology, Democritus University of Thrace, ALEXANDROUPOLIS; 7Department of Hematology, University of Larissa, LARIS examination.

#### Methods

- **Patients**: 67 patients with relapsed/refractory multiple myeloma (MM) were included in the study.
- **Treatment**: Lenalidomide/dexamethasone (LenDex) was administered at the 1st line treatment and 2nd line treatment with LenDex was administered at 2nd line treatment with LenDex was administered at 2nd line treatment.
- **Relapse**: Biochemical relapse in 67.5% (95% CI: 61.1% > 73.9%) of patients and clinical relapse in 32.5% (95% CI: 26.1-38.9) of patients. The overall response rate was 24 months (95% CI: 18.0-34.8) for patients in group A and 131 patients (63.3%) have relapsed.

#### Results

- **Outcome**: The overall response rate was 24 months (95% CI: 18.0-34.8) for patients in group A and 131 patients (63.3%) have relapsed.
- **Prognosis**: Prognostic scoring integrating clinical biological data could identify the patient who may benefit the most dialysis. This results need to be matched by sex and age with non-dialysis and dialysis for another cause.

**E1267**

**FDG-PET IN MULTIPLE MYELOMA: DUAL TIME POINT FDG UPTAKE IN FOCALE RELAPSE CORRELATE TO RESPONSE TO CHEMOTHERAPY**

1Hematology, Odense University Hospital, Odense, Denmark; 2Radiology, Hospital of the University of Pennsylvania, Philadelphia, United States; 3Nuclear Medicine, 4Radiology, Odense University Hospital, Odense, 5Nuclear Medicine, 6Hematology, Vejle Hospital, Vejle, Denmark

#### Background

Dual Time Point (DTP) 18F-FDG PET imaging has been shown to be useful in differentiating malignant from benign lesions in that increasing uptake from 1 to 3 hours is a characteristic feature of malignancy in contrast to inflammation.

#### Aims

The aim of this study was to evaluate the predictive role of DTP 18F-FDG PET/CT imaging in assessing response to chemotherapy in multiple myeloma (MM).

#### Methods

- **Patients**: 23 patients with MM (21 male, aged 53-75 years) underwent 18F-FDG PET/CT in a prospective study (NCT02187731) before start of treatment and two months after high dose chemotherapy with stem cell support. All scans were performed at 60 and 180 minutes after tracer injection at Odense University Hospital and Vejle Hospital. Thirteen patients with ≥ 3 focal lesions of at least 10 mm were selected for analysis. Images were analyzed using an adaptive thresholding algorithm (ROVER software, ABX GmbH, Radeberg, Germany).
- **Response to Chemotherapy**: Focal malignant lesions were localized in pre-treatment scans; maximum standard uptake value (SUVmax) and mean SUV (SUVmean) and partial volume corrected SUVmean (pvcSUVmean) were obtained for each lesion.

#### Results

- **SUVmean**: The increase in pvcSUVmean is a better index than those of SUVmean and SUVmax for this purpose.
- **SUVmax**: The increase in SUVmax for this purpose.
- **Response to Chemotherapy**: The increase in pvcSUVmean was more significant than the increase in SUVmean (+12.0%; P=0.003). The increase in SUVmax of delayed scans was not significant (P=0.082).

#### Summary/Conclusions

These preliminary data show that a more significant increase of FDG uptake in delayed scans of DTP PET before treatment correlated with a better response to chemotherapy in MM.

The increase in pvcSUVmean is a better index than those of SUVmean and SUVmax for this purpose.

**UNDERSTANDING THE CONTRIBUTE OF THE NOTCH PATHWAY IN MULTIPLE MYELOMA BONE MARROW NICHE: A FOCUS ON EXTRACELLULAR VESICLES-MEDIATED COMMUNICATION**

M. Colombo1,2, F. Baccianti1, L. Cantone2, N. Moschini3, N. Platonova3, S. Garavelli1,2, M.T. Palano1, R. Adami1, A. Neri3, V. Bollati2, R. Chiaramonte1,2, N. Abildgaard1, P.F. Højland-Carlsten8

1Department of Hematology, University of Milan, Italy; 2Department of Oncology and Hemato-Oncology, Università degli Studi di Milano, Milano, Italy

#### Background

Multiple myeloma (MM) is an incurable cancer stemming from malignant plasma cells. MM is characterized by a strong tropism to the bone marrow (BM), where tumor cells accumulate and establish complex interactions with the normal stroma, which in turn promotes tumour survival, drug resistance and the development of bone disease. The Notch oncogenic pathway provides a key contribute to the ability of MM cells to shape the BM niche, affecting both BM cell biology and the interplay between MM cells and the BM stroma. Extracellular vesicles (EVs) have been reported as novel mediators in creating a supportive milieu for MM. Here we investigate the role of the activated Notch signaling in EV-mediated cross-talk.

#### Aim

The aim of this work was to further elucidate the role played by the Notch pathway in the shaping of the BM microenvironment to provide a supportive milieu for MM cells, with a focus on the contribution of EVs to the crosstalk between MM cells and the BM stroma cells.

---

**S519**

haematologica | 2017; 102(s2) | Madrid, Spain, June 22 – 25, 2017
We established two MM cell lines stably retaining the doxycycline-inducible pTRIPZ vector containing anti-Jagged1 and Jagged2 shRNAs and a BM mesenchymal stromal cell line expressing shRNAs for Notch1 and Notch2. EVs were isolated by ultracentrifugation and used for functional assays and molecular analysis. qPCR was performed using SYBR Green. Apoptosis analysis was performed by flow cytometry; evaluation of protein expression was performed by western or eastern blot.

Results: We present evidences that EVs play a crucial role in the dysregulated interactions of MM cells with the BM microenvironment and that Notch regulates their release. Indeed, BMSCs knockdown for Notch1/2 results in a decrease in EVs release and reduce their ability to induce Bortezomib resistance in MM cells and to stimulate their migration. On the other side, MM-derived EVs are able to increase the production of pro-tumor factors by BMSCs (i.e. SDF1α), promoting their ability to boost tumor growth; interestingly, this effect is lost when EVs are isolated from MM cells where the Notch pathway was inhibited. Finally, EVs released by co-cultures of BMSCs and MM cells where the Notch pathway is blocked display a reduced ability to increase osteoclastogenesis compared to EVs from control co-cultures. This is particularly relevant due to the crucial role played by bone disease in MM progression.

Summary/Conclusions: These new insights in the pathophysiology of the de-arranged BM niche represent the rationale for a Notch-directed therapy aiming to uncouple the crosstalk of MM with the surrounding microenvironment by inhibiting Notch signaling.

E1269

THE USE OF CARFILZOMIB AND BORTEZOMIB IN ROUTINE CLINICAL PRACTICE: RESULTS FROM PREAMBLE, AN ONGOING, OBSERVATIONAL COHORT STUDY IN MULTIPLE MYELOMA

B. Dure,1,2,* G. Cook,2 H. Goldschmidt,3 D. Kuter4, T. Zyczynski5, S. Popov6, M. Goorisb, C. Davidsb, R. Vii

1 Cedars-Sinai Medical Center, Los Angeles, United States, 2 University of Leeds, Leeds, United Kingdom, 3 Heidelberg University Hospital, Heidelberg, Germany, 4 Massachusetts General Hospital Cancer Center, Boston, 5 Bristol-Myers Squibb, Lawrenceville, United States, 6 Parexel, St Petersburg, Russian Federation, 7 Washington University School of Medicine, St. Louis, United States

Background: Multiple myeloma (MM) remains largely incurable despite improvements in clinical outcomes following the approval of immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs) (Rajkumar et al 2010). Previous findings suggest that the optimal combination of therapy and duration of therapy (DoT) with PIs and IMiDs (5 and 9 mo, respectively; Palumbo et al 2016) vs clinical trials (Stewart et al 2014). Understanding real-world use of therapies for relapsed/refractory (RR) MM is important to determine their position in the treatment paradigm.

Aims: In this subsequent PREAMBLE analysis, treatment patterns in patients (pts) with RRMM receiving bortezomib (bort) and carfilzomib (carf) were evaluated to better understand the use of PIs in routine clinical practice.

Methods: PREAMBLE (NCT01838512) is an ongoing, observational, international cohort study exploring real-world treatment patterns and outcomes in pts with MM. Eligible pts were aged ≥18 yrs with diagnosis of RRMM, treatment naive or treated with at least one line of therapy. A unique sample of pts receiving carf and bort were evaluated. Data were collected using a web-based questionnaire and electronic medical records over 19 months of treatment (January 1, 2013 to May 31, 2014) as part of the PREAMBLE study. The primary and secondary outcomes were the percentage of pts progressing by 6 mo and the percentage of pts discontinuing therapy due to AEs.

Results: A total of 369 pts were included in the final analysis. Of these, 117 (32%) pts were treated with bort, 162 (44%) were treated with carf, and 88 (24%) were treated with both, resulting in a total of 569 evaluable treatment episodes. Of the 369 pts, 153 (41%) had received a total of 725 treatment cycles, with a median of 2 (range 1–12) cycles per pt. The median DoT was 4 mo (range 1–12) for bort and 6 mo (range 3–10) for carf. The median duration of therapy was significantly longer for carf compared to bort (p < 0.0001). The median time to treatment failure (TTNT) was 2 mo for bort and 4 mo for carf (p = 0.005). The most common reasons for treatment discontinuation were disease progression (67%) and AEs (24%). The most commonly reported AE was myelosuppression, occurring in 58% and 52% of pts on bort and carf, respectively.

Summary/Conclusions: The safety and efficacy data from this analysis suggest that carf may offer a potential treatment option for pts with RRMM. Future studies are needed to further evaluate the role of carf in the treatment of RRMM.

E1270

ROLE OF SERUM FREE LIGHT CHAIN VS BENCE JONES MEASURE- MENT IN LIGHT CHAIN MULTIPLE MYELOMA (LCMM) AT DIAGNOSIS, DURING TREATMENT AND FOLLOW-UP FOR RESPONSE EVALUATION AND RELAPSE DETECTION

M. Stadenn1,*, M. Berardi2, A. Caldini2, C. Nozzi1, E. Antonio1, A. Bosi1

1 Hematology Department, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy, 2 BMT Unit, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Background: According to IMWG recommendations for response assessment in multiple myeloma (MM), serum free light chain (sFLC) measurement should be used to define a “stringent” complete response in symptomatic MM and, only in cases when Bence Jones protein (BJP) is deemed not quantifiable (<200mg/24h), in light chain multiple myeloma (LCMM). However, data are available suggesting that sFLC could be a more sensitive tool than BJP for minimal residual disease assessment and an earlier indicator of progressive disease (PD). BJP measures shorter than 2 years after the last response evaluation and immunofixation, it is time-consuming for technicians and could be limited by poor patient compliance.

Aims: Aim of our study was to retrospectively compare sFLC and BJP results in LCMM patients (pts) at diagnosis, during treatment and follow-up.

Methods: Serum and urine samples were collected from pts affected with plasma cell dyscrasia referring to the Azienda Ospedaliero-Universitaria Careggi between 1st February 2012 and 31 December 2013. Serum and urine protein electrophoresis was performed using Capillaries II, serum and urine immunofixation using Hydrasys II (both from Sebia), sFLC were measured on Immage 800 nephelometer (Beckman Coulter) using Freelite reagents (The Binding Site).

Results: We analyzed samples from 387 pts having positive serum and/or positive urinary immunofixation and/or normal sFLC ratio. Among them, 43 symptomatic LCMM pts were identified having both sFLC and BJP measurement at baseline (at MM diagnosis or first relapse). Serum and urine lab tests results were evaluated at baseline, monthly during therapy and every 3 months during follow-up. Median duration of laboratory monitoring for the whole group was 42 months (range 3-120). Autologous stem cell transplantation was performed in 30% of pts previously treated with proteasome inhibitors (81%) and/or immunomodulating agents (40%) or chemotherapy (9%). sFLC or BJP were not available in 10% of 872 pair of samples from 43 pts. In 10% of cases (68/696 pair of samples) sFLC ratio was abnormal with increased involved FLC without any detectable BJP (FLCr+;iFLC+;BJP-); the opposite (FLCr-;iFLC-;BJP+) occurred in 1% of cases (8/696 pair of samples). Renal failure was found in 9% vs 13% of discrepant cases. At baseline, of the 43 LCMM pts, 27/43 (63%) had relapse/disease progression with only sFLC due to BLP-200mg/24h and were therefore considered not evaluable for response assessment. Median time to BOR was 3 months by both sFLC and BJP (range: FLCR: 1-11 mesi; range: BJP: 1-10 mesi). Among the remaining 37 pts evaluable for best overall response, 6/37 had complete response according to BJP but not to sFLC; interestingly 5/6 progressed after 2-8 months. Twenty-one pts progressed during follow-up: PD was detected only by sFLC in 4, only by BJP in 1. Both tests were able to detect PD in 16 pts: at the same time in 5, with sFLC-PD occurring earlier in 7 and BJP-PD occurring earlier in 4 pts.

Summary/Conclusions: Both sFLC and BJP measurement are useful in LCMM pts for disease monitoring, however sFLC assessment appears to be more sensitive in MM and early relapse identification. These data suggest that BJP could be substituted by sFLC assessment in LCMM. In our series only 1 case showed BJP-PD according to IMWG occurring earlier than sFLC-PD but was considered not clinically significant. On the contrary 5 pts in BJP-PD had progression after 2-8 months. Twenty-one pts progressed during follow-up: PD was detected only by sFLC in 4, only by BJP in 1. Both tests were able to detect PD in 16 pts: at the same time in 5, with sFLC-PD occurring earlier in 7 and BJP-PD occurring earlier in 4 pts.

E1271

SUPPRESSION OF THE NON-MONOCLONAL PAIR AS NEW BIOMARKER AND RELAPSE DETECTION DURING TREATMENT AND FOLLOW-UP FOR RESPONSE EVALUATION AND AFTER AUTOLOGOUS STEM CELL TRANSPLANT

1 Department of Laboratory Medicine, Complejo Hospitalario Universitario de Granada, Granada, Spain, 2 Department of Clinical Biochemistry, Hospital Universitario Virgen de las Nieves, Granada, Spain, 3 Hematology and Immunology, Complejo Hospitalario Universitario de Granada, Granada, Spain

Background: The outcome for patients with Multiple Myeloma (MM) is highly
variable. Understanding the prognosis for a particular patient can help when selecting the intensity of treatment to be used and the frequency of reviews. The quantification of heavy/light chains pairs by the immunossay Hevylite (HLC) allows us a precise measurement of monoclonal and non-monoclonal immunoglobulins of the same isotype.

**Aims:** The aim of the study is to evaluate i) the impact of the “HLC ratio” defined as monoclonal immunoglobulin over isotype matched non-monoclonal immunoglobulin (involved/uninvolved HLC ratio or i/u HLC ratio), ii) the suppression on non-monoclonal pair denominated “HLC-matched pair suppression” and iii) the effect of “systemic immunoparesis” at diagnosis and at +100 days after autologous stem cell transplant (ASCT).

**Methods:** 85 patients (50 Male:35 Female) with a median age of 70 years (56-78) were followed (35 IgGK, 18 IgGL, 17 IgAK and 15 IgAL). The median follow-up of the patients was 19 (5-30) months. Sixteen patients (18%) presented ISS stage I, 15 (28%) with stage II and 54 (64%) with stage III disease. Thirty patients that reached ASCT were evaluated at +100 days after ASCT. Immunoglobulin heavy/light chains pairs (HLC) were assessed by Hevylite assays (The Binding Site). Clinical variables were evaluated for their impact on patient’s outcome. Overall survival (OS) and progression-free survival (PFS) were evaluated by Kaplan-Meier method and Cox regression. Statistical analysis was made with Prism 6.0.

**Results:** The median OS of the 85 patients was 54% and 26 patients deceased during the study due to MM. The median value of i/u HLC ratio was 80 (31.5-319.7). At diagnosis, a i/u HLC ratio>80 was significantly associated with worse OS (46 vs 61%, p=0.005) and shorter PFS (23% vs 42%, p=0.006). Severe HLC-matched pair suppression (i.e. more than 50% below the lower reference range) was identified in 68% of the newly diagnosed patients and was associated with significantly shorter OS (35% vs 81%, p=0.004) and PFS (21% vs 50%, p=0.013). Severe (>50%) systemic immunoparesis of non-monoclonal immunoglobulins was identified in 64% of the patients at diagnosis and was also significantly associated with shorter OS (32% vs 81%, p=0.030) and not with shorter PFS (26% vs 44%, p=0.306). The evaluation of other clinical variables on patient’s outcome are shown in table (see Table). In multivariate analysis, severe HLC-matched pair suppression and albumin were found as independent risk factors for OS whereas creatinine and i/u HLC ratio >80 were found as independent risk factors for PFS. In patients after ASCT, severe HLC-matched pair suppression reflects the persistence of clonal cells that is not associated with severe systemic immunoparesis.

**Summary/Conclusions:** Severe HLC-matched pair suppression and i/u HLC>80 are associated with worse OS and shorter PFS in MM patients suggesting a potential use of these parameters as prognostic biomarkers in newly diagnosed patients. Severe HLC-matched pair suppression is an independent risk factor for OS whereas i/u HLC>80 is independently associated with shorter PFS. In patients after ASCT, severe HLC-matched pair suppression reflects the persistence of clonal cells that is not associated with severe systemic immunoparesis.
**Aims:** To document current strategies of clinical characteristics at diagnosis, management, outcomes and treatment adverse effects of non-selected newly diagnosed MM patients in a recent period.

**Methods:** This registry includes all MM diagnosed from January 2012 in all institutions, nationwide. Smoldering MM are not included. We present the analysis of the first 3 years of data collection. Information was obtained from medical records and was stored in a relational database. The analysis included clinical and laboratory characteristics, treatment, disease-related and treatment-related adverse events, response, progression free survival, overall survival and cause of death. Survival is obtained from the Uruguayan Ministry of Health database.

**Results:** With a 71% institutional coverage, 224 patients were included. Median age at diagnosis was 66 years (range 33-94 years), 54.5% were male; 10% were younger than 50 years and 34.5% older than 70 years. Distribution according Ig subtype was: IgG 50.4%, IgA 23.3%, Light chains 18.7%, non-secretor 2.2% and IgM <1%. Most patients had advanced disease: 79.6% Durie-Salmon stage III (176/224), 48.6% ISS 3 (86/177). Anemia (hemoglobin <10 g/dl) was present in 29.5% and hypercalcemia in 10%. Cytogenetics was evaluated in 150 patients; high risk features were detected in 6.3% by conventional cytogenetics and 19% by fluorescence in situ hybridization. First-line treatment included at least one of the new drugs (Thalidomide, Bortezomib or Lenalidomide) in 92% of patients ≥70 years and in 50% of<70 years. First-line response was available in 73%. Overall response rate (≥ PR) was 82.3%, VGPR 23.2% and CR<15.2%; 9.8% patients achieved stable disease and 7.9% were refractory. (Fig 1.) Comorbidities and treatment-related toxicities were observed in 43.8% (47% in >70 y vs 41%). Most common adverse events were recurrent infections (28%), neuropathy (17%), thromboembolic events(5.4%) and grade 3-4 cytopenias(5%). Sixty out of 146 potential candidates have been transplanted as first line consolidation at the time of this analysis. After a median follow-up of 30 months, overall survival was 62.8% (median NR in ≥70 years and in 32 months in >70 years) and median progression free survival (PFS) was 17 months.

**Summary/Conclusions:** This first national registry provides a thorough insight into the characteristics of MM patients in our country. With a high institutional coverage, we show MM characteristics at diagnosis are similar to other real-life reports. 1) MM is detected in advanced stage with a high percentage of renal impairment. Diagnosis is performed according to international recommendations. First-line treatment is defined by local policies which restrict Bortezomib to high-risk cytogenetic features and/or renal impairment and do not provide Lenalidomide. Reasons for 59% potential candidates not receiving ASCT should be addressed in future research. This analysis provides relevant real-life information to plan strategies to improve MM management and perform high quality population-based research on the field.

**Reference**
a higher recruitment rate than females (58% vs 42%), but this could be explained by the higher incidence of MM in this subgroup. Enrollee’s median age was 62 years. Younger pts (<65 years) were more likely to be enrolled in CT than the elderly (66% vs 34%, p<0.0001). Industry sponsored trials were less likely to recruit AA compared with investigator initiated trials (7.6% vs 12%, p<0.0001).

Table 1.

Aims: To determine the prognostic significance of t(11;14) in a single-institution MM cohort.

Methods: 87 pts with t(11;14) by CD 138 selected FISH at diagnosis were identified, pts without symptomatic MM were excluded. Cox regression was used for statistical analysis. Progression free survival (PFS), and overall survival (OS) from diagnosis and post autologous stem cell transplant (ASCT) were analyzed by Kaplan-Meier.

Results: Median age at diagnosis was 62 years, 45 pts (52%) were male, and 24 pts (27%) had ISS 3. All pts received either a proteasome inhibitor or an immunomodulatory agent, and 42% (48%) received triplet treatment as induction. Sixty-nine (79%) pts had ASCT, and overall response rate (ORR, partial response or better) post ASCT was 73%. For pts with HR FISH (defined as t(14;16), p53 del, 1q21 gain or 1p del) compared to SR FISH, the ORR post ASCT was 70% vs 77% (p=0.67). OS from diagnosis was 93% at 3 years, 74% at 4 years and 51% at 5 years. Seven patients (8%) developed plasma cell leukemia, and there was no association between HR and SR FISH (p=0.66).

In multivariate analysis, ISS stage was an independent risk factor for mortality; pts with stage 3 had 7.3 times (CI: 1.16-36.4) and 5.7 times (CI: 1.63-20.0) the risk of mortality than pts with stage 1 and 2. Having an ASCT reduced mortality by 87% (CI: 0.04-0.41).

Conclusions: Despite the use of novel therapies the OS at 5 years of our pts with MM was not significantly improved compared to SEER data from 1992-2013 (51% vs 48.5%). Pts with t(11;14) who had ASCT had increased survival compared to those who did not. Our results suggest that t(11;14) may confer a worse prognosis. Further prospective studies evaluating the risk of t(11;14) are warranted.

E1275

EVALUATION OF TREATMENT NEUROTOXICITY IN MULTIPLE MYELOMA AND ITS INFLUENCE ON PHYSICAL AND ROLE FUNCTIONING

B. Sidi Mohamed El Amine1,*, H. Asma1, O. Fouzia1, S. A. Najet1, Z. Zahia1
1Hematology department, University hospital of Sidi Bel Abbes, Sidi Bel Abbes, Algeria

Background: Peripheral neuropathy (PN) is a major dose limiting and potentially disabling adverse event of commonly therapeutic drugs used in the management of multiple myeloma (MM), including the immunomodulatory drugs (IMIDS, Thalidomide and Lenalidomide), and the proteasome inhibitor (Bortezomib).

Aims: The aims of this study were to (1) perform a psychometric evaluation of PN and (2) examine the prevalence of this complication and its influence on physical and role functioning of MM patients.

Methods: The FACT/GOG-Neurotoxicity (Ntx) subscale for assessing treatment induced PN was evaluated. The 11-item of this questionnaire was administered to patients with MM treated with IMIDS and/or Bortezomib. The subscale was evaluated in 32 patients for internal reliability, construct validity, and compared to similar adverse events (CTCAE version 3). Spearman rank correlation was calculated to determine the impact of PN on functional, physical and role functioning of MM patients, assessed by EORTC quality of life scale (EORTC QLG-C30). A Cronbach coefficient ≥ 0.8 is good. Spearman rank correlation is significant if p < 0.05 or r > 0.5.

Results: Cronbach alpha coefficient for internal consistency of FACT/GOG-Ntx subscale was 0.92, and its correlation with the full CTCAE scale as follows: P=0.0001. All the 11 items exhibited high correlations with the NTX subscale score (r= 0.65-0.79), and the Construct validity of NTX was good. According to FACT/GOG-NTX and NC-CTCAE, 24 (75%) patients presented PN secondary to IMID or Bortezomib. The PN prevalence in 14 (43, 7%) patients, especially those who received Bortezomib associated with IMIDS (71, 4%). PN did not influence the achievement of a very good response of MM to therapy neither a complete remission (P=0.6), but patients with high scores of NTX subscale have reduced functional activities, especially physical and role functioning (P<0.0005. R=0.0001 respectively).

Summary/Conclusions: The 11-item FACT/GOG-Ntx subscale reliably and validly assesses Bortezomib/IMIDS induced PN. This complication is frequent and can alter the functional abilities of MM patients.

E1277

ANALYSIS OF THE CONNECT MM REGISTRY: TREATMENT OUTCOMES AND HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA WHO RECEIVED LENALIDOMIDE MAINTENANCE OR NO MAINTENANCE

R.M. Rifkin1,*, S. Jagannath2, B.G. Durie3, J.J. Shah4, M. Narang5, H.R. Terebelo6, R. Abonour2
1US Oncology Research, Rocky Mountain Cancer Centers, Denver, 2Mount Sinai Hospital, New York, 3Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles, 4MD Anderson Cancer Center, Houston, 5US Oncology Research, Maryland Oncology Hematology, Columbia, 6Providence Cancer Institute, Southfield, 7Duke University Medical Center, Durham, 8Steeplechase Cancer Center, Somerville, 9University of South Carolina, Columbia, 10Wake Forest University School of Medicine, Winston-Salem, 11Celgene Corporation, Summit, 12Indiana University Simon Cancer Center, Indianapolis, United States

Background: Maintenance therapy post autologous stem cell transplant (ASCT) has been shown to improve clinical outcomes, including time to progression, progression-free survival (PFS), and overall survival (OS) in patients with newly diagnosed multiple myeloma (NDMM) (Sonneveld, J Clin Oncol, 2012; McCarthy, N Engl J Med, 2012; Attal, N Engl J Med, 2012; Palumbo, N Engl J Med, 2014; Attal, ASCO, 2016). However, the effect of continued treatment on healthcare resource utilization (HRU) is mostly unknown. Connect MM registry is a community-based, US prospective observational cohort study designed to characterize diagnosis, treatment patterns, and outcomes in patients with MM in clinical practice.

Aims: This analysis used the Connect MM registry to analyze the impact of maintenance treatment on clinical outcomes and HRU in a largely community setting. Methods: Adult patients with NDMM who were eligible for enrollment in the registry within 60 days of diagnosis. Patients who completed induction and single ASCT without subsequent consolidation and received lenalidomide (LEN)-only or no maintenance were included in the analysis. HRU (hospitalization rates and length of stay, surgery/procedures, concomitant medications including growth factor, bisphosphonate, and neuropathic pain medication) was assessed from 100 days post-ASCT to the end of years 1 and 2. Data cutoff was Jan 7, 2016 and the median follow-up was 39.3 months.

Results: A total of 1493 patients with NDMM were enrolled in Cohort 1 from Sep 2009 to Dec 2011: 421 patients met the analysis criteria stipulated above. Of these patients, 616 did not receive maintenance. The median age was 60 y (range, 24-78); 60% were men, and 86% were white. Baseline patient characteristics except serum
creatinine, calculated International Staging System stage, history of monoclonal gammopathy of unknown significance, presence of del(17p), and induction regimen were similar across groups. LEN-only maintenance significantly extended PFS compared to no maintenance (median 54.5 months vs 30.8 months; hazard ratio [HR]=0.98 [95% CI: 0.83, 1.17]; P=0.0005; Table). OS was also significantly improved with LEN-only vs no maintenance (HR=0.64 [95% CI: 0.46, 0.90]; P=0.01). HRU results are detailed in the Table. The rate of hospitalization/100 person-years (PY) was similar across groups (P=not significant [NS], all comparisons) at the end of years 1 and 2. The median duration of hospitalization was numerically longer for patients who received no maintenance. Procedures/surgeries and concomitant medication use were similar across both groups at the end of years 1 and 2.

| Table 1. |

**Summary/Conclusions:** For patients with NDMM, LEN-only maintenance significantly improved PFS and OS vs no maintenance with no apparent impact on HRU.

**E1278**

**SERUM-FREE LIGHT-CHAINS (SFLC) INSTEAD OF URINE PROTEIN ELECTROPHORESIS (UPEP) FOR MONITORING MULTIPLE MYELOMA (LCMM)**

1Haematology, 2Clinical Biochemistry, Hospital 12 de Octubre, Madrid, 3Haematology, Hospital U de Salamanca, Salamanca, 4Haematology, Hospital Clinic i Provincial de Barcelona, Barcelona, 5Haematology, Hospital Germans Trias y Pujol de Badalona, Badalona, 6Haematology, Hospital Clinic de Valencia, Valencia, 7Haematology, Hospital Lozano Blesa, Zaragoza, 8Haematology, 9Hospital Morales Meseguer, Murcia, 10Haematology, Hospital U Son Llatzer, Mahon, 11Haematology, Hospital Germans Trias i Pujol de Badalona, Badalona, 12Haematology, Hospital de la Santa Creu i Sant Pau, Barcelona, 13Haematology, Hospital U de la Santa Creu i Sant Pau, Barcelona, 14Haematology, Hospital U Ramon y Cajal, Madrid, 15Haematology, Hospital U de Salamanca, Salamanca, 16Haematology, Hospital Clinic de Valencia, Valencia, 17Haematology, Hospital U Son Espases, Mallorca, 18Haematology, Hospital U de Salamanca, Salamanca, 19Haematology, Clinic Universitaria de Navarra, Pamplona, Spain.

**Background:** Response and follow-up criteria in multiple myeloma (MM) are still based on the protein electrophoretic (PEP) quantification of the monoclonal protein (MP) in serum (s) and/or urine (u). Monitoring MP by urine (u) PEP has a very low sensitivity for evaluating variations of small amounts of MP. Since 2001, serum free light-chain assays (sFLC) are available, with demonstrated clinical utility. Dejoe et al. have recently reported the usefulness of sFLC for evaluating response in LCMM.

**Aims:** In this work, we try to validate the use of sFLC assay in the context of GEM/PETHEMA clinical trials in order to evaluate the responses and its advantages in comparison to standard quantification of MP by PEP in serum and urine. We also led to a situation where many different treatment combinations are used, without a clear indication which patient will benefit most from which treatment. It is increasingly recognized that genetic heterogeneity between tumors influences treatment response. Patient outcomes may be improved by selecting the right treatment for the right patient at the moment of diagnosis. This requires the discovery of predictive markers, for example gene expression signatures, that can aid in this treatment decision. Here we present TOPSPIN (Treatment Outcome Prediction using Similarity between PatienTs), a novel algorithm to discover such markers from tumor gene expression data. We use it to identify patients more likely to benefit from bortezomib.

**Methods:** This algorithm aims to develop a classifier that identifies a subset of patients that will benefit more from a treatment of interest than similar patients who receive a different treatment. TOPSPIN aims to predict whether a patient will benefit (class 1) or not (class 0) from a certain treatment of interest based on the gene expression profile of the patient. This algorithm relies on the idea that genetically similar patients who received a different treatment should have a large difference in survival, given that genetic similarity is defined in a manner that is relevant to treatment response. This principle is used to identify prototype patients: patients who received the treatment of interest and have a larger than expected survival difference with the genetically most similar patients who received another treatment. Genetic similarity is defined separately for 10 581 gene sets based on Gene Ontology (GO) annotation. These prototype patients are used to define a classifier: new samples who exhibit a similar gene expression profile as the prototypes are also expected to benefit more from the treatment of interest. Here we use TOPSPIN to predict which patients will benefit from the proteasome inhibitor bortezomib. We combine tumor gene expression data from the Total Therapy 2, Total Therapy 3 and HOVON-65/GMMG-HD4 phase III clinical trials into one dataset comprising 910 patients, split into a bortezomib arm (n=407) and a non-bortezomib arm (n=503). Progression free survival is used as outcome measure. This dataset was split in a training set (n=606) and a test set (n=304). The test set is not used at any point in the training procedure and is only used for independent validation.

**Figure 1.**

**Summary/Conclusions:** There is an acceptable agreement between both methods for response evaluation. The sFLC assays provide a greater sensitivity than the urine protein electrophoresis for monitoring low levels of disease in certain cases with measurable disease at diagnosis (isFLC ≥100) being useful for its follow-up, and also provide prognostic value as a predictor of progression.

**TOPSPIN: A NOVEL ALGORITHM TO PREDICT TREATMENT SPECIFIC SURVIVAL IN CANCER**

J. Uebels1,2,3,*, E.H. van Beers, A. Broijl, P. Sonneveld, M.H. van Vliet, J. de Ridder,
1Center for Molecular Medicine, UMC Utrecht, 2Department of Hematology, Erasmus MC Cancer Institute, 3SkylineDx, Rotterdam, Netherlands.

**Background:** In recent years many novel treatments have been introduced for Multiple Myeloma (MM), leading to an improved survival. However, this has also led to the situation where many different treatment combinations are used, without a clear indication which patient will benefit most from which treatment.

**Methods:** TOPSPIN aims to predict whether a patient will benefit (class 1) or not (class 0) from a certain treatment of interest based on the gene expression profile of the patient. This algorithm relies on the idea that genetically similar patients who received a different treatment should have a large difference in survival, given that genetic similarity is defined in a manner that is relevant to treatment response. This principle is used to identify prototype patients: patients who received the treatment of interest and have a larger than expected survival difference with the genetically most similar patients who received another treatment. Genetic similarity is defined separately for 10 581 gene sets based on Gene Ontology (GO) annotation. These prototype patients are used to define a classifier: new samples who exhibit a similar gene expression profile as the prototypes are also expected to benefit more from the treatment of interest. Here we use TOPSPIN to predict which patients will benefit from the proteasome inhibitor bortezomib. We combine tumor gene expression data from the Total Therapy 2, Total Therapy 3 and HOVON-65/GMMG-HD4 phase III clinical trials into one dataset comprising 910 patients, split into a bortezomib arm (n=407) and a non-bortezomib arm (n=503). Progression free survival is used as outcome measure. This dataset was split in a training set (n=606) and a test set (n=304). The test set is not used at any point in the training procedure and is only used for independent validation.

**Figure 1.**
Results: We successfully identify gene sets that enable us to predict which patients will benefit most from bortezomib. The top 8 performing GO sets based on Hazard Ratio (HR) were combined to achieve the final classification. In the training set 28.4% of patients are classified a class 1, resulting in an HR of 0.13 (p=7.1*10^{-11}) between the two treatment arms. More importantly, in an independent test set an HR of 0.47 (p=0.03) was found, as shown in Figure 1.

**Figure 1.**

Summary/Conclusions: TOPSPIN is successful in predicting bortezomib specific survival in independent data. TOPSPIN can be applied to any dataset with two treatment arms and a continuous outcome measure. In a disease like MM, where many different treatment are available, selecting the right treatment is critical and TOPSPIN can aid in this decision.

AMYLOIDOSIS RESEARCH CONSORTIUM CARDIAC AMYLOIDOSIS SURVEY: RESULTS FROM PATIENTS WITH AL AMYLOIDOSIS AND THEIR CAREGIVERS

I. Lousada1,*, M. Maurer2, S.D. Guthrie3, K. Hsu1, M. Grogan4

1Amyloidosis Research Consortium, Boston, 2Columbia University, New York, 3Prothena Biosciences Inc, South San Francisco, 4Mayo Clinic, Rochester, United States

Background: Cardiac amyloidosis is a severe disease that can lead to cardiac dysfunction and death. Amyloid light chain (AL) amyloidosis, hereditary transthyretin (hATTR) amyloidosis, and wild-type transthyretin (wtTTR) amyloidosis may result in cardiac amyloidosis. AL amyloidosis is caused by an accumulation of misfolded light chain and often involves organs other than the heart (eg, kidneys, nervous system). Initial symptoms are often nonspecific (eg, weight loss, fatigue). Consequently, a diagnosis is frequently made only after the disease has become advanced. Previous patient-directed research found that despite patients being initially referred most often to cardiologists (as opposed to hematologists and nephrologists), cardiologists diagnosed the condition much less frequently than other specialists.

Aims: To understand delays, errors, and inconsistencies in the diagnostic pathway for patients with AL cardiac amyloidosis and validate using caregiver responses.

Methods: An online survey consisting of 36 questions (for patients) and 37 questions (for caregivers) was developed by the Amyloidosis Research Consortium (ARC) and distributed to the patient mailing lists of ARC, the Amyloidosis Foundation, and Amyloidosis Support Groups in January 2017. The survey was designed for patients with all forms of cardiac amyloidosis and their caregivers; however, the present analysis is limited to AL amyloidosis.

Results: In this subanalysis, 137 patients and 115 caregivers completed the survey. Most patient respondents were >55 years of age (n=111; 81.0%); of those, 16.1% (n=22) were >70 years of age. Composition of the population was 81.8% white/Caucasian (n=112), 2.2% Asian (n=3), 4.4% African American (n=6), 2.2% Latino (n=3), 5.1% other (n=7), and 3.6% unknown (n=5). Most patients had lived with their diagnosis for >1 year (17.5% [n=24] <1 year; 23.4% [n=32] 1-2 years; 29.2% [n=40] 3-5 years; 21.2% [n=29] 6-10 years; 8.8% [n=12] >11 years). A significant percentage of patients had multorgan involvement (54.7% [n=75] kidney; 29.9% [n=41] nerve; 14.6% [n=20] liver; 43.8% [n=60] GI; 14.6% [n=20] skin; 22.2% [n=30] other site). Before diagnosis, 43.8% (n=60) of patients were incorrectly diagnosed with one or more other conditions, predominantly by cardiologists and general practitioners (Table 1). Furthermore, more than 75% of patients visited 3 or more different physicians before diagnosis. Nearly all misdiagnosed patients (83.3%; n=50/60) reported receiving treatment for their misdiagnosed condition. Both patients and caregivers reported correct diagnoses being made most frequently by cardiologists and hematologists (Table 1). Caregivers echoed the multitude of distinct physicians visited before diagnosis (Table 1). Patients reported that biopsy of fat pad, kidney, or heart was the predominant diagnostic test performed (Table 1). Hospitalization was prevalent: 55.5% (n=76) patients reported amyloid-related cardiac hospitalization. Moreover, 31.3% (n=43) of patients reported the need for air travel for physician consultation.

**Table 1.**

Summary/Conclusions: This represents the first survey compiling both caregiver and patient experiences with AL amyloidosis. Alignment of caregiver with patient responses validates our patient-directed research. Patients with AL cardiac amyloidosis frequently receive misdiagnoses and sometimes receive incorrect treatment for the misdiagnosed condition. Disease awareness among all specialists is vital, especially among those to whom patients are initially referred due to the nature of their initial symptoms.

EFFICACY OF DARATUMUMAB-BASED REGIMENS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA – A SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS

M.A. Dimopoulos1, K. Weisler2, J. Kaufman3, P. Sommeve4, M. Rizzo5, Y. Xu6, K. Fahrbach6, M. Gaudig7, M. Slavcev8, L. Dearden8, A. Lam8

1National and Kapodistrian University of Athens, Athens, Greece, 2Universiteitskliniek Tueningen der Eberhard-Karls-Universitat, Abteilung fuer Innere Medizin II, Tuebingen, Germany, 3Hematology and Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA, United States, 4Department of Hematology, Erasmus MC, Rotterdam, Netherlands, 5Evidera, London, United Kingdom, 6Evidera, Waltham, MA, United States, 7Janssen-Cilag, Neuss, Germany, 8Janssen Global Services, LLC, Raritan, NJ, United States

Background: Daratumumab is a new monoclonal antibody aimed to improve outcomes in relapsed or refractory multiple myeloma (RRMM), and has been investigated in combination with lenalidomide plus dexamethasone (DRd), and with bortezomib plus dexamethasone (DVd), in randomized controlled trials (RCTs), POLLUX and CASTOR, respectively. Although DRd and DVd have been compared against current standard of care (SOC), namely Rd, and Vd, it is important to assess how daratumumab plus SOC compares with other routinely used treatment regimens and investigational regimens expected regulating approvals.

Aims: Therefore, the objective of this analysis is to compare DRd and DVd with other relevant treatment options via network meta-analysis (NMA) techniques.

Methods: A systematic literature review (SLR) based on searches of Medline, Embase, and the Cochrane Library was conducted to identify and then assess RCTs of treatments for RRMM. The specific studies of interest were those that had investigated the efficacy of other treatment options considered to be comparators to DRd or DVd. Data from trials that met the SLR’s inclusion criteria had been compared against current standard of care (SOC), namely Rd and Vd, it is important to assess how daratumumab plus SOC compares with other routinely used treatment regimens and investigational regimens expected regulating approvals.

TRENDS IN TREATMENT PATTERNS AND SEQUENCING IN PATIENTS WITH MULTIPLE MYELOMA DiAGNosed 2011-2016 IN THE UNITED STATES USING AN ENHANCED ELECTRONIC HEALTH RECORDS DATABASE.

B. Ung1, S. Abouzaidi1, O. Ni1, K. Parkh1, A. Agarwal1
1Celgene Corporation, Summit, NJ, United States

Background: Over the past few years, the multiple myeloma (MM) treatment (Tx) landscape has changed considerably. Immunomodulating (IMiD) drugs and proteasome inhibitors (PI) have emerged as mainstays of MM Tx. However, the limitations and lag time of available administrative claims databases makes it difficult to assess current real-world trends in the Tx of MM.

Aims: The study aimed to describe trends in demographics, Tx patterns, and sequencing for newly diagnosed MM (ndMM) patients (Pt) in the United States (US) using an enhanced Electronic Health Records (EHR) database.

Methods: A retrospective observational study of ndMM Pts was conducted utilizing EHR from a nationally-representative database (Flatiron Health). The Flatiron MM provider network comprises over 260 clinics throughout the US. Pts with an ICD-9 (203.0x) or ICD-10 (C90.xx) diagnosis of MM between 01/01/2011–12/31/2016 were randomly selected into the study. Pts were excluded if they did not have ≥2 documented clinical visits during the study period. Diagnosis of MM was confirmed through review of unstructured chart data. Index date was defined as the Pt’s date of diagnosis with MM. NdMM Pts were defined as those without a MM Tx more than 14 days prior to their first diagnosis date. Start of first-line (1L) therapy was defined as the 1st episode of an eligible systemic Tx given after or up to 14 days before the index date. Regimen were defined using the 1st eligible drug episode plus other eligible drugs given within 28 days of each other. A maximum gap of 90 days was allowed among patients with HLC pair suppression given within a given line of therapy (LOT) and was considered concluded the day before the start date of the next LOT.

Results: For the 3367 ndMM Pts identified, mean(SD) age was 68.5(11) years at the time of diagnosis, 45.9% were female, 57.6% were white, 14.7% African American, and 11.1% other race. The most common immunoglobulin (lg) class at diagnosis were IgG (51.8%) and IgA (18.9%). Median follow-up time for ndMM Pts was 15.9 months. During the study period, 1611 received only one line (L), 567 were treated with 2L, 325 with 3L, 252 with 4L+, while 442 (13%) received no Tx. Mean follow-up time for these groups was 471, 730, 928, 1132, and 610 days respectively. Among treated Pts, 205 (12.7%), 208 (28.2%), 109 (33.5%), and 98 (38.1%) received at least 1 stem cell transplant (SCT), respectively. Of Pts receiving 1L therapy, 984 (33.6%) received IMID compound +PI, 714 (24.3%) IMID +PI, and 556 (19%) received IMID compound-based therapy in 1L. The use of IMID compound +PI in 1L increased during the study period for SCT and non-SCT Pts (NSCT) from 40.6% and 21.5% in 2011, to 66.7% and 46.8% in Pts diagnosed in 2016. In Pts who received a SCT (n=618), the most common 1L regimens were lenalidomide + bortezomib + dexamethasone (RVD; n=217, 43.9%), cyclophosphamide + bortezomib + d (CBD; n=124, 21.1%), lenalidomide + d (RD; n=70, 11.3%), and bortezomib + d (VD; n=57, 9.2%). In NSCT Pts (n=2307), the most common 1L regimens were defined using the 1steligible drug episode plus other eligible drugs given within 28 days of each other. A maximum gap of 90 days was allowed among patients with HLC pair suppression given within a given line of therapy (LOT) and was considered concluded the day before the start date of the next LOT.

Results: For the 3367 ndMM Pts identified, mean(SD) age was 68.5(11) years at the time of diagnosis, 45.9% were female, 57.6% were white, 14.7% African American, and 11.1% other race. The most common immunoglobulin (lg) classes at diagnosis were IgG (51.8%) and IgA (18.9%). Median follow-up time for ndMM Pts was 15.9 months. During the study period, 1611 received only one line (L), 567 were treated with 2L, 325 with 3L, 252 with 4L+, while 442 (13%) received no Tx. Mean follow-up time for these groups was 471, 730, 928, 1132, and 610 days respectively. A maximum gap of 90 days was allowed among patients with HLC pair suppression given within a given line of therapy (LOT) and was considered concluded the day before the start date of the next LOT.

E1284

DARATUMUMAB SIGNIFICANTLY IMPROVED PROGRESSION-FREE SURVIVAL IN COMBINATION WITH LENALIDOMIDE AND DEMETHASOME IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA

D. Katalinic1
1Department of Internal Medicine, Faculty of Medicine, J. J. Strossmayer University of Osijek, Osijek, Croatia

Background: Daratumumab is a human IgG1k monoclonal antibody which binds with high affinity to the CD38 molecule on the surface of multiple myeloma cells. It induces rapid tumor cell death through multiple immune-mediated mechanisms and showed encouraging results alone and with lenalidomide and dexamethasone in a phase 1-2 study involving patients with relapsed multiple myeloma.

Aims: The primary end point of the study was progression-free survival (PFS) among patients who enrolled a total of 134 patients (74 male and 60 female, mean age 65.4±18.2 years) with multiple myeloma who had received at least three lines of therapy to receive lenalidomide with dexamethasone (68 patients, control group A) or in combination with daratumumab (66 patients, therapy group B).

Figure 1.

Summary/Conclusions: HLC pair suppression provides information on immune status and associates with an increased risk of bloodstream infections and early mortality in newly diagnosed MM patients. Our findings highlight the importance of recognising this status at time of diagnosis, and suggest that HLC pair suppression may help guide clinical decisions about the need for adequate antimicrobial treatment during myeloma therapy.

Results: At a median follow-up of 9.8 months in a protocol-specified interim analysis, 67 patients had disease progression or death were observed (in 18 of 66 patients (27.2%) in the group B vs 28 of 68 (41.1%) in the control group (p<0.001)). A significantly higher rate of overall response was observed in the group B than in the group A (88.7% vs 62.9%, p<0.001), as was a higher rate of complete response or better (39.2% vs 16.1%, p<0.001). The most common adverse events during the treatment was myelotoxicity (neutropenia in 88.6% of the patients in the therapy group B vs 42.1% of those in the control group A), anemia (in 21.5% vs 13.6%) and thrombocytopenia (in 13.8% vs 8.7%).

Summary/Conclusions: In patients with relapsed multiple myeloma, the addition of daratumumab to lenalidomide and dexamethasone appeared active and resulted in significantly improved progression-free survival. However it was associated with a higher risk of myelotoxicity.

E1285
COMPARISON BETWEEN IMMUNOFIXATION NEGATIVITY AND NORMAL FREE LIGHT CHAIN RATIO WITH MULTICOLOUR FLOW CYTOMETRY FOR MRD ASSESSMENT IN PATIENTS WITH MULTIPLE MYELOMA WITH VGPR OR BETTER

K. Narita1,*, H. Takamatsu2, Y. Abe1, Y. Usui1, M. Takeuchi1, K. Matsue1
1Department of Medicine, Hematology/Oncology Cambodia Medical Center, Kamogawa, 2Department of Hematology and Respiriology, School of medicine, Institute for Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Japan

Background: Urine and serum Immunofixation electrophoresis (uIFE and sIFE, respectively) and free light chain assay (FLC) are widely accepted as standard tests for diagnosis and monitoring of multiple myeloma (MM). However, there is significant discordance between the electrophoretic method and FLC test for response assessment. Despite this discordance, previous studies did not address the differences in assessment of treatment response between the intact immunoglobulin MM (IIMM) and light chain only MM (LCMM)/oligosecre-
tory MM (OSMM). uIFE results are poorly correlated with the serum FLC level, however, treatment response of LCMM has still been recommend to assess by 24-hour uIFE by International Myeloma Working Group guideline. However, MRD levels on uIFE negativity or normal FLC ratio (rFLC) in patients with various types of MM have not been studied.

Aims: To explore the relationship between uIFE, sIFE negativity and normal rFLC for MRD assessment in patients with IIMM and LCMM.

Methods: We initially selected 162 patients with MM (LCMM and OSMM, n = 41; IIMM, n=21) that received treatment at Kameda Medical Center, Kamogawa-shi, Japan and Kanazawa University Hospital, Kanazawa-shi, Japan between April 2008 and January 2016. Among them, 126 patients (LCMM/OSMM 40, IIMM 86), who achieve VGPR or better response, were selected on the basis of the availability of simultaneous serum and urine test, FLC data, and bone marrow MRD. To explore the relationship between uIFE and sIFE negativity and normal rFLC, MRD levels were compared by multi-colour flow-cytometry (MFC) in patients with LCMM/OSMM, and IIMM that obtained VGPR or better. MRD negativity was defined as MRD <10^-4. Complete response (CR) was divided into conventional CR (cCR, CR but MRD-positive) and MRD CR (CR and MRD-negative).

Results: One hundred forty complete IFE, FLC, and MFC data set of 126 patients (LCMM/OSMM 40, IIMM 86) with ≥2 FLC were analysed. Normal FLC at vIFE, cCR and MRD CR was 65.0%, 78.4% and 76.8% in IIMM, and 0%, 21.4% and 100%, respectively, in LCMM/OSMM. The percentages of sample at MRD levels of MRD >10^-3, 10^-3 ≥MRD >10^-4 and 10^-4 >MRD in LCMM/OSMM are significantly higher (12.5%, 50.0%, and 100% for negative uIFE, and 0%, 11.5% and 100% for normal rFLC, respectively. These figures in IIMM were 23.0%, 41.6%, 81.4% for negative sIFE, and 53.8%, 75.0% and 88.8% for normal rFLC, respectively. Positive/negative predictive value (PPV/NPV) of uIFE and rFLC for MRD in LCMM/OSMM was 100%/94.8% and 100%/85.0%, respectively, while those were 90.6%/45.8% and 88%/32.4% in IIMM, respectively.

Summary/Conclusions: Our observations confirmed that FLC test has greater sensitivity than uIFE for detection of the monoclonal component, and that normalization of sFLC ratio is highly predictive of MRD negativity in patients with LCMM/OSMM. The proportion of negative sIFE samples increased with depth of MRD, but the FLC response did not appear to parallel with the depth of response in IIMM. We recommend that FLC test should be incorporated into evaluation of MRD negativity in LCMM/OSMM as an alternative to 24 h uIFE, and both negative sIFE and normal rFLC are still useful for response assessment of residual clonal PCs in IIMM.

E1286
DARATUMUMAB IS AN EFFECTIVE AND SAFE SAVAGE THERAPY IN RELAPSED/REFRACTORY PATIENTS WITH MULTIPLE MYELOMA AFTER ALL-TRANSPLANTATION STEM CELL TRANSPLANTATION

E. Klyuchnikov1,*, U.-M. von Pein 1, F. Ayuk1, M. Christopeit 1, R. Adjalle 1, A. van Randenbourgh1, C. Wolschke1, N. Kroeger1
1Department for Stem Cell Transplantation, University Cancer Center Hamburg-Eppendorf, Hamburg, Germany

Background: Daratumumab is a human monoclonal antibody that targets CD38, a cell surface protein that is overexpressed on multiple myeloma cells. The drug became the first monoclonal antibody as single agent therapy approved by the FDA for the treatment of multiple myeloma. The role of allo-SCT in myeloma patients (pts) remains unclear; nevertheless, the registry study of EBMT suggests an increasing rate of allografts in Europe in last years. Despite the potentially curative potential of this approach, the increased relapse rate and low PFS remain a central clinical problem.

Aims: In this single center retrospective analysis, we report on our experience of use of daratumumab in first post allo-SCT setting.

Methods: A total of 16 pts (male, n=9) with median age of 66 years (39-72) relapsing after allo-SCTs that had been performed during a period 2008-2015 at the University of Hamburg and received daratumumab as single agent sal-
vage therapy. Before allografting 9 pts received one and 7 pts 2 autografts, respectively. All but one pt received at least 1 salvage therapy line prior to the allo-SCT. The allografts were performed from unrelated donors (MUD, n=9; MMUD, n=4) or matched related donors (MRD, n=3). The median number of salvage lines post-transplant and prior to first daratumumab infusion was 3 (1-4). The salvage regimens included bortezomib, lenalidomide, pomalidomide and/or carfilzomib. Daratumumab infusions were started at a median of 21 months (0-30) after relapse/progress.

Results: The median number of administrations was 13 (3-22). A total of 16 and 15 pts were available to safety and efficacy evaluation, respectively. The safety was assessed according to the Common Toxicity Criteria (CTC). A total of 20 adverse events were observed in 16 pts: dyspnea (CTC1, n=3; CTC2, n=1), bronchospasm (CTC2, n=2) shivering (CTC1, n=3), cough (CTC1, n=1; CTC2, n=1), musculoskeletal pain (CTC1, n=4), acute coronary syndrome (CTC3, n=1), skin rash (CTC2, n=1), pressure on eyes (n=1). Two patients developed late onset infections (pneumonia and infection of urinal tract) followed by temporarily therapy interruption. We observed a decrease of Tregs (CD4+CD25highCD127low) num-
ber from a median of 5.05% at start to 0.65% at day 21 after first daratumumab infusion in four pts. There were no cases of GVHD. The adverse events appeared in all pts after the first infusion, with improved tolerance of following infusions. There were no cases, where the therapy had to be stopped due to adverse events. Within a median follow-up of 32 months (1-45) from the relapse/progression 12 of 16 pts remain alive. Two pts died due to progress of myeloma and another 2 pts died due to severe infection/sepsis. A total of 9 of 15 evaluable pts responded (60%, PR, n=7, vgPR, n=2). The responses (decrease of paraprotein and/or free light chains; reduction of extramedullary tumor in 2 pt) occurred at a median of 7 days (7-75) after the first administration of daratumumab. The median response duration is 4.5 mo (1.5-8). Six pts show ongoing responses. All responding and 2 non-responding pts (stable disease) showed clinical improvement of constitutional symptoms.

Summary/Conclusions: Daratumumab demonstrated encouraging efficacy in relapsed/refractory pts with myeloma after allo-SCT. The administrations of the drug in these heavily pre-treated pts were associated with good safety profile and development mostly non-severe adverse events mostly after the first infu-
sion. Further studies on the use of daratumumab in post-transplant setting are warranted.

E1287
PROGNOSTIC RELEVANCE OF VEGF AND VEGFR EXPRESSION IN CD138+/CD19- AND CD138+/CD19+ PLASMA CELLS FROM PATIENTS WITH MONOCIONAL GAMMOPATHIES

C. Geraldes1,2,*, A.C. Gonçalves1,2, R. Alves2,3, E. Cortesão1,2,3, L. Ribeiro1, J.M. Nascimento Costa1,2,4, A.B. Sarmento-Ribeiro1,2,3
1Department of Hematology, Centro Hospitalar e Universitário de Coimbra (CHUC), 2Applied Molecular Biology and University Clinic of Hematology, 3CIMAGO, 4 University Clinic of Oncology, Faculty of Medicine University of Coimbra, Coimbra, Portugal

We investigated the expression of VEGF and VEGFR1-3 in CD138+/CD19- and CD138+/CD19+ plasma cells from patients with monoclonal gammopathies. We found that the expression of VEGF and VEGFR1-3 was higher in CD138+/CD19- compared to CD138+/CD19+ plasma cells. The expression of VEGFR2 was also higher in CD138+/CD19- plasma cells. These findings warrant further investigation to understand the biological implications of these observations.
Background: Vascular endothelial growth factor (VEGF) is a potent angiogenic peptide with biologic effects that include regulation of extracellular matrix remodeling and inflammatory cytokine generation with an important role in the bone marrow microenvironment of multiple myeloma (MM). Angiogenesis is heightened in the bone marrow of MM patients in parallel with tumor progression. Myeloma and stromal cells secrete angiogenic factors that include VEGF. Previous studies showed increased gene expression in the expression of VEGF between plasma cells (PCs) from the same MM patient. However, no clear association with expression levels, phenotypic subtypes of PCs and prognosis was demonstrated.

Aims: The present study aimed to evaluate the expression levels of VEGF and VEGF receptor (VEGFR) on phenotypic subtypes of PCs in patients with monoclonal gammopathies and to explore its role as diagnostic and prognostic biomarkers.

Methods: We include 128 patients with monoclonal gammopathies, 60 patients with newly diagnosed symptomatic MM and 68 with monoclonal gammapathy of uncertain significance (MGUS) and also from 11 non-neoplastic controls (CN). The expression levels of VEGF and VEGFR were determined by flow cytomery in the two populations of bone marrow PCs, identified by gating CD138+/CD19- (clonal PCs) and CD138+/CD19+ (non-clonal PCs). The results are presented as percentage of PCs expressing VEGF/VEGFR and as expression levels of this antiangiogenic molecules expressed in mean intensity of fluorescence (MIF). The effects of these parameters on progression-free survival (PFS) and overall survival (OS) were analyzed with Kaplan-Meier method. For statistical analysis, software IBM SPSS Statistics v22 was used. ROC curves were performed to assess the VEGF and VEGFR accuracy as diagnostic and prognostic biomarkers.

Results: In our cohort of patients, median age was 70 (39-86) years, 52% were male. We found increased expression levels of VEGF in CD138+/CD19- PCs from MM (80±7.5 MIF) compared toomUS patients (61±6.2 MIF) (p=0.011), and also higher to the observed in CD138+/CD19+ PCs (39,9±7.4 MIF) in both populations of patients (p=0.001 and p=0.02, respectively). No differences were observed in the expression levels of VEGF in CD138+ in CD19+ PCs from MM (39,9±7.4 MIF), mgUS patients (41,1±8.19 MIF and controls (32,8±1.5 MIF). However, the percentage of CD138+/CD19+ cells expressing VEGF was significantly higher in imUS (39,4±4%) and in MM patients (48,7±4.5%, p) compared to Ct (13,5±4.5%, p=0.019 and p=0.003, respectively). The differential expression of VEGF showed that MS patients with VEGF levels higher than 23,5 MIF in CD19+ PCs have higher probability to progress to MM [AUC 0.688 (95%CI 0.592-0.784), p=0.0001, 90% sensitivity, 56% specificity, 65% PPV, 84% NPV]. In MM patients, we also found an association between increased VEGF expression levels in CD138+/CD19+ PCs (11.8±2.5 MIF) and high risk FISH abnormalities between W and M. This study confirms the biological racial disparities that exist in minorities with MM. Further studies with more inclusion of minorities are needed to elucidate these disparities and its effects on risk stratification and outcomes.

Summary/Conclusions: W had significant differences in FISH compared to M. W had more IGH r and t(11;14) than M, and there was no difference in high risk FISH abnormalities between W and M. This study confirms the biological racial disparities that exist in minorities with MM. Further studies with more inclusion of minorities are needed to elucidate these disparities and its effects on risk stratification and outcomes.

E1289

POMALIDOMIDE ALONE OR IN COMBINATION WITH LOW DOSE DEXAMETHASONE AS MAINTENANCE INDUCTION WITH POMALIDOMIDE AND LOW DOSE DEXAMETHASONE IN RELAPSED AND REFRACTORY MYELOMA (ALLG MM14)

A, Kaffl1,2, N. Kenney3, J. Reynolds1, H. Quach4, P.J. Ho5, N. Horvath6, P. Moller7, J. D Rozanuic8, K. Taylor7, J. Eevelt9,10, A. Spencer11,12, K. Tempe11, M. Wiesmuller2, K. Bruckl1,2

1Internal Medicine, Rutgers NJMS, Newark, United States, 2CES University, Medellin, Colombia, 3Mayo Clinic, Rochester, 4Saint George University, 5John Theuer Cancer Center, Hackensack University Medical Center, Hackensack, United States

Background: Whilst the addition of dexamethasone to upfront therapy with Immunomodulatory (IMiD®) agents is important to mediate rapid reduction in disease burden, preliminary findings suggest that the NK stimulatory effects of IMiD® compounds are best harnessed without the co-administration of dexamethasone, and may be especially effective in the setting of minimal disease burden (in the maintenance setting for example) when some inherent immune recovery has occurred. However this has yet to be confirmed in a prospective clinical trial.

Aims: To evaluate the effect of maintenance with POM alone (Arm 1) versus POM-LoDEX (Arm 2) on progression free survival (PFS), overall survival (OS), and kinetics of response (overall response rate (ORR)) in relapsed myeloma (MM) patients refractory to lenalidomide (L-R)-lenalidomide (L-R) refractory MM (L-R) (R-L) is known to induce stable disease (SD) or better in 22% of the patients. A subset of these patients had partial response with POM-LoDEX (POM-LoDEX) in the maintenance setting for example when some inherent immune recovery has occurred. However this has yet to be confirmed in a prospective clinical trial.

Methods: Multicentre, open-label, randomized phase 2 study of relapsed R-Len patients who had received=2 prior lines of therapy. POM 4mg days 1-21 (28 day cycle) was administrated alone or in combination with LoDEX (40mg weekly) as maintenance following an induction with 4 cycles of POM and LoDEX. Treatment continued until toxicity or progression. Peripheral blood samples for immune studies were collected pre-induction and prior to cycles 1, 3, 6 and 10 of maintenance.

Results: 154 patients from 11 sites were enrolled on to the study (M:F 80:74), with a median age of 67 years (range 35-88). Median number of prior lines of therapy was 4.5 (2-14). All patients had failed LEN (100%), 127 (82.5%) were also refractory to bortezomib (double refractory) and 94 (61%) had received a prior autologous stem cell transplant. 72 (47%) patients achieved SD or better with the addition of LoDEX induction and were randomised, 35 to POM (Arm 1) and to 37 to POM-LoDEX (Arm 2). After a median follow-up of 19 months, median PFS for all patients from study entry was 4.2m (IQR 2.1 – 8.6m). PFS for randomised patients (from time of randomisation) was 2.7m for POM (arm 1) versus 5.6 for POM-LoDEX (arm 2) (p=0.039). The PFS hazard rate for Arm 2 was relatively constant compared to Arm 1 which started with a hazard rate double that of Arm 2 but dropped to less than half of the rate in Arm 2 by 15 months, suggesting that with longer follow-up, there may be an emergent advantage to maintenance with POM versus POM-LoDEX (Figure 1). Median OS for all patients from study entry was 13.2m (IQR 8.3-26.8m). For randomised patients, median OS from randomisation was 19m for POM (Arm 1) versus 13.7m for POM-LoDEX (Arm 2) (p=0.41). ORR (n=91) for all patients was 45.5% [CR=5 (3.3%), VGPR=13 (8.4%), PR=52 (33.8%)]. Clinical benefit rate (CBR) (n=91) was 55.2% [MR=15 (9.7%)].
Background: Multiple myeloma is a heterogeneous disease that accounts for approximately 10% of all haematological malignancies. While European treatment guidelines exist for multiple myeloma, there is limited understanding about the characteristics of patients with multiple myeloma in Europe and how these characteristics vary by disease stage. Numerous patient and disease-related factors can have an impact on treatment choice. Data surrounding these factors would help to better characterise European patients and inform management and treatment practices in multiple myeloma.

Aims: The aim of the current study is to describe multiple myeloma patients from 5 European countries (France, Germany, Italy, Spain, and the UK) across the disease continuum.

Methods: Data were drawn from the Adelphi Real World Multiple Myeloma Disease-specific Programme (DSP), which was conducted across France, Germany, Italy, Spain, and the UK in Q1 2015. The Multiple Myeloma DSP is a real-world, cross-sectional survey that involves haematologists and haematology-oncologists who completed patient record forms for the next 8 multiple myeloma patients with whom they consulted. Study variables included patient demographics and background clinical information.

Results: A total of 262 physicians reported on 2,024 patients with multiple myeloma. Of these patients, 73.2% were receiving first-line treatment; the remaining 26.8% were receiving second-line treatment or later. The median age of multiple myeloma patients was 70 years, 58.4% were male, and most patients (88.5%) were white/Caucasian. Only 4.3% of patients had a family history of cancer. Patients had a mean height of 168.8 cm, a mean weight of 72.8 kg, and a mean body mass index of 25.5 kg/m². In terms of performance status, 79.8% of patients had an Eastern Cooperative Oncology Group (ECOG) status of 0 or 1, whereas 20.2% had an ECOG status of ≥2. While 12.9% of patients had smouldering myeloma, 47.5% of patients had advanced disease (stage III) disease. The most common symptoms experienced by patients were anaemia (31.0%), bone pain (32.4%), fatigue/weakness (28.4%), and kidney impairment or failure (12.6%). Furthermore, 34.6% of patients had bone complications at some point in time. Over half (51.1%) of patients had comorbidities; of these, 22.8% had hypertension and 12.5% had diabetes. Overall, 33.7% of patients were considered eligible for transplant. Variences in patient characteristics, both by country and by line of therapy, were observed.

Summary/Conclusions: Results from this analysis provide valuable insight into multiple myeloma patients in European countries. These findings can help to inform future treatment practices in Europe.
stable disease and one progressed during the 4th cycle of treatment. After ASCT the ORR was 84.4% (6 (13.3%) patients achieved CR, 13 (28.9%) VGPR and 19 (42.2%) PR. Adverse events of grade 3 or 4 included mainly anemia (4 patients, 9%), neutropenia (3, 6.6%) and febrile neutropenia (one patient). After a median follow-up of 1.1 months (range: 11.0-24.9), 11 patients have progressed and 4 died (all had achieved less than VGPR post-ASCT). The PFS, TTP and OS rates at 12 months were 88.6%, 88.6% and 100%, respectively.

Patients’ characteristics are reported in Table 1. Median number of therapy lines was 2 (1-9). Among pts >65 yrs treated as follows: 16 (8.5%) received ASCT, 53 (28.2%) other therapy. Median age 68 years) were treated with thalidomide based regimens as a first-line treatment. The patterns of proteins’ expression were scored independently by two hematopathologists on a semi-quantitative scale and the cutoff was defined as ≥ 30% positive cells. Associations between studied proteins’ expression and clinical characteristics and outcomes.

CUL4A and other proteins were seen. Patients with high CUL4A expression (mean±SD: 8.94±6.50 x10⁶/kg CD34+ cells). Patients at baseline had elevated levels of CTX, TRACP-5b, sRANKL/OPG, Dkk-1, Ang, VEGF, VEGF-A, bFGF and reduced levels of Ang-1/Ang-2, bALP and P1NP compared to 30 healthy subjects of similar age and gender (p<0.01 for all comparisons). RAD therapy resulted in a reduction of circulating CTX (p=0.03), TRACP-5b (p=0.01), Ang (p=0.02), VEGF (p=0.01) and bFGF (p<0.01). Moreover, RAD increased serum levels of bALP (p=0.036), P1NP (p=0.028) and Ang-1/Ang-2 ratio (p=0.022). These alterations occurred irrespective of response, although patients who achieved at least VGPR tended to have more profound differences in the above parameters.

Background: Therapeutic Multiple Myeloma (MM) scenario has completely changed in the last 30 years: conventional chemotherapy (CT) has been gradually abandoned and autologous stem cell transplantation (ASCT), proteasome inhibitors as Bortezomib (Bor) and immunomodulatory drugs as Thalidomide and Lenalidomide (Len) have become the new actors in MM treatment (Tx).

Aims: aim was to outline how the management of MM patients (pts) had changed in the last 15 yrs reporting the experience of a single center. Aims: was to outline how the management of MM patients (pts) had changed in the last 15 years reporting the experience of a single center. Methods: Overall survival (OS) was measured from disease onset to death for any cause or last follow-up. Progression free survival (PFS) was defined as the time from first-line to disease progression or last-follow-up. The effect of variables on OS and PFS was evaluated by log-rank test.

Results: We analyzed 584 MM pts diagnosed in our center from 2000 to 2015. Patients’ characteristics are reported in Table 1. Median number of therapy lines was 2 (1-9). Among pts >65 yrs, 242/371 (71.8%) received ASCT as 1st line tx. Patients >65 yrs were treated as follows: 16 (8.5%) received ASCT, 53 (28.2%) VRMP.21 (11.2%) MPT.45 (23.9%) MP and 53 (28.2%) other therapies. As 2nd line tx our pts received: 27 ASCT (8.9%), 115 Bor-based tx (38.1%), 48 Len-based tx (16%), 53 CT (17.5%) and 59 other therapies (19.5%). As 3rd line tx: 5 pts received ASCT (2.8%), 65 Bor-based tx (35.9%), 42 Len-based tx (23.2%), 39 CT (21.5%) and 30 other therapies (16.6%). The percentage of pts receiving a new drug in 1st line was 64% (338/525). This percentage was significantly different in pts treated before and after 2007 (42% vs 87%, p=0.001). Similar results were observed in 2nd line, 75% of pts treated before 2007 received a new drug and 90% after 2007 (p=0.002). Median PFS in pts >65 yrs was 1.7 vs 2.4 yrs (p<0.001); median PFS in pts >65 yrs receiving or not ASCT was 3.2 vs 1.9 yrs (p=0.001); of note, PFS was not different when comparing pts undergoing to ASCT after a CT-based or a Bor-based induction (3 vs 2.5 yrs, p=0.2). Time to next treatment (TTNT) in pts receiving ASCT was not 30.1 months (5-122.7) vs 10.3 months (0.7-70.5) (p<0.001) from 1st to 2nd line tx and 11.2 months (0.3-121.9) vs 6.3 months (1.4-11.6) from 2nd to 3rd line tx (p=0.028). The early mortality (within the first year) was 5.9% (3/1525), in details only 1/268 of those eligible to ASCT (0.4%) and 30/267 of those not candidate to transplant (11.2%). When considering this last group before and after the 2007, we observed a significant higher incidence of early mortality in the first period [21 (17.2%) vs 9 (6.6%), p=0.006]. About new drugs toxicity: with Bor-based tx 30% of pts complaint neurological, 20% gastrointestinal and 18.2% hematologic toxicity; with Len-based tx 36.4% infective events and 29.8% hematologic toxicity. Median OS in pts >65 yrs was 7 vs 4.8 yrs (p=0.001), of note considering pts >65 yrs treated before 2007 median OS was 5.5 vs 3.1 yrs (p=0.001) and after 2007 median OS was not reached vs 7.5 yrs (p=0.034).

Summary/Conclusions: Our real life data show how MM therapeutic scenario have changed during the last 15 yrs. The tremendous improvement observed in this study was mainly evident in older pts with a strong reduction of early mortality and median OS reaching, in the second time frame after year 2007, 7.5 yrs. For younger pts ASCT confirmed to be of great benefit in term of TTNT and PFS. Thus, considering the real advantage of new drugs a palliative approach is not anymore justified even in very old pts.

E1294
CUL4A EXPRESSION AS A POTENTIAL PROGNOSTIC MARKER IN MULTIPLE MYELOMA PATIENTS TREATED WITH IMMUNOMODULATORY DRUGS
A. Malanda1,1, J. Barankiewicz1,2, A. Szumeria-Ciećkiewicz3, M. Prochorec-Sobieszek3, K. Warzocha1, P. Juszczynski4, E. Lech-Maranda1,1
1Department of Hematology, Institute of Hematology and Transfusion Medicine, 2Department of Hematology and Transfusion Medicine, Centre of Post-Graduate Medical Education, 3Department of Diagnostic Hematology, 4Department of Experimental Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: Despite the clinical effectiveness of immunomodulatory drugs (IMiDs) in multiple myeloma (MM), neither their mechanisms of action nor the biomarkers that could identify patients who would benefit most from IMiDs treatment are yet known. While the identification of the IMiDs action via cerebrol (CRBN), Ikaros (IKZF1) and Aiolos (IKZF3) was a milestone, the role of other pathways including CRBN and E3 ubiquitin ligase complex proteins (CUL4A, DDB1, Roc1) are not fully understood so far.

Aims: The aim of this study was to 1) evaluate CUL4A, IKZF1, IKZF3, MUM1 and IRF4 expression in bone marrow trephine biopsies obtained from multiple myeloma patients before treatment with thalidomide, 2) analyze the associations between the expression of these proteins and clinical characteristics and outcomes.

Methods: IHC staining for CUL4A, IKZF1, IKZF3, MUM1 and IRF4 expression was performed in bone marrow trephine biopsies obtained from multiple myeloma patients before treatment with thalidomide. 2) analyze the associations between the expression of these proteins and clinical characteristics and outcomes.

Results: Prior to treatment with thalidomide, 13 patients (52%) showed high expression (≥ 30%) of CUL4A protein. No associations between expression of CUL4A and other proteins were seen. Patients with high CUL4A expression more often presented low disease stage according to Durie-Salmon classification (p=0.02), beta-2-microglobulin level within normal ranges (P=0.07) and higher median platelet count (P=0.003) compared to patients with low CUL4A expression. Moreover, patients with high CUL4A expression before treatment showed longer PFS compared to those with low CUL4A expression (P= 0.03).

Additionally, a significant association between high Aiolos expression and high-IRF4 and high-IRF4 and low-CD38+ cells in bone marrow was observed (P=0.01) compared to low Aiolos expression, however no other associations with clinical course of MM patients were seen. No associations between IKZF1, IKZF3, IRF4, MYC expression and patients’ characteristics or outcome were revealed.
Summary/Conclusions: In conclusion, our results suggest that CUL4A expression could serve as a prognostic marker for patients assigned to IMiDs containing regimens. Further analysis of the expression of other E3 ligase complex proteins in a larger patient cohort is in progress.

MAINTENANCE THERAPY WITH BORTEZOMIB IN PATIENTS WITH MULTIPLE MYELOMA (MM) AFTER ASCT AND MINIMAL RESIDUAL DISEASE (MRD)
M. Solovev1, L. Mendeleeva1, O. Pokrovskaya1, E. Gemdzhian2, I. Galtseva3, J. Davydova4, M. Firsova1, M. Nareyko1, T. Abramova4, V. Savchenko4
1Dept. of High-Dose Chemotherapy of Paraproteinemic Hemoblastosis, 2Bio-statistics Laboratory, 3Immunophenotyping of Blood Cells and Bone Marrow Laboratory, 4Research Center for Hematology, Moscow, Russian Federation

Background: MRD-negativity status in patients with MM after autologous stem cell transplantation (ASCT) directly correlates with higher Relapse-Free Survival. It remains unclear whereas these patients should all receive maintenance therapy with it's toxicity and cost.

Aims: To assess efficacy of maintenance therapy with Bortezomib in patients with MM, who have achieved complete remission after ASCT with MRD positive and negative status.

Methods: From January 2014 to February 2016 52 patients with MM (19 male and 33 female) ages from 24 to 66 years (median 54 years) who have achieved complete remission after ASCT were randomized for a year-long maintenance therapy with Bortezomib. On 100th day after ASCT and after completion of maintenance therapy samples bone marrow from all patients was assessed using 6-color Flow Cytometry to detect MRD. We chose Relapse-Free Survival (RFS) as the indicator of maintenance therapy efficacy. Kaplan-Meier survival curves were compared using log-rank test. Statistical analysis was performed using SAS 9.4.

Results: 2-year Relapse-Free Survival in patients with MRD-negative status after ASCT was higher (p=0.05) than that in MRD-positive patients - 52.9% (95% CI: 35.5–70.6%) vs 37.2% (95% CI: 25.4–49.3%). The MRD-positivity significantly increases the rate of relapse (HR=1.7; 95% CI: 1.2–3.4; p=0.05). Two year cumulative probability of relapse after ASCT in patients with MRD-negative status, who had (n=15) and hadn’t received (n=10) maintenance therapy with Bortezomib was not different (p=0.58). Average time of relapse in MRD-positive patients who received maintenance therapy with Bortezomib was 5 months longer than in the group of patients without maintenance therapy - 17.3 months vs 12.3 months. In the group of MRD-positive patients who did not completed maintenance therapy, relapse was diagnosed in 6 patients. After the end of the treatment 42% of MRD-positive patients achieved MRD-negative status. RFS in this group of patients was significantly higher than in the group of treated MRD-positive patients who retained that status after maintenance therapy (MT) - 100% vs 20% (p=0.02, Fig.1).

Summary/Conclusions: In cases when MRD-negative status was achieved after ASCT, maintenance therapy does not increase the RFS. In comparison – patients with positive MRD status after ASCT require maintenance therapy to improve their survival rate.

E1296
LONG-TERM OUTCOME OF MULTIPLE MYELOMA (MM) PATIENTS TREATED UP-FRONT WITH SINGLE OR TANDEM AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) - SINGLE CENTRE EXPERIENCE WITH 334 PATIENTS
J. Batinic1,2*, S. Basic-Kinda1, B. Dreta1, I. Hude1, A. Ostojic1, D. Sertic1, R. Servedi-Seiwerth1, P. Roncevic1, I. Bojanic1, K. Gjadrov-Kuvezdic4, K. Dubravcic5, I. Ilic4, I. Aurer1,2, D. Nemet1,2
1Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, 2Medical School, University of Zagreb, 3Department of Transfusionology, 4Department of Pathology and Cytology, 5Department of Laboratory Diagnostics, University Hospital Centre Zagreb, Zagreb, Croatia

Background: ASCT after induction treatment has been standard of care for MM for almost 30 years. Some centers routinely perform two transplantation up-front (so-called tandem transplants), while others advocate postponing the second transplant until after progression. In recent years novel antimyeloma agents have significantly improved the prognosis of MM patients, thus casting further doubts on the value of the more aggressive tandem ASCT approach.

Aims: To describe long-term outcomes of MM patients treated with ASCT (single and tandem) in a single centre. alled tandem transplants), while others advocate postponing the second transplant until after progression. In recent years novel antimyeloma agents have significantly improved the prognosis of MM patients, thus casting further doubts on the value of the more aggressive tandem ASCT approach.

Methods: This was a retrospective analysis of outcomes of 334 MM patients who underwent 470 ASCT procedures at our center between 1993 and 2014. During that period treatment policies changed from single to tandem to salvage second ASCT, as data from different clinical studies became available.

Results: 296 patients received VAD (vincristine, doxorubicin, dexamethasone) as induction therapy and 38 regimens based on immunomodulatory drugs or proteasome inhibitors. All received high-dose melphalan for pretransplant conditioning, 32 in combination with total body irradiation. Tandem ASCT (defined as second transplantation performed within 6 months after the first) was performed in 136 patients. single ASCT in 168 and salvage second (after relapse/progression) in 30 patients. Transplant related mortality was 1.5%. Median follow up is 70 months (range 4–238). Median overall survival (OS) for the entire group is 123 months and median progression free survival (PFS) 40 months. Tandem ASCT in comparison to single and second salvage transplantation resulted in superior OS (203 vs 86 vs 68 months respectively, p<0.0001) and PFS (60 vs 38 vs 25 months respectively, p<0.0001) (figure). Thirteen percent of patients who underwent tandem ASCT are alive and progression-free more than 10 years after the procedure. Fourteen patients developed secondary malignancies.

Figure 1.

Summary/Conclusions: Our results suggest that tandem ASCT is a very effective treatment modality that can partially substitute for the absence of expensive novel agents with low long-term and lethal toxicities. Tandem ASCT seems to result in superior OS and PFS in comparison to single or salvage second ASCT. More than 10% of patients treated with tandem ASCT experience very long PFS.

EXTRAMEDULLARY DISEASE IN MULTIPLE MYELOMA PATIENTS UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION: CLINICAL IMPACT IN DIAGNOSIS, TREATMENT AND OUTCOME
A. Roque1,2*, A. L. Pinto1, E. Cortesão1,2, A. I. Espadana1, A. B. Sarmento-Ribeiro1,2, C. Geraldes1, L. Ribeiro1
1Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra, 2Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Extramedullary disease (EMD) is defined as an infiltrate of clonal plasma cells outside of the bone marrow. The presence of EMD in multiple myeloma (MM) patients (pts) at diagnosis is a relatively uncommon presentation and accounts for about 13% (6-20%) of MM pts. Although several studies
showed an association of EMD with other adverse prognosis factors and unfavorable outcomes, reports evaluating EMD over pts undergoing autologous hematopoietic stem cell transplantation (aHSCT) are scarce. Aims: We aimed to evaluate the clinical and laboratory characteristics of pts with EMD as well as its impact in outcomes of MM pts submitted to aHSCT (response to treatment, overall survival [OS] and progression-free survival [PFS]). Methods: We analysed 155 MM pts submitted to aHSCT in our centre between January/2007 and December/2015, excluding second procedures. The assessment of response to treatment was based in the International Myeloma Working Group consensus criteria (2016). Results: The median age of the cohort was 58 years (27-69), with 58% of males. The most common subtype was IgGκ (45%). In our cohort, 66 (43%) presented EMD at diagnosis, which was significantly higher compared to reports in the literature (p<0.001; 95% CI 0.22-0.37). The more common involved sites were vertebral column (49%), ribs (13%) and pelvis (13%). EMD occurred more frequently in males (38 vs 18%; p=0.012) and in pts with bone disease at diagnosis (56 vs 29%; p<0.001), than in pts without (29.6 vs 41%; p=0.022) and without anaemia at diagnosis (28 vs 11%; p=0.023). No other significant differences in characteristics at diagnosis were found between pts with and without EMD. Pts with EMD achieved lower complete response very good partial response (CR/VGPR) proportions previously to aHSCT (30.4 vs 53.2%; p<0.009) as well as at 100 days after aHSCT (D100) (41.3 vs 59.6%; p=0.037). However, no differences were found concerning refractoriness to first line therapy or proteasome inhibitor (PI) treatment, despite EMD pts received a higher mean number of therapeutical lines previously to aHSCT (10 ± 3 vs 6 ± 3; p=0.023). After a median follow-up of 46.6 months, the median OS was not reached for global cohort and both groups, and there was no difference between them (p=NS). The median PFS was 51.3 months for global cohort, with no differences seen between pts with and without EMD (50.2 vs 54.1; p=NS). Pts with EMD treated with a PI (57%) presented a higher OS (NR vs 104 months; p<0.04), but with no impact in PFS (p=NS), and there were no differences concerning radiotherapy treatment (72%) or thalidomide maintenance after aHSCT (32%) (p=NS). Summary/Conclusions: In our cohort, EMD prevalence was significantly higher than usually described in the literature. This observation was probably associated with the more careful surveillance of EMD in aHSCT candidates. EMD was associated with a lower proportion of CR/VGPR previous to aHSCT and at D100 evaluation, even after a higher number of therapeutical lines, although we failed to demonstrate that EMD was an independent prognosis factor for PFS and OS. PI seem also to be the best first line therapeutical approach for EMD pts. In our study, OS and PFS in EMD pts is underlined. It is necessary to achieve a better knowledge of the physiopathology of EMD, in order to define better treatment options that may overcome its negative impact in therapeutic response.

DIFFERENCES IN PATIENT AND DISEASE CHARACTERISTICS OBSERVED AT INITIATION OF FIRST-LINE AND INITIATION OF SECOND-LINE TREATMENT IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA IN THE CZECH REPUBLIC
V. Maisnar1,2,*, Z. Szabo 3, W. Bouwmeester 4, L. DeCosta 5, L. Pour 6,7, F. Krajnovich 8, J. Hájek 11,12
1Faculty of Medicine, Charles University Hospital, 2Department of Medicine – Haematology, Charles University Hospital and Faculty of Medicine, Hradec Králové, Czech Republic, 3Amgen (Europe) GmbH, Zug, Switzerland, 4Pharmacentral International, Rotterdam, Netherlands, 5Amgen Ltd, Uxbridge, United Kingdom, 6Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, 7Faculty of Medicine, Masaryk University, Brno, 8Department of Internal Medicine and Hematology, University Hospital Hradec Králové Vinohrady, Prague, 9Department of Hemato-Oncology, University Hospital Olomouc and Falacky University Olomouc, 10Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, 11Department of Haematology, University Hospital Ostrava, 12Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic

Background: Tools such as the International Staging System (ISS) and the revised ISS (R-ISS) are used to stratify risk of relapse for patients with multiple myeloma (MM), enabling assessment of survival expectations. These tools are based on factors measured at diagnosis only; understanding the role of these factors at relapse is less clear. Patient characteristics change between first-line (1L) and second-line (2L) treatment. Predicting survival using tools that take into account patient characteristics measured at diagnosis may only, therefore, be less relevant than other tools that consider factors measured at relapse. The Registry of Monoclonal Gammapathies (RMG) is a large hematological disease registry, collecting data from patients in the Czech Republic and Slovakia. Data from the RMG can be used to explore real-world characteristics of MM pts who have relapsed and of those who did not start 2L treatment may have in remission, lost to follow-up or had died. Results: Patient and disease characteristics are summarized in the table (all patients starting 1L and those who started 1L+2L). In general, for patients who received 1L+2L treatment, their health status improved between initiation of 1L and of 2L treatment. At 2L, patients tended to have a lower ISS stage (re-measured at 2L) than when they started 1L (stage I at 1L: 26.6%; at 2L: 41.1%). Similarly, the proportion of patients with R-ISS stage III disease was lower at start of 2L (24.6%) than at start of 1L (31.1%) treatment. Eastern Cooperative Oncology Group performance status scores were also better for patients when they started 2L than when they started 1L (stage 3–4 at 1L: 9.7%; at 2L: 5.5%). Laboratory measurements indicated that patients were in better health at the start of 2L treatment than at initiation of 1L treatment: median M protein levels decreased from 31.2 g/L at 1L to 17.7 g/L at 2L, and elevated calcium and creatinine levels were less common at 2L than at 1L. Median lactate dehydrogenase levels were slightly elevated at start of 2L vs start of 1L treatment (184.4 U/L vs 206.6 U/L).

Table 1.

**Summary/Conclusions:** Patient health was better at initiation of 2L treatment than at initiation of 1L treatment. At relapse, patients are likely to be closely monitored and are able to initiate the next treatment line while in relatively good health; at initiation of 1L, patients may have experienced deterioration in health which could have triggered their diagnosis. These findings illustrate how patient characteristics change over time and that the influencing survival may evolve; therefore, restaging patients at relapse may be beneficial and could contribute to improved predictive tools that can better define survival estimations at first relapse by considering patients’ experiences at 1L.

AN EARLY GOOD RESPONSE AFTER BORTEZOMIB-BASED INDUCTION REGIMENS REPRESENTS A SIGNIFICANT PREDICTOR FOR IMPROVED PFS IN NDMM PATIENTS
G. Rivoli1,2, M. Cea1, S. Aquino2, A. Dego1, N. Di Felice1, N. Bisso1, D. Avenoso1, R. M. Lemoli1, M. Gobbi1, L. Canepa1
1Clinica Ematologica, 2Ematologia 1, IRCCS San Martino IST, Genova, Italy

**Background:** Introduction of triplets-based induction regimens containing proteasome inhibitors (PIs) in clinical practice have led to higher response rates and prolonged life expectancy in newly diagnosed multiple myeloma (NDMM)
patients. Different studies have linked complete response (CR) with better PFS (progression-free survival), but not always with prolonged overall survival (OS), most likely due to the impact of novel agents in the management of relapsed-refractory patients. Overall, these observations suggest PFS as a more reliable predictor of clinical outcome. Also, the biological aggressiveness is emerging as a pivotal disease characteristic which affects clinical behavior and response to therapy. In this context, little is known about the association of response kinetic with survival outcomes.

Aims: In order to evaluate whether early achievement of a good quality response impacts on outcome, we retrospectively analyzed 87 NDMM patients treated at our institution with bortezomib containing regimens (BRs).

Methods: From 2004 to 2016, 87 patients with NDMM and measurable disease (serum and/or urine M protein) were treated with BRs. Both patients eligible and non-eligible for ASCIT were included in the study; patients undergoing ASCIT were censored at the time of transplant. Median age was 66 (range 32-87); males were 51 (59%); 72 (83%) patients were in III stage; median follow up was 30.7 months; median number of administered courses was 5 (range 2-9). PFS was defined according to IWG criteria. Cytogenetic risk evaluation performed by a standardized FISH panel, including del17p, del13q, t(11;14), t(4;14), was available in 37 patients (42.5%). Among these high risk abnormalities were identified in 20 patients. Early good response (EGR) defined an M protein reduction ≥75% after 2 courses of therapy. Survival curves were calculated for PFS and OS by Kaplan Meyer method, using log-rank test.

Results: PFS and OS were both assessed in patients who achieved EGR as well as in patients who did not. No significant differences were observed in terms of OS between the two groups, whilst PFS was significantly longer in patients achieving EGR (p = 0.036, median PFS 44.7 vs 29 months, respectively). Next, we analyzed patients with high risk cytogenetic. Among these, EGR vs non-EGR patients reached a PFS of 43.7 and 18.7 months, respectively. Remarkable PFS differences between these two groups were not significant (p value=0.11).

Summary/Conclusions: Overall, our data demonstrate a significant impact of EGR on PFS in NDMM patients after BRs, irrespective of median age at diagnosis. In presence of high cytogenetic risk EGR is associated with prolonged OS, as well as in patients who did not. No significant differences were observed in terms of OS between the two groups, whilst PFS was significantly longer in patients achieving EGR (p = 0.036, median PFS 44.7 vs 29 months, respectively). Next, we analyzed patients with high risk cytogenetic. Among these, EGR vs non-EGR patients reached a PFS of 43.7 and 18.7 months, respectively. Remarkable PFS differences between these two groups were not significant (p value=0.11).

E1301 POMALIDOMIDE WITH LOW-DOSE DEXAMETHASONE IN PATIENTS WITH RELAPSED OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A PROSPECTIVE ANALYSIS IN A POPULATION-BASED REGISTRY

R. Wester1,*, A. Dinmohamed1,2,3, P. Sonneveld1, A. Brojil1, N. Blijlevens4
1Department of Hematology, Erasmus Medical Center Cancer Institute, Rotterdam, 2Department of Research, Netherlands Comprehensive Cancer Organisation (NKI), Utrecht, 3Department of Public Health, Erasmus University Medical Center, Rotterdam, 4Department of Hematology, Radboud umc, Nijmegen, Netherlands

Background: Patients with relapsed and/or refractory multiple myeloma (RRMM) have limited treatment options and a poor prognosis. Previous trials showed that pomalidomide combined with low-dose dexamethasone is effective in these patients with improvement in response and survival. These studies led to the approval of pomalidomide as third line treatment in patients with RRMM. In this prospective analysis in a population-based registry was conducted to assess response and survival in patients with RRMM treated with a pomalidomide-based regimen. Also, we defined subgroups who benefit most of this treatment regimen.

Methods: Patients were eligible for pomalidomide if they received ≥2 prior lines of therapy including bortezomib, lenalidomide and alkylator therapy and developed progressive disease on their last therapy. This is a prospective analysis of patients registered at the nationwide Netherlands Cancer Registry. Treatment consisted of 4mg pomalidomide, day 1-21, combined with corticosteroids. Treatment was discontinued in case of progressive disease or unacceptable toxicity. Primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), overall response rate (ORR), toxicity, response per risk group (based on cytogenetics and ISS at initial diagnosis) and response per age group (≥65 vs >65 years).

Results: From 2004 to 2016, 87 patients with NDMM and measurable disease (serum and/or urine M protein) were treated with BRs. Both patients eligible and non-eligible for ASCIT were included in the study; patients undergoing ASCIT were censored at the time of transplant. Median age was 66 (range 32-87); males were 51 (59%); 72 (83%) patients were in III stage; median follow up was 30.7 months; median number of administered courses was 5 (range 2-9). PFS was defined according to IWG criteria. Cytogenetic risk evaluation performed by a standardized FISH panel, including del17p, del13q, t(11;14), t(4;14), was available in 37 patients (42.5%). Among these high risk abnormalities were identified in 20 patients. Early good response (EGR) defined an M protein reduction ≥75% after 2 courses of therapy. Survival curves were calculated for PFS and OS by Kaplan Meyer method, using log-rank test.

Results: PFS and OS were both assessed in patients who achieved EGR as well as in patients who did not. No significant differences were observed in terms of OS between the two groups, whilst PFS was significantly longer in patients achieving EGR (p = 0.036, median PFS 44.7 vs 29 months, respectively). Next, we analyzed patients with high risk cytogenetic. Among these, EGR vs non-EGR patients reached a PFS of 43.7 and 18.7 months, respectively. Remarkable PFS differences between these two groups were not significant (p value=0.11).

Summary/Conclusions: Overall, our data demonstrate a significant impact of EGR on PFS in NDMM patients after BRs, irrespective of median age at diagnosis. In presence of high cytogenetic risk EGR is associated with prolonged OS, as well as in patients who did not. No significant differences were observed in terms of OS between the two groups, whilst PFS was significantly longer in patients achieving EGR (p = 0.036, median PFS 44.7 vs 29 months, respectively). Next, we analyzed patients with high risk cytogenetic. Among these, EGR vs non-EGR patients reached a PFS of 43.7 and 18.7 months, respectively. Remarkable PFS differences between these two groups were not significant (p value=0.11).

E1300 RELATIVE PROGRESSION-FREE SURVIVAL OVER TIME OF NOVEL TRIPLET REGIMENS FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA

K. Betts1, C. Chen2, M. Zichlin1, A. Brun2, J. Signorovitch1, D. Makenhaevea*,1
1Analysis Group, Inc., Boston, MA, 2Bristol-Myers Squibb, Inc., Plainsboro, NJ, United States

Background: In combination with lenalidomide (RELVIMID®) and dexamethasone (d), elotuzumab (EMPLICITI™), carfilzomib (KYPROLIS®, K), and ixazomib (NINLARO®, N) were recently approved for the treatment of relapsed/refractory multiple myeloma (RRMM). In randomized controlled trials, all three drugs showed a significant relative reduction in the risk of disease progression or death as compared to patients who received Rd. To date, there have been no head-to-head trials comparing Erd, KrD, and/or Nrd.

Aims: To describe the time-specific progression-free survival (PFS) based on published Kaplan-Meier PFS curves for ErD, KrD, and NdR relative to Rd.

Methods: Individual patient-level data (IPD) were reconstructed from the published Kaplan-Meier PFS curves from the ELOQUENT-2 (ErD), ASPIRE (KrD), and TOURMALINE-MM1 (NdR) randomized, controlled, Phase III trials using digitization software and the methods described by Guyot, et. al. Using the reconstructed IPD, Kaplan-Meier survival curves were estimated for each arm within each trial. PFS curves were digitized by two independent researchers and reconstructed curves were overlaid with the published data to validate the IPD. In each trial, the relative PFS benefit over time was calculated as the difference in the Kaplan-Meier PFS estimate of each triplet regimen and the Kaplan-Meier PFS estimate of Rd divided by the Kaplan-Meier PFS estimate of Rd: \( rPFS(t) = S_{RXD}(t) - S_{Rd}(t) / S_{Rd}(t) \). Where \( S(t) \) denotes the Kaplan-Meier survival estimate of each triplet regimen at time \( t \), and \( X \) denotes E, K, or N, respectively.

Results: IPD from the three randomized controlled trials was successfully reconstructed and validated. Numerically, ErD had the highest relative PFS over the initial 10 months of treatment and showed sustained benefit from month 24 onwards (Figure 1). At 12 months, the relative PFS benefit was 17.9% for ErD, 21.7% for KrD, and 9.7% for NdR. At 24 months, the relative PFS benefit was 45.1% for ErD, 34.3% for KrD and 24.1% for NdR. At 36 months, the relative PFS benefit was 39.9% for ErD and 19.1% for KrD. ErD had a higher relative PFS than NdR for almost the entirety of RRMM treatment. At the end of data availability, NdR and KrD showed no additional PFS benefit relative to Rd, while ErD showed a sustained benefit through 40 months. Data will be updated for the conference, where available.

Figure 1.
Results: A total of 82 patients (median age 68 years [range: 43-88]) were included in this analysis. CRAB criteria included anemia in 23 patients (28%), renal insufficiency in 8 (9.8%), hypercalcemia in 13 (16%) and bone lesions in 54 (66%). Median time from diagnosis to start pomalidomide was 5.75 years [range: 0.8-18.4], median number of treatment cycles was 3 [range: 1-17]. At time of analysis 59 patients had stopped pomalidomide treatment: 24 patients had progressive disease, 10 had unacceptable toxicity, 6 patients were refractory, 4 patients died during treatment and 15 patients stopped due to various other reasons. Grade ≥3 hematological adverse events occurred in 11% of patients, 4% had neutropenic fever. Grade ≥3 non-hematological toxicities occurred in 57% of patients, including infection in 22%, gastrointestinal disorders in 5% and renal disorders in 5%. Of 69 patients evaluable for response ORR was 41%, with a partial response (PR) rate and a very good partial response (VGPR) rate of 36% and 4% respectively. Response based on age was not significantly different (p=0.426). Median PFS for all patients was 3.8 months (95% confidence interval [CI] 2.3-6.6), Patients ≥65 years had a longer PFS of 5.7 months (95% CI 2.3-8.0) versus 2.8 months (95% CI 1.9-6.6) in patients ≤65, however, this was not statistically significant (p=0.427) (figure 1). For patients achieving ≥PR, median PFS was 9.6 months (95% CI 5.7-not reached [NR]). Median PFS in patients diagnosed more than ten years prior to initiation of pomalidomide treatment was 9.6 months (95% CI 5.7-NR), as compared to 2.2 months (95% CI 1.9-6.6) among patients treated within 5 years after diagnosis (p=0.05). Data about previous treatment, ISS stage, cytogentic at diagnosis and an update of OS will be presented at EHA.

Figure 1.

Summary/Conclusions: In this analysis the experience in clinical practice of patients with RRMM treated with a pomalidomide-based regimen is reported. These data support results shown in clinical trials. Preliminary data presented here suggest that older patients and patients with a long interval between initial diagnosis and pomalidomide treatment (indicating a less aggressive multiple myeloma) may benefit from this treatment.

E1302

INVOLVED/UNINVOLVED HEAVY/LIGHT CHAIN INDEX CAN PREDICT PROGRESSION IN MULTIPLE MYELOMA PATIENTS AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM TRANSPLANT. PRELIMINARY EXPERIENCE

1Immunology, University Hospital Ramon y Cajal, 2Clinical Analysis, 3Haematology, 4Immunology, University Hospital La Princesa, 5Haematology, University Hospital Ramon y Cajal, Madrid, Spain

Background: High-dose therapy followed by autologous peripheral blood stem transplant (APBSCT) has demonstrated to improve overall survival and progression free survival with a high complete remission rate in multiple myeloma (MM) patients. However, most patients eventually present progression or relapse (P/R). Detection of P/R is mainly based on a significant increase of monoclonal protein (MC) or free light chains (sFLC). The identification of new biomarkers to early predict P/R might be clinically useful for an anticipated therapy.

Aims: The aim of our study was to evaluate the potential role of the Involved/Uninvolved Heavy/Light Chain index (I/Ui) in this setting.

Methods: We prospectively followed 44 MM transplanted patients: 19 with IgG-kappa isotype, 11 with IgG lambda, 9 with IgA-kappa and 5 with IgA-lambda. They were followed for 29.03±6.8 months (mean±standard error). Serial serum samples from each MM patients were collected periodically after APBSCT. Relapse or progression was defined according IMWG criteria. To identify factors that predict disease progression in MM transplanted patients, we studied heavy/light chains (HLC) pair quantification, sFLC and total immunoglobulins levels in serial serum samples collected during the follow-up. Involved/uninvolved index (I/Ui) was calculated using the monoclonal chain (Involved) as numerator and the polyclonal chain of the same class (Uninvolved) as denominator. The HLC ratio (HLC) was calculated as IgGk/IgGa or IgAx/IgAa with normal reference ranges established in 1.3-3.7 for IgG and 0.7-2.2 for IgA.

Results: In IgG MM patients, values of I/Ui were significantly increased in pre-relapse compared to basal samples (8.49±4.01 vs 2.23±0.67 p=0.012). By contrast, this index remained stable along follow-up in patients in complete remission (CR) or with a partial response (PR). However, the later showed higher values of I/Ui ratio, suggesting that the presence of an M-component induces immunosuppression of the uninvolved chain. Our results show that HLC-pair measurement could detect progression or relapse and the increase of MC in transplanted MM patients earlier than other methods. Future studies will need to demonstrate the real value of the I/Ui index as a biomarker to anticipate progression in MM patients subjected to APBSCT.

Figure 1.

Summary/Conclusions: Our results show that HLC-pair measurement could detect progression or relapse and the increase of MC in transplanted MM patients earlier than other methods. Future studies will need to demonstrate the real value of the I/Ui index as a biomarker to anticipate progression in MM patients subjected to APBSCT.

E1303

MULTIPLE MYELOMA IMMUNOPHENOTYPIC REMISSION IS A SIGNIFICANT PREDICTOR OF PROGRESSION FREE SURVIVAL AFTER FIRST AUTOLOGOUS STEM CELL TRANSPLANTATION - PILOT STUDY

K. Beranova1, J. Radocha1, O. Soucek2, K. Machalikova3, J. Hanousek1, P. Zak3, V. Maisnar3
1IV. interni hematologicka klinika, 2Institute of Clinical Immunology and Allergology, Fakultni nemocnice Hradec Kralove, Hradec Kralove, Czech Republic

Background: Minimal residual disease in multiple myeloma assessed by multiparameter flow cytometry has become an increasingly important predictor of progression-free survival (PFS). The aim of our study was to evaluate the potential role of the Involved/Uninvolved Heavy/Light Chain index (I/Ui) in this setting.

Methods: We prospectively evaluated prognostic importance of minimal residual disease detection by multiparameter flow cytometry (MFC) in multiple myeloma patients treated with a pomalidomide-based regimen. We evaluated 44 patients: 19 with IgG-kappa isotype, 11 with IgG lambda, 9 with IgA-kappa and 5 with IgA-lambda. They were followed for 29.03±6.8 months (mean±standard error). Serial serum samples from each MM patients were collected periodically after APBSCT. Relapse or progression was defined according IMWG criteria. To identify factors that predict disease progression in MM transplanted patients, we studied heavy/light chains (HLC) pair quantification, sFLC and total immunoglobulins levels in serial serum samples collected during the follow-up. Involved/uninvolved index (I/Ui) was calculated using the monoclonal chain (Involved) as numerator and the polyclonal chain of the same class (Uninvolved) as denominator. The HLC ratio (HLC) was calculated as IgGk/IgGa or IgAx/IgAa with normal reference ranges established in 1.3-3.7 for IgG and 0.7-2.2 for IgA.

Results: In IgG MM patients, values of I/Ui were significantly increased in pre-relapse compared to basal samples (8.49±4.01 vs 2.23±0.67 p=0.012). By contrast, this index remained stable along follow-up in patients in complete remission (CR) or with a partial response (PR). However, the later showed higher values of I/Ui ratio, suggesting that the presence of an M-component induces immunosuppression of the uninvolved chain. Regarding IgA MM, we established a cut-off value of 2.0 for I/Ui that allowed the discrimination of patients at high risk of early progression (values above 2.0) from those in CR, whose levels of I/Ui are always below 2.0 (p=0.02).

Summary/Conclusions: Our results show that HLC-pair measurement could detect progression or relapse and the increase of MC in transplanted MM patients earlier than other methods. Future studies will need to demonstrate the real value of the I/Ui index as a biomarker to anticipate progression in MM patients subjected to APBSCT.
myeloma patients who underwent autologous stem cell transplantation from January 2014 until December 2016. All patients were uniformly treated with bortezomib based induction therapy followed by high dose chemotherapy (Melphalan 200mg/m²) and autologous stem cell transplantation. Minimal residual disease (MRD) status was determined by 8-colour MFC 1 month after autologous transplantation from bone marrow aspirate in all patients who achieved at least conventional VGPR or CR.

Results: We identified 56 patients who fulfilled the above mentioned criteria, 30 were males and 26 females, median age was 61.62% of patients (35/56 patients) achieved CR, 37.5% of patients (21/56) did not. Median follow up of the cohort was 19 months (6-59), 32.1% of patients (18/56) relapsed during the follow-up period. 16.1% of patients (9/56) died. 22.9% (13/56) patients in CR and 47.6% (10/21 patients) not in CR relapsed during the follow up. Patients in iCR showed significantly longer PFS with median 42 months than those in less than iCR with PFS median 29 months (p=0.0196, log-rank test).

This was reflected in a hazard ratio of relapse (0.3565) in iCR group.

Summary/Conclusions: Achieving immunophenotypic CR is clearly associated with longer progression free survival compared to conventional CR. Reaching iCR should be a goal of myeloma treatment.

E1304
REGULATION OF NORMAL AND MONOCLONAL IMMUNOGLOBULIN SECRETION BY CYTOKINES (S- SYNDECAN-1, BLYS & TGF-BETA-1) IN PATIENTS WITH IG-SECRETING B-CELL DISORDERS AT PRESENTATION. PROGNOSTIC IMPLICATIONS

Hematology Section - 1st Department Of Propaedeutic Internal Medicine, Laikon General Hospital, Athens, Greece, 2Binding Site Ltd, Birmingham, United Kingdom, 3Immunology Laboratory, Laikon General Hospital, 4Therapeutic Clinic, Alexandra’s Hospital, 5Hematology Clinic, Medical Center Psychico, Athens, Greece

Background: The most common neoplastic lymphoproliferative diseases that secrete paraprotein are multiple myeloma (MM), Waldenstrom’s Macroglobulinemia (WM) and chronic lymphocytic leukemia (CLL). The two first entities secrete paraprotein by definition, while serum free light chains (sFLC) are used separately HLC-IgA, -G, -M kappa or lambda), thus allowing exact quantification and for monitoring patients, while in CLL, sFLC has prognostic value. The total Ig can be accurately determined with the ‘Heavylight’ method (that measures the heavy chains), but determination of light chains is necessary in MM and WM for diagnostic purposes and for monitoring patients, while in CLL, sFLC has prognostic value. The total amount of secreted Ig does not really reflect disease burden. The heavy chain Ig can be accurately determined with the Heavylight method (that measures separately HLC-IgA, -G, -M kappa or lambda), thus allowing exact quantification of the amount of pure monoclonal fraction but also the degree of suppression of polyclonal lgs, both being reflected by the corresponding ratios (HLCR).

Summary/Conclusions: A small fraction of patients with MM could be considered potentially cured as long as they remain for more than six years in long term complete remission (MM-LTCR) and for patients in MM-LTCR the exhaustive study of the immune status of these patients could highlight interesting information.

Aims: Here we present an observational study that evaluates the numbers and phenotype of T- and B-cells subsets in the peripheral blood (PB) of MM-LTCR patients.

Methods: After approval by the ethics committee, we selected 13 patients diagnosed with MM, in sCR according to IMWG criteria for at least six years after APBSCT, and 15 healthy adults (HA) of similar ages as a comparative group. Group MM: 7 males and 6 females; median age: 61. Median follow-up in sCR was 8 years (range 6-19). Group HA: 5 males and 10 females, median age 60 (36-78). Immunophenotype characterization was done using a comprehensive 8-color flow cytometry panel. Subpopulations of CD4+ and CD8+ T-cells from PB were quantified, including naïve, central and effector memory, regulatory T-cells, as well as subpopulations of B-cells: naïve, transitional, marginal zone-like, class-switched memory and plasmablasts. In order to confirm their specific immune signature, the analysis was repeated in the same LTMR-MM patients one year after the first analysis was done. A Kruskal-Wallis test was used to evaluate differences among the studied groups. A posteriori test was done to compare the control group with the two patient’s group (patients and patients +1 year), independently of each other. A Wilcoxon matched test was used to compare a patient under group “patients” with the status of the same patient in the second group “patients +1 year”. Statistical analysis was done using GraphPad Prism software.

Results: In the patients the percentage of total CD4+ T-cells (p=0.0004) together with a decrease in the naïve CD4+ T-cells (CD27+CCR7+CD45RA+; p=0.0004) and an increment of the effector memory CD4+ T-cells (CD27+CCR7−; p=0.0028), both CD27+CCR7+CD45RA and CD27−CCR7+CD45RA+ similar results were found within the CD8+ T-cells. No differences were observed in the transitional CD4+CD25+Foxp3+CD127+ but the percentage of transitional B-cells in the patients was within the normal range and no significant differences were found when compared to HA. However, naïve B-cells (CD27+lgD+lgM+) proportion was higher in patients and a corresponding reduction of marginal zone-like B-cells (CD27−lgD−lgM−; p=0.0047) and class-switched memory B-cells (CD27+lgD+lgM−; p=0.0043) was observed. No differences were observed in the percentage of transitional B-cells (CD27+CD10−CD38−) or plasmablasts (CD27+ CD38+) in the PB of the two groups. When the analysis was repeated in the same LTMR-MM patients one year after the first analysis, no changes were detected neither when analysed as a group nor when analysed individually.

Aims: To determine any possible relationship between the amount of lgs secreted by B cells (sFLC) and TGFβ1, as well as with disease outcome.

Methods: We studied 269 patients: 105 with MM (79 IgG and 26 IgA, of whom 33%, 31%, and 36% were staged ISS 1, 2 and 3 respectively), 64 suffering from WM (44%, 28%, 28% staged WM-ISS 1, 2, 3 respectively), and 100 with CLL (67%, 23%, 10% staged Binet 1, 2, 3 respectively). Patients were regularly followed before last visit or at and up to 36 months follow-up (median follow-up time 19 months).

Results: The main correlations observed between the Ig levels secreted in the 3 diseases and cytokines studied, as well as their impact, with regard to patients’ outcome, are shown in table.

PATIENTS WITH MULTIPLE MYELOMA (MM) IN LONG TERM COMPLETE REMISSION (LTCR) AFTER AUTOLOGOUS TRANSPLANT (APBSCT) EXPRESS A DISTINCTIVE IMMUNE PROFILE WITH POTENTIAL PROGNOSIS VALUE

A. Arteche-Lopez1,2, A. Alegre Amor2, A. Kreutzmann3, B. Aguado5, M. Espírito Martínez2, L.M. Villar4, P. Sanz1, A. Arriero2, C. Muñoz-Calleja4, S. Sachanis 5, L. Tarin-Arzaga1,*, V. Martinez-Pacheco1, A. Gomez-De Leon1, P. Colunga

1Clinic Analysis, 2Haematology, 3Immunology, University Hospital La Princesa, 4Haematology, 5Immunology, University Hospital Ramon y Cajal, Madrid, Spain

Background: MM-LTCR (by International Myeloma Working Group criteria, IMWG-LTCR) is a rare and potentially curable outcome, with a median survival of 28 months and a median progression free survival of 76 months. The main correlations observed between the Ig levels secreted in the 3 diseases and cytokines studied, as well as their impact, with regard to patients’ outcome, are shown in table.

Aims: The main correlations observed between the Ig levels secreted in the 3 diseases and cytokines studied, as well as their impact, with regard to patients’ outcome, are shown in table.

Summary/Conclusions: sSynd1 in MM and BlyS in WM and CLL correlated with MRD status. By inhibiting both monoclonal and polyclonal lg, TGFβ1 correlated with MM in both HLC and FLC ratios and differences. In addition, the aforementioned variables are prognostic with regard to patients’ outcome.

E1306
IMPACT OF THE AFFORDABILITY OF NOVEL AGENTS IN PATIENTS WITH MULTIPLE MYELOMA: REAL WORLD DATA ON CURRENT CLINICAL PRACTICE IN MEXICO

L. Tarín-Arzaga1,2, V. Martínez-Pacheco1, A. Gomez-De Leon1, P. Colunga

Study partially performed with research grants from the spanish Leukemia and Lymphoma Foundation and Grant P12/09449P from the Fondo de Investigaciones Sanitarias and FEDER funds.
Background: The success of bortezomib and lenalidomide in improving outcomes as first-line therapies in multiple myeloma (MM) patients has been achieved at a very high cost. Treatment has become difficult to access for patients living in low to middle-income countries, as most receive assistance by public healthcare systems wherein novel drugs are unaffordable.

Aims: To compare the outcomes of MM patients who can afford private insurance and treatment in a private center (PrivC), with those managed in a public center (PubC), who do not have access to healthcare coverage and are treated on an out-of-pocket basis.

Methods: We analyzed records of 148 patients diagnosed with MM in two health sectors in Monterrey, Mexico, from October 2007 to July 2016; 77 (52%) from PubC, where the most common induction therapy was cyclophosphamide-thalidomide-dexamethasone, followed by thalidomide maintenance, and 71 (48%) from PrivC wherein bortezomib or lenalidomide-based induction and lenalidomide maintenance were used. We compared demographics, disease stage, response rate and survival among both groups.

Results: Median age, gender and frequency of immunoglobulin isotype did not differ significantly between the two groups. Patients treated in PubC were more likely to be diagnosed with advanced stage disease (ISS III 42% vs 26% p<0.05). Median follow-up was 36 months (range 3-120 months). Autologous transplantation was performed in 80% of the transplantation-eligible patients in PrivC and only in 31% of PubC. At least a very good partial response to induction therapy was achieved more often in the PrivC among transplantation-eligible (65% vs 42%, p<0.05) and ineligible patients (66% vs 41%, p<0.05). Overall survival was significantly higher in PrivC for transplantation-eligible (median 84 vs 42 months, p<0.05) and ineligible patients (66% vs 57%, p<0.05). After controlling for disease stage and transplantation factors, the risk of mortality was still higher in PubC (HR 1.49; 95% CI:1.0-2.2, p<0.05).

Summary/Conclusions: Stage at diagnosis, induction therapy and autologous stem cell transplantation were contributors to survival disparities between patients treated in public vs private health care facilities in Mexico. These findings underscore the need for more efforts to improve the affordability of novel agents and transplantation settings in public health services.
Ruxolitinib largely activates MAPK signaling in MPN, while slightly PI3K/AKT signaling in PV and JAK2V617F negative PMF. Specific JAK2 inhibitor Hexabromocyanohexane activates PI3K/AKT signaling in JAK2V617F positive ET, but reduced in JAK2V617F negative ET and PMF.

Summary/Conclusions: This observation support cross-talk between examined pathways, where inhibition of JAK/STAT signaling is compensated by activation of MAPK pathway irrespective of JAK2V617F mutation, while PI3K/AKT signaling demonstrates JAK2V617F dependence in MPN.

CIRCUITING PLATELET AND MEGAKARYOCYTE-DERIVED MICROPAR-
TICLES OF JAK2V617F MUTATED PATIENTS WITH MYELOFIBROSIS ARE DISRUPTIVE: A NOVEL LIQUID BIOPSY TOOL OF RESPONSE TO RUXOLITINIB?

M. Barone 1, F. Ricci2, D. Forte1, D. Sollazzo1, M. Romano1, M. Spinsanti1, E. Ottavi1, M. Cavo1, N. Vianeell1, P. Tazzari2, F. Palandrini1, L. Catani1.

1Department of Experimental, Diagnostic and Specialty Medicine, Institute of Hematology, University of Padua, Padua, Italy, 2Immunohematology and Blood Bank Service, Azienda Ospedaliero-Universitaria S. Orosia-Malpighi, Bologna, Italy

Background: Microparticles (MPs) are small vesicles (0.1-1 micron) deriving from plasma membrane budding during homeostasis and cell activation. MPs express antigens and contain constituents from cell of origin and are increased in conditions that are characterized by high cell turnover or death, particularly inflammatory, autoimmune and neoplastic diseases. Myelofibrosis (MF) is a clonal neoplasia of the hematopoietic stem/progenitor cells characterized by ineffective bone marrow development and plastratelet (PLT) activation. Mutations in three genes (JAK2, CALR, MPL) and chronic inflammation are the main pathogenetic drivers of MF. Ruxolitinib (RUX), a JAK1/2 inhibitor, suppresses both clonal myeloproliferation and release of proinflammary cytokines, reducing splenomegaly and constitutional symptoms in around 50% of patients (pts). We hypothesized that MPs, as mediators of inflammation, could be overexpressed in MF and possibly predict responses to RUX.

Aims: This study aims to: 1) enumerate circulating MK and PLT-derived MPs of MF pts; 2) evaluate the effect of RUX on MPs production by PLT and MK; 3) investigate whether circulating MK and PLT- MPs may be a biomarker of response to RUX.

Methods: EDTA-anticoagulated peripheral blood from healthy donors (HD, n=10) and JAK2V617F positive MF pts (n=12) at intermediate-2 high IPSS risk was collected at baseline and 3 and 6 months after RUX therapy and immediately centrifuged. MPs (MEGAMIX) in PLT poor plasma samples by flow cytometry (CytoFLEX, Flow Cytometry Beckman Coulter). The instrument was calibrated with MEGAMIX Beads (Beckman Coulter) with various diameters to cover the MPs (0.5 and 0.9μm). All analyses were performed in triplicate. PLT (CD61+CD62P+) and MK (CD61+CD62P-) derived MPs were analysed at baseline and 3 and 6 months after RUX therapy.

Results: Among the TN cases we identified four MPL S204F/P cases that were analyzed separately given that part of their hematological parameters (MVC, RBC counts) were not similar to the rest of the ET cases. Additionally, flow cytometry analysis also showed that MPL S204F/P platelets are larger and express higher levels of marker expression (CD41, CD62P, GPIIb/IIIa, GPVI and GPIA/IIA) upon specific agonist stimulation.

Summary/Conclusions: These preliminary results suggest that MPL S204F/P platelets are intrinsically defective (hypo-reactive), in contrast to JAK2 V617F platelets (hyper-reactive), while in other genetic subgroups, potential defects are most probably synergistic and/or acquired by treatment. Data suggests that JAK2 V617F and CALR type I platelets could also undergo basal degranulation or vesiculation in the circulation. Analysis of the platelets has identified characteristics in different genetic groups of ET that should be further investigated.

ASSOCIATION ANALYSIS OF CYTOGENETIC AND GENETIC ALTERATIONS IN PRIMARY MYELOFIBROSIS

R. Norvilas1,2, V. Dirse1,3, E. Gineikiene1, O. Mickeviciute1, S. Pakstyte1, M. Stoskus1, L. Griskevicius1,3

1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, 2Department of Innovative Medical Technologies and Health Research State Center for Innovative Medicine, 3Department of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania

Background: A number of genomic abnormalities have been associated with primary myelofibrosis (PMF). Next-generation sequencing (NGS) and single-nucleotide polymorphism arrays (SNP-A) methodology are methods used for PMF genomic studies and certain cytogenetic and genomic abnormalities have been determined. To better characterise the genomic landscape of PMF we performed comprehensive analysis of gene mutations and chromosomal aberrations in a population-based cohort of PMF patients.

Aims: To characterize genetic abnormalities in PMF using SNP-A and NGS methods.

Methods: PMF peripheral blood samples were screened by Infinium HD whole-genome genotyping assay with the HumanCytoSNP-12 BeadChips (Illumina Inc., CA). NGS analysis was performed using TruSight Myeloid 54 gene panel (Illumina), NGS SNP-A panel (Illumina) and single-nucleotide polymorphism array (SNP-A) methylation analysis for PMF genomic studies and certain cytogenetic and genomic abnormalities have been determined. To better characterise the genomic landscape of PMF we performed comprehensive analysis of gene mutations and chromosomal aberrations in a population-based cohort of PMF patients.

Aims: To characterize genetic abnormalities in PMF using SNP-A and NGS methods.
Results: 110 patients diagnosed with PMF according to WHO criteria between years 2013 and 2014 were included into this study. SNP-A analysis identified 77 chromosomal abnormalities in 61 patients (55.4%). These comprised the loss of heterozygosity (LOH) (59.7%), hemizygous deletions (23.4%) and copy number gains (16.9%). The most common aberrations in affected patients were: 5p LOH (57.5%), 20q deletion (11.5%), 1q duplication (4.9%), 19p deletion (5.5%), 1p deletion (3.2%) and 6q LOH (3.2%). NGS analysis detected 219 gene mutations (in a total of 27 genes) in 108 patients (98%). The most frequently mutated genes were: JAK2 (62.9%), CALR (27.8%), ASXL1 (20.3%), TET2 (16.6%), MPL (7.4%), <5% ZRS2, EZH2, DNM73A, U2AF1, ETV6, SF3B1, IDH1, IDH2. Recurrent specific mutations were identified in 10 genes. Sixty-two patients (57.4%) had more than one somatic mutation. Six patients (5.5%) had no JAK2, CALR or MPL mutations and were defined as “triple-negative”. Previously not described ZRS2 gene 12 bp insertion was indentified in four patients (3.7%). The correlation analysis showed significant associations between 9p LOH and JAK2 insertion (p<0.001), EZH2 (p<0.01), ASXL1 mutations (p=0.011); 19p deletion and CALR mutations (p=0.004). Notably, the affected genes are located in core-sponding affected chromosome regions, indicating disruption of both alleles by different biological mechanisms. KRAS and ETV6 mutations were statistically associated with ASXL1 mutations (p<0.001 and p=0.005, respectively) while JAK2 and CALR mutations were mutually exclusive in all cases (p=0.001).

Summary/Conclusions: A number of associations between gene mutations and chromosomal aberrations was revealed in PMF. Co-presence of 9p LOH with JAK2V617F and CALR mutations with 19p deletion indicate that further deregulation of these key signaling pathways may take place disrupting the second allele of the affected genes by different biological mechanism – LOH or deletion.

E1312 FREQUENCY OF CONCURRENT BCR-ABL1, JAK2, CALR AND MPL MUTATIONS IN A COHORT OF 5,545 CASES WITH SUSPECTED MPN BY A DEEP SEQUENCING APPROACH
S. Jeromin1,*, M. Meggendorfer1, A. Fasan1, C. Haferlach1, W. Kern1, T. Haferlach1
1MLL Leukemia Laboratory, Munich, Germany

Background: Chronic myeloid leukemia (CML) is a myeloproliferative neo-plastic disease characterized by a fusion of the ABL1 and BCR genes in CML, whereas in about 90% of BCR-ABL1-negative MPN a mutation in CALR, JAK2 or MPL can be detected. These genetic alterations are thought to be nearly mutually exclusive, however, an accurate frequency is still missing.

Aims: To determine the incidence of genetic markers occurring in parallel in a large cohort of patients with suspected MPN and characterize double mutated cases.

Methods: From July 2016 till January 2017 5545 samples were sent to our laboratory with suspected MPN. The male:female ratio was 1:1, and the median age was 60 years (range: 18-95 years). Median white blood cell count was 9x10^9/L, hemoglobin level (Hb) was 15g/dl, and platelet count was 321x10^9/L. All of these cases were analyzed by an amplicon deep sequencing approach for mutations in JAK2 (exon12, exon14), CALR (exon9) and MPL (exon10) with a sensitivity of 1%. 3070 patients were additionally screened for BCR-ABL1 fusion by a multiplex PCR approach. Samples that were double mutated for JAK2, CALR and MPL were analyzed by amplicon deep sequencing for additional mutations in 13 myeloid genes.

Results: In total 1775/5545 (32%) of suspected MPN patients showed JAK2, CALR and/or MPL mutations. 1438 (26%) were JAK2, 267 (5%) CALR, and 89 (1%) MPL mutated. Of note, the analysis of a subgroup (n=3070) for BCR-ABL1 fusion identified 123 (4%) as CML cases. The JAK2 mutated cases presented mainly with VaSh17Phe (99%) and rarely with JAK2 exon12 mutations (1%). CALR mutations were primarily type 1 (54%) and type 2 (30%). MPL mutations were located at amino acid Trp515 in 96% of cases. Double mutated cases were present in 19/1775 (1%) cases: JAK2/MPL (63%), JAK2/CALR (32%), and CALR/MPL (6%). In nearly all CALR mutated cases (67%) the CALR mutation was detected with the higher load, whereas in JAK2/MPL double mutated cases the ratio was equal. Most of the patients (18/19) had one mutation with a load below 10% and could have been missed by other approaches. BCR-ABL1 together with JAK2 or CALR mutation was found in one patient, each (0.6%). In total, 50% of all mutation cases (267) of the 267 cases, 3 patients had already received treatment for CML but were suspected to have independent BCR-ABL1-negative MPN. For two of these patients, samples 1 and 6 years prior to diagnosis of CML were available. Both showed CALR mutations already at this former time-point at high loads. In 10/19 (53%) double mutated patients, both mutations were detected in 8 different genes. SSFS2 and TET2 were the most frequently mutated genes (n=3, each). No significant difference in mutation frequency was detected to the overall frequency in MPN patients with single mutations. The JAK2, CALR and/or MPL mutated vs wild-type cases showed higher age (mean: 67 vs 56 years, p<0.001) and higher platelet count (median: 150x10^9/L, p=0.001) but no significant difference in hemoglobin level (median: 15.4 vs 15 g/dl, p=0.28). In 19/100 (19%) patients, both mutations were significantly different according to the presence of mutations as follows: triple-negative (56%), CALR (63 years), JAK2 (67 years), MPL (71 years) and double mutated (74 years).

Summary/Conclusions: One-third of the cases can be diagnosed having More than one mutation (of BCR-ABL1, CALR and/or MPL) in an unselected cohort with suspected MPN. The frequency of double mutated JAK2, CALR and MPL cases is 1%. In CML cases BCR-ABL1 fusion and JAK2 or CALR mutation were detected in 2% of the patients. The impact of these parallel genetic events on the clinical course of the disease has to be evaluated in the future.
was 0.9 years in TNG/ASXL1mutm, 3.6 years in TNG/ASXL1wt, 13.8 years in DM(+)ASXL1wt and was not reached in DM(+)ASXL1mut (with follow-up period of 10.3 years) group (p<0.0001). Differences in OS depending on the ASXL1 status were statistically significant in the TN (p=0.007) but not for DM(+) group (p=0.788). The better OS was observed in ASXL1 wt pts with low risk (LR) karyotype (Me 6.4 years, p=0.0005). There were no differences in OS of ASXL1 wt vs HR, ASXL1mut vs LR and ASXL1mut vs HR pts (1.4 vs 1.6 vs 1.2 years, p=0.493).

Summary/Conclusions: The differences in OS were more statistically relevant in groups divided by TN/ASXL1 and karyotype/ASXL1 status. The presence of ASXL1mut significantly worsens OS in the TN group. OS in pts with any of the findings: HR karyotype or ASXL1mut was significantly shorter than in cytogenetically favorable ASXL1wt counterparts.

E1314

JAK2 HAPLOTYPE 46/1 (GGCC) HAS NO EFFECT ON THE PRIMARY RISK OF JAK2 V617F MUTATION, BUT IT STRONGLY POTENTIATES THE PROGRESSION OF GROWN ALLELE BURDEN IN MYELOPROLIFERATIVE NEOPLASMS

M. Stolyar1,2,*; O. Klimova3,4; A. Gobreken1; S. Titov3,4; I. Likhovskiy1,5

1Krasnoyarsk Branch of the Federal State-Funded Institution "National Research Center for Hematology" of the Ministry of Healthcare of the Russian Federation; 2Siberian Federal University, Krasnoyarsk; 3AO Vector-Best; 4Institute of Molecular and Cellular Biology, Siberian Branch of Russian Academy of Sciences, Novosibirsk; 5Federal Research Center "Krasnoyarsk Scientific Center of the Russian Academy of Sciences, Siberian Branch", Krasnoyarsk, Russian Federation

Background: Several research groups have determined that the JAK2 46/1 (GGCC) haplotype in multiple ethnic groups is strongly associated with a pre-disposition to acquiring JAK2 V617F-positive MPNs. The role of the JAK2 46/1 haplotype in the natural evolution of the mutant JAK2V617F allele burden in PV but not ET or PMF has been shown [Alvarez-Larrán A et al. Leukemia 2012, 36(3):324-326]. However, the data on the impact of the haplotype on the JAK2 V617F allele burden do not always agree. Using a highly sensitive test allowed to reveal a high prevalence JAK2 V617F among persons without symptoms of hematological disorders [Krivchikov S et al. Blood Cells, Molecules and Diseases., doi: 10.1016/j.bcmd.2017.01.001]. Influence of haplotype 46/1 for such cases is not known. There are two competing hypotheses of "hypermutability" and "fertile ground" explaining the causes of the higher frequency of mutations of JAK2V617F in haplotype 46/1 carriers. The "hypermutability" hypothesis refers to an increased risk of a primary mutation in carriers of haplotype 46/1. In this case, the increasing frequency of the haplotype in patients with low allelic burden (<5%) must also be observed, including those individuals without evidence of hematological disorders.

Aims: Studying the relations of haplotype 46/1 and JAK2 V617F allele burden

Methods: The diagnosis of chronic myeloproliferative neoplasms was based on the WHO (2008) criteria. The cohort included patients with JAK2 V617F mutation: 100 patients with PV, 51 with ET, 14 with MF, 41 patients with unclassifiable MPN and 47 patients with asymptomatic V617F+ carriers. Among all patients, 17 patients were treated with hydroxyurea and 20 were treated with interferon. The control group included 100 healthy donors without JAK2 V617F mutation.

Results: The JAK2 46/1 haplotype (GG and CC) was present in 170 patients (80.6%) with MPN, in 25 (52%) patients with suspected MPN, in 23 (49%) asymptomatic JAK2 V617F+ patients and in 42 (42%) cases of control group. G variant of rs10974944 was more frequent in all JAK2 V617F-positive MPNs, than in the control population (χ²=46.5, p<0.0001). These results were similar to findings of previous studies, which have shown that the 46/1 haplotype predisposes to the acquisition of JAK2 V617F mutation. JAK2 V617F allele burden was significantly higher in patients with PV than in patients with ET (p=0.001), but no differences were observed with from patients with the PMF. 46/1 haplotype was closely associated with MPN patients if the allele burden exceeds 5% (Fig. 1) regardless of the phenotype or the treatment. In this case with an increase in JAK2V617F allele burden the JAK2 V617F haplotype frequency was significantly increased. However, there was no significant difference in the JAK2 46/1 haplotype frequencies between patients with allele burden less than 5% and the control group.

Summary: No significant differences of the carrier haplotype frequency between control group and patients with minimal allele burden (less than 5%) JAK2 V617F have been observed. This is evidence against primary "hypermutability" hypothesis. A further increase in allelic load is more pronounced in carriers of haplotype 46/1 that supports the "fertile ground" hypothesis. We hypothesize that DNA mutation JAK2V617F repair is down-graded in 46/1 haplotype carriers.

E1315

MINIMAL RESIDUAL DISEASE MONITORING BY DIGITAL PCR FOR JAK2V617F DETECTION IN PATIENTS WITH MYELOFIBROSIS (MF) OR ACUTE MYELOID LEUKEMIA SECONDARY TO MF AFTER ALLOGENIC STEM CELL TRANSPLANTATION

S. Salmoiraghi1,2; C. Belotti, M.C. Finazzi, M.C. Micò1; A. Algarotti1; G. Finazzi1; M. Mascheroni1; A. Salvi1; A. rambaldi12; O. Spinelli1

1Hematology and Bone Marrow Transplant, ASST Papa Giovanni XXIII, Bergamo; 2Oncology and HematonoLOGY, University of Milan, Milan, Italy

Background: Myelofibrosis (MF) is one of the BCR-ABL1-negative Chronic Myeloproliferative Neoplasms (MPNs), characterized by clonal expansion of abnormal hematopoietic progenitors and gradual replacement of normal bone marrow with fibrous tissue. MF patients' prognosis is widely variable and the median survival can vary from months to many years. At present, Allogeneic Stem Cell Transplantation (ASCT) is the only curative treatment option for these patients. The most frequent phenotype-driving mutation in MF is the V617F mutation in the JAK2 gene. A high sensitive quantification of JAK2V617F mutation load can be useful to assess Minimal Residual Disease (MRD) in treatment directed to eradicate the malignant clone, such as ASCT. Droplet Digital PCR (ddPCR) is a quantitative approach for the detection of rare allele characterized by a high level of sensitivity and specificity.

Aims: To evaluate the efficacy of ddPCR JAK2V617F mutation detection assay in monitoring the MRD level at consecutive time-points in a small cohort patients who underwent an ASCT for MF or MF-derived Acute Myeloid Leukemia (s-AML). Methods: DNA from 9 patients affected by primary, secondary MF or s-AML were serially collected during the follow-up after ASCT (50-2500 days). These samples were investigated for hematologic chimerism by PowerPlex System (Promega, USA) and were evaluated both by conventional allele specific PCR (ASO-PCR) and by a validated ddPCR mutation detection assay (Bio-rad, USA). Results were expressed as percentage of JAK2V617F mutated alleles on total evaluated alleles.

Results: The JAK2V617F ddPCR mutation assay was able to detect low mutation load (up to 0.006%), confirming to be much more sensitive than ASO-PCR (0.5-2%). In 4 patients, early after transplantation, we observed by ddPCR a low level of MRD that progressively increased during the follow-up and anticipated a decrease in donor chimerism level and a worsening of clinical situation. In 2 patients, who showed a full donor chimerism and complete hematologic remission of the disease, very low levels of MRD (ranging from 1% to 0.006%) could be detected by ddPCR in the 2 years after ASCT. With a longer follow-up, a full molecular remission was achieved as demonstrated by ddPCR. In 2 other patients, we observed a very early achievement of full donor chimerism and JAK2V617F molecular negativity (within 90 days post H SCT), also when evaluated by ddPCR. These patients entered a complete hematologic remission of the disease which still persists (after 1 and 5 years after transplantation, respectively). Interestingly, in one patient whose post-transplant hematopoiesis proved full donor and negative for JAK2V617F mutation for 2 years, a weak positive signal revealed by ddPCR (0.075%) became apparent after 2 years, corresponding to an extra-hematologic relapse (skin and bone). In a subsequent second allogeneic transplant from the same sibling donor restored clinical and molecular remission.

Summary: The ddPCR proved to be a sensitive and accurate method in detecting JAK2V617F mutation. Therefore, this assay can be a valid tool in MRD monitoring both during ASCT and post-ASCT. However, the use of this highly sensitive PCR should be considered with caution in the clinical management of transplanted patients to avoid inappropriate use of donor leukocyte infusion (DLI) and tampering of immunosuppression. A large
number of patients have to be studied with ddPCR to better understand the clinical significance of low mutation load.

**E1316**

**S100A8/9 ACTIVATION OF MAPK PATHWAY IS SUPPORTED BY ITS RECEPTORS RAGE AND TLR4 IN POLYCYTHEMIA VERA**

M. Kovačić1,2, O. Mitrović-Ajić1, B. Beleslin-Čokić2, M. Diklić3, T. Subotić3, D. Djilić4, S. Momčilović5, D. Leković4,5, M. Gotić6, V. Čokić3,1

1Laboratory of neuroendocrinology, Institute for Medical Research, 2Clinic for Endocrinology, Diabetes and Metabolic Diseases, Genetic laboratory, Clinical Center of Serbia, 3Laboratory of experimental hematology, Institute for Medical Research, 4Clinic of Hematology, Clinical Center of Serbia, 5Medical Faculty, University of Belgrade, Belgrade, Serbia

**Background:** S100A proteins have been shown to regulate cell proliferation, excessively augmented in myeloproliferative neoplasms (MPN). S100A8/9 is produced by cells of myeloid origin as mediator of inflammation, while AKT pathway is generally reduced by S100A8/9 factor, further on ameliorated by S100A8/9.

**Aims:** This study analyzed activation of AKT and MAPK pathways by S100A8/9 proteins in healthy controls and MPNs: polycthemia vera (PV), essential thrombocythemia (ET), primary myelofibrosis (PMF), according to JAK2V617F and calreticulin (CALR) mutation status.

**Methods:** S100A8/9 factor is examined in granulocytes of MPN using immunoblotting to reveal the presence of S100A8/9 and its activation. The presence of CALR mutations is determined by flow cytometry. Mutations of JAK2V617F and CALR exon 9 are analyzed by DNA sequencing. Besides JAK2V617F+ PV patients, we formed three groups of patients: JAK2V617F+, JAK2V617F-/CALR+ and JAK2V617F-/CALR- for ET and PMF.

**Results:** S100A8/9/Atoineits demonstrated a common significant increase in plasma of MPN patients, whereas the presence of CALR mutation augmented S100A8/9 levels in granulocytes of ET and PMF patients. Activation of AKT pathway is generally reduced by S100A8/9 factor, further on ameliorated by inhibition of the receptor for advanced glycation end products (RAGE) in granulocytes of JAK2V617F+ and JAK2V617F-/CALR+ groups of ET and PMF patients, while it has been prevented by Toll-like receptor 4 (TLR4) inhibition in PV patients. MAPK pathway is significantly inhibited by S100A8/9 only in JAK2V617F+ ET patients and JAK2V617F-/CALR- PMF patients, partially prevented by TLR4 inhibition in PMF. Inhibition of TLR4 reduced S100A8/9 mediated AKT and MAPK activation in contrast. S100A8/9 mediated MAPK activation has been significantly augmented by TLR4 and RAGE inhibition in PV patients. S100A8/9 stimulated granulocyte cyclin arrest in G2M phase has been stopped by JAK1/2 inhibition.

**Summary/Conclusions:** S100A8/9 protein levels demonstrated stable elevation in MPN patients. Inhibition of AKT controlled pathway by TLR4, whereas MAPK pathway activation by TLR4 and RAGE in PV, during treatment with S100A8/9.

**MUTATIONAL PROFILE STUDY OF DOUBLE-NEGATIVE ESSENTIAL THROMBOCYTHEMIA BY HIGH-DEPTH NEXT GENERATION SEQUENCING (NGS)**

G. Carreno-Tarragona1, I. Rapado1, R. Ayala1, A. Arenas1, J. Martínez-López1

1Haematology, Hospital Universitario 12 de octubre, Madrid, Spain

**Background:** Essential thrombocythemia is one of the three classical philadelphia-negative myeloproliferative neoplasms. It is frequently difficult to diagnose and some molecular markers are used as diagnostic criteria according to WHO classification. Despite this, a significant proportion of patients do not present a clonality marker.

**Aims:** To identify the mutational profile of ET negative for V617F and CALR mutations and to correlate it with clinical data.

**Methods:** A cohort of 22 ET negative for mutations in JAK2 (qPCR) and CALR (GENESCAN) was selected. Median age at diagnosis was 46 years (range: 14-88), male:female ratio 9:13; 2 patients had a record of thrombotic event prior to diagnosis, 4 patients had symptoms at the time of amelodiagnosis, 3 patients suffered thrombotic event after diagnosis, 1 patient underwent transformation to AML. Median Hb, WBC and platelet at diagnosis were respectively 14.75 g/dl, 8.5 x10^9/L and 720 x10^9/L. We performed targeted gene sequencing by NGS (Ion Torrent Proton System–Life Technologies) using a panel of 33 genes implicated in leukemia prognosis. X2 and I Student tests were used to find association between mutations and clinical data.

**Results:** On average, 97.94% of the target sequence showed a mean depth coverage around 2500. We discovered 17 non-synonymous mutations which were probably significantly increased in plasma of MPN patients, whereas the presence of CALR mutation augmented S100A8/9 levels in granulocytes of ET and PMF patients. Activation of AKT pathway is generally reduced by S100A8/9 factor, further on ameliorated by S100A8/9.

**Conclusion:** S100A8/A9 proteins demonstrated a common significant increase in plasma of MPN patients, whereas the presence of CALR mutation augmented S100A8/9 levels in granulocytes of ET and PMF patients. Activation of AKT pathway is generally reduced by S100A8/9 factor, further on ameliorated by S100A8/9.

**TCR GAMMA CLONALITY ASSESSED BY NGS DOES NOT HELP TO DISTINGUISH EGPA FROM HES**

S. Galimberti1,2, E. Ciabatti2, F. Guerini1, M. R. Metelli1, I. Petrinj2, G. Tarini3, M. Laterre1, E. Elefante4, F. Ferro5, R. Grossi2, N. Pissanti6, S. Grassi7,8,9, M. Petri6, M. Mosca6, C. Baldini1

1Clinical and Experimental Medicine, University of Pisa, Hematology, 2Clinical and Experimental Medicine, University of Pisa, Hematology, 3Hematology Molecular Laboratory, AOUP, 4Department of Translational Research and New Technology in Medicine, General Pathology, 5Cardio-Thoracic and Vascular Department, 6Department of Clinical and Experimental Medicine, University of Pisa, 7Department of Immunology, 8University Department of Hematology, 9Genome and Cell Centre, University of Siena, Siena, Italy

**Background:** Hypereosinophilic syndrome-associated syndromes are a heterogeneous group of diseases characterized by sustained and elevated blood eosinophilia with evidence of eosinophil-induced organ damage. Classically, Eosinophilic Granulomatosis with Polycythaemia (EGPA) and Hypereosinophilic Syndrome (HES), present several overlapping clinical and laboratory features, making it challenging to correctly insert patients in restricted and well-defined categories with specific and more effective therapeutic approaches in daily practice. Therefore, great efforts are ongoing searching for novel biomarkers able to differentiate these two disorders.

**Aims:** To detect T cell receptor gamma (TCRG) clonal rearrangements in EGPA and HES, comparing the frequency of distribution of the V and J region segments in 21 patients afferent to the hematology, rheumatology or pulmonology divisions.

**Methods:** Consecutive patients with a diagnosis of EGPA and HES were enrolled into the study. Inclusion criteria were: documentation of a persistent pathological eosinophilic count of ≥1.5 x10⁹/L and signs or symptoms of organ involvement. Clinical and laboratory data of the patients were collected. Sequence-based determination of the frequency distribution of TCRG Gene Rearrangements was performed using next-generation sequencing with the illumina MiSeq (LymphoTrack TRG assay).

**Results:** We included 21 patients (9 with EGPA and 12 with HES). Four EGPA patients were MPO-ANCA positive. We detected TCRG clonal rearrangements in 44% patients with EGPA and in 42% patients with HES. No association was observed between TCRG clonal rearrangements and ANCA status in EGPA patients. Following recurrent TCRG gene rearrangements were observed: Vtg10Jg1 (5 cases) and Vg4Jg1/2 (4 cases) were observed in both EGPA and HES, whereas Vg9Jg1/2 (2 cases) and Vtg10Jg1/2 (2 cases) were observed only in patients with HES. The presence of TCRG rearrangement was not different according to the symptoms (asthma, vasculitis, skin, gut, lung involvement, splenomegaly). IL2, IL5, IL4, eosinophilic calionic protein (ECP), absolute eosinophils were measured: ILS and ECP were higher in the polyclonal than in the clonal cases (9±2.5 vs 17±4.0, p=0.021 and 121.8±61.5 vs 39.5±1.5; p=0.07). On the contrary, no difference was observed in the absolute eosinophil count. Finally, the presence/absence of TCRG clonality did not significantly impact treatment response to treatment (immunosuppressive or interferon) and on the progression-free survival length.

**Summary/Conclusions:** Conclusions: Even if preliminary, this study reveals a similar T cell receptor gamma repertoire in EGPA and HES, with recurrent rearrangements, thus suggesting a possible antigen-driven inflammatory involvement. Other analysis underlying in both EGPA and HES. Interestingly, this study confirms our previous results showing the TCR delta rearrangement (assessed by qualitative PCR) in 40% of the EGPA patients.

**E1319**

**PROINFLAMMATORY CYTOKINE IL-6 STIMULATION OF ANGIOGENIC FACTORS AND DNA REPLICATION IS BLOCKED BY JAK-STAT PATHWAY INHIBITION IN MYELOPROLIFERATIVE NEOPLASMS**

T. Subotić1,2, B. Beleslin-Čokić1,2, D. Leković4,5, S. Molsjović5,6, O. Mitrović-Ajić1, M. Kovačić1,7, M. Diklić3,6, M. Gotić5,4, V. Čokić3,1

1Clinic of Hematology, Clinical Center of Serbia, 2Laboratory of experimental hematology, Institute for Medical Research, 3Laboratory of experimental hematology, Institute for Medical Research, 4Clinic of Hematology, Clinical Center of Serbia, 5Medical Faculty, University of Belgrade, Belgrade, Serbia

**Summary/Conclusions:** In ET, around 60% of patients present the JAK2V617F mutation, 15-30% show CALR mutations and around 5% present MPL mutations. In spite of this, there is still a significant percentage of ET patients without a molecular marker. Our study shows that the use of a NGS panel allows identifying markers of clonality as for example TET2. NGS also makes affordable to interrogate whole genes classically associated to ET, to detect mutations that were not found by traditional approaches. Finally, we can conclude, as previously described, that ET is an entity with a low mutational burden in comparison with other MPNs as primary myelofibrosis.
Background: We already demonstrated augmented proinflammatory IL-6 and angiogenic vascular endothelial growth factor (VEGF), hypoxia inducible factor-1α (HIF-1α) and endothelial nitric oxide synthase (eNOS) levels in myeloproliferative neoplasms (MPN).

Aims: To observe IL-6 activated signaling pathways during stimulation of angiogenic factors and their JAK-STAT dependence in MPN.

Methods: We analyzed phosphorylation of JAK/STAT3, PI3K/AKT and MAPK signaling by immunoblotting in HEL 92.1.7 cells (with JAK2V617F mutation) and granulocytes of MPN. The granulocyte cycle phases have been studied by flow cytometry.

Results: We demonstrated IL-6 stimulated angiogenic factors in HEL cells and HEL-derived macrophages, blocked by JAK-STAT inhibition for eNOS and HIF-1α. IL-6 stimulated JAK-STAT3 and angiogenesis related PI3-AKT and MAPK signaling by immunoblotting in HEL 92.1.7 cells (with JAK2V617F mutation) and granulocytes of MPN. The granulocyte cycle phases have been studied by flow cytometry.

Summary/Conclusions: Therefore, we concomitantly revealed that inflammation stimulated angiogenic factors and signaling pathways involved in cell proliferation, apoptosis and angiogenesis are regulated by JAK-STAT inhibition.
than pts felt that MPN symptoms have an impact on pt quality of life (92% vs 76%) and that pts had a substantial emotional burden associated with their disease. For instance, 34%, 29%, and 26% of pts with MF, PV, or ET reported feeling anxious or worried compared with 70%, 46%, and 36% of physicians reporting that their pts experience substantial anxiety or worry. Some pts did not recognize that their symptoms could be MPN related; for example, = one-fifth of pts did not think that their night sweats could result from their MPN (16% MF, 21% PV, 25% ET). Consistent with this, 60% of physicians indicated that pts could identify only few or some of their symptoms as MPN related. Pts and physicians were both concerned about reducing symptoms (pts: 70% MF, 61% PV, 53% ET; physicians: 80% MF, 55% PV, 60% ET); however, pts were also concerned about delaying MPN progression (58% MF, 57% PV, 66% ET; physicians: 43% MF, 28% PV, 37% ET; Figure 1). Compared with pts, physicians indicated a greater focus on prevention of vascular/thrombotic events in PV (66% vs 48%) and ET (80% vs 60%). Overall, only 27% of physicians felt they completely agreed with their pts on treatment goals; 66% felt they “somewhat” agreed. However, most pts (87%) were satisfied with their physician’s disease management/communication.

Summary/Conclusions: This study revealed a potential disconnect between physician and pt perceptions relating to communication and disease management, and an apparent lack of standardization in symptom assessment. Of note, some pts did not recognize that their symptoms could be MPN related and had different treatment goals than their physicians, indicating a need for improved pt education and pt-physician communication and a treatment plan that includes standardized monitoring of symptoms and agreement on treatment goals.

E1321

BASELINE QUALITY OF LIFE INDEPENDENTLY PREDICTS OVERALL SURVIVAL IN THE MYELOFIBROSIS: KEY INSIGHTS FROM THE COMFORT-I STUDY

R. Scherber1,2, H. Kosiorek3, H. Geyer4, S. Verstovsek5, J. Sloan6, B. Langlais3, L. Padrnos1, J. Palmer1, A. Fleischman7, A. Dueck3, R. Mesa1, A. Scherber1,2,*, H. Kosiorek3, H. Geyer4, S. Verstovsek5, J. Sloan6, B. Langlais3, 1Hematology and Oncology, Mayo Clinic, Scottsdale, 2Hematology and Oncology, MD Anderson, Houston, 3Biostatistics, 4Internal Medicine, Mayo Clinic, Scottsdale, 5Hematology and Oncology, MD Anderson, Houston, 6Hematology and Oncology, University of California Irvine, Irvine, United States

Background: Quality of life (QOL) is a critical aspect of cancer treatment and survival. A strong association exists between QOL and overall survival (OS) for numerous malignancies including breast, gastro-esophageal, colorectal, lung, prostate, ovarian, and head and neck cancer (Sloan 2012, Montazeri 2009, Nils- son 2017). Healthcare organizations have used symptom burden as a primary therapeutic endpoint when assessing the benefit of JAK inhibitors in myelofibrosis (MF) in clinical trials, although QOL was also considered. To date, little is known about the association of these items in regards to overall survival in MF.

Aims: To evaluate the prognostic relevance of QOL and symptom burden among patients with MF from the COMFORT-I study.

Methods: Data from the COMFORT-I trial of ruxolitinib (Verstovsek 2012) versus placebo was obtained from Incyte® for independent analysis. Association of total symptom burden (TSS; divided by the sample quartiles) and QOL (divided by the sample median) at baseline with OS among MF patients was estimated using the Kaplan-Meier method and tested using log rank tests and Cox regression. Symptom burden and QOL were assessed using the 5-symptom Global Health Status/QOL scale (Aaronson 1993), respectively. The PROMIS instrument was used to assess fatigue (Cella 2007).

Results: A total of 309 patients were available for analysis including 155 ruxolitinib-treated and 154 placebo-treated MF patients. Baseline demographics, disease-related variables, and calculated overall survival were similar to previous published results (Verstovsek 2015). Symptom Burden: When comparing OS by TSS quartiles at baseline, no significant associations in OS were observed (Figure 1A). Individual symptoms of bone or muscle pain, feeling full, pain under ribs on left side, abdominal discomfort, itchiness, or night sweats did not demonstrate significant associations when comparing OS by quartile symptom score. Baseline fatigue score demonstrated no difference in OS when stratified by median or quartiles. Global Health Status/QOL: Intention to treat analysis demonstrated significant survival advantage for patients with higher QOL at baseline (HR 1.47, p=0.02, Figure 1B). When censoring placebo patients at crossover, this hazard ratio improved to a HR 1.79 (p=0.008). Cox Proportional Hazards Modeling: Cox regression for survival analysis reached significance for items of age (p<0.001), sex (p<0.001), and QOL (p<0.009) when taking into consideration TSS, IPSS prognostic risk score, age, sex, COMFORT-I treatment arm, and QOL. When censoring for placebo patients at crossover, this analysis demonstrated that the same items remained significant (age [p<0.001], sex [p<0.001], and QOL [p<0.002]).

Summary/Conclusions: For the patients prospectively evaluated in the COMFORT-I trial, pre-treatment QOL is strongly prognostic for overall survival and MF-specific survival. Cox proportional hazards modeling revealed that QOL is highly prognostic even when adjusting for symptom burden, disease risk, age, sex, and treatment. Prior literature has confirmed the importance of QOL in prognosticating survival in other cancer types. However, this is the first study that has identified the key correlation among individuals with MF. Neither individual nor combined symptom scores at baseline appeared prognostic for overall survival, emphasizing the importance of QOL assessment in addition to symptom assessment. Weight loss (a prognostic factor for DIPSS scoring) was not included in this symptom burden assessment and may represent an independent factor associated with increased survival.

E1322

CHARACTERIZATION OF DISEASE AND OUTCOMES OF PATIENTS WITH MYELOFIBROSIS: A POPULATION BASED STUDY

J. He1, J. Methrall1, J. Bussolari2, A. Rizzo2, S. Mundle1, R. C. Cuzick1, J. Janssen Global Services LLC, 2Janssen Research & Development, LLC, Raritan, United States

Background: Myelofibrosis (MF) is a myeloproliferative neoplasm with profound negative effects on health related quality of life and survival. It is characterized by clonal myeloproliferation, ineffective erythropoiesis, bone marrow stromal changes, hepatosplenic extramedullary hematopoiesis, and aberrant cytokine expression. Although progress has been made in the understanding of the pathogenesis and management of MF, there are still unresolved issues regarding prognosis and causes of death.

Aims: This population-based study characterizes disease and outcomes in patients (pts) with MF by using the U.S. Surveillance, Epidemiology, and End Results (SEER) database.

Methods: We identified a total of 3,367 pts with primary myeloid fibrosis (PMF, ICD-O-3 morphology code as 9961/3 and primary site code as C420, C421 or C424) diagnosed between January 2000 to December 2013. Pts with missing survival status (n=753), pts lost to follow up (n=4), and pts with missing age record (n=1) were excluded. Kaplan-Meier analysis was performed to determine overall survival (OS) and cancer specific mortality. The effects of specific covariates on OS were analyzed using a Cox proportional hazards model.
Results: The final study cohort comprised of 2,619 PMF pts. Median follow up period was 28 months (interquartile range 9-77 years) with 60.6% (n=1,586) ≥ 65 years old. More than half of the pts were male (58.5%; n=1,531); 82.2% (n=2,153) were white, and 16.4% (n=430) were diagnosed between 2012 and 2013. The geographic distribution was as follows: East 14.8%, South 18.4%, West 54.2% and Midwest 12.6%. Median OS was 42 months (Figure 1). The hazard ratio of all-cause mortality for age was 1.05 (95% Confidence interval (CI) 1.04-1.05), for female vs male was 0.72 (CI 0.64-0.80), for nonwhite vs white 1.01 (CI 0.87-1.16), for unmarried vs married was 1.04 (CI 0.94-1.16), for patients diagnosed 2012-2013 vs 2000-2011 was 0.95 (CI 0.75-1.20). Compared to West, the hazard ratio of OS for East, South and Midwest was 1.05 (CI 0.90-1.22), 1.28 (CI 1.12-1.47), 1.03 (CI 0.88-1.19) respectively.

Summary/Conclusions: This population based study showed that the overall survival of pts with PMF was short. Older and male pts were associated with higher mortality risk. There were significant differences across geographic regions of the United States. Although there is a trend of improvement in the period of 2012 to 2013, the result is not statistically significant, partially due to short follow up. These findings underscore the continuing need for effective therapies for pts with MF.

E1323

SERUM ALBUMIN IS A STRONG PREDICTOR OF SURVIVAL IN MYELOFIBROSIS, INDEPENDENT OF IPSS, DIPSS, AND DIPSS+ SCORES

A.T. Kuykendall 1,*, C. Talati 1, D.A. Sallman 2, K.L. Sweet 2, E. Padron 2, J.E. Lanceti 2, A.F. Lis 2, K.S. Zuckerman 2, R.S. Komrokji 2

1University of South Florida/Moffitt Cancer Center, 2Moffitt Cancer Center, Tampa, Florida, USA

Background: Albumin is the main protein in human plasma. Serum albumin (SA) is used as a surrogate marker of nutritional status and inflammation. The prognostic role of SA has been studied in many diseases, including hematologic malignancies. In myelofibrosis (MF), ruxolitinib has been shown to improve SA levels in addition to other metabolic parameters. SA holds particular significance in MF given its ability to capture both nutritional status and inflammation level in a disease hallmark by hyperactive inflammatory pathways and constitutional symptoms.

Aims: We aim to closely evaluate the significance of SA in MF patients as it pertains to clinical presentation, laboratory correlations, disease genomics, comorbidities and outcomes.

Methods: We retrospectively reviewed an institutional database of 376 MF patients who presented to Moffitt Cancer Center between 1/1/1998 and 12/31/2012 and had available SA levels within 30 days of presentation. Laboratory values and prognostic scores were determined at time of first presentation. Overall survival (OS) was measured from time of first presentation until date of death or censored at time of last follow-up. Progression free survival (PFS) was defined as time from first presentation to development of acute myeloid leukemia (AML).

Figure 1.

Results: Our cohort of MF patients had median age of 67 and 69 at diagnosis and presentation, respectively. Most patients had primary MF (73%) with 11% and 16% having post-PV MF and post-ET MF, respectively. First, we looked at the correlation between SA and other clinical factors. SA was positively correlated with hemoglobin (p<0.01) and platelet count (p<0.01), and negatively correlated with age (p<0.01), peripheral blast percentage (p=0.03), ferritin (p<0.01), prognostic scoring models (p=0.01 for IPSS, DIPPS and DIPSS+) and pack-year smoking history (p<0.01). SA did not correlate with spleen size or any specific somatic mutation, but negatively correlated with somatic mutation burden (p=0.03). On univariate regression, SA was associated with inferior PFS (HR: 0.31 [0.13-0.72]; p<0.01) and OS (HR: 0.25 [0.17-0.36]; p<0.01). Four cohorts were created based on SA: cohort I=SA 2.5-3.5 g/dl (n=31); cohort II=SA 3.6-4.0 g/dl (n=89); cohort III=4.1-4.5 g/dl (n=182); and cohort IV=4.6 g/dl (n=84). OS increased with increasing SA; with median OS (in months) of 9.34, 25.3, 48.4, and undefined in cohorts I-IV, respectively. On focused comparison, each cohort was significantly different than all others. On multivariate analysis, the influence of SA on OS remained significant after controlling for prognostic scorers (IPSS, DIPPS, DIPSS+) and comorbidities. For PFS, SA remained significant when controlling for IPSS and DIPPS, but lost significance (p=0.08) when controlling for DIPSS+. Multivariate analysis was performed on a cohort of patients with available molecular data (n=138). SA significantly influenced OS after controlling for prognostic systems, comorbidities and mutations of SRSF2 and ASXL1. Lastly, given its independent prognostic influence in incorporating SA, we explored its role as an independent variable in standard prognostic modeling (see figure).

Summary/Conclusions: SA level is independently prognostic in MF and correlates with variables known to hold prognostic value. Its representation of nutritional status, inflammation, and comorbidities imbues it with special status in predicting outcome. Its incorporation into known prognostic scoring systems provides an improved ability to accurately capture low and high-risk subgroups.

E1324

CLINICAL UTILITY OF NEXT-GENERATION SEQUENCING IN THE MANAGEMENT OF MYELOPROLIFERATIVE NEOPLASMS

W. Alduaij1,*, C. McNamara1, A. Schuh2, A. Arruda1, M. Sukhai3,4, M. Thomas3, J.Y. Spiegel1, J.A. Kennedy2,5, T. Stockley2, H. Tsutui7, R. Devlin1, N. Siddiqi1, H. Sibai1, D. Maze1, A. Schimmer2, K. Yee2, S. Chan2, S. Kamel-Reid7, V. Gupta1

1MPN program, Princess Margaret Cancer Centre, 2Hematology- Princess Margaret Cancer Centre, 3Advanced Molecular Diagnostics Laboratory, Princess Margaret Cancer Centre, 4Applied Molecular Oncology, Ontario Cancer Institute, 5University Health Network, University of Toronto, Toronto, Canada, 6Division of Hematology, Department of Medicine, Brigham and Women’s Hospital, Boston, MA, United States, 7Department of Hematopathology, Toronto General Hospital, Ontario Cancer Institute, 8Molecular Diagnostics, Department of Pathobiology and Laboratory Medicine, University Health Network, University of Toronto, Toronto, Canada

Background: Although Next Generation Sequencing (NGS) has helped characterize the complex genomic landscape of myeloid malignancies, its clinical utility remains not well defined. Funding for NGS testing by healthcare systems or third party payers is variable due to the lack of data on its utility in a routine care setting. At our centre, targeted sequencing (TAR-seq) is offered to all new patients referred for myeloid malignancies as part of the Advanced Genomics in Leukemia (AGILE) program.

Aims: In this study, we evaluate the impact of TAR-seq on the management of patients with a diagnosis of MPN or post-MPN acute myeloid leukemia (MPN/AML).

Methods: All consenting patients referred to the MPN program at the Princess Margaret Cancer Centre between February 15 and December 15, 2016 with a suspected or confirmed diagnosis of MPN were evaluated (n=188). TAR-seq was performed on DNA extracted from peripheral blood (n=159, 85%) or bone marrow (n=29, 15%) using the TruSight Myeloid Sequencing Panel (Illumina), a targeted NGS panel of 54 genes (39 hotspot region; 15 complete coding region) implicated in myeloid malignancies. Reporting was limited to high quality exonic nonsynonymous, intronic splice site, frameshift, nonsense and known pathogenic synonymous variants. Variants with global mean allele frequency >1% were identified using multiple population databases (1000 genomes, ESP, ExAC) and excluded. Each patient’s TAR-seq results were reviewed alongside their clinical information systematically by at least two hematologists with expertise in MPN, and disagreements were resolved by consensus.

Results: 179 patients fulfilled the 2008 WHO diagnostic criteria for MPN: 107 were diagnosed with myelofibrosis (MF), 26 with polycythemia vera (PV), 21 with essential thrombocythemia, 13 with other MPNs (unclassifiable and 12 with MPN/AML). In 6 patients with ‘triple negative’ MPN, who lacked mutations in the driver genes JAK2, CALR and MPL, TAR-Seq confirmed clonal hematopoiesis through identifying other mutations. In 61 transplant-eligible patients with MF, 32 (52%) were considered to carry a high molecu-
inhibitor (JAKi) therapy. All high-risk, transplant-eligible MF patients were con-
sidered for transplantation irrespective of their HMR status. Nine patients with
low/intermediate-1 risk MF bearing HMR mutations were considered for a clin-
tical trial of early JAKi therapy, and one patient was successfully enrolled. Seven
patients were identified with IDH1/2 mutations (five with MF and two with
MPN/AML), and therefore can be potential candidates for enrolment into clinical
trials with IDH inhibitors. In PV and ET, TAR-seq identified HMR profiles in 6/26 (23%) and 5/21 (24%) patients, respectively. These
patients are monitored closely, but no therapeutic decisions were taken based
on their HMR profile. In MPN/AML, TP53 mutations were detected in 4/12
(33%) patients. However, these patients progressed rapidly before their TAR-
seq data become available to inform clinical management.

Summary/Conclusions: We have determined that TAR-seq enables the characteriza-
tion of triple negative MPN patients, refines risk stratification and decisions related
to the timing of transplant in MF, and can potentially identify candidates for future targeted therapies. Therefore, we suggest that NGS
should become part of the standard of care in MF, be a part of the investigation of triple
negative MPN. Based on these findings and in conjunction with ongoing studies
in the MPN program, an algorithm integrating NGS in the management of MF
has been developed, and will be evaluated prospectively.

E1325
IMPACT OF COMORBIDITIES AND BODY MASS INDEX ON SURVIVAL IN
PATIENTS WITH MYELOFIBROSIS TREATED WITH RUXOLITINIB

Ematologia, Ospedale Nuovo Regina Margherita, Roma, Italy

Background: Charlson Comorbidity Index (CCI) and body mass index (BMI)
are significantly associated with outcome in patients (pts) who receive continue
treatment with tyrosine kinase inhibitors. Ruxolitinib (RUX) is the first JAK1/2
inhibitor that may induce spleen/symptom responses and improve quality of
life in pts with myelofibrosis (MF). No data are yet available on the impact of comorbidities on pts treated with RUX.

Aims: To evaluate the impact of CCI and BMI on overall survival (OS) in a
cohort of RUX-treated MF pts.

Methods: A multicenter observational study on WHO-defined MF treated with
RUX according to standard clinical practice was conducted in 20 Italian Hema-
tology Centers. Response to RUX was evaluated according to 2013 IWG-MRT
criteria. OS was calculated from the date of RUX start to the time of death or
last follow-up. Baseline parameters evaluated for correlation with OS were:
blood cell count, spleen ≥10cm, marrow fibrosis grading, time from MF
diagnosis to RUX start, transfusion dependency, mutation status, Total Symptom
Score (TSS), CCI and BMI.

Results: Between June 2011 and Apr 2016, 343 pts with PMF (51.9%), or
post-ET (20.1%) / post-PV (28.0%) were treated with RUX in participating Cen-
ters. At RUX start, median age was 67.6 years (range 35.6-89.0) with a male
prevalence (57.1%); International Prognostic Score System (IPSS) was inter-
medial in 12 (16.0%), intermediate 2 (47.5%), and high (36.4%). Transfusion depend-
ence and spleen enlargement were present in 23.9% and 97.4% of pts, respec-
tively (62.4% with spleen ≥10 cm). TSS was <20 in 131 pts (38.2%); 62 (18.1%)
pts had a BMI<21 (corresponding to lower quartile). CCI was zero in 105 pts
(30.6%), one in 74 pts (21.6%), two in 58 pts (16.9%) and three in 106 pts
(30.6%). Notably, 22/122 pts (18%) from MF diagnosis was 3.6 yr (range 0.4-25.6)
and median RUX exposure was 21.2 months (3-56.2). In multivariable Cox regres-
sion analysis, factors negatively correlating with OS from RUX start were:
transfusion dependence (HR: 2.65; p<0.001), CCI ≥3 (HR: 1.67; p=0.031), BMI≥21
(HR: 1.74; p=0.039), and IPSS (intm-2 HR: 3.19; p=0.057; high risk= HR:
6.83; p=0.002). CCI ≥3 and BMI ≥21 were significant predictors for lower OS
and pPV-MF patients (pts) participating in clinical trials are well analyzed, data
should be part of the standard of care in MF, and in the investigation of triple
negative MPN. Based on these findings and in conjunction with ongoing studies
in the MPN program, an algorithm integrating NGS in the management of MF
has been developed, and will be evaluated prospectively.

E1326
ANALYSES OF 845 PATIENTS WITH PMF, PET-MF AND PPV-MF TREATED IN
35 GERMAN HEMATOLOGY CENTERS – A RETROSPECTIVE FIELD
STUDY
K. Bрага1, M. Wassenberg2, H. T. Steinekettz3, G. Springer4, K. Jentsch-Ulrich5, A. Gaumann6, J. Dengler7, C. Junghanss1
1Department of internal medicine 3, Hematology, Oncology, Palliative Care, Uni-
versity Hospital Rostock, Rostock, 2Gastroenterology, Rostock University Hospital, Rostock, 3Department of Gastroenterology, University of Ulm, Ulm, 4Department of Gastroenterology, University of Münster, Münster, 5Department of Gastroenterology, University of Hamburg, Hamburg, 6Department of Gastroenterology, University of Münster, Münster, 7Department of Gastroenterology, University of Münster, Münster

Background: Primary myelofibrosis (PMF) as well as secondary post essential
thrombocythemia (pET)-MF and post polycythemia vera (pPV)-MF are consid-
ered rare diseases associated with significant morbidity. Diagnostics and ther-
apeutic options have significantly improved during the last decade by develop-
ment of novel drugs, improvement of allogeneic stem cell transplantation (SCT)
procedures and supportive care. Whereas the characteristics of PMF, pET-MF and
pPV-MF patients (pts) participating in clinical trials are well analyzed, data
are rare for the general MF population including patients not included in or eli-
bile for clinical trials.

Aims: In order to gain a broader, more comprehensive data set on the general
MF population we performed a questionnaire poll in 35 German hematology
centers gathering characteristics on 845 pts who were currently under care.

Methods: A questionnaire asking for general patient and disease specific data
as symptoms, comorbidity, prognostic factors, past/ current treatment and
blood count, degree of MF in bone marrow and transfusion frequency was
designed. It was distributed to participating centers (n=35, mostly private offices)
throughout Germany and analyzed centrally. Time period of collection

Figure 1.

Summary/Conclusions: Together with transfusion requirement, CCI and BMI
may influence survival in RUX-treated MF pts. Taking into account these addi-
tional parameters may allow to better define survival probability beyond IPSS
risk assessment. Unfavorable CCI and BMI did not hamper responses to RUX;
also, the achievement of a spleen response counterbalanced the negative
prognostic effects of a lower BMI.
Results: Gender was equally distributed (50%/50%). Pts ages at initial diagnosis were as follows:<50 years (y) (11%), 50–69 y (19%), 70–89 y (31%), and >89 y (20%). The haemoglobin values were ≥89 g/dL in 69% of patients, 8–10.9 g/dL in 20%, and <8 g/dL in 11%. The mean platelet counts were >1000 x 10^9/L (34%), 100–499 x 10^9/L (28%), and <100 x 10^9/L (38%). The plateletcrit was above 0.4 (61%) and below 0.2 (39%).

Conclusions: The CALR type-1like patients showed a higher risk of thrombosis compared to the CALR type-2like patients. The use of antiplatelet or anticoagulant therapy was more frequent in the CALR type-1like group. The frequency of thrombosis was highest in the CALR type-1like group, with a 5-year thrombosis-free survival of 83% compared to 97% in the CALR type-1like group. The CALR type-2like group had a 5-year thrombosis-free survival of 97%, which was significantly higher than that of the CALR type-1like group (p=0.001). These results highlight the importance of CALR mutation type in the risk of thrombosis in patients with ET.
Summary/Conclusions: We have found elevated of blood and endothelial cell activation markers at baseline in Ph-MPN. Cytoreductive and antiaggregatory therapy reduced the mean level of Le-Plt aggregates and concentration of soluble selectins. In subset of pts with thrombosis, therapy led to normalization of Le-Plt aggregate levels, with incompletely normalized soluble selectin levels. Even with normal Le-Plt aggregates, observed elevated selectin levels can explain persistent thrombotic risk due to intrinsic changes in relationship between blood and endothelial cells as a part of biology of Ph-MPN itself.

E1329
HEAT SHOCK PROTEIN 27 EXPRESSION IS INCREASED IN PATIENTS WITH PRIMARY AND SECONDARY MYELOFIBROSIS AND MAY BE AFFECTING THEIR SURVIVAL
1Hematology department, 2Clinical Institute of Laboratory Diagnosis, Division of Molecular Diagnosis and Genetics, 3Department of Clinical Cytology and Cytometry, 4Pathology department, University Hospital Dubrava, Zagreb, Croatia

Background: Increased heat shock protein 27 (HSP27/HSPB1) expression and phosphorylation were observed in a large number of neoplastic diseases and they have mostly been associated with aggressive disease features and poor prognosis. There are only few reports investigating HSP27 in primary myelofibrosis (PMF), a myeloproliferative neoplasm characterized by high inflammatory state reflecting in debilitating clinical symptoms.

Aims: To analyze HSPB1 mRNA expression in patients with PMF and secondary myelofibrosis (SMF) and to correlate it with clinical and hematological features.

Methods: We analyzed HSPB1 relative expression in bone marrow aspirates of 26 patients with PMF, four patients with SMF and 13 controls using quantitative real time polymerase chain reaction (RT-PCR). Spleen size was assessed by palpation. Association with overall survival was analyzed in 27 PMF and SMF patients evaluated at the time of diagnosis. The Kusak-Wallis one way analysis of variance, The Mann Whitney U test, the Chi squared test, the Spearman rank correlation, the log-rank test and the Cox regression analysis were used, cut-off point for survival analyses was determined using the ROC curve analysis.

Results: Relative expression of HSPB1 differed significantly between diagnoses (P<0.001); it was significantly higher in patients with PMF and SMF than in control group (P<0.05 for both comparisons), but did not differ between PMF and SMF patients (non significant). Increased expression was associated with increase in the spleen size (P=0.009) and JAK2 V617F mutation (P=0.073). We did not detect significant associations with other disease specific features. Lower HSPB1 expression was associated with inferior overall survival in both univariate (HR 3.2; P=0.04) and multivariate analysis (HR 6.12; P=0.034) where effect was independent of age (non significant), gender (non significant) and the International Prognostic Scoring System (IPSS) score (HR 3.31; P=0.033).

Figure 1.
Summary/Conclusions: Both PMF and SMF patients have increased HSPB1 mRNA expression in their bone marrows which is associated with increased spleen size. Surprisingly, higher expression is also associated with improved overall survival which is independent of IPSS score. We speculate this to be due to atheroprotective properties of HSP27.
In post-PV/ET MFs, 11 (64.7%) subjects showed that JAK2 mutation as an only ancestral mutation as G121517R00701 in Figure 1c.

Methods: One third and one half of the pooled standard deviations (SD) of scores and change scores (raw and percentage change) were used as distribution-based estimates. The anchor-based approach estimated meaningful changes (raw and percentage change) relative to the patient’s change in global health status/QOL (GH/QOL; 0=worst, 100=best) as measured by the EORTC QLQ-C30 where a decrease of 12.1 or more points was considered as deterioration; an increase of 7.6 or more points was considered as improvement; and all other changes were considered as stable based on change scores established in a multiple myeloma population (Kvam et al., Eur J Hem, 2011). Analysis of covariance (ANCOVA) was used to investigate whether estimated meaningful changes were consistent across the spectrum of observed baseline TSS. This model of TSS changes at week 24 included a continuous term for baseline TSS, a 3-level grouping factor for GH/QOL change (deterioration vs stable vs improvement), and an interaction term between baseline TSS and the GH/QOL grouping factor.

Results: 301 patients randomized to ruxolitinib [N=149] or placebo [N=152] completed TSS at baseline (45% female, median age 68 [range 40-91]). Median baseline TSS was 16.8 (range 0 to 52.7). Pooled SD at baseline and week 24 in TSS was 11.4 and 11.6, respectively, resulting in estimated meaningful changes of 3.8-5.6 points. For change and percentage change from baseline at week 24 in TSS, the pooled SDs were 9.8 and 75%, respectively, resulting in estimated meaningful changes of 3.3-4.9 points or 25%-38%. Among patients with TSS and QLQ-C30 data at baseline and week 24, 51 (23%) patients had deterioration, 61 (27%) were stable, and 110 (50%) had improvement based on QLQ-C30 GH/QOL changes. Mean (95% CI) changes in TSS for the three groups were 0.8 (-2.5 to 4.2), -1.4 (-3.6 to 0.8), and -6.8 (-9.0 to -4.6), and for percent changes 20% (-6% to 46%), 17% (-11% to 44%) and -34% (-45% to -22%). ANCOVA revealed that baseline TSS statistically significantly impacted im-p02. Figure 1 shows that changes as small as 3-6 points on a 0-60 scale of the MFSAF v2.0 TSS may be meaningful to patients. However, estimates of meaningful change appear to increase in magnitude for higher baseline scores, though in a way that a static percentage change criterion would either require too much change for lower baseline TSS or not enough change for higher baseline TSS. All analyses suggest that some changes in symptoms which do not meet a 50% improvement may still be meaningful to patients.

E1332

ERYTHROPOIESIS STIMULATING AGENTS CAN IMPROVE ANEMIA IN PATIENTS WITH MYELOFIBROSIS TREATED WITH RUXOLITINIB

E. Crisà1,2, C. Daniela2, E.M. Elló1, E. Beggio1, C. Frairìa, M. Carraro1, G. Lanzaroni1, M. Marchetti5, M. Mezzabotta6, M. Boccadoro1, D. Ferrero1

1Hematology Division, A.O. Città della Salute and della Scienza di Torino, University of Turin, 2Department of Clinical and Biological Sciences, University of Turin, 3Hematology Division, Ospedale San Gerardo, ASST Monza, 4Hematology, A.O. Ospedale Maggiore di Novara, Novara, 5SOC Oncologia, Ospedale Cardinal Massaia, Asti, 6Hematology Division, Ospedale Mauriziano - Ospedale Umberto I, Torino, Italy

Background: Anemia is common in patients with myelofibrosis (MF) and it is one of the main cause of symptoms in this setting. Erythropoiesis stimulating agents (ESA) have been used in MF but mostly small series and no randomized trials have been published so far. Anemia response rate ranged between 23 and 60% in different reports (Cervantes et al, BJH 2004; Cervantes et al, BJH 2006; Tsiara et al, Acta Haematologica 2007) and a larger study recently published by Cervantes group on 163 patients (Hernandez-Boluda J et al, EJH 2016) showed a response rate of 50%. Ruxolitinib is currently approved for the treatment of intermediate 2 or high DIPSS/IPSS risk MF and it is highly effective in reducing spleen size and controlling the symptoms of MF, thus resulting in a marked improvement in the patients’ quality of life (Verstovsek S. et al, NEJM 2012; Harrison C. et al, NEJM 2012) and possibly a prolonged survival (Cervantes F. et al Blood 2016). However, one of ruxolitinib main side effects is anemia, which occurs in 40% of the patients and can be a limiting factor for treatment tolerability and thus compliance and optimal dosage, mostly in the first weeks of treatment.

Aims: To evaluate the efficacy and safety of combination therapy with ruxolitinib and ESA.

Methods: We retrospectively evaluated 32 patients who received concomitant therapy with ruxolitinib and ESA. ESA (epoetin alpha or zeta or darbepoetin) were given off-label after obtaining patient written consent and local pharmacy approval. Erythroid response was defined as transfusion independence with normal haemoglobin (HB), transfusion decrease of >50% or sustained HB increase of >2g/dl, partial response as a sustained HB increase of 1-2g/dl.

Results: We included 32 patients diagnosed with MF, 23,1% primary, 34,6% secondary to PV and 42,3% to TE. 20 patients (62,5%) were male and median age at ESA start was 70 years (range 41-80). 87% of patients were transfusion dependent 2 and 13% at high risk according to DIPSS. Fifty-nine% of patients received epoetin alpha, 28% darbepoetin and 13% epoetin zeta. Median dose for epoetin alpha/zeta was 40000 U/week and for darbepoetin 150 mcg/week. Seven patients had started ESA treatment before ruxolitinib therapy, whereas 25 patients received ESA after ruxolitinib start. Six patients developed or worsening of anemia. In particular, 5 were already RBC transfusion dependent. Of those, 3 patients were RBC transfusion dependent before commencing ruxolitinib while 13 patients required red blood cell (RBC) transfusions only after treatment start. Overall ruxolitinib treatment worsened anemia leading to RBC transfusion requirement in 52% of patients. Median time to ESA start was 8.2 (10) weeks and ESA start was 52,1 (10) days after ruxolitinib and ESA transfusion dependent. Median basal endogenous erythropoietin level was 58 U/I (range 8-146 U/I). Overall response rate was 87,6%, with 68,8% of erythroid response and 18,8% of partial response. Median time to response and median
response duration were 4 and 31 months respectively. 23% of patients lost response after a median time of 16 months. Seventy-five percent of patients responded to ruxolitinib in terms of spleen size, of whom 86.4% also achieved an erythropoietic response to ESA. A spleen increase during ESA treatment in patients responding to ruxolitinib was observed in 2 patients only.

No thrombotic events and no toxicity were reported over treatment with ESA. Subgroup analysis showed that ESA was effective in improving anemia in MF patients treated with ruxolitinib. We observed a high response rate in this patients series without significant toxicities. In particular no thrombotic event and no negative impact on response to ruxolitinib was reported. This results may be partially explained by the selection of patients with endogenous erythropoietin level below 250 U/I, but they could also suggest synergistic activity of ESA and ruxolitinib.

E1333 COMPARING THE SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS (PTS) WITH DIPSS LOW/INTERMEDIATE-1–, INTERMEDIATE-2–, AND HIGH-RISK MYELOFIBROSIS (MF) IN JUMP, A PHASE 3B, EXPANDED-ACCESS STUDY

Ltd, Hyderabad, India, 14CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

Background: RUX is a potent JAK1/JAK2 inhibitor that led to improvements in splenomegaly and symptoms and increased overall survival in pts with intermediate (Int)-1–, and high-risk MF by the Intergroupe Francophone des Myélofibrose (IFM) Dynamic IPSS (DIPSS) prognostic scoring system (IPSS) in the phase 3 COMFORT II studies. JUMP is a large, phase 3b, expanded-access trial in countries with no access to RUX outside a clinical trial and includes pts with IPSS Int–1–, Int–2–, and high-risk MF. To further evaluate RUX, we conducted an analysis assessing safety and efficacy of RUX by Dynamic IPSS (DIPSS) prognostic risk.

Aims: To compare the safety and efficacy of RUX in pts with DIPSS low/Int–1– vs Int–2– vs high-risk MF

Methods: Eligible pts had IPSS high- or Int–2–risk MF, or Int–1–risk MF and a palpable spleen (≥25 cm). Starting dose was based on baseline platelet (PLT) count (5 mg bid [≥50 to <100 × 109/L], 15 mg bid [100-200 × 109/L], or 20 mg bid [>200 × 109/L]) and could be titrated during treatment. The primary endpoint was safety and tolerability of RUX. Changes in palpable spleen length and symptom scores were also assessed. DIPSS scores were determined using pt characteristics at baseline.

Results: Based on available pt data, DIPSS status was determined for 1840 of 2233 enrolled pts. JUMP included 893 low/Int–1–, 754 Int–2–, and 193 high-risk pts (primary MF, 57%, 63%, 62%) who started treatment ≥1 y before data cutoff (01 Jan 2016). Pts with higher-risk MF were older (62, 66, and 72 y), had lower Hb (<10 g/dL, 3%, 64%, 100%), and had higher blast counts (21%, 18%, 44%, 84%). Disease duration (50, 51, and 55 mo) and spleen size (12, 13, and 14.5 cm) were similar in all 3 groups. Most pts started at 20 mg bid (68%, 57%, 59%) or 15 mg bid (26%, 32%, 33%). Median exposure was 16, 11, and 9 mo; mean average daily dose was 30, 28, and 29 mg. At data cutoff, most pts remained on treatment or had completed per protocol (70%, 56%, 45%). Reasons for treatment discontinuation included adverse events (AEs; 15%, 5%, 11%), death (2%, 5%, 11%), and disease progression (6%, 11%, 11%). Main reasons for treatment discontinuation included adverse events (AEs; 15%, 5%, 11%), death (2%, 5%, 11%), and disease progression (6%, 11%, 11%).

Overall rates of nonhematologic grade 3/4 AEs were <2%, except for pneumonia (4.5%), pyrexia (2.3%), asthenia (2.2%), and dyspnea (2.2%). Infections in ≥5% of pts were pneumonia (7.3%), urinary infection (6.1%), and nasopharyngitis (5.3%). Herpes zoster was reported in 4.8% of pts. At wk 48, 64% (226/355), 52% (121/232), and 50% (26/52) of pts had a ≥50% reduction from baseline in spleen length; 19% (68/355), 19% (43/232), and 23% (12/52) had ≥50%-50% reductions. Best response in spleen length by wk 72 is shown in the Figure: 69%, 57%, and 51% of pts achieved ≥50% reductions. Median time to response was 4.7 wk (2.5–75 wk), 5.3 wk (2.6–80 wk), and 8.1 wk (3.1–72.3 wk). From wk 4 to 48, 39%, 43%, 41%, 44%, and 48% of pts achieved a clinically meaningful response on the FACT-Lym TS: proportions of responders on the FACT-Fatigue were 42%–49%, 46%–49%, and 55%–61%.

Figure 1.

Summary/Conclusions: RUX was safe and generally well tolerated. Interestingly, lower-risk pts received higher starting doses yet had lower rates of hematologic AEs. Additionally, lower-risk pts remained on treatment longer than higher-risk pts, with fewer discontinuations due to AEs. Lower-risk pts also achieved slightly better spleen size reductions and symptom improvement than higher-risk pts, suggesting that earlier RUX treatment may lead to greater benefits in pts with MF.

E1334 SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS WITH MYELOFIBROSIS (MF) WHO STARTED TREATMENT AT 10mg BID AND HAD THE DOSE UPTITRATED IN THE PHASE 3B EXPANDED-ACCESS JUMP STUDY

1St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 2Azienda Ospedaliera Bianchi-Melacarino-Morelli, Reggio Calabria, Italy, 3Azienda Ospedaliera Bianchi-Melacarino-Morelli, Reggio Calabria, Italy, 4St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 5Federal Almazov Medical Research Center of the Russian Ministry of Health, St. Petersburg, Russian Federation, 6University Hospital of Halle, Halle (Saale), Germany, 7Universidade Federal de Goiania, Goiania, Brazil, 8Ospedale di Circolo e Fondazione Macchi, Varese, Italy, 9Rabin Medical Center, Petah Tikva, Israel, 10Miguel Servet University Hospital and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain, 11Johannes Wesling Clinic, Minden, Germany, 12Novartis Pharma AG, Basel, Switzerland.
Methods:

Aims: To assess the safety and efficacy of RUX at a starting dose of 10mg bid in pts with MF.

Methods: Pts with high-, Int-2-, or Int-1–risk MF were eligible. Int-1–risk pts had a palpable (≥5 cm) spleen. Protocol starting doses (5, 15, or 20mg bid) were based on baseline platelet (PLT) counts (≥50 to <100×10⁹/L, 100 to 200×10⁹/L, >200×10⁹/L, respectively). Although not per protocol, some pts started RUX at 10mg bid. The primary endpoint was safety. Secondary endpoints involved changes in spleen length and symptoms.

Results: A total of 48 pts (primary MF, 60%) started RUX at 10mg bid ≥1 y before data cutoff (01 Jan 2016). Mean baseline characteristics were: median age, 65.5 y (range, 20-83 y); male, 44%; spleen length, 12.3 cm; time since diagnosis, 56.6 mo; hemoglobin (Hb), 112.1 g/L (<100 g/L, 33.3%); PLT count, 351×10⁹/L (<100×10⁹/L, 10.4%). Pt characteristics were similar to those of the overall population and did not indicate an increased risk of developing cytopenias. At data cutoff, most pts remained on treatment or had completed treatment per protocol (58.3%). Primary reasons for treatment discontinuation included adverse events (AEs), disease progression, and death (8.3% each). Overall, 41.7% of pts had dose modifications (AEs, 33.3%); 20.8% had interruptions (all due to AEs). Median exposure was 14.4 mo. The mean average daily dose was 25.8mg/day (SD, 10.1) and was comparable to those (33.2 and 23.3mg/day) of patients starting at higher doses (20 and 15mg bid).

Figure 1.

Summary/Conclusions: A small cohort of pts in JUMP started at 10mg bid, and had the dose uptitrated during the first 8 wks to a mean average daily dose comparable to those of pts starting at higher doses, leading to safety and efficacy outcomes consistent with those in the overall JUMP population. This alternative approach will be prospectively evaluated in anemic MF pts in the REALISE study (NCT02966635).
positive MPNs, where they associate with an accelerated phase of disease, and seem to correlate with worse survival in myelodysplastic syndromes. However, the impact of these three findings at diagnosis in PMF remains unclear.

Aims: The aim of this work is to evaluate, at diagnosis, the prognostic impact of basophilia, eosinophilia and monocytophagocytosis in patients with PMF.

Methods: We identified all PMF patients diagnosed and followed-up in our Centres (2001-2015) and who still fulfilled WHO criteria under the WHO 2016 diagnostic revision, have synchronous bone marrow (BM) and peripheral blood (PB) analyses dating from the time of diagnosis, and have complete charts with no missing data. After the exclusion of reactive causes, monocytophagocytosis was defined as an absolute count (AC) >1.0 G/L, eosinophilia as an AC >0.6 G/L and basophilia as an AC >0.2 G/L.

Results: We studied 55 evaluable patients (73% male) with a median age at diagnosis of 70.1±11.7 years old. At diagnosis, 20% of patients had monocytophagocytosis, with no significant differences according to gender or age. The median overall survival (OS) in PMF patients with monocytophagocytosis was 27.3 months, and twice as long in patients with no monocytophagocytosis (57.3 months), compared to 43.8 months for patients under the cut-off. A total of 30.9% of patients had basophilia at diagnosis, with no differences according to gender or age. The median OS in patients with basophilia was 25.6 months, and 32.5 months in patients without. With a new cut-off of 0.25 G/L of basophils, with a specificity of 88.9% (95% CI: 70.8-97.6%), 20.0% of patients had basophilia above the cut-off and a median OS of 19.7 months, compared to 46.4 months for patients under the cut-off. Considering the whole cohort, 61.8% of patients had normal monocyte, eosinophil and basophil ACs; the median OS in these patients was 56.1 months, compared to 28.5 months in patients with an increase in at least one AC. Applying the new cut-off, the difference in OS increased to 79.9 vs 64.4 months. Progression-free survivals were not calculated, since only 2 patients had BM- or PB-documented progression during follow-up.

Summary/Conclusions: We observed that the presence of monocytophagocytosis at diagnosis in PMF was associated with a halving of the median OS, while eosinophilia decreased the median survival to one-fifth; basophilia also associated with a reduction in survival, of approximately 20%. The application of specific cut-offs calculated for the cohort improved the differentiation and stratification of patients, with moderate to high specificity, further clarifying the negative prognostic impact of these three variables, at diagnosis, in PMF. Our results show that even simple, inexpensive and readily available parameters can be used to predict survival in PMF patients, and suggest that their integration into established scores could further increase the prognostic accuracy of the latter.

BLAST PHASE IN PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS: A SINGLE INSTITUTION RETROSPECTIVE ANALYSIS OF 85 PATIENTS

E. Roncoroni1,*, M. Bellini2, E. Rumi1,2, V. Ferretti1, D. Pietra1, C. Cavalloni1, M. Ciboddo2, I. Casetti2, P. Zappasodi1, P. Benvenuti2, C. Astori1, M. Cazzola1,2

1Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy. 2Department of Molecular Medicine, University of Pavia, Pavia, Italy.

Background: Classic Ph-negative myeloproliferative neoplasms (MPN) include essential thrombocythemia (ET), polycythemia vera (PV) and primary myelofibrosis (PMF). Chronic evolution can lead MPN patients in chronic phase (CP), to develop acute myeloid leukemia (AML), called blast phase (BP): this event occurs at rates of approximately 1% in ET, 4% in PV and 20% in PMF over the first decade from MPN diagnosis.

Aims: To evaluate differences in clinical features and outcome in 85 patients with MPN in Blast phase, according to MPN diagnosis and mutational profile.

Methods: We identified in our database all patients affected with ET, PV and PMF who developed acute myeloid leukemia according to 2016 WHO criteria (≥ 20% blasts in bone marrow or peripheral blood) and for whom at least one DNA sample was available to define the mutational status of the three MPN driver genes (JAK2, CALR, MPL). For each patient, we used HPC-PCR to develop accurate myeloid leukemia (AML), called blast phase (BP): this event occurs at rates of approximately 1% in ET, 4% in PV and 20% in PMF over the first decade from MPN diagnosis.

Results: We identified in our database all patients affected with ET, PV and PMF who developed acute myeloid leukemia according to 2016 WHO criteria (≥ 20% blasts in bone marrow or peripheral blood) and for whom at least one DNA sample was available to define the mutational status of the three MPN driver genes (JAK2, CALR, MPL). For each patient, we used HPC-PCR to develop accurate myeloid leukemia (AML), called blast phase (BP): this event occurs at rates of approximately 1% in ET, 4% in PV and 20% in PMF over the first decade from MPN diagnosis. The complete blood count at leukemic evolution was not influenced by treatment during blast phase, but only a few patients can actually undergo this procedure.

Summary/Conclusions: Clinical phenotype and outcome of BP is not influenced neither by the diagnosis in chronic phase nor by the driver mutation; moreover the outcome is poor irrespective of treatment. PMF patients have a shorter time to BP than ET and PV patients; in PMF JAK2 V617F mutation is associated with a shorter time to BP compared to CALR mutation. The only potentially curative treatment is represented by allogeneic stem cell transplantation, but only a few patients can actually undergo this procedure.

TELOMERE LENGTH IS REDUCED IN ESSENTIAL THROMBOCYTHAEMIA PATIENTS COMPARED TO AGE AND GENDER MATCHED HEALTHY CONTROLS

S. Alman1,2, J. Jie3, D. Mc Corman3, D. Radia1, G. Mufli2, C. Harrison1

1Haematology, Guys and St Thomas’ NHS Foundation Trust, 2Haematology, King’s College London, London, United Kingdom

Background: Essential thrombocythaemia (ET) is a clonal stem cell disorder, commonly diagnosed in the 6th or 7th decade of life. ET is associated with risk of thromboembolic events, hemorrhage, constitutional symptoms, progression to myelofibrosis and acute myeloid leukemia. In over 85% of patients a clonal driver can be identified with mutations in JAK2 (50-60%), Calreticulin (CALR) (25-30%) or the thrombopoietin receptor (MPL) (3-5%); the remainder of patients are termed “triple negative” (TN). Telomeres are non-coding regions of DNA consisting of thousands of repeated sequences (TTAGGG) and are considered central to chromosomal integrity and genomic stability. In healthy adults, telomere length (TL) progressively shortens with age; therefore, TL is considered a marker of aging and genome telomere loss in hematopoietic cells in several hematological malignancies have been shown to be characterized by shortened TL.

Aims: Determine if there is TL shortening in patients with ET when compared to age and gender matched controls and establish the effects of cytochrome 2D6 (CYP2D6) status and ET JAK2 V617F mutation on TL.

Methods: 100 patients were included in the study (27 with CALR, 35 JAK2V617F and two MPL515W mutations. 36 patients were TN). Most patients were female (70% 70/100); median age was 45 years (range 20 - 86 years).
TL was determined in peripheral blood mononuclear cells using a monochrome multiplex quantitative PCR based on the original methods described by Cathwom. All results were corrected for age and gender.

**Results:** Regardless of driver mutation status ET patients had significantly shortened TL compared with age and gender matched controls, p<0.001. Considering individual mutation status these differences remained significant e.g. TP53 (n=21): p=0.0060; JAK2V617F (n=5): p=0.0067 and p=0.012 in TN patients. TL appeared more markedly short in the CALR cohort; for the 18 patients, whose TL was below the first centile, 55% (10/18) were CALR positive vs 28% (5/18) JAK2V617F positive vs 17% (3/18) who were TN. Concerning the potential impact of therapies 3/110 patients were treated with hydroxyurea (HC) (80% of these had prior exposure to HC), 3/140/100 were not on cytoreductive therapy. Remaining treatments were ruxolitinib (5), busulfan (4), anagrelide (1) and vorinostat (1). Independent of mutation status there was significant TL shortening in untreated patients, p=0.05; however, upon evaluating the impact of cytoreductive therapy on TL we noted that ET patients, with either current, or prior exposure had significantly shortened TL, p= 0.0015 and p<0.0001 respectively. Strikingly, there was no significant difference in TL in IFN patients who had no previous exposure to HC, p=0.2 but those ET patients currently on IFN but with prior HC exposure still had shortened TL.

**Summary/Conclusions:** We document for the first time that ET patients, when compared to age and gender matched healthy controls, have shortened TL. This shortening is more pronounced in CALR and JAK2 V617F positive patients. Concerning therapy whilst present in untreated patients TL shortening was more pronounced in HC treated patients indicating that there may be a therapy effect as has been observed after HC treatment in sickle cell disease. Of note IFN treated patients had more normal TL suggesting that the disease related TL effects may be reversed by this agent.

**NUTRITION IN MYELOFIBROSIS: CORRELATES FROM THE COMFORT-1 STUDY**

R. Scherer1,2,*, H. Kosirek3, H. Geyer4, S. Verstovsek5, B. Langlais3, L. Padronos1, J. Palmer1, A. Dueck3, A. Fleischman6, R. Mesa1

1Hematology and Oncology, Mayo Clinic, Scottsdale, 2Hematology and Oncology, Oregon Health and Science University, Portland, 3Biostatistics, 4Internal Medicine, Oregon Health and Science University, Portland, 5Hematology and Oncology, MD Anderson, Houston, 6Hematology and Oncology, University of California Irvine, Irvine, United States

**Background:** Nutritional status declines in most patients with myelofibrosis (MF). Sixty-seven percent of patients with MF lose weight over time and 27% of patients have a BMI decrease of at least one body mass index (BMI) category (Mesa et al. Blood. 2008;112(11):5224). MF also leads to deficient LDL and cholesterol levels compared to age matched controls (Mesa R A et al. Blood. 2007;110(11):2548). Both hypocholesterolemia (p<0.001) and weight loss>10% (p<0.001) have been associated with decreased survival in PMF patients (Mesa et al. Blood 2009 114:3918). JAK inhibitor therapy has been found to improve nutritional markers including weight, cholesterol, albumin, and leptin compared to placebo in the COMFORT-1 study (Mesa et al. Clin Lymphoma Myeloma Leuk. 2015 Apr; 15(4): 214–221; Verstovsek et al. N Engl J Med 2012; 366:799-807). However, the correlation of these factors with other disease related variables and overall survival has not been established.

**Aims:** To evaluate the correlation, if any, between nutritional markers other variables collected in the COMFORT-1 study.

**Methods:** Data from the COMFORT-1 trial of ruxolitinib versus placebo was obtained from the Incyte for independent analysis. Data was analyzed for correlation with symptom burden and survival along with other variables. Symptom burden was assessed by the MF-SAF v2.0 (Mesa et al. Leuk Res 2009) for individual items and total symptom score (TSS).

**Results:** A total of 309 patients were available for analysis including 155 ruxolitinib and 154 placebo treated patients. At baseline, the average BMI was 24.9 (SD=4.5). Baseline demographic and other disease-related variables can be found in previous publications (Verstovsek et al. N Engl J Med 2012; 366:799-807). Correlatives: Baseline: For all patients at baseline, numerous correlations between baseline nutritional markers and markers of nutrition (Figure 1) were identified. Total Symptom Scores (TSS) inversely correlated with albumin, cholesterol, alpha-feto protein, HDL, and serum erythropoietin levels. Baseline lepim levels correlated with many items including BMI, albumin, cholesterol, LDL, erythropoietin, insulin and CRP. Placebo: For patients treated with placebo, changes in BMI inversely correlated with changes in CRP (r= -0.22, p=0.002). Significant correlations were observed between baseline TP53 (n=64) and CRP (r=0.87, p<0.001) and HDL (0.41, p=0.001). In addition to LDL, HDL change inversely correlated with TSS score (-0.24, p=0.02), and positively correlated with changes in bone pain (0.23, p=0.02), abdominal fullness (r=0.22, p=0.02), erythropoietin levels (0.27, p=0.01) and cholesterol levels (r=0.39, p=0.01). Ruxolitinib: Most correlations with nutritional and metabolic markers mirrored with baseline scores (Figure 1b). For ruxolitinib-treated patients, changes in JAK2V617F mutational status inversely correlated with changes in serum cholesterol (-0.26, p=0.008), lepim (-0.38, p<0.0001), and LDL (-0.23, p=0.02). CRP changes were inversely correlated with change in cholesterol levels (-0.18, p=0.03).

**Summary/Conclusions:** Nutrition decline remains an unmet need for many MF patients. JAK2 inhibition represents a potential source to improve symptom burden in those who qualify for therapy. Leptin closely correlated with many other nutritional values suggesting this may be a good marker of nutritional status in MPN patients. CRP was inversely correlated with BMI, suggesting the importance of inflammation as a contributor to weight loss. Further study into the unique nutritional needs of myelofibrosis patients is warranted.

**Background:** To evaluate the prognosis of patients with Essential Thrombocytemia (ET) the first decade of the century we assessed retrospectively the thrombosis free survival (TFS) and the overall survival (OS) of the patients diagnosed from 01/01/2000 to 31/12/2009 and collected on the database of our group.

**Aims:** Diagnosis of ET was performed with PVSG, WHO 2001 or 2008 criteria, according to the date of the first observation. The whole population of 757 patients was then divided in two groups: the first (group I) with the diagnosis performed between 01/01/2000 to 31/12/2005 (334 patients), presented a median follow-up of 111.9 months, the second (group II) diagnosed between
01/01/2006 to 31/12/2009 (385 patients), with a median follow-up of 58.2 months.

Methods: The characteristics of two groups of patients are reported in the Table 1. No differences could be found between the two groups according age, gender, platelet and WBC count and Hb level. Cardio-Vascular Risk Factors (CVRF), spleen enlargement and the occurrence of previous thrombotic events. The frequency of the JAK-2 V617F mutation resulted significantly different (49.1% vs 68.4%), but in the group I the search of the mutation was never performed at the diagnosis. TFS and OS were calculated from the date of diagnosis of ET to the date of event with Kaplan-Meier product limit method; the comparison of proportions and median values was computed with the Chi-squared and the Mann-Withney tests, as indicated.

Results: No significant differences emerged neither for TFS (p=0.09, HR 1.42, 95% C.I. 0.89-2.30) nor for OS (p=0.15, HR 1.34, 95% C.I. 0.87-2.06). We also evaluated the type of treatment used in the two groups to assess the potential link between the therapy and TFS or OS (Table 2). No difference emerged between the two groups as for anti-aggregating (mainly ASA), equally utilized in both groups, 287/369, 77.8%, and 330/383, 78.3%, respectively (p=0.95). As for the cyto-reductive therapy, Hydroxyurea was used in 74.8% vs 67.9% (p=0.60) and alkylating agents in 2.1% vs 1.9% (p=0.85), whereas the Anagrelide resulted utilized in 10.6% vs 3.3% (p=0.001) and Interferon in 9.5% vs 5.2% (p=0.037), respectively. The more frequent use of Anagrelide and Interferon in the first group (2000-2005) didn’t modify the prognosis (as for TFS and OS) of the patients.

Figure 1.

Summary/Conclusions: Unfortunately, no improvement, neither as the TFS nor the OS was observed (Fig. 1 and 2): more efforts to better identify the groups at risk and, hopefully, the introduction of new drugs as JAK-2 inhibitors could change the prognosis of ET patients.

CUTANEOUS INVOLVEMENT IN PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS-SINGLE-CENTER EXPERIENCE

J. M. Sanchez-Raga1,2,*, N. Knöpfel3, M.D.M. Escudero-Góngora3, F. Sartori2, B. Lopez1,2, I. Herraez2, M.D.C. Ballester2, M. Torres2, A. Martin-Santiago3, A. Sampol2, M.A. Durán2

1Hematology and Hemotherapy, Fundación de Investigación Sanitaria de las Islas Baleares, Palma de Mallorca, Spain
2Hematology and Hemotherapy, Hospital Universitari Son Espases, Palma de Mallorca, Spain
3Dermatology, Hospital Universitari Son Espases, Palma de Mallorca, Spain

Background: Philadelphia-negative chronic myeloproliferative neoplasms (MPNs) may present chronic dermatological manifestations at the time of diagnosis, as well as during the course of the disease. On the other hand, also its treatments can present skin side effects.

Aims: We have performed a dermatological review of a cohort of patients we follow-up at our center with the aim of assessing the cutaneous manifestations.

Methods: A randomized selection of patients with a diagnosis of essential thrombocythemia and polycythemia vera was performed. We create a specific consultation in which a detailed history of each patient (sex, age, diagnosis, signs and symptoms, treatments and its duration) as well as a deep dermatological examination was done. All data was collected in an Excel database and analyzed using the SPSS system.

Results: 63 patients (54 ET and 9 VP) were reviewed. The most frequent skin lesions were xerosis and/or keratosis pilaris (76.2% patients), nail changes (41.3%), actinic keratosis (39.7%), hyperpigmentation of the skin (23.8%), pruritus (23.8%) and non-melanoma skin cancer (22.2%). In figure 1 we detail all the skin alterations that we have found.

Summary/Conclusions: Cutaneous involvement in MPNs is more frequent than expected and it is usually underdiagnosed. Some of these lesions could be prevented with the correct treatment of their pathology and adequate protective measures. The results obtained support the recommendation of an annual review by a dermatologist in a systematic way, especially in patients with higher risk factors: low phototype, high sun exposure, past dermatological history and prolonged cyto-reductive therapy.

HEMOGLOBIN AND WHITE CELL COUNT IN PATIENTS CLINICALLY SUSPECTED TO HAVE ESSENTIAL THROMBOCYTHEMIA MAY HELP IN PREDICTING EARLY PRIMARY MYELOFIBROSIS OR UNCLASSIFIABLE MYELOPROLIFERATIVE NEOPLASM

S. Sirhan1,*, C. Ross2, A. Orazi3

1Jewish General Hospital Montreal, Montreal, Canada, 2McMaster University, Hamilton, Canada, 3Weill Cornell Medical College, New York, United States

Background: Classification of myeloproliferative neoplasms (MPN) in patients presenting with thrombocytosis can be challenging. Relying only on clinical features may lead to misclassification of patients in the early stages of primary myelofibrosis (PMF) as essential thrombocytosis (ET). Although bone marrow (BM) biopsy examination is the gold standard necessary for accurate classification, in clinical practice it might be helpful to identify among patients with a working diagnosis of ET those most likely to have early PMF or unclassifiable MPN (MPN-U). To this end, Carobbio et al. (Am J Hematol. 2012;87:203-4) developed a simple algorithm based on presence of anemia (hemoglobin <120 g/L for females and <130g/L males) and/or leukocytosis (leukocytes ≥13x10⁹/L) or elevated LDH (>200 mU/mL). For an accurate classification, the clinical and laboratory features need to be correlated with BM findings, thus collaboration between hematologists and pathologists is essential.

Aims: To examine applicability of the Carobbio algorithm in routine practice and its potential use in identifying among patients presenting with thrombocytosis and clinically suspected to have ET, those with early PMF or MPN-U. To identify unmet needs in the diagnosis of MPNs in daily practice upon which further educational initiatives can be built which stress the importance of hematologist-pathologist collaboration.

Methods: A retrospective Personal Practice Assessment Program was conducted at 8 Canadian institutions. Eight hematology/pathology pairs reviewed charts of about 20 consecutive examined patients who presented with thrombocytosis suspected ET or PMF. The first 5 out of 20 cases who met the Carobbio algorithm were selected for BM evaluation. To avoid the impact of treatment and/or natural disease evolution on accurate classification, the requirement was for the BM biopsy to be collected within a year of patient's
presentation with thrombocytosis. No central pathology review was planned for this stage of the study.

Results: A total of 122 patients (58 males and 66 females; 54% >60 years of age; 65% with LDH ≥200 mU/mL) with a clinical history indicative of ET were initially assessed. A majority of patients (76%) presented with suspected ET within the last 5 years, likely because it was more difficult for clinicians to identify patients with SM at biopsy collected within a year of presentation with thrombocytosis if they presented more than 5 years ago. Out of 122 patients, 48 met the hemoglobin and/or leukocyte criteria outlined in the Carobbio algorithm, Figure. The BM examination was performed on 33 patients who met pre-specified criteria for the timing of bone marrow biopsy. About one third of the 33 patients met WHO classification for ET and one third for PMF. While 2 of the remaining patients met criteria for PV, the rest were uncertain whether to represent true ET or early PMF, i.e. represented MPN-U (Figure 1).

Summary/Conclusions: Despite its methodological limitations, this initiative confirms that in real world clinical practice the Carobbio algorithm can be used to identify patients with early PMF and patients clinically suspected to have ET. It suggests a need for educational initiatives on using diagnostic algorithms to separate ET from PMF. It confirms the importance of hematologist-pathologist collaboration in reaching a final integrated diagnosis based on the WHO classification. These findings warrant investigation in larger prospective studies.

E1343

PK/PD MODELING COMPARING DIVIDED DOSING (200mg TWICE-DAILY [BID]) vs SINGLE DOSING (400mg ONCE-DAILY [QD]) OF PACRITINIB (PAC) IN PATIENTS WITH MYELOFIBROSIS (MF) ON THE PERSIST-2 PHASE III STUDY

S. Al-Fayoumi1,*, J. Mascarenhas 2, R. Hoffman3, A.T. Gerds4, B. Weinhandl5, A. Reiter1, N. Cross2
1CTI BioPharma Corp., Seattle, WA, 2Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, 3University of Michigan, Comprehensive Cancer Center, Ann Arbor, MI, 4Cleveland Clinic, Cleveland, OH, 5Northwestern University, Feinberg School of Medicine, Chicago, IL, United States

Background: MF is a life-threatening hematologic malignancy characterized by splenomegaly and debilitating constitutional symptoms. At the present, the JAK inhibitors, ruxolitinib and its only therapeutic option (pts) with MF has garnered regulatory approval. Although ruxolitinib has been shown to reduce splenomegaly and symptoms in pts with MF, it is associated with dose-limiting cytopenias, and not indicated for pts with platelets <50,000/µL. PAC is an oral kinase inhibitor with specificity for JAK2, FLT3, IRAK1, and CSF1R. Using data from preclinical-gene expression studies, population PK modeling and simulations predicted that BID dosing would result in higher steady-state AUC and lower Cmax vs QD dosing, which may be associated with increased efficacy and comparable or improved safety. Thus, the phase 3 PERSIST-2 trial of PAC vs BAT (including ruxolitinib) in pts with MF and platelet counts ≤100,000/µL evaluated both PAC 400mg QD, with numerically lower adverse events (AEs) and a trend for improved survival.

Aims: Validate the clinical utility of PK/PD modeling to select the PAC 200mg BID regimen in pts with MF treated in the PERSIST-2 trial.

Methods: Pts with MF and baseline platelet count ≤100,000/µL were randomized 1:1:1 to PAC 400mg QD, PAC 200mg BID, or BAT. Blood samples were collected from PAC-treated pts for PK and PD analysis at a prespecified subset of trial sites. Blood samples were collected on day 1 of week 1 (4 h post-dose), week 3 (pre-dose and 4 h post-dose), week 12 (pre-dose), and week 24 (pre-dose). At the remaining sites, blood samples were collected from PAC-treated pts for PK analysis only at weeks 12 and 24 (pre-dose). Remaining PK samples were collected up to week 24 from 144 PAC-treated pts (76 BID, 64 QD). The PK of PAC was described by a 2-compartment model with first order absorption, first order elimination from the central compartment, and an absorption lag time. PAC QD was associated with higher Cmax and lower Cmin vs PAC BID (Table). Median PAC plasma concentrations during early phase PAC 400mg QD and PAC 200mg BID were almost identical with Cmin observed at week 3 (coincides with Cmax) was 12% higher with QD vs QD dosing. In an exposure-response analysis, with QD or BID dosing, no trends were detected for a relationship between observed Cminss and death, cardiac death, hemorrhagic death, hemorrhagic events, thrombocytopenia (grade ≥2 or ≥3), anemia (grade ≥2 or ≥3), or gastrointestinal events (any grade, grade ≥2, or ≥3). Eleven (15%) and 13 (17%) PAC QD pts achieved SVR ≥35% and TSS reduction ≥50% at week 24, respectively, vs 16 (22%) and 24 (32%) PAC BID pts. Treatment with PAC BID but not QD showed a trend of increased SVR vs Cminss.

Summary/Conclusions: As predicted by PK modeling and simulations analysis, PAC 400mg QD was associated with higher Cmax and lower Cmin vs PAC 200mg BID in pts with MF from the PERSIST-2 trial. These differences appear to translate into an improved benefit/risk profile of PAC BID vs QD regimens.

E1344

ZMYM2-FLT3 IS A RARE, RECURRENT, CYTOGENICALLY CRYPTIC FUSION IN MYELOID/LYMPHOID NEOPLASMS WITH EOSINOPHILIA THAT IS RESPONSIVE TO FLT3 INHIBITION

M. Jawhari1,*, N. Naumann1, M. Knut2, B. Schneider3, M. Ghazzawi4, K.-A. Kreuzer5, M. Hallek5, A. Fabarius1, J. Score6, A. Chase2, W. Tapper2, A. Reiter1, N. Cross2
1Department of Hematology and Oncology, Medical Faculty Mannheim of University of Heidelberg, Mannheim, Germany, 2Faculty of Medicine, University of Southampton, Southampton, United Kingdom, 3Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany

Background: Myeloid/lymphoid neoplasms with eosinophilia are characterised by diverse tyrosine kinase (TK) fusion genes, many of which can be effectively targeted by small molecule inhibitors. More than 70 TK fusions have been described, most of which are associated with visible cytogenetic abnormalities. However these fusions are rare, and the pathogenesis of the great majority of cases presenting as myeloproliferative neoplasms (MPN-eo) with eosinophilia (MPN-eo) remains unexplained. We hypothesized that some MPN-eo cases may be driven by hitherto undetected cryptic TK fusion genes.

Aims: To screen cases with MPN-eo for TK fusion genes and evaluate the significance of any novel fusions

Methods: PolyA RNA extraction from MPN-eo cases, RNA-Seq library preparation and 100bp paired-end sequencing was performed with multiplexing for a minimum of 75 million reads/sample using an Illumina Hiseq 2000. Bowtie, TopHat and TopHat-Fusion were used to align reads, resolve splice junctions, identify and filter potential TK fusion genes. Confirmation and screening of fusions was performed by RT-PCR and Sanger sequencing.

Results: Of 20 cases tested by RNAseq analysis, just one cryptic TK fusion was identified: ZMYM2-FLT3, predicted to arise as a consequence of an 8Mb inversion at 13q12. Unusually, both breakpoints fell within exons (ZMYM2 exon 20 and FLT3 exon 14, respectively) resulting in an in frame fusion. To test if this might be recurrent, we analysed 105 additional cases by RT-PCR. One additional positive case was detected, with similar but not identical breakpoints to the initial case. Case 1, a 48 year old female, presented with leukocytosis (30x10^9/L), eosinophilia (2x10^9/L, elevated serum tryptase (37µg/l), splenomegaly and a hypercellular bone marrow (BM). Cytogenetics was normal and FIP1L1-PDGFRα, KIT D816V and JAK2 V617F were all negative and no pathogenetically relevant mutations were identified by a myeloid NGS panel (28 genes). After 10 months, she progressed to myeloid blast phase. Because the disease was resistant to AML-induction chemotherapy (FLAG-Ida), an allo-HSCT was performed from an unrelated donor. Following the finding of ZMYM2-FLT3 positivity, treatment with sunitinib was commenced. Blood counts started to improve from day 4 and normalized after 3 weeks. During a pause of 3 weeks due to pulmonary infection, leukocytosis/eosinophilia rapidly increased, but normalization was observed within weeks after restart of sunitinib. The patient has been maintained on sunitinib for 10 months (since re-start) and remains in complete hematologic remission.

Summary/Conclusions: ZMYM2 is the fourth gene reported to fuse to FLT3 in myeloid neoplasms but the first FLT3 fusion that is cytogenetically cryptic. Cancer patients with ZMYM2-FLT3 may be amenable to treatment with FLT3 inhibitors and thus, although very rare, this fusion should be considered in the work up of MPN-eo cases. Due to their extensive diversity, we anticipate that RNAseq will become the method of choice to detect rare TK fusions.

COMPLETE HEMATOLOGIC AND CYTOGENETIC RESPONSE IN A
PATIENT WITH FIBROBLAST GROWTH FACTOR RECEPTOR 1 ACTIVATED
MYELOPROLIFERATIVE NEOPLASM RECEIVING INCB054828
N. Daver1,*, V. Subbiah1, E. Asatiani2, S. Verstovsek1
1MD Anderson Cancer Center, Houston, TX, United States, 2Incyte Europe,
Geneva, Switzerland

Background: Fibroblast Growth Factor Receptor (FGFR) inhibitors have
demonstrated efficacy in solid tumors with FGFR pathway activation.
INCB054828, a novel, highly selective FGFR1, FGFR2, and FGFR3 inhibitor,
is being assessed for the treatment of several advanced malignancies (AACR
2015; Abstract 771). 8p11 myeloproliferative syndrome is an aggressive myeloproliferative neoplasm (MPN) associated with FGFR1 translocation on chromosome 8p11.
Aims: To describe the characteristics of a patient with FGFR1 activated MPN
who achieved a complete hematologic and cytogenetic response with
INCB054828 in an ongoing phase 1/2 trial (NCT02393248)
Methods: In this 3-part, phase 1/2 dose-escalation and expansion trial, eligible
adults had any advanced solid tumor (parts 1 and 3) or malignancy with
FGF/FGFR alteration (part 2), had Eastern Cooperative Oncology Group performance status score ≤1 (part 1) or ≤2 (parts 2 and 3), and were refractory to
prior therapy with no known effective standard therapy available to them.
Patients received INCB054828 orally on a 21-day cycle (2-weeks on/1-week
off) starting at 9mg QD and increasing to 13.5mg QD.
Results: This 51-year-old male patient with 8p11 translocated MPN diagnosis
(currently the only patient with MPN enrolled in this trial), presented with abnormal white blood cell (WBC) count (eosinophils, 15%; peripheral blood [PB]
blasts, 4%) and abnormal platelet count (68×109/L). The patient had prior therapy with hydroxyurea. Bone marrow (BM) biopsy at study entry showed 95%
cellularity, 4% BM blasts, decreased megakaryocytes, t(8,9)(11.2,q33) in 19 of
20 metaphases, and European Myelofibrosis Network grade MF-1. After 6
weeks of treatment with INCB054828 at a dose of 9mg QD in part 2 of the
study, WBC count normalized with disappearance of eosinophilia and PB
blasts. BM biopsy demonstrated a normalization of bone marrow differential
with 50% cellularity, 1% BM blasts, adequate trilineage hematopoiesis, MF-1
fibrosis, and a complete cytogenetic response. After 4 months of treatment
the patient was hospitalized for pneumonia and study treatment was held. The
patient progressed to AML shortly after therapy interruption, with BM blasts
increasing to 83% and evidence of clonal evolution (47,XY: +8 t(8,9) (11.2;q33)
[3]/48 idem, +19 [17]). The patient was taken off study at this time (end of cycle
6) and subsequently achieved a complete remission on intensive chemotherapy
with fludarabine, cytarabine, idarubicin, and allogeneic BM transplantation. The
patient is currently alive and in complete remission.
Summary/Conclusions: INCB054828 showed efficacy in this patient with
FGFR1 activated MPN using a 21-day (2-weeks on/1-week off) regimen. Continuous treatment may be necessary to sustain response and avoid rebound
as has been seen with other kinase inhibitor therapies. A phase 2 trial has
been initiated to evaluate INCB054828 in patients with myeloid/lymphoid neoplasms with FGFR1 rearrangement (NCT03011372).

Maggiore Policlinico Hospital Foundation, 3Department of Clinical Sciences
and Community Health, University of Milan, Milano, Italy

Background: Recently, a detailed grading system for the assessment of bone
marrow stromal changes has been proposed in primary myelofibrosis, proved
to be reproducible and adopted by the updated WHO 2016 classification.
Aims: In this study, we aim to evaluate any possible prognostic implications of
this grading system in a series of patients with primary myelofibrosis.
Methods: The study involved 122 consecutive patients with primary myelofibrosis diagnosed between 1998 and 2015 at the Oncohematology Division of
the Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico of Milan,
for which an adequate bone marrow trephine biopsy (more than 1 cm in length)
performed at the time of first observation was available, together with complete
clinical, laboratory and follow-up data.
Results: Reticulin myelofibrosis (MF), collagen deposition (Co) and osteosclerosis (Ost) were evaluated and graded from 0 to 3 in the bone marrow trephine
biopsies for each patient at diagnosis. In detail, the stromal changes were graded as follows: bone marrow fibrosis: MF-0 in 9 cases, MF-1 in 60, MF-2 in 31
and MF-3 in 22; collagen deposition: Co-0 in 64 cases, Co-1 in 23, Co-2 in 21
and Co-3 in 14; osteosclerosis: Ost-0 in 72 cases, Ost-1 in 24, Ost-2 in 19 and
Ost-3 in 7. Patients’ population was composed of 56 males and 66 females

554 | haematologica | 2017; 102(s2)

(M/F=1/1,2) with a median age at diagnosis of 68 years (range 30–85). Clinically, at presentation, anemia with hemoglobin values less than 10 g/dL was
present in 20 (16%) patients, leukocytosis more than 25 x10 9/L was identifiable
in 4 (3%) patients, and platelets count less than 100 x109/L in 7 (6%) cases.
JAK2V617F mutation was detected in 81 cases (66%). Among the remaining
41 JAK2-negative patients, 4 and 27 carried MPL and CALR mutations, respectively; 10 out of 122 resulted “triple-negative”. According to the International
Prognostic Scoring System, 38 cases were stratified as low risk, 51 as intermediate-1 risk, 21 as intermediate-2 risk, and the remaining 12 as high risk. By
the time of the analysis, 21 (17%) patients had died: leukemic evolution
occurred in 14 (11.5%) patients, whereas thrombotic or hemorrhagic events
occurred in 25 (20.5%). Subsequently, a comprehensive grade of bone marrow
stromal changes ranging from 0 to 9 allows us to distinguish 88 (72%) cases
with low-grade stromal changes (total score: 0-4) and 34 (28%) with high-grade
stromal changes (total score: 5-9). Clinically, patients with high-grade stromal
changes presented more frequently with anemia, thrombocytopenia, leukocytosis, peripheral blood blasts and increased lactate dehydrogenase levels. The
grade of bone marrow stromal changes resulted strictly associated with the
International Prognostic Scoring System and the overall mortality (low-grade:
10 dead out of 88 vs high-grade: 11 dead patients out of 34; p=0.013). Finally,
the grade of bone marrow stromal changes was effective in discriminating the
overall survival of the patients with low-grade and high-grade stromal changes
(Log-Rank test: p=0.0002).
Summary/Conclusions: A detail evaluation of the bone marrow stromal
changes has important prognostic implications and can be used at diagnosis
in the clinical stratification of the patients affected by primary myelofibrosis.
Further studies are needed to test if the prognostic significance of this grading
system remains during the follow-up.
E1347

INCREASED RISK OF INFLAMMATORY BOWEL DISEASE IN PATIENTS
WITH PHILADELPHIA NEGATIVE CHRONIC MYELOPROLIFERATIVE
NEOPLASMS
M. Bak1,*, T. Jess2, E. M. Flachs3, A.-D. Zwisler4, K. Juel5, H. Frederiksen6,7,

5National Institute of Public Health, University of Southern Denmark, Copenhagen, 6Department of Haematology, Odense University Hospital, Odense,
7Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark

Background: Studies reveal that patients with inflammatory bowel disease
(IBD) may have increased risk of haematological cancers. Moreover, Philadelphia negative chronic myeloproliferative neoplasms (MPNs) have previously
been associated with autoimmune diseases, including IBD. Nevertheless, to
our knowledge, the risk of IBD has not been investigated in patients with MPN.
Aims: We undertook a nationwide population-based matched cohort study,
and estimated the risk of IBD in patients with MPN.
Methods: We used valid Danish national registries, covering more than 5 million individuals, and included all patients diagnosed with either essential thrombocythemia (ET), polycythaemia vera (PV), myelofibrosis (MF), or unclassifiable
myeloproliferative neoplasm (MPN-U) between 1994 and 2013. For each
patient, 10 individually age- and sex-matched comparisons were included.
Patients and comparisons were followed until first occurrence of any IBD diagnosis (ulcerative colitis or Crohn’s disease), death, emigration or end of 2013.
Patients and comparisons with prior IBD were excluded from the analysis. Hazard ratios (HRs) between MPN patients and comparisons were estimated using
cox regression models, and used as measure of the relative risk. The risk was
only calculated if five or more individuals were diagnosed with IBD.
Results: Of the 8,210 MPN patients, 80 individuals were diagnosed with IBD
during the study period; including 37 ET patients, 28 PV patients, 1 MF patient
and 14 MPN-U patients. During a total risk time of 45,241 years, the rate of
IBD per 1000 person years at risk was 1.8 (95% confidence interval [95%
CI]:1.4-2.2) for the MPN patients. The corresponding rate for the 81,326 comparisons was 0.8 (95% CI: 0.7-0.8).The 10-year risks of IBD for MPN patients
and comparisons were 0.8% (95% CI: 0.6-1.0) and 0.4% (95% CI: 0.4-0.5),
respectively. The overall HR of IBD was 2.4 (95% CI: 2.1-2.9) for MPN patients,
with HRs of 2.6 (95% CI: 2.1-3.2) for ulcerative colitis and 2.4 (95% CI: 1.73.4) for Crohn’s disease. The risk of IBD was increased 2 to 3 fold among ET,
PV and MPN-U patients, with HRs of 2.8 (95% CI: 2.1-3.7) for ET patients, 2.1
(95% CI: 1.6-2.7) for PV patients and 2.2 (95% CI: 1.3-3.7) for MPN-U patients.
Summary/Conclusions: Patients with MPN are at increased risk of IBD compared to the general population. The absolute risks of IBD are low, but abdominal discomfort may in few patients be caused by underlying IBD.


ESSENTIAL THROMBOCYTHROMIA WITH AQUAGENIC PRURITUS: AN ENTITY WITH MORE AGGRESSIVE CLINICAL AND BIOLOGICAL PROFILE AT THE DIAGNOSIS AND A HIGH MORBIDITY DURING THE FOLLOW-UP
C. Le Gall-Ianotto1,2,*, R. Le Calloch3, L.-M. Mollard4, L. Misery1, J.-C. Ianotto4
1Service dermatologie, CHU Breton - Hôpital Augustin Morvan, 1Laboratory of interactions epithelium-neuromes, university of Brest, Breizh, 2Service Hématologie, CHU, Quimper, 3Service Hématologie, CHU Breton - Hôpital Augustin Morvan, Brest, France

Background: Polycythemia vera (PV) and essential thrombocythemia (ET) are Ph-negative myeloproliferative neoplasms in which arterial or venous thromboses and phenotypic evolutions (leukemia, myelofibrosis) are the most recurrent complications. Aquagenic pruritus (AP), induced by water contact, is a typical symptom of PV. However, we showed recently that ET patients also suffer from AP with clinical characteristics quite different from those observed in PV patients. In 2008, the presence of AP was associated with a lower risk of arterial thrombosis in PV patients.

Aims: It seemed particularly interesting to analyse the clinical relevance and the prevalence of the presence of AP in ET patients for such a risk.

Methods: In this study, we used the OBENE observatory (Observatoire Brestois des NEoplasies myéloprolifératives), a register of MPN patients followed in our University Hospital in which biological and clinical data of 396 ET patients have been collected. This register was approved by a local ethical committee and registered in clinicaltrials.gov (NCT02897297). To avoid masked polycythemia Vera diagnostics, all JAK2 positive cases were tested for isotopic red mass cells if appropriate.

Results: Among 396 ET patients, 42 (10.6%) suffered from AP. Interestingly, the median age of diagnosis of these patients was lower (51.6 vs 63.8%, p<0.0001). Furthermore, they presented more symptoms as erythrocytosis, hyperviscosity, constitutional symptoms and splenomegaly (p<0.01). ET patients with AP were more proliferative (more polycythemic but less thromboctopenic) (0.04 vs 0.01) and were more difficult to treat (2.2 vs 1.1 treatment lines, p=0.005).

Concerning the occurrence of thrombotic events (arterial or venous) at diagnosis, no significant difference between patients with or without AP was found. In contrast, the presence of AP induced an increase of thrombotic events during the follow-up (30.9 vs 17.2%, p=0.03). But surprisingly, these events appeared in the delayed timing. The arterial/venous rate of thrombotic events was also different with 50/50 vs 25/13. Furthermore, we observed that about one-third of the patients with AP had phenotypic evolutions against 13.3% in the other group (p=0.0007): the most frequent evolutions were PV and secondary myelofibrosis (16.7 vs 5.4%, p=0.005 and 19 vs 4.8%, p=0.0003, respectively).

Concerning the overall survival of the patients, we have noted that there was less death in the group with AP than without AP (11.9 vs 32.5%, p=0.006) in spite of a long follow-up (12.1 vs 7.7 years, p=0.002).

Summary/Conclusions: AP is classically associated to PV. But we confirmed here that AP is also present in ET. Furthermore, ET patients suffering from AP were more proliferative, more symptomatic at diagnosis but also had higher risk of thromboses and phenotypic evolutions than ET without AP. Despite that, these patients have a higher overall survival. So, the presence of AP in ET characterizes patients with high risk of morbidity (thromboses, phenotypic evolutions). So as in PV, the presence of AP in ET patients at the time of diagnosis should be systematically identified.

ANAGRELIDE RESPONSE ACCORDING TO THE MOLECULAR PROFILE: SOMETHING TO CONCLUDE ON THE MECHANISM OF ACTION OF THE DRUG IN MYELOPROLIFERATIVE NEOPLASMS (MPN)?
M. Montero1, T. Knight1, M. Dominguez1, E. Camillo1, F. Marquez1, V. Escamilla1, P. Guererro1, M. Suito1, A. Blum1, N. Alkadi1, J. González1, J. Falantes1, N. Rodriguez1, M. Martin1, I. Espigado1, J. Pérez-Simón1
1Haematology and haemotherapy Service, Hospital Universitario Virgen del Rocio, Sevilla, Spain

Background: Anagrelide is a useful drug in the control of thrombocytosis in MPN. Although it is known that in therapeutic levels it primarily influences in the post-mitotic phase of megakaryocytic development interfering with its complete maturation, its mechanism of action is still unknown.

Aims: The progress in the diagnosis of MPN due to the discovery of driver mutations (JAK2, calreticulin and MPL) leads us in the present study to correlate them with the response to anagrelide in a group of patients treated with this drug, investigating the possible interference in the referred biological pathways.

Methods: Anagrelide treatments in patients with MPN diagnosed in our centre between 1993 and 2015 were studied. The median age was 49 years, with 19 patients older than 60 years. 83% were female and 17% were male. The diagnosis was initially carried out based on the WHO criteria 2008 and subsequently reviewed the medical records with the new criteria of 2016. A molecular study on peripheral blood samples was carried out using quantitative allele-specific PCR technology for JAK2, qualitative for MPL (L515V mutation) and Sanger sequencing of exon 9 for calreticulin. Type 1 mutation was considered at 52 bp deletion and type 2 at 5 bp insertion. In all patients, the goal of anagrelide therapy was to control thrombocytosis (platelet count below 600x10e9/L), with dosage within the range of efficacy and safety recommended in the datasheet. The results were analysed with the statistical software SPSS vs 15.0

Results: 80.5% of the patients were diagnosed with ET, 12.5% of PV, 3.5% of myelofibrosis and 3.3% of unclassifiable MPN. 59% of the patients had a V617F JAK2 mutation, with allelic load higher than 20% in 47.5% of the cases. 28.3% presented mutation in calreticulin; of which 50% were type 1 and 50% type 2. Only one patient had a mutation in MPL (2%), the remaining 6% being classified as “triple negative”. The median daily dose of anagrelide received was 1.5mg. 17.5% of the patients required more than 2mg for an adequate control, half of them being positive for mutations in calreticulin and the other 50% of the mutation V617F JAK2 with allelic load higher than 20%. 26% of the patients received daily dose of 1mg, being 70% positive for the mutation V617F JAK2 with allelic load lower than 20%, although there were no statistically significant differences between the groups according to the mutational profile. 16% of patients discontinued treatment due to toxicity, with the most common adverse effects being mild (headache and palpitations).

Summary/Conclusions: Patients requiring higher doses of anagrelide present mutations in calreticulin or JAK2 V617F allelic load higher than 20% and patients with lower allelic load having greater sensitivity to the drug, with no statistically significant differences. It is possible that the first situation is associated with a greater pro-mitotic deregulation in the megakaryocyte where the drug does not interfere whereas the second one could be related to anagrelide interference through the JAK2 pathway in post mitotic maturation although larger exploratory studies are required.

THE DELAYED DIAGNOSIS OF PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS (MPN) IS COMMON AND RESULTS IN A HIGH INCIDENCE OF POTENTIALLY PREVENTABLE THROMBOTIC COMPLICATIONS
C. Forsyth1, C. Tiley2, B. Wylie2, M. Dean2, T. Armitage3, K. Melville2, K. Melville1
1Medicine, Wyong Hospital, Kanwal, 2Haematology, Gosford Hospital, Gosford, Australia

Background: Ph-negative MPNs are a heterogeneous group of stem cell derived, clonal bone marrow disorders characterised by increased production of mature blood cells. Patients with MPNs are at significantly increased risk of thrombotic and haemorrhagic complications which are a major cause of morbidity and mortality. The early diagnosis and treatment of MPN may reduce the incidence of thrombotic complications and the associated morbidity and mortality.

Aims: We performed a study to determine if the delayed-diagnosis of MPN was common and the implications of any such delay.

Methods: The medical records of patients treated at our centre with a new diagnosis of MPN between January 2010 and June 2016 were audited. We determined the duration from first appearance of a full blood count (FBC) abnormality to the diagnosis of MPN until the time of formal diagnosis. The occurrence of any thrombotic or haemorrhagic complications during this time was recorded.

Results: 143 patients were diagnosed with MPN; 35 with polycythaemia vera, 79 with essential thrombocythaemia, 25 with primary myelofibrosis and 13 with MPN-unclassifiable. Patients with PV had a mean diagnosis delay of 156 days (range 0-2650 days) and 26% had potentially preventable events. Patients with ET had median diagnosis delay of 823 days (range 0-8731 days) and 23% had potentially preventable thrombotic events including 2 patients with multiple events. Patients with PMF had a median diagnosis delay of 196 days (range 0-3684 days) and 12% had potentially preventable thrombotic events. In MPN-U the median diagnosis delay was 1371 days (range 42-3255) and 31% of patients had potentially preventable adverse events.

Summary/Conclusions: Over 5.5 years we identified 143 patients with a new diagnosis of Ph-negative MPN within our centre. The overall median diagnosis delay was 723 days (0-8731) with delays of more than 12 months in ET, PV and MPN-U, and more than 6 months in PMF. 21% of patients had potentially preventable thrombotic events and 2.8% had potentially preventable haemorrhagic events. Earlier recognition of FBC abnormalities consistent with MPN at an earlier stage in patients’ management, if possible, with earlier intervention, would be expected to prevent many thrombo-haemorrhagic complications and reduce MPN-associated morbidity and mortality.
(starting dose of 14mg/week up to obtain the complete hematological response 
(CHR) is associated with high risk of leukemic transformation and second malignancies. 

**Aims:** We analysed efficacy, toxicity, risk of Myelofibrosis (MF) and leukemic 
evolution in 31 of 352 ET pts collected in our database, treated with an alter-
native long-term schedule of BU, defined by low-starting dose (4-6mg/week) 
up to CHR (evaluated according to ELN response criteria), followed by dose 
de-escalation overtime.

**Methods:** Non parametric tests, such as Mann-Whitney, Pearson Chi-square 
and Fischer’s exact tests, were used for statistical analysis of continuous and 
categorical variables. Survival curves were calculated by Kaplan-Meier method 
and compared with Log-rank (Mantel-Cox) test.

**Results:** 27/31 pts were evaluable for analysis (8 male, 19 female). Median 
age at diagnosis and at BU start were 71.3 and 79 years (yrs) respectively. We 
found these driver mutations: JAK2V617F in 15 pts (55.6%), Calreticulin in 8 
pts (29.8%) and MPL in 1 patient (3.7%); 3 pts (11.1%) were triple negative. 
IPSET score at diagnosis was low-intermediate in 17 (63%) and high in 10 
(37%) pts. 26 pts started BU as 2nd line treatment: 11 (42.3%) were intolerant 
and 15 (57.7%) were resistant to HU respectively. Only one received BU as 1st 
line treatment. They received BU for a median time of 47.67 months (range: 
1.48 – 94.42). The median cumulative BU dose was 453mg (range: 32-1032).
22/27 pts (81.5%) obtained CHR, after a median time of 191 days. 6 pts (22,2%) 
presented hematological (5) and extra-hematological (1, cutaneous) side 
effects. Overall, 12 pts (44.4%) stopped BU: 4 for hematological toxicity, 4 for 
disease progression, 2 for drug intolerance/resistance; the remaining 2 not for 
drug-related side effects. After a median follow-up of 9.74 yrs (range: 1.82-
27.05), 9 (33.3%) and 2 (7.4%) pts presented MF evolution and leukemic 
transformation respectively. The MF-free-survival (MFS) was 48.8% at 15 yrs and 
appears to be significantly lower than the entire series of ET pts (77.4% at 15 
 yrs; p=0.002; figure 1). Median MFS was 12.7 yrs for pts treated with BU, 
whereas it was not reached at 15 yrs in the entire series of ET. There were no 
statistically significant differences in principal hematological and clinical features 
between “evolving-MF pts” and “not evolving-MF pts”, apart from lower hemo-
globin value at BU start (11,5 vs 13,05 g/dl; p=0,05) and lower time of exposition 
 to BU in MF subgroup (16 vs 53,7 months; p=0,026). Drug cumulative dose 
was the same in the two subgroups. Thrombotic complication after BU start 
were observed in 3 pts (11,1%). During time of analysis 5 pts (18,5%) died.

**Summary/Conclusions:** Our experience with an alternative long-term and 
low-dose BU administration is safe and effective in elderly patients with ET. 
92.5% of them obtained CHR, with acceptable hematological and extra-hema-
tological toxicity. We noticed a high rate of MF evolution with respect to global 
ET population, while the risk of leukemic transformation seems to be limited, 
considering that these pts were elderly and previously treated. Predictive factors 
for MF evolution should be analysed and confirmed in larger series.

PROTECTION AGAINST DEVELOPMENT OF B CELL LYMPHOMA BY TETRASPANIN CD37
C. de Windt1, S. Veenbergen1, K. Young2, M. van den Brand1, A. van der Schaaf1, S. Elfrink1, H. van Krieken1, C. Figdor1, S. van Deventer1, B. Scheijen1, A. Van Spriel1,2
1Radboud University Medical Center, Nijmegen, Netherlands, 2M D Anderson Cancer Center, Houston, United States

Background: B cell non-Hodgkin lymphoma, worldwide the most common hematological malignancy, remains a clinical problem. The molecular events leading to B cell lymphoma are only partially defined. CD37 is a member of the tetranspan superfamily that is highly expressed on mature B cells and is required for optimal GC function and long-lived antibody production.

Aims: We investigated the function of tetranspan CD37 in the development of B cell lymphoma.

Methods: A combination of studies was performed in mouse models (CD37/IL-6-deficient mice), and studies of DLBCL patient material using biochemical, immunological, genetic and microscopical approaches.

Results: We provide evidence that deficiency of CD37 induces the development of B cell lymphoma in vivo. Cd37-deficient mice develop germinal center-derived B cell lymphoma in lymph nodes and spleen with higher incidence than Bcl2-transgenic mice. We discovered that CD37 interacts with SOCS3, and when absent drives tumor development through constitutive activation of the IL-6 signaling pathway. The importance of the IL-6 pathway was highlighted by investigating Cd37xIl6 double knock-out strains that were fully protected against lymphoma development. Our unpublished data shows discovery of inactivating CD37 mutations in patients with DLBCL. Importantly, loss of CD37 on neoplastic cells in patients with diffuse large B cell lymphoma (DLBCL) is directly correlated with activation of the IL-6 signaling pathway and with worse progression-free and overall survival.

Figure 1

Summary/Conclusions: Together, this study identifies tetranspan CD37 as a novel tumor suppressor that directly protects against B cell lymphomagenesis, and provides a strong rationale for blocking the IL-6 pathway in patients with CD37-negative B cell malignancies as therapeutic intervention.

CONCOMITANT DUAL ABLATION OF BLIMP1 AND P53 IN B-CELLS AS A NOVEL IN VIVO MODEL FOR HIGH-GRADE B-CELL LYMPHOMA
A. Sacco1, Y. Kawano2, M. Moschetta3, J. Park1, O. Zavidij3, B. Scheijen1, A. Van Spriel1
1Radboud University Medical Center, Nijmegen, Netherlands, 2M D Anderson Cancer Center, Houston, United States, 3German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: B-Lymphocyte-Induced Maturation Protein-1 (BLIMP1)- and p53-inactivation contributes to the pathogenesis of a wide spectrum of malignancies, including large B-cell lymphomas. Nevertheless, there is lack of in vivo models that may be used for a better understanding of the biology and genomics of high-grade B-cell lymphomas characterized by dual loss of both BLIMP1- and p53.

Aims: 1) To develop and characterize a transgenic mouse model of BLIMP1-/p53- dual loss in B cells. 2) To provide an in vivo model that mirrors human ABC-DLBCL phenotype.

Methods: Cre recombinase under the control of CD19 promoter (C57BL/6 CD19Cre) were crossed with either C57BL/6 BLIMPflox/flox or C57BL/6 Cre recombinase under the control of CD19 promoter (C57BL/6 ABC-DLBCL phenotype.

Aims: 1) To develop and characterize a transgenic mouse model of BLIMP- and p53-deficient B-cell lymphomas. 2) To establish a systemic lymphoma model that mirrors human ABC-DLBCL phenotype.

Methods: We investigated the function of tetranspan CD37 in the development of B cell lymphoma. Aims: We investigated the function of tetranspan CD37 in the development of B cell lymphoma. Results: We provide evidence that deficiency of CD37 induces the development of B cell lymphoma in vivo. IDENTIFICATION AND CHARACTERISATION OF THE LYMPHOMA INITIATING CELL (LIC) POPULATION IN AN ALCL MOUSE MODEL
S. Kreutmaier1, C. Klinkenberg1, G. Andrieux2, A. Keller1, C. Miething1, D. Pfeifer1, M. Follo1, H. Busch2, M. Boerries2, J. Duyster1,2, A. Ilbert1,2,3
1Hematology, Oncology and Stem Cell Transplantation, University medical center Freiburg, 2Institute of Molecular Medicine and Cell Research, Freiburg, 3German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: In 60% of anaplastic large cell lymphoma (ALCL) patients a t(2;5) (p23;q35) is found, which results in NPM-ALK fusion gene expression and constitutive activation of the ALK tyrosine kinase. Immunophenotypic characterization of human ALCLs revealed highly CD30-positive cells of T- or Null-cell-origin.

Aims: However, the origin of the lymphoma initiating cell population as well as NPM-ALK signal transduction in course of the disease remains unclear and needs to be characterized.

Methods: In this regard, we established a retroviral murine bone marrow transplantation model resembling human ALCL. Therefore we use an inducible Cre/IoxP system where NPM-ALK expression is restricted to early T-cells. We infected bone marrow of Lac-Cre transgenic mice with our MSCV-Stop-NPM-ALK/ires-EGFP vector and transplanted into nulliparous irradiated CD3-/- mice. With a latency of 4-5 months, mice developed CD30-positive lymphomas and died from neoplastic T-cell infiltration of lymphatic organs and bone marrow.

Results: Immunophenotypic analysis confirmed T-cell origin of the lymphomas with a heterogenous combination of all T-cell stages with mainly CD4-/CD8- double negative (DN) T-cells including all DN T-cell subpopulations as well as hematopoietic stem cells and lymphatic precursors. Staining of the T-cell sub-populations demonstrated high NPM-ALK expression in immature CD4-/CD8- double negative T-cells and undifferentiated CD4+/CD8+ double positive T-cells with highest expression of proliferation marker Ki67 as well as the activation marker CD25. A novel cell subset, comprising CD4-/CD8- double negative lymphoma population further more abnormally expressed the T-cell receptor alpha/beta chain, which may allow these early T-cells to establish a systemic lymphoma. To further proof this hypothesis and identify the LIC population we performed secondary transplantsations with sorted DN and CD4/CD8 T-cells from CD19/Bl-/p53- derived lymphomas. DN and CD4/CD8 T-cells from CD19/Bl-/p53- derived lymphomas could give rise to secondary lymphomas, whereas sorted DN1, DN2, CD4+, CD8+ or CD4+CD8+ transplanted lymphoma cells failed to established serial lymphomas in recipient mice. Immunophenotypic analyses of secondary lymphomas caused by transplantation of the DN3 and DN4 lymphoma cells, which were positive CD4+ and CD8+, as well as positive CD4+ and CD8+ cells next to the DN3/DN4 population. However, we were not able to detect rederifferentiation of the DN3/DN4 cells to more immature DN1/DN2 lymphoma cells. To substantiate our findings, we performed microar-
Figure 1.
Aims: Here, we aim to recapitulate MCL in a mouse model of hematopoietic-specific overexpression of cyclin D2. Next, we want to use this preclinical mouse model to evaluate novel therapeutic strategies for the treatment of MCL.

Methods: To evaluate if cyclin D2 could act as a bona fide oncogene in the pathogenesis of MCL, we developed a conditional R26-driven Ccnd2 overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the Ccnd2 gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs using recombinase-mediated cassette exchange (RMCE).

Results: The resulting R26-Ccnd2 mice were crossed to VavCre mice to enable biallelic R26-driven overexpression of Cyclin D2 in the entire hematopoietic system. Interestingly, these mice developed large lymphomas starting from 36 weeks of age (Figure 1A), with tumor cells showing characteristic MCL immunophenotype (CD19+, CD5+, CD23-). Of note, these malignant B-cells were monomorphic small-sized cells with slightly irregular hyperchromatic nuclei and disseminated into other organs such liver, spleen and the gastrointestinal tract (Figure 1B). The infiltrating MCL cells contained SOX11 positive, as evaluated by IHC, suggesting that these tumors indeed reflect a murine form of MCL. Noteworthy, the MCL cells from this mouse model also contain a luciferase reporter, allowing accurate in vivo tracing of tumor cells in xenograft experiments. These xenograft experiments can be used as preclinical models, in which bioluminescence is used to assess the tumor burden and to monitor tumor regression upon drug treatment.

Summary/Conclusions: In conclusion, our preliminary data suggest that modeling cyclin D2 in mice, mimicking the elevated cyclin D2 levels of human MCL patients with transllocations involving the CCND2 locus, is sufficient to form MCL.

CARD11 DUPLICATION AT DIAGNOSIS IDENTIFIES VERY LOW-RISK MANTLE CELL LYMPHOMA PATIENTS: RESULTS OF THE LYMA GENOMIC PROJECT CONDUCTED ON BEHALF OF THE LYSA GROUP

Background: Mantle cell lymphoma (MCL) is an incurable heterogeneous disease with a median overall survival (OS) of around 4-6 years. There are 3 prognostic groups of patients: a high-risk (HR) group of 15-20% of patients having a median OS of 3-5 years, a low-risk (LR) group of 60-70% with an OS of around 7-8 years, and an intermediate risk (IG) group that includes patients remaining in response one year after EOT but with an incidence of relapse of 10-15%/yr thereafter, other patients defining the low-risk (LR) group remain in response three years at least. The MIPI score (age, leukocytosis, PS, stage) helps to classify patients according to their risk of relapse but it is not currently possible to treat patients according to risk factors. Investigation of the MCL genomic landscape could help to understand MCL biology complexity and build biology-driven medical decisions.

Aims: In the present work, we report a whole-genome copy number analysis performed with OncoScan® FFPE Assay, a new robust and validated single nucleotide polymorphism (SNP) array (Foster et al. BMC Med Genomics 2015). We investigated the prognostic value of somatic recurrent copy number alterations (CNA) detected in 96 young MCL patients treated in the LyMa trial (Le Gouill et al. Abstract 145, ASH 2016).

Methods: Samples were selected according to material availability. Lymph node biopsies collected at diagnosis, formalin-fixed and paraffin-embedded were used to extract DNA, usable even when highly degraded since the OncoScan® FFPE Assay is optimized for highly degraded FFPE samples. Whole-genome copy number profiling was analyzed with 50 ng of genomic DNA. TuScan algorithm (Afymetrix) was used to analyze data. The frequency and prognosis impact of CNAs were evaluated with univariate analysis of survival data.

Results: Characteristics of the 96 patients were as follow: median age 57y (41-65), 82% of males, MIPI-low/intermediate/high respectively 19%, 51% and 30%, blastoid morphology in 10%. No significant difference was observed between these patients and the LyMa patients (n=299). Among the 96 patients, 9 were HR patients with primary refractory disease or early relapse within one year post-diagnosis while 87 patients remained in response more than one year after diagnosis (including 64 LR patients who were still in complete remission more than 30 months after diagnosis). After ASCT, 41 patients (43%) were randomized in the rituximab maintenance arm and 40 (42%) in the observational arm. Median follow-up from EOT was 71 months (1.4-83.2). Overall, 68 recurrently altered regions were observed in 98% of patients. Deletions were more frequent than amplifications, at 9 vs 3 by patient respectively. HR patients were associated with TP53del (44%vs14%;p=.04), CDKN2A/CDKN2Bdel (56%vs22%;p=.04), 8p11del (44%vs15%;p=.05). Interestingly, we identified in 0 patients a duplication of a minimal common region of 5.3 Mb located on chromosome 7p22 and including CARD11. This lesion was associated with low MIPI (80%vs12%;p<.001), and other gains such as 21q21, 10q11 and 6p21 which together define a favorable subgroup (24% of the cohort). These anomalies were significantly linked to a better OS (HR:0.30; p=.02).

None of the patients with CARD11 duplication (n=10) had relapsed despite the presence of TP53 in 2 patients or CDKN2A deletion in 3 patients. This translates into a longer PFS (100%vs70%;p=.02) (fig.).

Figure 1.

Summary/Conclusions: Our study confirms the worse impact of TP53 and CDKN2A deletion on early relapse in MCL. By contrast, the CARD11 duplication
is associated with an absence of relapse and thus defines a new group of very low risk patients. These findings provide important clues for future theranostic-driven therapies in MCL.

CLINICOBIOLICAL FEATURES OF B-CELL NEOPLASMS WITH CDK6 TRANSLOCATIONS: FREQUENT ASSOCIATION WITH MARGINAL-ZONE LYMPHOMA, CONTINGENT OF PROLYMPHOCYTIC CELLS AND TP53 ABNORMALITIES. A GFCH STUDY

1Laboratoire de genetique, Hopital Robert Debre, Reims, 2Service d’Hematologie, Hopital Robert Debre, Reims, 3UNIVERSITE PIERRE ET MARIE CURIE, Paris, 4Laboratoire de Cyrogénétique, CHU Dijon, Dijon, 5Laboratoire de Cytogénétique, Institut Universitaire du Cancer de Toulouse, Toulouse, 6Laboratoire de Cyrogénétique Oncohématologique, CHU Grenoble, Grenoble, 7Laboratoire de Cyrogénétique, CHU CAREMEAU, Nimes, 8Laboratoire de Cyrogénétique Onco-Hematologique, Hopital Timone, Marseille, 9Laboratoire de Groupe Francophone de Cytogenetique Hematologique (GFCH), 10Laboratoire de genetique, Hopital Pitié-Salpetrière, AP-HP, PARIS, 11Laboratoire d’Hematologie, Hopital Robert Debre, Reims, 12Laboratoire de Cyrogénétique, CHU Dijon, Dijon, 13Laboratoire de Cytogénétique, Hopital Necker – Enfants Malades, APHP, Paris, France

Background: Translation involving the CDK6 gene is a rare but recurrent abnormality in B-cell neoplasms. Three different translations have been described: t(2;7)(p11;q21), which is the most frequent, (t(7;14)(q21;q32) and (t(7;11)(q32;p11)), leading to juxtaposition of CDK6 gene with IGK, IGH or IGL locus respectively.

Aims: The Groupe Francophone de Cyrogénétique Hematologique (GFCH) collected 35 chronic B-cell disorders with CDK6 translocations in order to document the clinicalbiological features of this uncommon aberration.

Methods: Clinical and biological data were gathered prospectively at the time of diagnosis when available. A cytological review was performed by 3 experts in 27/35 cases. FISH analysis for CDK6 was performed by real-time AS PCR.

Results: Our cohort included 22 M and 13 F, with a median age of 71 years. The involvement of CDK6 was confirmed in all cases. A t(2;7) IGK/CDK6 was found in 33/35 patients. One case had a t(7;14) IGH/CDK6, and one had a t(7;14)(q21;q11) involving the TRAD locus. There were 23 (66%) marginal-zone lymphoma (MZL), including 22 splenic MZL (SMZL) (including the t(7;14) TRAD), and 1 bronchus MALT type, 7 (20%) unclassified small B-cell lymphomas (USBCL) and 5 (14%) chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) with Matutes score 4/5 (including the t(7;14) IGH). Morphological and molecular review showed a contingent of prolymphocytes (median: 10%), 12/23 (52%) had abnormalities of the BCR signalling cascade by tamoxifen.

Background: NR4A1 (Nurr77) belongs together with NR4A2 (Nur1) and NR4A3 (NOR-1) to the Nurr77 family of nuclear orphan receptors. As immediate early- or stress response genes their expression is diverse as is the cellular outcome upon activation. Recently, there has been attributed a pivotal role to NR4A1 and NR4A3 as tumor suppressors in AML in humans and mice. In our comprehensive NR4A4 expression analysis in various lymphoma entities we demonstrated a significant reduction of NR4A1 expression in aggressive lymphomas, which was associated with poor cancer-specific survival. Moreover, ectopic expression of NR4A1 in aggressive lymphoma cells resulted in induction of apoptosis.

Aims: In order to better dissect the role of NR4a1 in lymphoid malignancies, we used a Myc-driven mouse model of lymphomagenesis and crossed the EµMyc mouse with the Nr4a1−/− mouse. Survival and tumor formation were monitored and QO-PCR was performed on selected tumor specimens, whereby genes, found to be associated with NR4A1 expression in the publicly available gene expression data set of DLBCLs generated by Lenz et al., were taken. Moreover, the driver-function of Nr4a1 in lymphomagenesis at the premalignant stage was investigated by using apoptotic assays and by carrying out transplantations of tumor cells into wt recipients.

Methods: Kaplan Meier analysis was performed for survival and tumor formation in EµMyc Nr4a1+/− (n=154), EµMyc Nr4a1−/− (n=54) and EµMyc Nr4a1−/− (n=56), respectively. For QO-PCR selected tumor specimens from wt and EµMyc mice with (n=14) and without (n=17) Nr4a1 loss were used. For investigation of the role of Nr4a1 at the premalignant stage, mice aged 4 weeks (n=4 per genotype) were sacrificed and AnnexinV staining and cleaved-caspase3 assay were performed on cells isolated from the spleen and bone marrow. In vivo, driver-function of Nr4a1 in lymphomagenesis at the premalignant stage was confirmed by using Nr4a1−/− mice (n=8) and EµMyc Nr4a1−/− (n=11) mice injected into the tail vein of wt mice. Kaplan Meier analysis was used for monitoring survival and tumor formation, and FACS analysis for analysis of bone marrow, spleen and tumor, respectively.

Results: EµMyc Nr4a1−/− mice showed decreased survival with a median of 92 days compared to EµMyc Nr4a1+/− with median survival of 123 days (p<0.001) and tumors developed faster with a median of 45 days for EµMyc Nr4a1−/−, vs 107 days for EµMyc Nr4a1+/−; p<0.001. Both, survival (median=101 days; p=0.037) and tumor formation (median=66 days; p=0.001) gave intermediate values for EµMyc Nr4a1−/+ mice. Furthermore, EµMyc Nr4a1−/− showed a more substantial response rates to rapamycin and analogs. Kaplan Meier analysis was performed for survival and tumor formation in EµMyc Nr4a1+/− mice (n=14) and without (n=17) Nr4a1 loss were used. For investigation of the role of Nr4a1 at the premalignant stage, mice aged 4 weeks (n=4 per genotype) were sacrificed and AnnexinV staining and cleaved-caspase3 assay were performed on cells isolated from the spleen and bone marrow. In vivo, driver-function of Nr4a1 in lymphomagenesis at the premalignant stage was confirmed by using Nr4a1−/− mice (n=8) and EµMyc Nr4a1−/− (n=11) mice injected into the tail vein of wt mice. Kaplan Meier analysis was used for monitoring survival and tumor formation, and FACS analysis for analysis of bone marrow, spleen and tumor, respectively.

Summary/Conclusions: Our results clearly demonstrate the influence of Nr4a1 loss on tumor formation and consequently survival in a Myc-driven model of lymphomagenesis. Importantly, Nr4a1−/− seems to impact cell death early in B cell development, even ahead of malignant transformation. Additionally, Nr4a1 seems to be involved in driving immune responses towards an anti-inflammation, tolerogenic phenotype, thereby facilitating tumor growth and in altering the tumor environment. Collectively, these data underpin the tumor suppressive function of Nr4a1 in aggressive lymphomas.

DISSECTING THE PI3K PATHWAY IN A CYCLIN D1-DRIVEN MODEL OF MCL
S. Ehrenfeld1,2,3,4,*, J. Mitschke1, P. Veratti1,2,3, K. Shoumariyeh1, D. Schneider1,2,3,4, C. Miething1,2,3
1Department of Medicine I: Hematology, Oncology, and Stem-Cell Transplantation, Medical Center, University Freiburg, 2German Cancer Consortium (DKTK) Partnersite Freiburg, Freiburg, 3German Cancer Research Center (DKFZ), Heidelberg, 4Faculty of Biology, University Freiburg, Freiburg, Germany

Background: Mantle cell lymphoma (MCL) presents as a highly disseminated B-Cell malignancy, accounting for about 6% of all Hodgkin lymphomas. Genetically, MCL is characterized by the t(11;14)(q13;q32) translocation, leading to the overexpression of the cell cycle regulator Cyclin D1. The disease is associated with a poor prognosis and can be treated with conventional chemotherapy and biological agents such as lenalidomide. However, the mechanisms of resistance remain largely unexplored.

Aims: The aim of this study is to functionally dissect the role of individual PI3K and mTOR pathway genes by performing a shRNA-based screen in genetically defined primary murine MCL tumors. Hereby, we want to identify synthetic lethal genes for Cyclin D1 and novel molecular dependencies in Cyclin D1-driven lymphomagenesis, thereby establishing novel potential therapeutic targets in MCL.

Methods: We have developed a new mouse model for MCL using Eµ-myc transgene mice that overexpress the MCL hallmark lesion Cyclin D1, as well as the reverse tet transactivator for inducible transgene expression. Using primary MCL tumor cell lines derived from this model as a platform, we performed shRNA loss-of-function screen entailing a two colored, antibiotic selectable and tet-inducible retroviral shRNA expression vector system. A shRNA library targeting more than 300 different PI3K related genes was introduced into primary murine MCL cells. After induction of shRNA expression by addition of Dox, shRNA representation in knockdown and control cells was deconvoluted by deep sequencing to identify differentially selected shRNAs. The shRNA screen identified more than 50 (>=4 fold) differentially regulated genes affecting MCL tumor growth and survival. We identified numerous targets within the PI3K pathway and the molecular dependency on this pathway was in line with the observed high sensitivity of these cells towards pharmacological mTOR inhibitor. Individual shRNA knockdown experiments confirmed the newly identified candidate genes including components of the lipid second messenger system, such as diacylglycerol kinase isoform alpha (DGkα) and gamma (DGkγ). Knockdown of these lipid kinases by three or two different hairpins lead to decreased cell proliferation. DGkα knockdown was further validated on protein level by Western Blot analysis. Furthermore, additional newly identified candidate genes will be further explored to characterize their role in Cyclin D1-driven lymphomagenesis, with the aim of identifying novel therapeutic targets in this difficult-to-treat disease.

MUTATIONAL PROFILING OF HODGKIN- AND REED-STERNBERG CELLS (HRSC) OF CLASSICAL HODGKIN LYMPHOMA (CHL) ENRICHED FROM ARCHIVAL FORMALIN-FIXED AND PARAFFIN-EMBEDDED TISSUE SAMPLES
D. Juskevicius1,2*, D. Jucker1, T. Dietsche1, V. Perrina1, C. Ruiz1, S. Dimhofer1, A. Tzankov1
1Institute of Pathology, University Hospital Basel, Basel, Switzerland

Background: CHL can be cured in the majority of cases. However, 10–20% patients die of the lymphoma after relapse or progressive disease. There are unmet needs for understanding the mechanisms that cause CHL relapses, for development of new prognostic/predictive markers and effective targeted therapies. Comprehensive genetic characterization and advance in understanding of CHL molecular pathways are key steps to effective targeted treatment. However, genetic information on CHL is still scarce mainly due to difficulties of isolating malignant HRSC, whose overall frequencies in the affected tissues range from 0.1-5%. Formalin-fixed paraffin-embedded (FFPE) tissue archives are the most abundant source of clinically annotated tumor specimens. However, FFPE tissue quality is limited because of poor DNA quality and difficulty to enrich neoplastic cells. Therefore, new enrichment techniques are necessary to enable larger scale comprehensive genetic investigations of CHL.

Aims: Our aims were: 1) to develop a technique for HRSC enrichment from the archival formalin-fixed paraffin embedded tissue; 2) to reliably detect genetic aberrations in the genomes of enriched tumor samples and to use this information for development of new prognostic and predictive markers as well as for better understanding of the genetic background of CHL.

Methods: We have developed a new high-throughput method for marker-based enrichment of archival FFPE tissue-derived HRSC nuclei by fluorescence-assisted cellular sorting (FACS). Genomic DNA extracted from sorted nuclei was used for identification of mutations in 68 genes that are frequently mutated in lymphomas by targeted high throughput sequencing (HTS). Chromosomal copy number aberrations were investigated by the Agilent SurePrint 180k microarray.

Results: Enzymatically extracted FFPE tissue-derived cell nuclei retain their DNA integrity and can be used with morphology and cytogenetic markers to identify mutations in genes like PUM1, PAX5 and cytoplasmic/cell surface (CD30) markers. A mean neoplastic cell purity of 70% (range 40-95%) was achieved by sorting HRSC cells according to their double expression of PUM1 and CD30 in 11 CHL cases. Using sorted non-malignant cells as a germline control we detected somatic single nucleotide mutations and indels in all investigated samples. Mutations of STAT6, PIM1, SOCS1, KMT2D occurred in at least 18% (2/11) of cases. Additionally, individual cases contained copy number aberrations such as gain of chr2 (CREL locus), focal deletions of chr4, chr7, chr16 and chr19 affecting genes such as ZAK3, CDK2ND2, MAP2K3 and NOTCH3. Taken together our study demonstrates that enrichment of DNA extracted from the enriched cell populations is suitable for wide-scale genetic profiling.

Summary/Conclusions: A novel rare-cell-enrichment technique is suitable for genetic CHL studies and opens the possibility for the wider use of archived
LACK OF STAT1 PREDISPOSES TO A DIFFUSE LARGE B-CELL LYMPHOMA-LIKE DISEASE

Background: The highly conserved JAK-STAT signaling pathway regulates proliferation, differentiation, apoptosis and immune responses. Activating mutations in STAT3 are considered to drive the development of diffuse large B-cell lymphomas (DLBCL). STAT1 is a critical counter player of STAT3. Of note, many STAT1 target genes are frequently altered or mutated in DLBCL patients, such as SOCS-1, B2M, PDL1, CARD11, CIITA and BCL6. We observed that the loss of STAT1 suffices to provoke spontaneous haematopoietic tumours in mice.

Aims: We aimed at investigating the underlying mechanisms of spontaneous hematopoietic tumor formation in STAT1-deficient mice.

Methods: We characterized the spontaneous haematopoietic tumors by FACS and morphological analysis. To identify the cell of origin for the disease, we performed bone marrow transplantation assays. We high-purity FACS-sorted individual cell populations of diseased STAT1−/− mice and transplanted them into recipient mice. Ex vivo and in vitro assays were used to characterize for lineage-specific surface marker expression and identified as B-cells. Malignant B-lymphoid STAT1−/− deficient cell lines were established and expression levels of typical lymphoid-specific tumor-suppressor and promoter genes were assessed by qPCR.

In parallel, Stat1−/− cell lines were used for RNA-seq analysis to identify the signaling pathways driving disease. RNA-seq data were compared to publicly available RNA-seq data from different hematological malignancies.

Results: STAT1−/− deficient mice develop a myeloid hyperplasia that manifests with an incidence of 60% and is characterized by the absence of Rigit Transplantation of bone marrow unmasked the development of a B-cell malignancy, which can be transferred by CD19+ cells. The malignant B-cells arising in Stat1−/− mice can be maintained in vitro and display alterations in gene expression that are typically found in human DLBCL such as IRF4, Prdm1 and p53. RNA-seq analysis revealed features shared with human DLBCL: increased reads a local heterozygous B2m, Metf2h, Card11 and Cd274 (PDL1) and decreased expression of Socs-1, Cdkn1a, B2m and Prdm1. Low levels of Stat1 expression in DLBCL combined with low levels of p16INK4A correlate with a reduced life expectancy in DLBCL patients.

Summary/Conclusions: Loss of STAT1 in B cells of mice provokes a myeloid hyperplasia which mimics a B-cell malignancy resembling human DLBCL. DLBCL patients with low levels of STAT1 have a poorer prognosis if they lack the tumor suppressor p16INK4A.

MOLECULAR HETEROGENEITY OF MANTLE CELL LYMPHOMA

Background: Mantle cell lymphoma (MCL) is a B-cell non-Hodgkin lymphoma characterized by t(11;14), (q13;q32) leading to constitutive cyclin D1 overexpression and cell cycle deregulation. The survival is still poor, especially for patients resistant to frontline drugs. Although patients are brought in remission, relapses often occur with disseminated lymphoma, which is more difficult to treat. There is a need for a better understanding of the clonal heterogeneity of this disease and to identify novel signaling pathways with genes which could be targeted by novel drugs or be used as biomarkers to predict response to treatment.

Aims: To address the genetic heterogeneity in MCL in paired patient samples at diagnosis and relapse.

Methods: Highly pure malignant B-cell populations were isolated using fluorescence activated cell sorting in four patients diagnosed with MCL. In addition T-cells were sorted from the same patients as paired non-malignant control samples. RNA-seq was performed on both the malignant B-cell population and pair T-cells (13 samples in total). Mutations were detected in parallel with CLC Biomedical Workbench 2.5 (Qiagen) and MuTect 1.04 (Broad Institute) (coverage ≥ 20, population allele frequency<0.01) and evaluated against the COSMIC (Wellcome Trust Sanger Institute), dbSNP and PubMed databases. Exclusion from informed consent was approved by the National Ethical Committee.

Results: Our data highlighted in each patient persistent gene modifications between diagnosis and relapse. We confirmed gene mutations already well-known in B-cell malignancies (e.g. TPS3, NOTCH1 and MV2D8). Interestingly, aberrations not previously described in the COSMIC database, were observed with high allele frequency both at diagnosis and at relapse. This included genes in B-cell signaling (e.g. transcriptional repressor SPEN associated to NOTCH pathway regulation and blockage of the precursor B-cell differentiation), inflammatory response (e.g. IRF1), genes found in invasive carcinoma (e.g. integrin β4 subunit) or with a role in the extracellular matrix (e.g. B3GAT1) and genes which could be targeted by oncoprotein mutations or hit in putative drivers, new gene modifications as well as loss of previous ones could be observed at relapse. For example, genes involved in embryonic development and cell fate (e.g. the transcription factor SOX1) and genes involved in inflammation (CCL13) were not previously correlated to MCL and were novel at relapse. This suggests that a modified malignant clone has evolved and progressed. No gene modification was observed to be shared by all four patients. However, aberrations in the same signaling pathways were identified across individuals. From allele frequency distribution detected with MuTect we could detect discrete clonal or competing subclonal involvement: A patient harbored one major discrete clone at diagnosis while at relapse two additional minor clones were detected, whereas another patient presented a diffuse clonal pattern at diagnosis and a more discrete biclonal pattern at relapse.

Summary/Conclusions: Our work shows examples of molecular progression from diagnosis to relapse in MCL and supports the heterogenic nature and genetic complexity of this disease. We confirm mutations in genes already known as involved in the disease progression, however of such techniques is the need for exogenously produced tagged proteins. Diffuse large B-cell lymphoma (DLCBL) patients with low levels of Stat1 have a poorer prognosis if they lack the tumor suppressor p16INK4A.
imimal conditions we found that a number of the captured genes corresponded to experimentally validated targets of miR-155. Crucially, ontology analysis of the PAR-CLIP-captured genes demonstrated an enrichment of genes involved in haematopoietic and/or lymphomagenesis pathways.

**Summary/Conclusions:** To fully understand the role of a particular miRNA in a specific malignancy, it is essential to identify its target genes in a relevant cellular context. Using a haematopoietic malignancy model of high clinical interest we have developed an optimised method for interrogating the miRNA:mRNA interface (targetome) within a cellular system without the need of ectopically expressed Ago2, keeping physiological levels of the core component of the RISC complex unaffected. Moreover, our optimized protocol allowed us to reduce the number of input cells, thereby opening the exciting possibility of interrogating the targetome of patient primary samples.

**DARATUMUMAB, A NOVEL HUMAN CD38 MONOCLONAL ANTIBODY FOR THE TREATMENT OF B-CELL NON-HODGKIN LYMPHOMA**

A. Matas-Céspedes1,2, A. Vidal-Crespo3, V. Rodríguez1, C. Ross1,2, G. Roué1, A. López-Guillermo3, E. Giné3, A. Wiestere1, C. Bezonm2, E. Campo2, D. Colomer2, S. Balasubramanian5, C. Chui6, P. Doshi6, P. Pérez-Galán1

1Hematology-Oncology, IDIBAPS, Barcelona, Spain, 2Hematology-Oncology, Centre de Recherche en Cancérologie de Toulouse (CRCt), Toulouse, France, 3Hematology-Oncology, Hospital Clinic, Barcelona, Spain, 4R&D, Janssen, Spring House, PA, USA

**Background:** Daratumumab (DARA) is a first-in-class human monoclonal antibody that targets the CD38 epitope and is approved for the treatment of relapsed/refractory (R/R) multiple myeloma (MM) patients. DARA is currently being evaluated in phase II clinical trials as monotherapy in patients with R/R Mantle Cell Lymphoma (MCL), Follicular Lymphoma (FL) and Diffuse Large B-Cell Lymphoma (DLBCL).

**Aims:** We tested DARA activity and modulation of the enzymatic activity of CD38 in two different mouse models (sc and iv) of Mantle Cell Lymphoma (MCL), Follicular Lymphoma (FL) and Diffuse Large B-Cell Lymphoma (DLBCL).

**Methods:** DARA activity was assessed using calcein release or flow cytometry. Penetration of DARA was analyzed in a 3D model by Selective Plane illumination Microscopy (SPIM). Molecules per cell were analyzed using Qifikit and flow cytometry.

**Results:** DARA (0.0001–1µg/mL) induced ADCC in a dose-response manner on MCL (n=6) and FL (n=4) cell lines in the presence of PBMCs. However, DARA did not induce significant CDC in any of these models due to a high density of CD59. DARA induced significant reduction of CDC in MCL (n=6) and FL (n=4) cell lines in the presence of murine macrophages in vitro. DARA did not induce significant CDC in any of these models due to a high expression of the complement inhibitors CD46, CD55 and CD59, and insufficient number of CD38 molecules per cell. In a 3D model of FL, SPIM analysis revealed a maximum penetration of DARA at 1µg/mL after 48h of treatment. We tested DARA activity in vivo in two different mouse models (sc and iv) of MCL and FL. In the prolymphocytic setting, DARA completely prevented the outgrowth and induced tumor regression of MCL (n=6) and FL (n=6) subcutaneous tumors. In the therapeutic setting, DARA significantly increased the overall survival time of mice and reduced organ infiltration of tumor cells both in the MCL (n=10) and in the FL (n=10) systemic xenograft models. In addition, the combination of DARA with Rituximab/CHOP regimen in FL resulted in a synergistic reduction of tumor growth (n=7-10).

**Summary/Conclusions:** DARA shows encouraging cytotoxic activity in MCL and FL cells and is effective as single agent on MCL and FL tumor cell growth in different mouse models and contributes to potent therapeutic efficacy in combination with current approved therapies. These results warrant further studies of DARA in the clinical setting for these conditions.

**ECTONUCLEOTIDASES CD39/CD73 ARE HIGHLY EXPRESSED ON ATLL CELLS AND RESPONSIBLE FOR GENERATING AMP/ADENOSINE**

Y. Nagate1,2, S. Ezeo1, J. Fujita1, M. Ichi1, J. Toda1, K. Oritani1, Y. Kanakura1

1Hematology and Oncology, Osaka University Graduate School of Medicine, Suita, Japan

**Background:** Adult T-cell leukemia/lymphoma (ATLL) is a mature T-cell neoplasm, linked to the human T-cell lymphotropic virus, HTLV-1. Patients with ATLL are often at the risk of opportunistic infections. It might be possible that the immunocompromised state could be induced by the function of ATLL cells having similar phenotypes with regulatory T cells (Tregs). However, difficulties of in vitro studies using primary tumor cells have hampered the progress of ATLL research, and it is still controversial whether ATLL tumor cells have the immunosuppressive characteristics.

**Aims:** In this study, we analyzed the roles of molecules expressed in ATLL cells associated with immunosuppressive functions of Tregs.

**Methods:** The protocol of this study was approved by the Investigative Review Board of Osaka University Hospital. Peripheral blood mononuclear cells (PBMCs) were collected from 8 asymptomatic HTLV-1 carriers and 20 ATLL patients (3 with smoldering type, 5 with chronic type, and 12 with acute type) after getting informed consent. PBMCs from 3 ATLL patients were separated into CD4+CD7-CADM1+ ATLL cells and adjacent CD4+ CD7+CADM1+ normal T cells using Fluorescence-activated Cell Sorter (FACS), and total RNA sequencing experiments were conducted. And we also examined the expression patterns of CD39 and CD73 in ATLL patients or carriers of each type of ATLL.

**Results:** We compared whole transcriptome of ATLL cells and normal CD4+ cells. Bioinformative analyses showed that many genes associated with immunosuppressive functions of Tregs were elevated or downregulated in ATLL cells. Among these genes we focused on CD39, CD73 and CD26, because recently it has been reported that extracellular adenosine, which is catalyzed by CD39, expressed in human Tregs, and CD73, expressed in murine but not in human Tregs, has strong anti-inflammatory function and plays major role in Treg-mediated immunosuppression. Therefore, we investigated the expression of CD39 and CD73 in ATLL cell lines and primary tumor cells. We found that all of 4 ATLL cell lines expressed CD39, but not CD73 just as human effector Tregs. In contrast, the expression patterns of CD39 in 20 ATLL patients were various (Table) and interestingly, some ATLL tumor cells express CD73. Also in asymptomatic carriers, we could detect CD39 and/or CD73 positive on CD7+CADM1+abnormal fraction of CD4+ cells. CD26, expressed in human naive but not in effector Tregs, was negative in all cell lines and primary cells except for abnormal cells in one smoldering patient. Next, the role of CD39 and/or CD73 in ATLL cells was assessed. Extracellular ATP is converted into AMP by CD39. As expected, CD39+ ATLL cells converted significantly more ATP than CD39+ ATL cells, which was not evident in normal CD4+. CD39+ ATP hydrolysis was extremely very low; less than 10% of mAMP was converted to adenosine by CD73+ ATL cells, indicating that the aberrant expression of CD73 could not efficiently increase adenosine synthesis.

**Table 1.**

<table>

</table>

**Summary/Conclusions:** In this study, we showed that about two thirds of ATLL samples were CD39+CD26+ just as effector Tregs and have comparable level of ATPase activity as Tregs, which are expected to play some immunosuppressive function in ATL patients. Recently it is also reported that in exhausted CD8+ T cells in cancer patients, CD39 is co-expressed with PD-1. CD39 expression in ATLL cells may also have some roles in immunosuppression and thus in the escape from anti-tumor immunity.

**ACTIVATION OF SYK TYROSINE KINASE INHIBITORE PLAYS A ROLE IN RESISTANCE AGAINST THE SELECTIVE BTK INHIBITOR ONO/GS-4059 IN DIFFUSE LARGE B CELL LYMPHOMA (DLBCL)**

K. Tsukamoto1,2, W. Harriet S.1,2,3, J. Sandrine1,3, M. J. Dyer1,2,3

1Cancer studies, 2Molecular and Cell Biology, 3The Ernest Waudby and Helen Scott Haematological Research Institute, University of Leicester, Leicester, United Kingdom

**Background:** Syk, a tyrosine kinase, is activated by B-cell receptor (BCR) and is implicated in the survival of lymphoid cells in haematopoietic and/or lymphomagenesis pathways. Syk is also involved in the development of experimental lymphoid malignancies. Syk siRNA treatment of T-cell acute lymphoblastic leukemia (T-ALL) cells reduces colony formation of cells and apoptosis induction in these cells. Syk inhibition by ibrutinib, a BTK inhibitor, increases the apoptosis induction of T-ALL cells. Furthermore, BTK is overexpressed in T-ALL cells. Therefore, we hypothesized that Syk is involved in the resistance of T-ALL cells to BTK inhibition. In this study, we investigated the roles of Syk in the resistance to BTK inhibition in T-ALL cells.

**Aims:** The B-cell receptor (BCR) pathway is implicated in the survival of B-cell acute lymphoblastic leukemia (B-ALL) cells. BTK is involved in the activation of Syk, and Syk inhibition by ibrutinib, a BTK inhibitor, increases the apoptosis induction of T-ALL cells. Therefore, we hypothesized that Syk is involved in the resistance of T-ALL cells to BTK inhibition. In this study, we investigated the roles of Syk in the resistance to BTK inhibition in T-ALL cells.

**Methods:** We established T-ALL cell lines (K562, B-ALL) and a T-ALL cell line (K562) expressing Syk in the T-ALL cell line (K562). K562 cells were treated with ibrutinib, a BTK inhibitor, at various concentrations. After 24 hours, cell viability was assessed by flow cytometry. The role of Syk in the resistance to BTK inhibition in T-ALL cells was examined using a Syk inhibitor (Bicalutinib).

**Results:** Syk inhibition by Bicalutinib (1µM) increased apoptosis induction of T-ALL cells (K562) treated with ibrutinib (1µM). In contrast, Syk inhibition by Bicalutinib (1µM) increased apoptosis induction of T-ALL cells (K562) treated with ibrutinib (1µM).

**Summary/Conclusions:** In this study, we showed that about two thirds of ATLL samples were CD39+CD26+ just as effector Tregs and have comparable level of ATPase activity as Tregs, which are expected to play some immunosuppressive function in ATL patients. Recently it is also reported that in exhausted CD8+ T cells in cancer patients, CD39 is co-expressed with PD-1. CD39 expression in ATLL cells may also have some roles in immunosuppression and thus in the escape from anti-tumor immunity.
and proliferation of several B-cell malignancies. BTK is a key regulator of this pathway. In a preliminary clinical study, the selective BTK inhibitor ORG-4059 showed therapeutic activity in relapsed/refractory DLBCL of the Activated B-cell phenotype (ABC-DLBCL) (Walter et al Blood 127 pp411-419, 2016). However, median treatment duration in ABC-DLBCL was only 3 months due to progressive disease and development of resistance. Two acquired resistant mutations, R665W and R665H, have been reported as dominant resistance mechanisms to BTK inhibition in CLL but resistance mechanisms in DLBCL have not been fully elucidated.

Aims: To determine resistance mechanisms in the ABC-DLBCL TMD8 cell line and determine new rational combinations to take into the clinic with ORG/OS-4059.

Methods: The BTK insensitive ABC-DLBCL cell line TMD8 was cloned ORG/OS-4059 and Ibrutinib resistant TMD8 cell lines (TMD8RO and TMD8RI) were used for this study. TMD8RO has PLCγ2 R665W whilst TMD8RI lacks both BTK C481S and PLCγ2 R665W. Cell viability and apoptosis after compound treatment were assessed using Cell Titer Glo assay and Annexin V FITC staining. Western blotting was used to assess normalized protein expression of immunoreceptor were assessed by immunoblot and Flow cytometry. The mutational status of BTK and PLCγ2 in TMD8 was determined by Sanger sequencing.

Results: ORG/OS-4059 induced apoptosis in TMD8 at nanomolar concentrations. The combination of ORG/OS-4059 induced rapid reduction in ERK and AKT activation, induction of ERK and AKT recombined within 24 hours in surviving cells. Interestingly, surface immunoglobulin M (sigM) expression was increased more than three times in these cells leading to subsequent activation of SYK. The specific SYK inhibitor, SB-953 combined with ORG/OS-4059 inhibited the downstream ERK and AKT reactivation and induced synergistic apoptosis in TMD8. On the other hand, SYK hyper-activation as determined by phosphorylation of SYK and its downstream target BLNK was also observed in the two BTK inhibitor resistant cell lines. Additionally, expression of CDS and CD22, which negatively regulates BCR signaling, was decreased in these cells. The combination of ORG/OS-4059 and GS-9973 restored sensitivity to ORG/OS-4059 and induced synergistic apoptosis in both resistance cell lines.

Summary/Conclusions: These data show that SYK is highly activated through increased sigM expression and/or downregulated CDS and CD22 following BTK inhibitor treatment in ABC-DLBCL. These changes may contribute not only the development but also the maintenance of resistance to BTK inhibitor. The combination of ORG/OS-4059 with SYK inhibitor is therefore a rational strategy for preventing and overcoming BTK inhibitor resistances.

STRO-001, A NOVEL ANTI-CD74 ANTIBODY DRUG CONJUGATE (ADC) FOR TREATMENT OF B-CELL NON-HODGKIN’S LYMPHOMA (NHL)

A. Yu1, C. Abrahams1, M. Embry1, X. Li2, V. DeAlmeida1, J. Lee1, S. Matheny1, T. Kline1, A. Yam1, R. Stafford1, T. Hallam1, M. Lusher1, A. Molina1,

1Sutro Biopharma, South San Francisco, United States

Background: CD74 is a type II transmembrane glycoprotein involved in the formation and transport of MHC class II protein. CD74 is rapidly internalized and highly expressed in many B-cell malignancies with limited expression in normal tissues (Stein R et al., CCR 2007). STRO-001 is a novel CD74-targeting ADC for the treatment of B-cell non-Hodgkin’s lymphoma (B-NHL). The ADC was efficiently sensitive.

Aims: The aim of this study was to assess the benefit of more sensitive techniques, i.e. immunophenotyping by flow cytometry (FCM) and clonality by PCR, in the diagnosis of leptomeningeal disease in patients with suspected leptomeningeal dissemination.

Methods: This study was conducted on 326 CSF samples (236 patients) referred to our laboratory between January 2015 and December 2016. CM, FCM and PCR results were recorded and classified as positive (+), negative (-) or insufficiently sensitive (±). Cytospin examination (CM) is still considered as the “gold standard” but remains insufficiently sensitive.

Aims: The aim of our study was to assess the benefit of more sensitive techniques, i.e. immunophenotyping by flow cytometry (FCM) and clonality by PCR, in the diagnosis of leptomeningeal dissemination (LD) in NHL cell lines and anti-tumor activity in NHL xenograft models, including prolonged survival in the disseminated Mino MCL model. STRO-001 depletes B cells in a dose-dependent manner. Clinical studies of this novel ADC for treatment of B-cell malignancies are under development.

DETECTING MALIGNANT B-CELLS IN CEREBROSPINAL FLUID: DOES THE IDEAL METHOD EXIST?

J. Osman1, S. Tarif1, M. Armand1, C. Houiller2, S. Choquet3, H. Aynego1, H. Strub1, P. Bonneyre1, K. Hoang-Xuan2, M. Le Garff-Tavernier1,1, M. Costopoulos1, F. Davi1

1Biological Haematology Department, Neuro-Oncology, 3Clinical Haematology, Pitié-Salpetrière Hospital, Paris, France

Background: Leptomeningeal dissemination (LD) is a relatively rare but often fatal complication of lymphomas, confirmed by the analysis of the cerebrospinal fluid (CSF). The diagnosis is suspected in case of neurological symptoms, parenchymal brain involvement detected with neuroimaging techniques and the absence of the analitic files does not confirm (CSF). Cytological examination (CM) is still considered as the “gold standard” but remains insufficiently sensitive.

Aims: The aim of our study was to assess the benefit of more sensitive techniques, i.e. immunophenotyping by flow cytometry (FCM) and clonality by PCR, in the diagnosis of leptomeningeal dissemination (LD) in NHL cell lines and anti-tumor activity in NHL xenograft models, including prolonged survival in the disseminated Mino MCL model. STRO-001 depletes B cells in a dose-dependent manner. Clinical studies of this novel ADC for treatment of B-cell malignancies are under development.
formed following the BIOMED-2 design and protocol. All PCR experiments were done in duplicates, and cases were considered PCR+ when both duplicates showed the same clonal pattern, ruling out false positivity (pseudoclonal pattern) often seen in paucicellular samples.

Results: We confirm that FCM and PCR are more sensitive than CM. Indeed, every CM+ cases (n= 16) was also FCM+ and/or PCR+, while 13 cases were FCM+ and/or PCR+ but CM-. A total of 269 samples showed similar results by FCM and PCR with presence (n=22) or absence (n=247) of lymphomatous cells whereas 25 samples were classified as suspicious by at least one technique. Eleven samples were FCM+ but PCR-. False negative (FN) PCR results can be explained in part by extensive somatic mutation in IG genes, preventing optimal amplification of the targeted gene. In contrast, the levels of other targets less prone to somatic mutations, such as IGL, should therefore be evaluated. Conversely, 21 samples were PCR+ but FCM-. Absence of FCM detection might have resulted from the presence of very large lymphomatous cells outside the scope of analysis. Also, rapid cell death is an issue with FCM (preventing optimal amplification of the targeted gene). In contrast, molecular techniques do not systematically require intact cells. Most of the difficulties encountered with both methods are due to occult blood contamination and poor cellularity, leading to low-intensity clonal signals by PCR and inconsistent cluster of events with FCM. In addition discordant results between FCM and PCR might be explained by sampling heterogeneity. Considering these limitations, it seems highly advisable to choose the best suited method for the follow-up according to the results at diagnosis.

Summary/Conclusions: Our results suggest that a multimodal investigation using FCM and PCR is necessary for improved detection of leptomeningeal dissemination in B-cell malignancies. It seems premature to make clinical decisions based on a single technology. Both methods, which suffer limitations that need to be acknowledged, are complementary and should be performed at diagnosis. Specific limitations of each of them should be taken in consideration for follow-up studies.

E1376
THE SYK INHIBITOR R406 DRAMATICALLY INCREASES THE SENSITIVITY OF GCB AND ABC DLBL CEL LINES TO THE BCL-2 INHIBITOR VENETOCLAX
B. Sasi1,*, S. Turkaj1, D. Efremov1
1Molecular Hematology, International Centre for Genetic Engineering & Biotechnology, Trieste, Italy

Background: The BCL-2 inhibitor venetoclax demonstrated significant single-agent activity in recent clinical trials of relapsed/refractory chronic lymphocytic leukemia (CLL). However, results in some other B-cell malignancies characterized by BCL-2 overexpression have not been equally impressive. This particularly refers to diffuse large B cell lymphoma (DLBCL), where only 18% of patients responded to treatment with venetoclax in a recent phase I clinical trial (Davids MS et al, J Clin Oncol. 2017).

Aims: To investigate whether the SYK inhibitor R406 can increase sensitivity of DLBCL to venetoclax.

Methods: The following cell lines were used: Ly4, Ly7, Ly18, DHL4, Toledo and BJAB (all GCB DLBCL) and U2932, DHL2, Ly3, Ly10, HBL1 and TMD8 (all ABC DLBCL). The percentage of apoptotic cells was determined by Annexin V/FITC-PE and propidium iodide (PI) staining. Expression of BCL-2 family members was determined by immunoblotting or RQ-PCR analysis.

Results: In a recent study, we showed that MCL-1 increases the resistance of anti-IGM stimulated CLL cells to venetoclax, and that SYK inhibitors can effectively overcome this resistance by blocking B cell receptor (BCR)-mediated MCL-1 upregulation (Bojarczuk K et al. Blood. 2016). Since constitutive activation of the BCR pathway has been described in both ABC and GCB DLBCL (Davis RE et al, Nature 2010; Chen L et al, Cancer Cell. 2013), we investigated whether treatment with the SYK inhibitor R406 can sensitize DLBCL cells to venetoclax. Single-agent venetoclax had only modest activity against most DLBCL cell lines at concentrations ranging up to 0.25 μM (Figure 1). Substantial apoptosis induction (>20%) was observed in only 2 GCB (Ly1 and Ly18) and 2 ABC (U2932 and Ly10) cell lines. R406 as single agent had almost no effect on tumor cell viability, with only one cell line showing >20% apoptosis induction (HBL1). However, addition of R406 to venetoclax resulted in a dramatic increase in the percentage of apoptotic cells in six of the investigated cell lines (Ly18, DHL4, U2932, Ly10, HBL1 and TMD8). A synergistic effect was also observed with Ly1 using a lower concentration of venetoclax, whereas no effect or only a minimal additive effect was observed in the remaining cell lines (Ly4, Ly7, Toledo, BJAB, DHL2 and Ly3). Among these, only Toledo expressed similar levels of MCL-1 to the other investigated cell lines whereas the levels of BCL-2 in the other cell lines were extremely low or undetectable. To understand the mechanisms how R406 increases the sensitivity of DLBCL cells to venetoclax, we evaluated changes in the expression of MCL-1 and other antiapoptotic BCL-2 family proteins that have been associated with venetoclax resistance. Five of the seven R406 + venetoclax sensitive cell lines (Ly1, DHL4, U2932, HBL1 and TMD8) showed a 20-45% reduction in MCL-1 levels following 24 hours culture with 2μM R406, whereas no changes were observed in Ly18 and Ly10. However, a substantial reduction in A1 levels was observed in Ly18 and U2932 cells, whereas no substantial changes in A1 and BCL-2L1 expression were detected in any of the other investigated cell lines. Finally, we also investigated the effects of R406 on expression of HRK, which is a propapoptotic BCL-2 family member that was recently shown to be induced by SYK inhibition in a subset of GCB DLBCLs (Chen L et al, Cancer Cell. 2013). A substantial increase in HRK expression (140-640%) was observed in 5 of the 7 R406 + venetoclax sensitive cell lines (Ly1, Ly18, DHL4, U2932 and TMD8).

Figure 1.

Summary/Conclusions: These data show that the SYK inhibitor R406 can significantly increase the sensitivity to venetoclax in the vast majority of BCL-2 positive DLBL cell lines. The mechanisms of action require further investigation, but are likely to involve downregulation of MCL-1 and upregulation of HRK in a substantial proportion of cases.

E1376
VB EXPRESSION ASSESSMENT AND CLONALITY DETECTION IN T-CELL PROLYMPHOCYTIC LEUKEMIA (T-PLL) BY FLOW CYTOMETRY (FCM) AND NEXT GENERATION SEQUENCING (NGS): A COMPARISON OF BOTH METHODS
M. Kotrović1,2, M. Nováková2,3, S. Oberbeck3, P. Mayer3, A. Schrader3, H. Knechtle2, M. Herling3, M. Brüggemann2
1contributed equally, 2Medical Department II, Unit for Hematological Diagnostics, University Hospital Schleswig-Holstein, Kiel, 3Dept. of Medicine I, Cologne University, Cologne, Germany

Background: VB repertoire analysis can distinguish monoclonal from polyclonal (reactive) T-cell proliferations. The molecular quantification of clonal T-cell receptor (TR) gene rearrangements can also be used to record minimal residual disease (MRD) in T-cell malignancies. TR clonality can either be assessed by FCM employing VB antibody panels covering ~70% of the normal human TR VB repertoire or by molecular techniques like NGS with primers that amplify virtually all possible VB-JB rearrangements. T-PLL is the most common mature (post-thymic) T-cell leukemia. Clonal TR gene rearrangements are detected in virtually all T-PLL by FCM or PCR from peripheral blood (PB) or bone marrow samples.

Aims: To compare the results of parallel TRB-based clonality analyses by FCM and NGS in T-PLL.

Methods: We investigated diagnostic PB leukocytes of 73 T-PLL patients with median lymphocytes at 66% (range 13-93; harboring T-cells at 97% (55-100)). FCM of surface (not intracellular) VB expression was assessed by the IOTest Beta Mark kit (Beckman Coulter). Libraries for NGS were prepared using 100ng of DNA via a 2-step PCR and sequenced on the Illumina MiSeq (2x250bp, v2) with a median coverage of 17,908 reads (range 1,125–41,193/sample). In the first PCR TRB rearrangements were amplified using TRB BIOMED-2 V- and J-segment primers (van Dongen et al, Leukemia 2003). In the second PCR step, sequencing adaptors and sample-specific barcodes were added. Annotation of V-, D- and J-regions of TRB sequences was done using ARRest/Interrogate (Bystry et al, Bioinformatics 2016).

Results: In all samples one or two dominant clonal TRB rearrangements were detected by NGS and represented in median by 83% of reads (range 15-90%). FCM of surface (not intracellular) VB expression was assessed by the IOTest Beta Mark kit (Beckman Coulter). Libraries for NGS were prepared using 100ng of DNA via a 2-step PCR and sequenced on the Illumina MiSeq (2x250bp, v2) with a median coverage of 17,908 reads (range 1,125–41,193/sample). In the first PCR TRB rearrangements were amplified using TRB BIOMED-2 V- and J-segment primers (van Dongen et al, Leukemia 2003). In the second PCR step, sequencing adaptors and sample-specific barcodes were added. Annotation of V-, D- and J-regions of TRB sequences was done using ARRest/Interrogate (Bystry et al, Bioinformatics 2016).

Results: In all samples one or two dominant clonal TR rearrangements were detected by NGS and represented in median by 83% of reads (range 15-90%). In 36/73 (49%) of these cases, also FCM demonstrated clonality. Interestingly, in 8/36 (22%) of cases the dominant VB by FCM differed from the molecular clonotype. In 5 of these cases the discrepancy was most likely accountable to a non-functional TRB clone detected by NGS corresponding to a bi-allelic TRB rearrangement with the second non-functional allele being preferentially identified by NGS. In 37/73 (51%) of cases no reaction with any of the VB antibodies was seen. In 16 (43%) of these cases this could be attributed to expression of a TRB rearrangement for which the appropriate VB antibody was not present in the FCM panel. In another 12 (33%) of these cases a non-productive TRB rearrangement represented the dominant NGS clonotype. However, in further cases (24%), the functional TRB clonotype (TRBV 5-5, 6-5, 25-1, 18-20-1, 27) was not detected by FCM despite theoretical coverage. Of note, overall 10/73 T-PLL (14%) lacked surface TRα/β chain expression. Summary/Conclusions: T-cell clonality is detected by TRB NGS in all T-PLL, whereas FCM-based VB repertoire analysis identifies a dominant single VB
domain expression in only 49%. A substantial proportion of such failures of FCM-based clonality detection can be best explained by lost surface TR expres-
son and the limited coverage of the Vβ antibody panel. NGS-based clonality
analysis can overcome these limitations, because it detects virtually all TR
Vβ-JB rearrangements. On the contrary, NGS is more sensitive and therefore
enables the detection of minor subclones, which has great appeal for MRD
analysis. Nevertheless, flow cytometric Vβ spectratyping is a faster, cheaper,
and less labourious alternative. It has the additional advantage of detecting
the actual TR Vβ chain expression and of visualizing individual T-cell subsets
for quantification of Vβ cell populations.

**IRF4 EXPRESSION IS ASSOCIATED WITH RESPONSE OF MANTLE CELL Lymphoma TO BRUTON’S TYROSINE KINASE INHIBITORS**

H. P. Thompson1, 2, D. L. Tucker2, S. A. Rule1, 2, C. V. Hutchinson1, 2

1Institute of Translational and Stratified Medicine, Plymouth University, Penin-
sula Schools of Medicine and Dentistry. 2Clinical Haematology, Plymouth Hos-
pitals NHS Trust, Derriford Hospital, Plymouth, United Kingdom

**Background:** Mantle cell lymphoma (MCL) responds poorly to conventional chemotherapy. Inhibitors of Bruton’s tyrosine kinase (BTKi) have unexpectedly shown significant clinical effect; however despite this success, approximately one third of MCL patients have primary resistance to the drug, and patients who initially respond to treatment frequently acquire secondary resistance and aggressive relapse of the disease. Understanding how BTKi-resistance or sen-
sitivity is mediated can identify new targets for therapy or predictive biomarkers of response. Using an in vitro model system we have identified the transcription factor IRF4 as a sensitive indicator for BTKi response in MCL cell lines and pri-
mary cells.

**Aims:** To identify molecules or pathways responsible for resistance to BTKi drugs in mantle cell lymphoma using cell line models and primary cells.

**Methods:** Primary cells and validated MCL cell lines (REC-1, G519, JEKO-1, JVM2) were cultured either alone, or together with murine stromal cells (with or without CD40L transfection). The BTKi sensitive REC-1 cell line was continu-
ously treated with BTKi to generate an acquired resistance model. Cultures were treated with BTKi drugs: ibrutinib or acalabrutinib in the presence or absence of B-cell receptor or CD40L stimulation, and their sensitivity or resist-
ance to treatment was determined using flow cytometry to assess proliferation (Ki67), apoptosis (Annexin-V), or phosphorylation of BTK (pY223). Changes in downstream targets were determined by protein expression or phos-
phorylation analysis (immunoblotting) and by mRNA expression (RT PCR).

**Results:** Each MCL cell line showed basal phosphorylation of BTK (Y223) and its downstream effector molecule ERK1/2 (Y204/187); in each case phosphory-
ation was prevented by BTKi. Of the cell lines tested however, only REC-1 cells showed growth inhibition by BTKi (ibrutinib and acalabrutinib), demonstrat-
ing both dose-dependent apoptosis (p<0.01) and inhibition of proliferation. Further investigation showed that only the BTKi-sensitive REC-1 cell line down-
regulated IRF4 in response to BTKi; this downregulation was an early and spec-
ific response (mRNA downregulated after 4 hours, and protein expression after 8 hours). Furthermore in REC-1 cells with acquired partial resistance to
BTKi, the downregulation of IRF4 was significantly less than in the parental

cell line. Finally in vitro co-culture of REC-1 cells with CD40L prevented IRF4 downregulation, which indicated the involvement of CD40L in IRF4
expression. Both IRF4 downregulation and protection of the cells from BTKi-induced death. These findings were confirmed using ex vivo samples from treated patients (n=7) analysed before and during BTKi treatment. IRF4 was downregulated in 6 samples from patients shown to be clinically responding to BTKi and was not downregulated in 1 refractory case.

**Summary/Conclusions:** IRF4 downregulation in lymphoma cells following BTKi treatment is an early and specific response that can predict response to BTKi treatment. This study reveals a novel pathway during IRF4-dri-
genesis that may be a biomarker for BTKi-sensitivity in MCL, and that proteins modulated by IRF4 may play an important role in MCL treatment response.

**Background:** While MYC-driven non-Hodgkin lymphomas have aggressive clinical behavior and respond poorly to treatment. However, MYC-dependent lymphomagenesis is believed to require additional oncogenic alterations, such as deregulation of genes that counteract the proapoptotic functions of MYC. TPL2 is a MAP3 kinase with an obligatory role in inflammatory signal transduction on the MEK/ERK axis but little is known about its involvement in B lymphocyte biology and lymphomagenesis.

**Aims:** The aim of this study is to define the impact of and the mechanism by which TPL2 kinase affects MYC-induced lymphomagenesis.

**Methods:** CD19+ positive B lymphocytes were isolated from peripheral blood of human healthy individuals and mouse B cells from spleens of WT (C57BL/6) and lymphomagenic mice engineered to overexpress c-myc in B cell pro-
genitor cells under the control of the IgH chain enhancer. Mouse pre-B lym-
phocytes were isolated from bone marrow by flow cytometric cell sorting. Dif-
ferentiation status of lymphomas was analysed by flow cytometry using B220, IgM and IgD antibodies. The TPL2 RNA and protein expression levels were assessed by qPCR and Western blot analysis, respectively. The extent of apop-
tosis was estimated by immunohistochemical evaluation of activated caspase-
3 in paraffin embedded mouse lymphoma tissues and by flow cytometry using Annexin and 7AAD staining of ex vivo cultured lymphoma cells following cytokine deprivation.

**Results:** TPL2 RNA levels were found dramatically decreased in various human Burkitt lymphoma cell lines as well as in 7 primary Burkitt lymphoma biopsies compared to B lymphocytes of healthy individuals. In line with this finding, both pre-B and B lymphomas derived from Eμ-myc mice express very low levels of TPL2 RNA and protein levels, compared to pre-B and splenic B lymphocytes isolated from WT mice. Interestingly, pre-B and B lym-
phocytes of healthy (premalignant) Eμ-myc mice express TPL2 in comparable levels to their WT counterparts, suggesting that the reduction of TPL2 expres-
sion in lymphomas is an additional oncogenic alteration. In this regard, genetic ablation of TPL2 in Eμ-myc mice (Eμ-myc/tpl2−/−) significantly shortened their survival to 92 days from 140 days of Eμ-myc/tpl2−/+ mice (p<0.005). Eμ-
myc/tpl2−/− mice also displayed a trend to develop more pre-B cell lymphomas compared to Eμ-myc/tpl2−/+ mice. This may be attributed to the decreased TPL2 expression in mouse pre-B lymphocytes, while it is upregulated in mature B lymphocytes. Finally, Eμ-myc/tpl2−/− lymphomas displayed reduced levels of apoptosis.

**Figure 1.**

**Summary/Conclusions:** This study reveals a novel pathway during myc-dri-
genesis that may be a biomarker for BTKi-sensitivity in MCL, and that proteins modulated by IRF4 may play an important role in MCL treatment response.
mation in several diseases analyzable by liquid biopsies, representing minimally invasive methods for precision diagnostics and prognosis. Blood extracellular microRNAs (miRNAs) are under investigation as novel biomarkers. While tissue miRNAs in DLBCL patients have been extensively studied, only few reports, and limited to a small subset of miRNAs, evaluated the role of circulating/serum miRNA as potential prognostic factors.

Aims: To identify and validate a serum miRNA signature with prognostic value in a cohort of newly diagnosed DLBCL patients.

Methods: This is a on-going prospective non-interventionist study on a cohort of newly diagnosed de novo DLBCL patients uniformly treated with six courses of R-CHOP (Rituximab, Cyclophosphamide, Vincristine, Doxorubicin and Prednisone). Serum samples of patients were collected at diagnosis and after the end of treatment. Treatment response was evaluated by standard Chenon criteria. The expression profile of selected circulating miRNAs described as associated with lymphoid malignancies by us (let-7c/miR-99a/miR-125b cluster) and by previously published studies (miR-22, miR-18a and miR-20a) was evaluated by RT-qPCR in a set of aseverase-challenged cell samples collected at diagnosis of the first 18 patients enrolled into the study.

Results: Our results showed that the expression level of serum miR-22 as well as let-7c/miR-99a/miR-125b cluster was significantly higher at diagnosis, in patients unresponsive to R-CHOP treatment when compared with responsive patients. On the contrary, miR-18 and miR-20 levels appeared to be not significantly associated to treatment response. In addition, a global expression profile of circulating miRNAs was evaluated in serum samples derived from a smaller cohort of patients (n=4) after first-line chemo-immunotherapy. Interestingly, we found a striking difference in miRNA modulation upon treatment between unresponsive and responsive patients. In particular, we found 31 miRNAs significantly modulated after R-CHOP in the group of responsive patients, including miR-22. In contrast, this miRNA subset did not show remarkable expression changes in unresponsive patients. Moreover, we performed a study interrogating The Cancer Genome Atlas (TCGA) database about miRNA expression levels in samples of DLBCL patients. We found that the only available data are relative to the miRNA expression levels in tumor tissue samples of 47 out of 58 DLBCL patients. Kaplan Meier method and log-rank test revealed a signature of 13 miRNAs with potential prognostic value. Among these we found that miR-22, also emerged as modulated in our genome-wide analysis, was linked to risk of disease recurrence.

Summary/Conclusions: These preliminary data suggest that the serum miR-22 as well as miR-99a/miR-125b cluster are of potential interest as non–invasive biomarkers to predict therapeutic response in DLBCL patients. Ongoing experiments in a wider cohort of patients are aimed to confirm these results and unveil potential miRNA signature with predictive value.

INTRACELLULAR CALCIUM AND METABOLISM HAVE CRITICAL ROLES IN DETERMINING ANTI-CD20 ANTIBODY EFFICACY IN DLBCL

E. Vilvenhraraaja 1, 2, G. Grinbin 1, A. Braum 1
1Centre for Haematolog-Oncology, Barts Cancer Institute, London, United Kingdom
2Institute of Ille-allergy, Leiden University Medical Centre, Leiden, Netherlands

Background: Since the discovery and utilisation of the Type-I anti-CD20 antibody Rituximab, many have tried to enhance the efficacy of anti-CD20 antibodies in order to improve first-line treatment of B cell malignancies, leading to the development of anti-CD20 antibodies. To date, the precise biological role of CD20 and the mechanism of anti-CD20 antibody action remains unclear. However, CD20 has been shown to be involved in the store operated calcium (Ca2+) system. This complex has the ability to facilitate mitochondrial function, causing a significant reduction in basal OxPhos and in maximal respiratory capacity observed with anti-CD20 antibody treatment alone. When analysing the clonogenic survival of cell lines, we have found that only the cytotoxicity of Type-II anti-CD20 antibodies is enhanced by simultaneously treating cell lines with Metformin.

Results: Intracellular calcium concentration was decreased across our panel of cell lines following a 24-hour treatment with all Type-II anti-CD20 antibodies in our panel. This decrease was not observed following treatment with the Type-I anti-CD20 antibody Rituximab. Treatment with anti-CD20 antibodies resulted in a significant increase in the maximal respiratory capacity of our panel of cell lines; cells were able to produce more ATP in response to oxidative stress. Concomitantly, changes in mitochondrial biogenesis of OxPhos impaired mitochondrial function, causing a significant reduction in basal OxPhos and in maximal respiratory capacity. Under this condition, cells were unable to increase ATP production in response to oxidative stress. We also show that treatment combining Metformin with either Type-I or Type-II anti-CD20 antibodies prevents the increase in maximal respiratory capacity observed with anti-CD20 antibody treatment alone. When analysing the clonogenic survival of cell lines, we have found that only the cytotoxicity of Type-II anti-CD20 antibodies is enhanced by simultaneously treating cell lines with Metformin.

Summary/Conclusions: Our data show for the first time that when cells are simultaneously treated with Type-I and Type-II anti-CD20 antibodies, intracellular calcium is decreased. Intracellular calcium remains unchanged following treatment with Rituximab. Next, we show anti-CD20 antibody treatment causes cells to increase maximal mitochondrial respiratory capacity to compensate for reduced basal mitochondrial function. We show that inhibition of OxPhos disables the cells from being responsive to Type-II anti-CD20 antibodies. Interestingly, we found a striking difference in miRNA modulation upon treatment between unresponsive and responsive patients. In particular, we found 31 miRNAs significantly modulated after R-CHOP in the group of responsive patients, including miR-22. In contrast, this miRNA subset did not show remarkable expression changes in unresponsive patients. Moreover, we performed a study interrogating The Cancer Genome Atlas (TCGA) database about miRNA expression levels in samples of DLBCL patients. We found that the only available data are relative to the miRNA expression levels in tumor tissue samples of 47 out of 58 DLBCL patients. Kaplan Meier method and log-rank test revealed a signature of 13 miRNAs with potential prognostic value. Among these we found that miR-22, also emerged as modulated in our genome-wide analysis, was linked to risk of disease recurrence.

Summary/Conclusions: These preliminary data suggest that the serum miR-22 as well as miR-99a/miR-125b cluster are of potential interest as non–invasive biomarkers to predict therapeutic response in DLBCL patients. Ongoing experiments in a wider cohort of patients are aimed to confirm these results and unveil potential miRNA signature with predictive value.

CYCLIN D1 ONCOGENIC OVEREXPRESSON LEADS TO A GLOBAL TRANSCRIPTIONAL DOWNREGULATION IN MALIGNANT LYMPHOID CELLS

R. Albero 1, A. Enjuanes 2, S. Demajo 1, G. Castellano 3, M. Pinyol 2, N. Garcia 1, C. Capdevila 1, H. Suarez-Cisneros 2, K. Kurabe 2, S. Beal 1, I. Martín-Subero 1, E. Campo 1, P. Jareš 5
1IDIBAPS, Barcelona, Spain, 2Genomics Unit, IDIBAPS, 3Molecular Biology Core, Hospital Clinic, Barcelona, Spain, 4University of the Ryukyus, Okinawa, Japan, 5Hospital Clinic, Barcelona, Spain

Background: Cyclin D1 is an oncoogene frequently overexpressed in human cancers. In hematologic neoplasms, mantle cell lymphoma and multiple myeloma are clear examples of deregulated cyclin D1 expression. It plays a dual function as cell cycle and transcriptional regulator, although the latter is widely unexplored.

Aims: In this study, we investigate the transcriptional role of cyclin D1 in lymphoma initial. We use a high-throughput study to investigate cyclin D1 oncogenic overexpression in B cells as a model of the first steps in MCL oncogenesis.

Methods: Chromatin immunoprecipitation (ChIP) followed sequencing was performed in four established MCL cell lines. RNA-Sequencing (RNA-Seq) and information from histone ChIP-Seq were correlated with genomic intervals displaying cyclin D1 binding. Transcriptional downregulation was studied through cytometric RNA total quantification in lymphoblastic cyclin D1-overexpressing models and RNA Pol II ChIP-Seq.

Results: Endogenous cyclin D1 showed widespread binding to active promotors. Its overexpression was responsible for a global transcriptional down-modulation. Cyclin D1, instead of showing specific gene activation, seems to globally decrease cell transcription. Mantle cell lymphoma and multiple myeloma cell lines displayed an inverse relation with cyclin D1 quantity. This transcriptional effect was associated with an increased RNA polymerase II pausing in promoters due to cyclin D1 overexpression.

Summary/Conclusions: This mechanism expands the oncogenic cyclin D1 functions and places the transcriptional machinery as a potential therapeutic target in cyclin D1 overexpressing tumors.

Background: Over the past decade, new biologic insights have revealed a key role of tumor microenvironment in the pathogenesis of classical Hodgkin’s lymphoma (cHL). cHL infiltrating cells produce cytokines and growth factors that provide essential stimulatory signals for survival and proliferation of Hodgkin’s and Reed–Stemberg cells. Moreover, clinical behavior of cHL may be directly regulated by the cross-talk between tumor cells and infiltrating immune cells.
Aims: The aim of our study was to estimate the role of microenvironment expression of immunoregulatory molecules (PD-1 ligands, IDO) and cytokines (TGF-β, IL-13) in clinical outcome of cHL.

Methods: 74 patients (median age: 44, range: 17-71 years; males: 22, females: 52) were included in the study. 55.4% of patients were diagnosed with an early stages of HL, while 44.6% - with advanced stages. ABVD or BEACOPP (14/esc) were administered as a 1st-line therapy. 78.3% of patients achieved remission (CR/PR), while 8% had progression of disease during the therapy. We recorded 14.8% relapses in patients after the 1st line therapy during the follow-up period (median duration – 36 months; range 6-66 months). PD-L1, PD-L2, IDO, TGF-β, IL-13 mRNA expression levels were analyzed in fresh pre-treatment lymph node biopsies using qRT-PCR.

Results: Expression of PD-L1 and IDO were not to have a favourable outcome of cHL. A 5-year event-free survival (EFS) rate was 80% for double negative PD-L1/IDO patients vs 20% for double positive PD-L1/IDO+ patients (p=0.008). IL-13 was expressed at various levels depending on the stage of HL with the highest expression levels in advanced stages. A trend for a higher risk of relapse was observed for HL patients with increasing level of IL-13 (p=0.23). TGF-β expression was positively correlated with histological variants of HL, however, multivariate analysis showed that TGFβ expression is a significant increase EFS in cHL patients with HRs of 6.7 [95% (CI) 1.3-2.1, p=0.04].

Summary/Conclusions: Our results suggest that tumor microenvironment plays an important role in clinical behavior of cHL. Hence, better understanding of molecular mechanisms of interaction between tumor and immune cells probably can provide us with a novel promising strategy for relapsed/refractory cHL treatment.

AN IN VIVO TRACEABLE AND MULTIPLEXING CRISPR/CAS9 GENOME EDITING SYSTEM
L. Cheng1, Y. Liu2
1Department of Hematology and Research Laboratory of Hematology, 2State Key Laboratory of Biotherapy and Cancer Center, West China Hospital Sichuan University, Chengdu, China

Background: Gene gain of function and loss of function mutations, oncogene overexpression, gene amplification, chromosome deletion and epigenetic changes, may lead to lymphoma onset. The CRISPR-Cas9 genome editing system has become a feasible tool for exploring the functions of specific genes in different contexts. We want to use this technique to screen for lymphoma suppressor genes.

Aims: Construct an in vivo traceable and multiplexing CRISPR-Cas9 gene editing system, which is high efficient for studying in vivo functions of both individual genes or any given chromosome fragment.

Methods: Two retroviral vectors were constructed via molecular clone, one of which contains a locus for tandem U6-sgRNAs and inducible GFP reporter gene and the other contains Cas9 and TRIM21 genes. This system’s function of traceable and simultaneously mutate multiple gene efficiencies were validated in vitro. Eμ-myc HSPCs retrovirally transduced with sgp53 and Cas9 were transplanted into sublethally irradiated C57/BL6 mouse.

Figure 1.

Results: Co-transduced cells can be tracked by the expression of GFP protein and multiple sgRNA can be efficiently introduced to the GFP-labeled cells for simultaneously mutating multiple genes or deleting a large chromosome fragment. Further we applied this system for both in vitro and in vivo genome editing. As an example, we show that Tpz53 mutation accelerated Eμ-Myc driven lymphoma onset in vivo.

Summary/Conclusions: This traceable and multiplexing CRISPR/Cas9 system might be useful for various genome editing applications.

HDAC6 INHIBITION SENSITIZES TUMOR CELLS TO ANTI-CD20 IMMUNOTHERAPY IN VIVO
M. Bobrowicz1,*, M. Dwojak1, J. Stachura1, M. Angelika1, P. Beata1, S. Marta1, N. Miazek1, P. Zapala1, J. Golab1, M. Winiarska1
1Department of Immunology, Medical University of Warsaw, Warsaw, Poland

Background: Down-regulation of CD20, a molecular target for monoclonal antibodies, constitutes a clinically significant issue leading to decreased efficacy of anti-CD20-based therapeutic regimens. The epigenetic modulation of CD20 coding gene (MS4A1) has been proposed as a mechanism for the reduced therapeutic efficacy of anti-CD20 antibodies and confirmed previously with clinically available non-specific histone deacetylase pan-inhibitors (HDACis). However, the identification of particular HDAC isozymes involved in CD20 regulation seems to be of paramount importance. Since the use of pan-HDACi is associated with substantial side effects, especially difficult to manage in elderly and frail patients, the new specific HDAC6 inhibitors are currently being tested in multiple myeloma and non-Hodgkin lymphoma. They have already been shown to sensitize tumor cells to proteasome inhibitors and novel kinase inhibitors e.g. Ibrutinib and demonstrated promising results in in vitro studies in chronic lymphocytic leukemia (CLL).

Aims: HDAC6 has been known for its regulatory role in protein degradation. We previously reported that inhibition of proteasome activity can effectively increase CD20 levels in tumor cells. In our study we tested the hypothesis that selective HDAC6 inhibition sensitizes tumor cells to immunotherapy with anti-CD20 monoclonal antibodies (mAbs) by regulating CD20 levels.

Methods: We assessed the influence of HDAC6 inhibition in a panel of different subtypes of human lymphoma cell lines (Burkitt, DLBCL: both EBV+ and EBV-) on CD20 expression using flow cytometry and Western blotting. We confirmed our observations in primary samples from the patients with CLL, known to express low CD20 levels. Moreover, we performed cytotoxic assays using flow cytometry in order to assess complement-dependent cytotoxicity (CDC) as well as apoptosis. We used HDAC6-specific chemical inhibitors (tubacin, trichostatin A and clinically tested ricolinostat), as well as HDAC6 shRNA assay.

Results: The results of our studies demonstrate that HDAC6 inhibition significantly increases CD20 level and sensitizes tumor cells to rituximab- and obinutuzumab-induced CDC, as well as to direct cytotoxicity of obinutuzumab. In vivo settings HDAC6 inhibition potentiated the efficacy of rituximab by significantly reducing tumor size and prolonging the survival of the mice.

Summary/Conclusions: Our results clearly indicate that HDAC6 inhibition sensitizes tumor B-cells to anti-CD20 immunotherapy. Therefore, we propose HDAC6 inhibition with specific inhibitors as an effective strategy to be associated with the therapy with anti-CD20 mAbs. This strategy seems to be highly promising in CLL patients, often expressing very low CD20 level and do not fully benefiting from immunotherapy.

NKPR46 EXPRESSION IS A DIAGNOSTIC AND PROGNOSTIC BIOMARKER IN PRIMARY GASTROINTESTINAL T-CELL LYMPHOPROLIFERATIONS: A CELAC NETWORK STUDY
M. Cheminant1,2,*, J. Bruneau3, M. Galmot4,5, N. Guegan4,6
1Hematology Unit, Necker Hospital - Paris Descartes – Sorbonne Paris Cité

Methods: We have previously reported that inhibition of proteasome activity can effec-

Results: The role of microenvironment expression of immunoregulatory molecules (PD-1 ligands, IDO) and cytokines (TGF-β, IL-13) in clinical outcome of cHL.
Background: Primary gastrointestinal (GI) T-cell lymphoproliferations (T-CL) are heterogeneous entities, which diagnoses are difficult to perform. T-CL include aggressive lymphoma such as enteropathy-associated T-cell lymphoma (EATL) as well as indolent monoclonal lymphoproliferations. Refractory coeliac disease type II (RCDDII) is one of the indolent T-CL that complicates coeliac disease (CD) and may evolve toward an overt EATL. The differential diagnosis of RCDDII from CD and RCDD is difficult and essentially based on negative expression of sCD3 and CD8 and the presence of a clonal TCR rearrangement. Lymphocytes from RCDDII are dependent for survival on IL-15, which reprograms T lymphocytes towards a cytotoxic NK phenotype.

Aims: We thus studied the expression of NKp46 on a representative panel of GI T-CL to assess its diagnosis and prognosis value.

Methods: Using formalin-fixed paraffin-embedded tissue biopsies, we assessed NKp46 expression by immunohistochemistry (IHC) and investigated its clinical and biologic significance on 177 intestinal, 11 lymph node and 7 other biopsies from 84 CD or RCDD patients (RCDD, n=20; RCDDII, n=40), 44 GI T-cell lymphoma patients (EATL, n=25; monomorphic epitheliotropic intestinal T-cell lymphoma_MEITL, n=4; indolent T-CLP, n=15), 11 healthy patients and 5 patients with a GI inflammatory environment as controls.

Results: By doing ROC analysis on number of cells expressing NKp46 on GI-TCL we identify that 25 intra-epithelial lymphocyte (IEL) per 100 epithelial cells (EC) clearly separates RCDDII from CD and RCDD patients, with a good positive and negative predictive values (100 and 95% respectively). In healthy controls, CD or RCDD patients, NKp46 was only expressed on scattered IEL (median 3%, 0-15). Based on NKp46 expression the overall survival is poor if over 25% of IEL are positive for NKp46 (OS-5-years 96.4% vs 72.8%, P=0.0004) (Figure 1A). Among patients with GI T-cell lymphoma, we show that NKp46 was expressed in most of aggressive lymphoma (EATL 80%, n=20/25 and MEITL 100%, n=4/4). On the other hand, NKp46 was not expressed in indolent T-CLP (n=15). The NKp46 expression was also associated with a poor prognosis in GI T-cell lymphoma patients (OS-5-years 50.5% vs 5.4%, P=0.0011) (Figure 1B).

Summary/Conclusions: The NKp46 expression in more than 25 IEL per 100 EC by IHC analysis can easily identify RCDDII from CD and RCDD. Furthermore, the NKp46 expression is associated with aggressive forms of GI T-cell lymphoma. Finally, the NKp46 expression was strongly associated with shortened survival. Thus NKp46 provides a new biomarker for both diagnosis and prognosis in GI T-CL.

HIGH EXPRESSION LEVELS OF MIR23A CLUSTER IN DLBCL ANTAGONIZE INDUCTION OF APOPTOSIS

N. Freytag1, C. Pommerenke2, Y. Merkhofer1, J. Arribas Arranz1, D. Kube3, H. Dre克斯, H. Quentmeier2, S. Eberth1.

1Junior Research Group Molecular Cancer Research, 2Department of Human and Animal Cell Lines, Leibniz-Institute DSMZ - German Collection of Microorganisms and Cell Cultures, Braunschweig, 3Haematology and Oncology, University Medical Center Göttingen, Göttingen, Germany

Background: The microRNA cluster MIR23A, which encodes for the mature microRNAs miR-23a, miR-27a and miR-24, was shown to be deregulated in many different malignancies including subtypes of B cell non-Hodgkin lymphoma (B-NHL). Furthermore, high expression of miR-23a was correlated with poor overall survival in diffuse large B-cell lymphoma (DLBCL) patients (Wang et al., Med Oncol. 2014) indicating that miR-23a might act as an onco-miR (tumor promoting microRNA) in this entity. However, both targets and function of the MIR23A cluster in B-NHL remain unknown.

Aims: This study aims to elucidate the role of the MIR23A cluster as a potential onco-miR in DLBCL by identification of the lymphoma-specific targetomes of miR-23a and miR-27a and subsequent analyses of associated functions.

Methods: We used a DLBCL model cell line U-2932 K1, which has a low basal expression level of MIR23A cluster, was used for the lentiviral-based generation of clones overexpressing miR-23a, miR-27a, or a scrambled control. Differentially expressed genes (DEG, fold-change >2, p-value <0.05) between samples were determined by mRNA sequencing (RNA-Seq). miR-23a and miR-27a targetomes were identified by immunoprecipitation of AGO2-bound miRNA (AGO2-RIP) followed by RNA-Seq. MicroRNA targets had to be enriched >2-fold with a p-value <0.05. Validations were performed by qPCR and immunoblotting.

Gene set enrichment analyses (GSEA) and GO-term analyses were applied on identified targetomes and DEG to predict microRNA associated functions. Apoptosis was assessed by Annexin-V staining followed by FACS analyses as well as in immunoblot.

Results: Overexpression of miR-23a and miR-27a, respectively, in a DLBCL model cell line resulted in global alterations of gene expression (so-called indirect targets) with a substantial overlap of 104 of DEG affected by both microRNAs. Using AGO2-RIP, 26 novel direct targets of miR-23a, and 20 novel direct targets of miR-27a were identified. GSEA and GO-term analyses of direct and indirect targets indicated that the MIR23A cluster might regulate processes in apoptosis. Moreover, BBC3 which encodes the pro-apoptotic protein PUMA was one of the identified direct targets of miR-23a. An ectoderm-induced apoptosis in miR-27a overexpressing DLBCL cells failed to induce PUMA on protein level. Importantly, functional analyses confirmed that miR-23a overexpression reduces and high levels of miR-27a significantly attenuate the ability of DLBCL cells to undergo apoptosis in response to DNA damage.

Summary/Conclusions: We demonstrate that high levels of miR-23a and miR-27a antagonize induction of apoptosis in a tumorogenic cell line. This might be one possible explanation why DLBCL patients with high miR-23a expression levels have a worse overall survival rate than patients with low levels. Thus, future studies should address the suitability of the MIR23A cluster as biomarker and potential target in DLBCL.

PLASMA CELLS ARISE FROM DIFFERENTIATION OF CLONAL LYMPHOCYTES AND SECRETIE SE IGM IN WALDENSTRÖM MACROGLOBULINEMIA

D. Talaulikar1,2,*, J.H. Lim1, J. Wang2, N. Hein2, A. El-Ayoubi2

1Haematology, Canberra Hospital, 2Australian National University, Australian National University, Canberra, Australia

Background: Waldenström Macroglobulinemia (WM) is an indolent non-Hodgkin lymphoma characterized by bone marrow infiltration with malignant cells and hypersecretion of monoclonal immunoglobulin M (IgM). The malignant infiltrate comprises of two distinct cellular populations: the plasmacytoid lymphoplasmacytic cells (LPLs), and a smaller number of plasma cells (PCs). The LPLs in WM arise from a common stem cell as the PCs through a process of terminal differentiation. However, the genetic and secretory function of PCs in 2 WM cell lines.

Methods: Using FACs, we identified LPLs as CD45 bright/CD38dim/CD138+ cells and PCs as CD45dim/CD38+/CD138+ cells from 2 cell lines (FR3) status. Finally to determine which population was predominantly responsible for IgM hypersecretion, isolated PCs and LPLs from both cell lines were kept in culture for 72 hours and the culture media analysed by ELISA for IgM secretion.

Results: IgM hypersecretion was observed in a WM cell line. This might be one possible explanation why WMCL patients with high miR-23a expression levels have a worse overall survival rate than patients with low levels. Thus, future studies should address the suitability of the MIR23A cluster as biomarker and potential target in DLBCL.

Summary/Conclusions: We demonstrate that high levels of miR-23a and miR-27a antagonize induction of apoptosis in a tumorogenic cell line. This might be one possible explanation why DLBCL patients with high miR-23a expression levels have a worse overall survival rate than patients with low levels. Thus, future studies should address the suitability of the MIR23A cluster as biomarker and potential target in DLBCL.

PLASMA CELLS ARISE FROM DIFFERENTIATION OF CLONAL LYMPHOCYTES AND SECRETIE SE IGM IN WALDENSTRÖM MACROGLOBULINEMIA

D. Talaulikar1,2,*, J.H. Lim1, J. Wang2, N. Hein2, A. El-Ayoubi2

1Haematology, Canberra Hospital, 2Australian National University, Australian National University, Canberra, Australia

Background: Waldenström Macroglobulinemia (WM) is an indolent non-Hodgkin lymphoma characterized by bone marrow infiltration with malignant cells and hypersecretion of monoclonal immunoglobulin M (IgM). The malignant infiltrate comprises of two distinct cellular populations: the plasmacytoid lymphoplasmacytic cells (LPLs), and a smaller number of plasma cells (PCs).

Aims: In this study, we aimed to characterise the immunophenotype, molecular genetics and secretory function of PCs in 2 WM cell lines.

Methods: Using FACs, we identified LPLs as CD45bright/CD38dim/CD138+ cells and PCs as CD45dim/CD38+/CD138- cells from 2 cell lines - WMCL1 (Ansell lab) and BCWM.1 (Treon lab). We used standard PCR and Sanger sequencing to assess MYD88 (using MYD88 L265P specific primers) and Immunoglobulin heavy chain (IgHV) (using Biomed2 specific primers for FR3) status. Finally to determine which population was predominantly responsible for IgM hypersecretion, isolated PCs and LPLs from both cell lines were kept in culture for 72 hours and the culture media analysed by ELISA for IgM secretion.

Results: Using a conservative sorting strategy, we analysed 2 WM cell lines WMCL1 and BCWM.1, and found that WMCL1 had 5-6% PCs and 20-30% LPLs; while BCWM.1 had 4-5% PCs and 10-20% LPLs. Cells that were CD38+/CD138- or CD38-/CD138+ were not included in the analysis. We observed heterozygous MYD88/L265P mutation in both PC and LPL populations. We also observed the expression of the same auto-reactive IgHV sequences (VH3-15’01) in both PCs and LPLs from WMCL-1, suggesting similar clonal origin and a role for auto-antigens in WM cell survival. We noted VH3-23’01 in the LPLs but not in the PC compartment. The significance of this remains uncertain. Cell culture studies showed that PCs alone were primarily responsible for IgM production despite the relative lack of proliferation and eventual cell death in WMCL-1 (~65% plasma cells remained after 72
hours and produced 8.7 – 9.3 X 10^3 ng/ml of IgM). PCs isolated from BCWM.1 increased to 130% and produced 2.5 – 2.8 X 10^4 ng/ml of IgM. LPLs from both cell lines proliferated in culture (~130 – 140% in MWCL-1 and ~170 – 200% in BCWM.1 at 72 hours), gave rise to the more differentiated PCs (7.5 – 9.0% of PCs at 72 hours in MWCL-1 and 1.2 – 1.4% PCs in BCWM.1), and secreted smaller amounts of IgM than PCs (3.5 – 5.0 X 10^4 ng/ml in MWCL-1 and 0.3 – 0.7 X 10^3 ng/ml in BCWM.1).

**Summary/Conclusions:** Our analysis of the 2 WM cell lines provides evidence to support the common hypothesis that malignant PCs arise from the clonal malignant LPL population, and are primarily responsible for IgM secretion in WM.

LMP-1 MEDIATED UPRREGULATION OF IL-2Rα PROMOTES LYMPHOMA-GENESIS AND CHEMOTHERAPY RESISTANCE IN NATURAL KILLER/T-CELL LYMPHOMA AND COULD BE A POTENTIAL THERAPY TARGET

X.-W. Bi1, W.-J. Lu1, Z.-J. Xia2, W.-G. Jiang3, H.-G. Huang4, Y. Lu5, L. Wang6,* 1Medicinal oncology, 2Hematologic Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

**Background:** Natural killer/T-cell lymphoma (NKTCL) is an Epstein–Barr virus (EBV)-associated, highly aggressive lymphoma. Treatment outcome remains sub-optimal, especially for advanced-stage or relapsed diseases. Our previous study demonstrated the prognostic value of IL-2Rα in NKTCL, but the role of IL-2Rα in the lymphomagenesis and chemotherapy resistance and its interactions with EBV in NKTLCL remain to be investigated.

**Aims:** This study investigated the mechanism of IL-2Rα expression in NKTCL, and explored the role of IL-2Rα in lymphomagenesis and chemotherapy resistance and its interactions with EBV in NKTLCL remain to be investigated.

**Methods:** Expression of IL-2Rα was measured in NK-92 (LMP-1 weak expression) and SNK-6 (LMP-1 strong expression) cell lines by western blot, quantitative distribution by FCM analysis, and IC50 values exposed to three chemotherapy drugs (adriamycin, gemcitabine, and asparaginase) by MTT. Finally anti-IL-2Rα antibody, which can be fully reversed by addition of anti-IL-2Rα antibody.

**Summary/Conclusions:** IL-2Rα expression was upregulated in NKTCL by LMP-1-mediated activation of MAPK/NF-κB pathway. IL-2Rα can promote NKTCL cell proliferation partially through regulation of cell cycles and induce chemotherapy resistance, which can be reversed by anti-IL-2Rα antibody, indicating the potential role of IL-2Rα as a therapy target in NKTCL.

San Martino-IST, Genova, 20Hematology Department, Annunziata Hospital of Cosenza, Cosenza, Italy

**Background:** PD1 binding to its ligand PD-L1 inhibits TCR/BCR signaling; impairs activation and effector functions of T- and B-cells; induces state of T-cell exhaustion; and ultimately provokes tolerance towards cancers. PD1 is expressed on Hodgkin lymphoma (HL) and B-cell non-HLTLTs. The TME may play an essential role in maintaining PD1-induced immune exhaustion. LEN is an oral immunomodulator (IMID) with direct antineoplastic activity and immune modulation properties. The aims of this study were: 1) to determine the PD1 axis; and 3) to determine whether LEN influences PD1 or cognate ligand expression.

**Aims:** 1) To better characterize the PD1, PD1L and the lesser-known PD2L, phenotype in peripheral neoplastic CD19+ lymphocytes and T-cell subsets in patients with low-grade B-cell lymphoma; 2) To evaluate the role of the TME in supporting the PD1 axis; and 3) to determine whether LEN influences PD1 or cognate ligand expression

**Methods:** Samples obtained from patients attending participating Hematology Units were used to determine PD1, PD1L, PD2L phenotype (%±SEM) by Flow-cytometry (FC). Autologous activated T-cells (AAT) were obtained by in vitro co-culture of patient T-cells with anti-CD3/CD28 beads, rIL2 and with PBMCs. Cultures were monitored daily until sizeable clumping was observed and tested for PD1 and ligand expression. In selected experiments LEN (provided by Celgene) was added to cell cultures.

**Results:** Twelve cases of lymphoma were evaluated for PD1, PD1L and PD2L expression on malignant B- and T-cells by FC. The expression of PD1 and PD1L was similarly expressed, while PD1L was almost undetectable on B-cells. Levels of PD1 expression on CD3+ cells were variable among samples, however they were significantly higher than those expressed on malignant B-cells. Significantly elevated PD1 expression and very low levels of ligands were detected in both CD4+ and CD8+ cells. Consistent formation of B/T-cell clusters. Higher numbers of CD19+CD52L-2 cells were detected than PD1+ cells compared to baseline cells. PD1 expression also significantly increased in AAT co-cultures on B-cells. PD1 expression

---

**Figure 1.** Results: Expression of IL-2Rα was significantly upregulated in SNK-6 cells than in NK-92 cells, at both protein and mRNA levels. Expression of IL-2Rα was remarkably upregulated in NK-92 cells transfected with LMP-1-harboring lentiviral vectors compared with those transfected with negative control vectors. Proteins in the MAPK/NF-κB pathway were upregulated in LMP-1-expressing NK-92 cells compared with the negative control. Selective inhibitors of those proteins induces significant downregulation of IL-2Rα expression in LMP-1-expressing NK-92 cells as well as in SNK-6 cells. When comparing with those transfected with negative control vectors, cell growth was significantly increased in both NK-92 and SNK-6 cells transfected with IL-2Rα-harboring lentiviral vectors, and the cell cycle assay displayed a significant decrease in the percentage of cells in the G0/G1 phase (p<0.05) and an increase in the percentage of cells in the G2/M phase (p<0.05), while apoptosis was not affected. Subsequent western blot tests demonstrated that cyclin A, B, and CDK1, 4 were involved in the regulation of cell cycle with overexpression of IL-2Rα. The IC50 values to all three chemotherapy drugs were significantly increased after overexpression of IL-2Rα, which can be fully reversed by addition of anti-IL-2Rα antibody.

---

**Conclusion:** IL-2Rα expression was upregulated in NKTCL by LMP-1-mediated activation of MAPK/NF-κB pathway. IL-2Rα can promote NKTCL cell proliferation partially through regulation of cell cycles and induce chemotherapy resistance, which can be reversed by anti-IL-2Rα antibody, indicating the potential role of IL-2Rα as a therapy target in NKTCL.
on CD3+ cells was unaffected by AAT, although the expression of both ligands remained unchanged. In contrast, PDL2 expression was increased in 2/3 cases following LEN treatment while, PDL1 expression by LEN, while the expression of both ligands remained unaffected. Evaluation of activated T-cell subsets showed similar results, with the exception of stronger induction of PD1 and PDL1 expression by LEN in CD8+ cells.

Summary/Conclusions: Our data provide support for the potential involvement of the PD1-axis in lymphoma patients. Interestingly, LEN further induces the expression of PD1 in CD8+ and CD4+ cells and may contribute to reactivating PD1 signaling under treatment. The PD1 pathway may be potentially targeted to overcome both the intrinsic and LEN-induced exhaustion phenotype.

IDENTIFICATION AND DIAGNOSTIC APPLICATION OF GENOMIC NPM-ALK FUSION SEQUENCES IN ANAPLASTIC LARGE CELL LYMPHOMAS
M. Krumbholz,1,2 C. Damm-Welk,2 W. Woessmann,2 M. Metzler1
1Department of Pediatrics, Justus-Liebig-University, Giessen, Germany
2Department of Pediatrics, Justus-Liebig-University, Giessen, Germany

Background: ALK positive anaplastic large-cell lymphoma (ALCL) account for 10-15% of pediatric Non-Hodgkin lymphomas. Most of these patients carry the chromosomal translocation (t(2;5)(p23;q35)) in their tumor, which leads to the expression of the NPM-ALK fusion transcription is a well-established tool for diagnostic purposes and risk stratification during the course of treatment.

Aims: Establishment of a PCR based assay to identify patient-specific genomic NPM-ALK fusion sequences for a DNA based monitoring of minimal residual disease in ALCL patients. Compared to RNA based methods the quantification of DNA is independent of the gene expression. Additionally, due to the higher stability of DNA, cell-free circulating tumor DNA (ctDNA) should be detectable in the patient’s plasma and may represent a tumor marker for ‘liquid biopsies’ in ALCL.

Methods: Using a specifically designed multiplex long-range PCR assay, genomic NPM-ALK fusion sequences were identified in 45 ALCL patients. The genomic NPM-ALK breakpoints were analyzed concerning fine structure and breakpoint distribution pattern. Furthermore, the patient-specific genomic NPM-ALK fusion sequences were evaluated for their use as biomarkers in selected cases. For this purpose patient’s blood and plasma samples were quantified using a high sensitive digital droplet PCR assay.

Results: In more than 60% of cases the identified breakpoint was localized within repeat regions. The genomic breakpoints within the breakpoint cluster regions of the fusion genes were randomly distributed. Most of the NPM-ALK fusion sequences were characterized by the occurrence of small insertions or deletions indicating the involvement of the non-homologous end-joining (NHEJ) repair system for chromosomal translocation initiation. Using a DNA based quantification assay in a subset of patients, the genomic NPM-ALK fusion sequences were detectable in circulating tumor cells in patient’s blood samples as well as cell-free tumor DNA in plasma samples.

Summary/Conclusions: The established multiplex long-range PCR assay is a useful diagnostic tool for the identification of genomic NPM-ALK fusion sequences. This individual tumor maker is independent of gene expression and can be used for therapy response monitoring and relapse detection.

E1392
ARSENIC TIOXIDE TARGETS BCL6 FOR DEGRADATION AND INHIBITS THE PROLIFERATION OF BCL6-DEPENDENT DIFFUSE LARGE B-CELL LYMPHOMA
E. Tse1,2, K. Yue1,2, D. Chau2, Y.-L. Kwong1
1Department of Medicine, 2Medicine, The University of Hong Kong, Hong Kong, Hong Kong

Background: B-cell lymphoma 6 (BCL6) is a transcription repressor and is frequently over-expressed in diffuse large B-cell lymphoma (DLBCL). It suppresses the expression of its target genes ATR, TP53 and CDKN1A, leading to dysregulation of DNA repair and cell proliferation. It has been shown that BCL6 is an oncoprotein involved in the pathogenesis of DLBCL and represents a potential therapeutic target. Arsenic trioxide (ATO) targets various oncogenic proteins, including PML-RARA in acute promyelocytic leukemia (APL). Tax in adult T-cell leukemia (ATL) and cyclin D1 in mantle cell lymphoma (MCL), and NPM-ALK in anaplastic large cell lymphoma (ALCL), for degradation through the ubiquitin-proteasome pathway. ATO is now used for the management of APL, ATL and MCL with proven clinical benefit.

Aims: To investigate if ATO targets BCL6 and inhibits the proliferation and growth of BCL6-dependent DLBCL.

Methods: BCL6-dependency of a panel of DLBCL cell lines (i.e. OCI-Ly1, OCI-Ly7, SU-DHL-6, OCI-Ly18 and Pfeiffer) was determined based on their sensitivity to proliferation inhibitory activity of the BCL6 inhibitor 76-9 (Calbiochem). The effects of ATO and cisplatin as single agent or in combination on cell viability and apoptosis of DLBCL cells were examined with MTT assay and flow cytometric analysis. Expression of BCL6 and its target genes was examined with quantitative RT-PCR and western immunoblotting. The therapeutic efficacy of ATO treatment was also examined in a DLBCL (OCI-Ly7) xenograft mouse model.

Results: OCI-Ly1, OCI-Ly7 and SU-DHL-6 were highly sensitive to inhibition activity of BCL6 inhibitor and were designated as BCL6-dependent. Treatment of DLBCL cells with ATO led to a decrease in BCL6 protein level and an upregulation of downstream targets of BCL6, including PRDM1, CD44 and CD69. The effect of ATO on BCL6 protein were abrogated by treatment with proteasome inhibitor (MG132), suggesting that ATO targets BCL6 for degradation through the ubiquitin-proteasome pathway. Interestingly, ATO also inhibited cell proliferation and induced apoptotic cell death of BCL6-dependent DBLCL cell lines, analogous to the effect of BCL6 inhibitor on these cells. In addition, there was a synergistic inhibitory and cytotoxic activity between ATO and cisplatin. Finally, ATO treatment suppressed the growth of DLBCL in a xenograft mouse model.

Summary/Conclusions: ATO targets BCL6 for proteosomal degradation and inhibits the proliferation and growth of BCL6-dependent DLBCL.

PROTEOMIC PHOSPHOSITE ANALYSIS IDENTIFIED CRUCIAL NIPA SERINE RESIDUES FOR NPM-ALK-MEDIATED TRANSFORMATION
A. Gengenbacher1,2, A. Rudort2, T. Poggio1, C. Rummelt1, S. Kreutmair1, V.i. Dumit3, J. Duyster1,2
1Dept. of Hematology, Oncology and Stem Cell Transplantation, University Medical Center, Freiburg, 2German Cancer Consortium (DKTK), Heidelberg, 3Center for Biological Systems Analysis, University of Freiburg, Freiburg, Germany

Background: Anaplastic large-cell lymphoma(ALCL) is an aggressive non-Hodgkin lymphoma that occurs mainly in children and younger adults. Patients typically show an advanced stage disease as well as an aggressive disease pattern with extralymphatic manifestations. At the molecular-genetic level, 60% of the patients with systemic ALCL exhibit a translocation (t(2;5)(p23;q35), which leads to the expression of the NPM-ALK fusion protein. Under the control of the NPM promoter, ALK activation causes increased and autonomous cell proliferation. Nuclear interaction partner of ALK (NIPA) was first identified as a new interaction partner of the oncogene NPM-ALK in a yeast-2-hybrid screen which defines an E3-SCF ligase and is physiologically involved in cell cycle regulation at the transition from G2 phase to mitosis. It has already been shown in preliminary studies that co-expression of NIPA with the oncogenic tyrosine kinase NPM-ALK results in the constitutive phosphorylation of NIPA (Illet et al., 2012a). Until now, the specific signal transduction pathway, the crucial phosphorylation sites as well as the functional effect of the pathological NIPA phosphorylation in NPM-ALK-induced lymphomagenesis still remain unclear. Molecular insights into the signal transduction pathways of the kinase NPM-ALK may help to identify new druggable targets for therapeutic implications.

Aims: In the present study, we investigated the molecular mechanisms as well as the functional impact of the NPM-ALK-induced NIPA phosphorylation.

Methods: For this purpose, biochemical methods with ALCL cells were used to examine functional effects of the constitutive NIPA phosphorylation. Moreover, we performed a “proteomic-phosphosite-analysis” to identify crucial NPM-ALK specific phosphorylation sites in NIPA. Based on these results, phospho-deficient NIPA mutants were generated to investigate the functional effect of this phosphorylation: MTI proliferation- and Softagar- Assays were performed and concluded, that NIPA is essential in the proliferation of 6 of the identified residues, phospho-deficient mutants were established and biological significance was completely abolished. To further prove biological significance of the identified residues, phospho-deficient mutants were established and transformation assays were performed. Here we were able to show drastically increased cell proliferation in NIPA mutants with silenced serine/threonine residues 338, 344, 370, 381 and 387 upon NPM-ALK expression.

Summary/Conclusions: Taken together, we identified five phosphorylation sites in NIPA to be highly upregulated upon NPM-ALK expression. However,
APPLICATION OF CELL-OF-ORIGIN SUBTYPES DETERMINED BY DIGITAL GENE EXPRESSION IN HIV-RELATED DIFFUSE LARGE B CELL LYMPHOMAS

Background: Diffuse large B cell lymphoma (DLBCL) is the largest and most malignant type of lymphoma. It is divided into two broad subtypes: Germinal Center B-Cell-like (GCB) and Activated B-Cell-like (ABC) (Table 1). ABC is associated with a poor clinical outcome. COO is a powerful tool to stratify DLBCL arising in immunocompetent individuals, its applicability on HIV-infected patients has been scarcely studied.

Aims: To study the characteristics and prognostic impact of COO subtypes in a series of HIV-related DLBCL using the Lymph2Cx assay and to compare the results with those obtained with an IHC-based algorithm.

Methods: A series of 55 patients with the diagnosis of HIV-related DLBCL (N=48), high-grade B-cell lymphoma (HGBL) with MYC and BCL2 and/or BCL6 rearrangements (N=3), or HGBL NOS (N=4) was studied. The following clinical parameters were collected from records: age, gender, ECOG, extranodal disease, symptoms (ABC=81.8%, P=0.003), gene expression and the percentage of infiltration levels (Spearman-Rho=0.764; p=0.001). Furthermore, remission in the bone marrow was assessed by biopsies, we observed a significant positive correlation between the side chain of AMD070 - a commercially available CXCR4 antagonist and its ligand CXCL12.

Results: We observed that the expression of CD10, 61.5% expressed BCL6, 55.8% expressed MUM1, and according to Hans algorithm 56.6% had a non-GC phenotype. COO subtype was the only factor associated with significantly different outcome both in GCB and ABC subtype. 20% were ABC subtype, and 16.4% were unclassified. The only clinical feature significantly associated with a defined COO subtype was B-symptoms (ABC=81.8% vs GCB=28.6%, P=0.003) and HIV-load tended to be more frequently observed in ABC (90%) than in GCB (58.1%, P=0.068). Regarding IHC-based results, MYC rearrangements were only detected in GCB cases and expression of CD10 and BCL6 tended to be associated with GCB (Table 1).

Summary/Conclusions: In HIV-related lymphomas, COO subtypes were discordantly assigned with Hans and Lymph2Cx assay and COO subtypes showed no impact on outcomes, independently of the method applied.

This work was supported by 2014 SGR225 (GRE) from CERCA Programme/ Generalitat de Catalunya, and by funds from Josep Carreras International Foundation, “La Caixa” Foundation and Celgene Spain.

CXCR4 AND CXCL12 ARE IMPLICATED IN BONE MARROW INFILTRATION PROCESS OF AGGRESSIVE B CELL LYMPHOMAS AND THEIR INHIBITION SUPPRESSES LYMPHOMA CELL GROWTH IN VITRO

A. Deutsch1, B. pursche1, B. Ehall1, M. Zoidi2, K. Fehrer1, E. Steinbauer3, M. Sedej4, H. Greinix1, K. Prochazka5, T. Wrodnigg5, C. Beham-Schmid3, P. Neubauer1
1Hematology, Internal Medicine, 2Organic Chemistry Technical University Graz, 3Pathology, 4Experimental and Clinical Pharmacology, Graz, Austria

Background: The chemokine receptor CXCR4 together with its ligand CXCL12 plays a pivotal role in tumorigenesis of solid and haematological neoplasms. Our comprehensive study on the CXCR4 expression in aggressive lymphoma demonstrated that high CXCR4 expression was associated with poor clinical course of aggressive lymphoma patients.

Aims: Therefore, we aimed to comprehensively study the implication of the CXCR4 - CXCL12 axis in bone marrow infiltration process of aggressive lymphoma to analyse the effects of CXCR4 antagonists on cell growth and migration of aggressive lymphoma cells in vitro.

Methods: To determine whether CXCR4 and CXCL12 expression have any effects on the bone marrow infiltration process of aggressive lymphomas, we performed gene expression analysis on bone marrow biopsies of our diffuse large B-cell lymphoma patient cohort. Therefore, we used 63 bone marrow specimens, whereby 52 bone marrow biopsies were taken at time of diagnosis. Additionally, we generated a novel CXCR4 antagonist -named WK1- by modification of the side chain of AMD070 - a commercially available CXCR4 antagonist. We treated various aggressive lymphoma cell lines (U2932 and R1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonists (AMD070 and its derivate WK1 and the FDA approved CXCR4 antagonist AMD3100) and determined cell growth by using the EZ4U assay. Transwell migration using the Boyden chamber was used to estimate migration indices for AMD070 and WK1.

Results: By correlating CXCR12 expression levels of infiltrated bone marrow biopsies, we observed that the strongest correlation between CXCL12 expression and the percentage of infiltration levels (Spearman-Rho=0.764; p=0.001). Furthermore, remission in the bone marrow was assessed by standard immunocytomorphology was associated with a reduction of CXCR4 expression (p=0.075). The cell growth of BL2 and R1 cell lines -exhibiting strong and moderate CXCR4 expression- was significantly inhibited by AMD070 and WK1. In the cell line case of U2932 -exhibiting weak CXCR4 expression- was just affected by WK1. AMD3100 did not show any effects on the lymphoma cell growth. The transmigration index to evaluate the chemotactic ability of lymphoma cells was reduced by AMD070 and WK1 treatment, however, the inhibitory effects of WK1 were lower compared to AMD070.

Summary/Conclusions: These data strongly suggest that CXCR4 and its ligand CXCL12 is implicated in the bone marrow infiltration process of diffuse large B-cell lymphomas. Additionally, our in vitro results indicate that treatment of lymphoma cells with CXCR4 antagonists might be a promising new therapeutic intervention to eliminate lymphoma cells.

Table 1.
Background: Epstein Barr virus (EBV) has been detected in the tumor cells of some non-Hodgkin lymphomas (NHL) and Hodgkin lymphomas (HL) and detectable EBV loads have been found in the plasma of immunocompetent patients with HL. In HIV-related lymphomas the importance of EBV load as potential lymphoma biomarkers has been scarcely studied.

Aims: We aimed to evaluate the usefulness of EBV load in plasma as lymphoma biomarker in HIV-infected patients.

Methods: One hundred and fifteen patients with NHL (EBV-infected=57 and HIV-uninfected=34) and HL (EBV-infected=16 and HIV-infected=8) were studied. EBV loads were determined in plasma by means of a commercial real-time PCR technique (EBV PCR kit, Qiagen GmbH, Hilden, Germany) at lymphoma diagnosis and in a group of HIV-infected patients also at one year before diagnosis (N=11) and at complete response (CR) (N=34). EBER expression was studied by in situ hybridization in tumor biopsies. The following clinical and biological parameters were collected from records: age, gender, date of lymphoma diagnosis, ECOG score, extranodal and bulky disease, B symptoms, Ann Arbor stage, serum lactate dehydrogenase and beta2-microglobulin. International Prognostic Index (IPI), HCV and HBV serology, history of opportunistic infection and of AIDS-defining illness, onset of combination antiretroviral therapy, CD4 counts, HIV loads, type and date of response, relapse date, last follow up or death date. McNemar’s test and Wilcoxon test were used to compare quantitative and qualitative variables, respectively. Survival analyses were performed using the Kaplan-Meier method. P-values of less than 0.05 were considered statistically significant.

Results: At diagnosis, EBV loads were detectable in more HIV-infected patients than HIV-uninfected (48% vs 14%, P=0.002) and in more HL cases than NHL (70% vs 26.3%, P=0.006). In HIV-infected patients, detectable EBV load was associated with EBER expression, 66.6% of the patients with detectable EBV loads had EBER-positive tumors and 92% of the patients with undetectable EBV loads had EBER-negative tumors (P=0.003). All the remaining clinical and biological features were not associated with detectable EBV load in plasma. In HIV-uninfected patients, associations between EBV load and EBER expression (P=0.006) and EBV load and HIV infection (P=0.017) were observed. From 16 out of 34 (47%) HIV-infected patients with detectable EBV loads at lymphoma diagnosis, 15 had undetectable EBV loads at CR (P=0.001) (Figure 1). The exception was one patient with HL whose EBV load substantially decreased at CR but was still detectable. Moreover, 4 out of 7 HIV-infected patients with detectable EBV loads at diagnosis had detectable loads one year before diagnosis, and no patient with negative EBV loads at diagnosis had detectable loads before it, pointing EBV load can be used as an early biomarker of lymphoma. EBV loads at diagnosis had neither impact on overall survival nor progression-free survival.

Summary/Conclusions: EBV-load in plasma can be used as early biomarker of lymphoma in HIV-infected patients since EBV-loads can be detected up to 1 year before lymphoma diagnosis and are virtually undetectable at lymphoma CR.

Figure 1. EBV loads in lymphoma patients at three clinical points. Lines connect as follows: 1) to evaluate the clonotypic repertoire in TCRγδ LGLL patients.

E1387

CLONOTYPE AND MUTATIONAL PATTERN IN TCRGΔ LARGE GRANULAR LYMPHOCYTE LEUKEMIA

A. Teramo1,2, E. Ciabatti3, G. Tarrina3, I. Petrini1, G. Barilà1, G. Calabretto1,2, C. Vicenzetto1,2,*, W. Zhong1

Background: T-cell large granular lymphocyte leukemia (T-LGLL) is a rare heterogeneous T-cell neoplasia whose leuemic cells usually express the αβ T-cell receptor (TCR): only a small subset of cases expresses the γδ TCR denoting the TCRγδ LGLL. Currently, among the different LGL diseases, TCRγδ LGLL remains less studied and several clinical and laboratory data already described in TCRαβ-LGLL have not yet been explored in TCRγδ-LGLL.

Aims: The aims of this work were 1) to characterize TCRγδ-LGLL defining STAT mutational pattern and CDR3 repertoire diversity/clonal composition (clonotype) and 2) to evaluate correlations among LGL phenotype, mutations, TCR rearrangement and clinical presentations.

Methods: In this work 11 patients affected by TCRγδ-LGLL were included. Sanger sequencing was used for mutational analysis on hot-spot regions in the two genes more frequently mutated in LGL disorders, STAT3 and STAT5b. Immunophenotype of LGL clone was defined by flow cytometry analysis. CDR3 repertoire and frequency distribution of TCR gamma gene rearrangements were determined by Next-Generation Sequencing (NGS).

Results: Our results showed that TCRγδ LGLL had a high incidence of STAT mutations, 9 out of 11 patients carrying STAT3 or STAT5b mutations in a mutually exclusive pattern. At variance from CD8+ TCRαβ LGLL and CD4+ TCRαβ LGLL, STAT3 mutations first being more characterized by STAT5b mutations, the latter by STAT7b5. TCRγδ LGLL patients were characterized by both the mutations. Thus, TCRγδ LGLL showed features shared by CD8 and CD4 TCRαβ-LGLL. Consistently, TCRγδ LGLL showed the same correlation between immunophenotype and kind of mutation observed in TCRαβ-LGLL: γδLGL patients with CD16+CD56-LGL immunophenotype were characterized by STAT3 mutations (as in CD8+ T-LGLL), whereas no correlation was found between mutations and clinical course. By NGS of TCR gamma gene, we observed that all patients were clonal but two, showing a polyclonal pattern borderline with clonality percentage defined by sequencing kit criteria. Interestingly, these two last patients were the only two patients without STAT mutations. As far as the remaining cases are concerned, among STAT3 mutated patients (n=4), 3 were polyclonal and one biclonal, while STAT5b mutated patients (n=5) were more frequently monoclonal (4/5 monoclonal and 1/5 biclonal). In terms of clonal rearrangements, Vg3-Jg1/2, Vg9-Jp and Vg8-J1/2 were the combination usage most frequently detected. Concerning the clonotype repertoire, CDR3 sequences of the dominant clone were present in almost all the other γδ patients and two different CDR3 sequences were found shared, each one in different patients at frequency >10% of the total rearrangements.

Summary/Conclusions: Our data indicate that TCRγδ LGLL can be considered as the intelectal, shared of the two types of TCRαβ-LGLL, since both γδLGL and CD4+ TLLGL mutational features. As already described in TCRαβ-LGLL, also in γδ disease a decreased diversity of TCR repertoire was demonstrated. However, in these γδLGL patients STAT mutations do not correlate with a symptomatic clinical behavior while STAT5b mutations seems to be more frequently linked to monoclonal nature of the LGL lymphoproliferation. Rather, the marker V81 appears to be correlated to symptomatic disease.

INCREASED EXPRESSION OF IRF8 IN TUMOR CELLS INHIBITS THE GENERATION OF TH17 CELLS AND PREDICTS UNFAVORABLE SURVIVAL OF DIFFUSE LARGE B CELL LYMPHOMA PATIENTS

Q. Li1,*, W. Zhong1

Background: The immunological pathogenesis of diffuse large B cell lymphoma (DLBCL) remains elusive. Searching for new prognostic markers of DLBCL is a crucial focal point for clinical scientists.

Aims: The aim of the present study was to examine the prognostic value of interferon regulatory factor 8 (IRF8) expression and its effect on the development of Th17 cells in the tumor microenvironment of DLBCL patients.

Methods: Flow cytometry, immunohistochemistry, and quantitative real-time PCR were used to detect the distribution of Th17 cells and related cytokines and IRF8 in tumor tissues from DLBCL patients. Two DLBCL cell lines (OCI-
LY10 and OGI-LY11 with IRF6 knockdown or overexpression and two human B lymphoblast cell lines were co-cultured with peripheral blood mononuclear cells (PBMCs) in vitro to determine the effect of IFR8 on the generation of Th17 cells. Quantitative real-time PCR and Western blotting were used to investigate the involvement of retinoic acid receptor-related orphan receptor gamma t (ROTY) in the effect of IFR8 on Th17 cell generation. The survival of 67 DLBCL patients was examined using the Kaplan-Meier method and the log-rank analysis.

Results: The percentage of Th17 cells was lower in DLBCL tumor tissues than in PBMCs and corresponding adjacent benign tissues. Relative expression of interleukin (IL)-17A was lower, whereas that of interferon (IFN)-γ was higher in tumor tissues than in benign tissues. Co-culture with DLBCL cell lines inhibited the generation of Th17 cells in vitro. IFR8 upregulation was detected in DLBCL tumor tissues, and it was associated with decreased DLBCL patient survival. Investigation of the underlying mechanism suggested that IFR8 upregulation inhibited Th17 cell generation by suppressing the effect of ROYR7 on CD4+ T cells.

Summary/Conclusions: Our findings suggest that IFR8 expression in the tumor microenvironment inhibits the generation of Th17 cells through its antagonistic effect on ROYR7 in the DLBCL tumor microenvironment, suggesting that it could be a prognostic factor for DLBCL.

GENOMIC PROFILING OF BCL2 AND MYC DOUBLE EXPRESSOR DIFFUSE LARGE B CELL LYMPHOMA

V. Dirse1,2,*, J. Drachneris3, U. Mickys3, M. Stoskus1, L. Griskevicius1,2

1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, 2Department of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, 3National Center of Pathology, Affiliate of Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania

Background: Diffuse large B cell lymphoma (DLBCL) is an aggressive disease featuring heterogeneous genetic, phenotypic and clinical characteristics. Recently, a negative prognostic impact of double expression of BCL2 and MYC (double expressor (DE)) lymphoma has been identified in several studies. SNP array (SNP-A) studies have already led to the identification of novel genomic aberrations in ABC and GCB subtypes of DLBCL whereas similar analysis has not been done in DE and non-DE DLBCL.

Aims: To characterize the landscape of genomic aberrations in DE and non-DE DLBCL groups using SNP-A and interphase fluorescence in situ hybridization (FISH).

Methods: Immunohistochemical and FISH analysis was performed on tissue microarray of formalin fixed paraffin embedded (FFPE) tumor tissue samples using Bcl2 (124, DakoCytomation) and MYC (Y69, Epitomics) antibodies and FISH MYC (Zytovision), Bcl2 (Abbott/Vysis), Bcl6 (Abbott/Vysis) break-apart probes and MYC/IgH (Zytovision) double-fusion probe. Infinium HD whole-genome genotyping assay with the HumanCytoSNP FFPE-12 BeadChip (Illumina Inc., San Diego, CA, USA) was performed for genomic analysis of the aberrations.

Results: A cohort of 91 primary DLBCL patients diagnosed between 2004 and 2012 was selected for the study. Immunohistochemical evaluation was informative in 89 cases (98.2%). The FISH analysis was informative for MYC, 56 cases for Bcl6, and 65 cases for Bcl2. 7 cases (11.4%) were positive for MYC translocation, 14 (25%) for Bcl6, and only 3 (4.8%) were positive for Bcl2. No cases of MYC and bcl2 double positive DLBCL were identified. Genomic DNA from FFPE tumor tissue for SNP-A was available in 66 DLBCL cases. Genomic DNA from matched normal DNA was detected in total 529 peripheral blood DNA samples (89% of all the patients, 59/66). These comprised 164 (50%) hemizygous and 2 (1%) homozygous deletions, 106 (32%) gains, 41 (12%) trisomies and 16 (5%) monosomies. The most common aberrations were 1p deletion, 1q gain, 6q deletions and 8q gains (3 or more aberrations (>3 aberrations)) was detected in 37/66 (56%) patients. Both DE and non-DE DLBCL groups had equal rate of aberrations per case (~5 aberr/case) and shared the most common aberrations – 1p deletion and 1q gain. In contrast, 11q deletion was more common in DE, while 6q and 17q deletions were more prevalent in the non-DE group. Notably, a proportional representation of dicentric karyotypes in non-DE group than in DE (16 vs 6 cases, respectively). Cases with MYC positive (FISH) and MYC gain (SNP-A) had the median number of two chromosomal aberrations with an exception of two MYC positive cases with complex karyotypes. These two cases shared the same 9q, 11q deletions and the monosomy of chromosome 19. Finally, of the 7 cases with normal SNP-A karyotype, BCL6 FISH-positive marker was detected in 3 patients.

Summary/Conclusions: SNP-A analysis highlights the genomic differences between the DE and non-DE DLBCL. Our finding of MYC positive (translocations and/or gains) association with low complexity karyotype status may suggest MYC to be an early initiating genetic event.

E1400

ARQ 531, A REVERSIBLE BTK INHIBITOR, DEMONSTRATES POTENT ANTI-TUMOR ACTIVITY IN ABC-DLCL AND GCB-DLCL

S. Eathathirai1, Y. Yu1, T. Hall1, B. Schwartz1, J.A. Woyauch2, S. Reif2, G. Abbadesoa1

1Clinical Development, ArQule Inc., Burlington, 2Division of Hematology, The Ohio State University, Columbus, United States

Background: B-cell receptor (BCR) signaling has emerged as a critical pathway for B-cell lymphoma development. BTK, a key mediator of BCR signaling, is a major target for ibrutinib. Ibrutinib has demonstrated efficacy in chronic lymphocytic leukemia (CLL), mantle cell lymphoma and Waldenstrom macroglobulinemia. However, as anticipated by preclinical models, clinical objective response rates of only 37% in ABC and 5% in GCB diffuse large B cell lymphoma (DLBCL) were reported. ARQ 531 is a potent reversible inhibitor of BTK, highly effective in targeting BCR signaling. Kinase profiling indicated additional targets such as SRC, TRK, FAK, and additional resistance in DLBCL not potent inhibition of HCK and BLK kinases. ARQ 531 caused significant growth inhibition (GI50=1 μM) of hematological malignant cell lines and showed greater efficacy than ibrutinib in a CLL mouse model.

Aims: We aim to assess biological and anti-tumor effects of ARQ 531 in in vitro and in vivo models.

Methods: Biochemical inhibition and kinase profiling were assessed using recombinant proteins. The ARQ 531 binding kinetics on BTK were determined by Surface Plasmon Resonance assay. Anti-proliferative activity of ARQ 531 was tested in a MTS-based assay against a panel of hematological malignant cell lines. Pathway inhibition assessments, in vivo efficacy and in vivo tumor inhibition were performed in TMD8 (ABC-DLCL) and SUDHL-4 (GCB-DLCL) cell lines and xenografts. ADME and pharmacokinetic properties of ARQ 531 were also evaluated in rats, dogs and monkeys.

Results: ARQ 531 potently inhibited BTK (IC50=0.85 nm) and displayed long concentration not reached in human blood, consistent with published studies. Pathway analysis in TMD8 and SUDHL-4 cells showed that ARQ 531 potently inhibited both upstream activating signals (Src kinase family) and downstream signaling pathways such as AKT and ERK. Cell cycle analysis indicated that ARQ 531 inhibited cell growth up to 91% after 4 days of dosing, with no re-growth observed for 17 days post dose interruption. In the ibrutinib-resistant SUDHL-4 mouse xenograft model, ARQ 531 potently suppressed tumor growth (>80% inhibition) compared to the control group.

Summary/Conclusions: ARQ 531 is a potent reversible inhibitor of BTK. Its disease selectivity can be used to target constitutive BCR signaling in DLBCL primarily resistant to ibrutinib, as demonstrated by the excellent efficacy in both ABC and GCB DLBCL xenograft models. These data support the clinical investigation of ARQ 531 in patients with hematological malignancies, expected to begin in mid-2017.

ROLE OF GENETIC POLYMORPHISMS ON R-CHOP EFFICACY IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS: AN INTERIM ANALYSIS OF A MULTICENTER PROSPECTIVE PHARMACOGENETIC STUDY

L. Rigacci1,2*, G. Perrone2, S. Nobili2, S. Kovalchuk1, B. Puccini1, R. Tassi2, M. Brugia2, I. Landini 2, L. Mannelli 1, G. Benelli 1, C. Napoli 3, E. Cencini 4, P. Bernardeschi9, A. Bosi1, E. Mini2

1Haematology, AOU Careggi University and Florence, 2Medicina Sperimentale e Clinica, 3Scienze della Salute, University of Florence, Florence, 4Haematology, AO Siena, Siena, 5Haematology, AO Pisa, Pisa, 6Oncologia, Ospedale Pescia, Pescia, 7Oncologia, Ospedale Lucca, Lucca, 8Oncologia, Ospedale Prato, Prato, 9Oncologia, Ospedale Empoli, Empoli, Italy

Background: Standard chemotheraphy represented by the R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone) regimen is successful in about 60% of patients (pts) with diffuse large B-cell lymphoma (DLBCL). Pts who do not benefit from this treatment, due to the development of tumor drug resistance, have a very poor prognosis. Currently, knowledge on reasons of treatment related failures in DLBCL are scanty and predictive biomarker of response are largely unknown.

Aims: We hypothesized that polymorphisms of genes involved in the pharmacokinetics and pharmacodynamics of drugs included in R-CHOP regimen may play a role in predicting the outcome in DLBCL pts. Thus, we designed a multicenter prospective pharmacogenetic trial aimed at identifying gene polymorphism that could improve drug efficacy/resistance and result in a better patient selection for R-CHOP. We are reporting update data of an interim analysis on the first 80 enrolled pts.

Methods: The study includes chemonaive DLBCL pts (Ann Arbor I-IV stages) candidate to an R-CHOP standard treatment. The Ethical Committee of each participating centre approved the pharmacogenetic protocol, and all pts signed a written informed consent. In this interim analysis, the impact of single nucleotide polymorphisms (SNPs) on R-CHOP efficacy was evaluated by objective response (OR) rate, progression-free survival (PFS) and overall survival...
vival (OS). The efficacy of R-CHOP was evaluated according to Cheson criteria by performing standard hematohemical and instrumental (TC and FDCG-PET) tests and defining complete remission (CR), partial remission (PR), non response or progressive disease (PD). Genomic DNA was extracted from peripheral blood of 80 pts. SNPs analysis was performed by an Affimatrix array. To date, 21 SNPs from 19 candidate genes (ABC21, ABC21C, ABC22, ABC22C, CHK1, CD20, CDKN1A, CDKN1B, CDKN1C, CDK4, CDK6, FGFR2A, GSTP1, IGF1, IL11, NCF4, NOQ1, NOQ2, RAC2, TNC, TOP2A, TP53, TUBB) involved in pharmacokinetics and pharmacodynamics of R-CHOP (www.pharmkgb.org) selected and analysed in relation to R-CHOP efficacy. Univariate and multivariate logistic regression analyses were performed to evaluate associations between SNPs and clinical/pathological characteristics or survival parameters (PFS and OS).

Results: Median age was 63 years. There were 37 men and 43 women. 47.5% of pts were in stage I-II, 52.5% of pts in stage III-IV. 27.5% of pts had bulky disease, 43.8% of pts had involvement of extranodal site. 47.5% of pts had pathological LDH value. According to the revised IPI, 15% of pts were in the low risk group, 58.7% in the intermediate, and 28.8% in the high risk group. 1,408 courses of R-CHOP had been administered (mean: 5.85 courses, range: 4-4). 88.7% of pts had CR to R-CHOP whereas the remaining showed PR or SD (7.5%) or PD (0.3%). Multivariate analysis identified FGFR2A rs1801274 as a predictor of OS (p=0.045). Pts with HR or RR genotypes showed shorter PFS than pts with HH genotype (HR: 2.43, 95% CI: 1.59-3.75; p<0.001).

Summary/Conclusions: No statistically significant correlation was found between SNPs and OS.

E1402

CDK4/6-INHIBITION BY ABEMACICLIB INDUCES POTENT EARLY G1-ARREST IN MCL CELL LINES AND SHOWS SEQUENCE-SPECIFIC INTERACTIONS WITH CYTARABINE AND IBRUTINIB

L. Fischer1,*, A. Mayer1, M. Irger1, B. Freysoild1, Y. Zimmermann1, G. Hutter1, W. Hiddemann1, M. Dreyling1

1Dept. of Medicine III, Univ. Hospital Grosshadern/LMU; Experimental Leukemia and Lymphoma Research (ELLF), Munich, Germany

Background: Mantle cell lymphoma (MCL) is characterized by t(11;14) resulting in a constitutive cyclin D1 overexpression. The cyclin D1-CDK4/6 complex inactivates Rb through phosphorylation, leading to G1/S-phase transition. Therefore, inhibition of CDK4/6 is an efficient and rational approach to overcome cell cycle dysregulation in MCL.

Aims: We evaluated the efficiency of the novel CDK4/6 inhibitor abemaciclib in various MCL cell lines and in primary MCL cells in combination with cytarabine (AraC) and ibritinib.

Methods: MCL cell lines (Granta 519, JeKo-1, Mav-1, Mino) and primary MCL cells were exposed to abemaciclib alone and combined with AraC or ibritinib. MCL cells were pretreated with abemaciclib and exposed to AraC or ibritinib with or without consecutive wash-out of the CDK4/6 inhibitor. Proliferation and viability were measured by trypan blue staining and Cell Titer Glo assay. Combination Index (CI) to assess synergy or antagonism was calculated using the Fractional Product method by Webb (1963). Flow cytometry was applied for cell-cycle (PI-staining) and apoptosis analysis (Annexin V/7AAD-staining). Protein expression and phosphorylation status of various downstream proteins was analyzed by Western Blot analysis.

Results: Abemaciclib inhibited cell proliferation by induction of early G1-arrest. We observed an almost complete and reversible G1-arrest in all sensitive cell lines by FACS analysis (JeKo-1: G1-phase +51.7%; S/G2-phase -51.7% at 31.25 nM after 24 h; G1-phase +35.4%; S/G2-phase -34.8% after 72 h), whereas cell viability was not reduced. IC50-values of sensitive cell lines (JeKo-1: G1-phase +51.7%; S/G2-phase -51.7% at 31.25 nM after 24 h; G1-phase +35.4%; S/G2-phase -34.8% after 72 h) were in accordance with the published IC50-values of sensitive cell lines (e.g.: Mino: G1-phase -20.4%; S-phase +30.5%). Accordingly, sequential combination of abemaciclib followed by AraC showed strong synergy in Mino cells (CI=0.22 for 31.25 nM abemaciclib / 3.3 µM AraC). In contrast, simultaneous exposure to abemaciclib had a protective effect against AraC treatment in all sensitive cell lines, due to an ongoing G1-arrest (Mino: CI=0.19 for 31.25 nM abemaciclib / 3.33 µM AraC). Sequential administration of abemaciclib and ibritinib had synergistic or additive effects in sensitive cell lines (CI: JeKo-1:CI=0.24; Mav-1:CI=0.19; Mino:CI=0.03 for 31.25 nM abe / 2.5 µM ibru), whereas the simultaneous administration of both showed additive effects at most (CI: JeKo-1:CI=0.19; Mav-1:CI=0.01; Mino:CI=0.09 for 31.25 nM abe and 2 µM ibru). In primary MCL cells abemaciclib had no impact on cell death or sensitization since no cell proliferation was observed and cells where resting in G1-phase.

Summary/Conclusions: The novel CDK4/6 inhibitor abemaciclib causes reversible G1 cell cycle arrest without loss of viability at low nanomolar doses. Rationale drug combinations exploiting the sequential effect may achieve major benefits. Pretreatment with abemaciclib might sensitize cells to ibritinib, resulting in synergistic drug effects. In contrast, simultaneous application of Abemaciclib protects cells from AraC treatment whereas Abemaciclib-induced S-phase synchronization sensitizes MCL cell lines to AraC. Further analysis needed to explore the interaction with other targeted approaches (inhibitors of the B-cell receptor pathway) to better understand the underlying molecular mechanisms.

E1403

CD8+ T-CELL CLONES PERSISTENT IN BONE MARROW AND PERIPHERAL BLOOD DURING COURSE OF CD4+ ANGIOIMMUNOBLASTIC LYMPHOMA

S. Smirnova1,*, Y. Sidorova1, N. Chernova2, E. Zvonkov2, M. Sinicina3, K. Sychevskaya4, O. Glinshchikova1, N. Ryzhikova1, A. Kovrigina3, A. Sudarikov1

1Department of Molecular Hematology, 2Department of Lymphoma Chemotherapy, 3Department of Pathology, National Research Center for Hematology, 4Faculty of Basic Medicine, Lomonosov Moscow State University, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) – peripheral T-cell lymphoma, characterized by polymorphous infiltration of the lymph nodes, proliferation of high endothelial venules (HEV) and follicular dendritic cells (FDC). In addition to the lymph nodes, AITL affects spleen, liver, skin and bone marrow. The disease is almost always associated with Epstein-Barr virus (EBV), suggesting its role in the etiology of AITL. Neoplastic T cells in most cases are CD4+ and express pan T-cell antigens CD3, CD2, CD5, markers of normal follicular T-helper cells – CD10, CXCL13, PD-1. To confirm the diagnosis and assess disease dissemination combined morphological, immunohistochemical and molecular studies of affected tissues are being used. We have found that T-cell clones detected in the tissue of the lymph node (LN), often differ in T-cell receptor gene rearrangements from those detected in the bone marrow (BM), peripheral blood (PB) and other tissues. T-cell clonality testing itself may not distinguish between neoplastic or reactive lymphoproliferation in the BM and PB. Therefore, T-cell clonality of CD4+ and CD8+ populations of peripheral blood lymphocytes in patients with AITL had been tested during the course of disease.

Aims: To determine immunological characteristics of persisting in the PB and BM T-cell clones in AITL patients.

Methods: The study included 26 patients (15 males and 11 females; age 36-92, median 67) with the diagnosis of AITL established on the basis of WHO 2008 diagnostic criteria. LN, BM and peripheral blood lymphocytes were tested for T-cell clonality according to BIOMED-2 protocol with subsequent fragments analysis on ABI PRISM 3130 (Applied Biosystems). The material was examined at the diagnostic laboratory of the Department of Hematology/Immunology. Genomic DNA was extracted from peripheral blood of 80 pts. SNPs analysis was performed by an Affimatrix array. To date, 21 SNPs from 19 candidate genes (ABC21, ABC21C, ABC22, ABC22C, CHK1, CD20, CDKN1A, CDKN1B, CDKN1C, CDK4, CDK6, FGFR2A, GSTP1, IGF1, IL11, NCF4, NOQ1, NOQ2, RAC2, TNC, TOP2A, TP53, TUBB) involved in pharmacokinetics and pharmacodynamics of R-CHOP (www.pharmkgb.org) selected and analysed in relation to R-CHOP efficacy.
CD5 POSITIVE DIFFUSE LARGE B CELL LYMPHOMA SHOWED FREQUENT MYC EXPRESSION AND AGGRESSIVE CLINICAL BEHAVIOR

H.-Y. Na1,*, J.Y. Choe2, H.-J. Kim3, H.K. Kim5, J.K. Cha4, J.E. Kim2
1Pathology, Seoul National University Hospital, Seoul, 2Pathology, Hallym University Sacred Heart Hospital, Anyang, 3Pathology, Sanggye Paik Hospital, Inje University college of medicine, Seoul, 4Pathology, Ajou University School of Medicine, Suwon, 5Pathology, Soonchunhyang University Hospital, Bucheon, 6Pathology, Seoul St. Mary’s Hospital, Seoul, 7Pathology, Ulsan University Hospital, Ulsan, 8Pathology, Seoul National University Boramae Hospital, Seoul, Korea, Republic Of

Aims: This study aimed to investigate clinicopathologic features of CD5 + DLBCL in Koreans.

Methods: A total of 350 cases of DLBCL were reviewed 4 university hospitals from 2004 to 2012. Review of the histologic features along with immunohistochemical study for BCL1, BCL2, BCL6, CD5, CD10, CD23, IFR4/MUM1, MYC, Ki-67 and EBV in situ hybridization was performed. Florescent in situ hybridization (FISH) for MYC rearrangement and amplification was also performed. The results were compared with DLBCL-NOS (N=195).

Results: Thirty cases of CD5+ DLBCL were retrieved among 350 cases of DLBCL (8.6%), which showed predominance of female (20/30), elderly (mean age 64), and extranodal presentation (16/30). Richter transformation was suspicious in 10 cases and EBV was negative in all. Most cases (22/30) belong to non-GCB subtype by Hans classifier. Rearrangement of MYC was found in 2 cases and amplification was found in one. Compared with DLBCL-NOS, CD5+ cases revealed significantly higher expression of MYC, BCL5, IFR4/MUM1 and Ki67 (all p<0.05). Double expression of both BCL2 and MYC was found in 9 of 30 cases (30%). Also, CD5+ DLBCL showed more frequent bone marrow involvement, advanced stages and high immunohistochemical score of Ki67 (all p<0.05). In univariable survival analysis, CD5+ DLBCL revealed significantly shorter progression free survival (median 8.2 months) compared with DLBCL-NOS (median 36.3 months) (p<0.05)

Summary/Conclusions: This study aims to document the clinico-pathological features of florid RBLP in the setting of HIV infection in order to provide an approach to differentiating reactive and clonal processes.

Aims: This study aims to document the clinicopathological features of florid RBLP in the setting of HIV infection in order to provide an approach to differentiating reactive and clonal processes.

Methods: A retrospective database search was performed of the laboratory information system (National Health Laboratory Service) that screened pathology reports for samples referred to the Departments of Molecular Medicine and Haematology and Anaemotology at the Johannesburg Academic Complex during 2007-2011, supplemented with results of immunophenotypic analysis from 2007-2016. Demographic and clinic-pathological findings were collected for patients identified with florid RBLP who showed no definite evidence of monoclonality.

Results: During this period, 38 patients were diagnosed with florid RBLP with up to 70–80% of cells in blood or bone marrow comprising reactive B cells (including mature B, plasmablasts and plasma cells). All patients tested were HIV positive, with a median age of 28 years (range 6 months - 79 years). There was a bimodal age pattern with a peak in children <1 year of age (34% of patients) and a secondary peak in those identified in LN for the majority of patients with ATL (76%). These clones can persist for a long time (the period of observation from 1 to 40 months), may not disappear in remission and probably have reactive nature. Therefore exclusive T-cell clonality in PB and/or BM should not be treated as minimal disease or relapse in ATL.

CD5 REACTIVE FLORID B-LINEAGE LYMPHOID PROLIFERATIONS IN HIV INFECTION MAY IMIC LYMPHOMA

T. Wiggill1,*, J. Vaughan1, E. Mayne1
1Molecular Medicine and Haematology, National Health Laboratory Service and University of the Witswatersrand, Johannesburg, South Africa

Aims: To examine the relationship between microvesSEL density (MVD) as a parameter of tumor angiogenesis, and the immunophenotype in patients with diffuse large B-cell (DLBCL) lymphomas.

Methods: We retrospectively identified cases of DLBCL diagnosed between January 2010 and January 2016 at our Institution. The following large B-cell lymphoma subtypes were excluded from this analysis: post-transplant lymphoproliferative disorders with a DLBCL morphology, Primary Mediastinal large cell lymphoma, and cases of plasmablastic lymphoma.

Results: Limited follow-up data was available, with only 8 patients documented to be attending an HIV clinic for long-term follow-up.

123p-value<0.001, Children excluded from CD4 count analysis.

Summary/Conclusions: In the setting of HIV, reactive conditions may mimic lymphoma and vigilance is needed in the confirmation of monoclonality. Patients with RBLP presented at a younger age when compared to their counterparts with lymphoma. They had extremely high VL with higher CD4 counts, suggesting this may be a feature of early HIV disease and the possibility of a seroconversion type illness should be considered.

123p-value<0.001, Children excluded from CD4 count analysis.

Summary/Conclusions: In the setting of HIV, reactive conditions may mimic lymphoma and vigilance is needed in the confirmation of monoclonality. Patients with RBLP presented at a younger age when compared to their counterparts with lymphoma. They had extremely high VL with higher CD4 counts, suggesting this may be a feature of early HIV disease and the possibility of a seroconversion type illness should be considered.
Microvessel quantification was performed by immunohistochemical staining, using monoclonal antibodies against platelets/endothelial cell adhesion molecule-CD31. A total of 82 cases of de novo DLBCL treated with R-CHOP were included in the training set for further analysis. There were 45 men and 37 women, with a median age of 57 years (range, 16-84); 35 patients (43%) presented with B symptoms, and 49 (60%) had advanced Ann Arbor stages. Most of the patients had a good performance status (Eastern Cooperative Oncology Group score 0-1, 87%), elevated serum lactate dehydrogenase level (61%), and low or low-intermediate International Prognostic Index (IPI) risk (IPI score 0-2, 63%). Involvement of multiple extranodal sites (≥2) was seen in 22% of cases, and bulky disease in 32% of cases.

Results: The median follow-up time was 47 months. Among the 82 cases in the training set, CD30 was positive in 24 cases (29%). No difference in response rate was observed between CD30 positive and CD30 negative patients. Patients with CD30+ DLBCL showed a significantly superior OS and PFS compared with CD30− patients. The 5-year OS was 79% in patients with CD30+ vs 59% in CD30− (P<0.05); 5-year PFS was 82% in patients with CD30+ vs 63% in CD30− (P<0.05).

Discussion: In CD30+ DLBCL treated with R-CHOP were included in the analysis. Overall, 1,129,289 filtered-in sequences from 6 samples were evaluated (median 188,095 sequences/sample). Major findings in the familial cases investigated include: (i) pronounced skewing of the TRBV repertoire; (ii) evidence of more than one immunodominant clonotype; (iii) in the analysis of longitudinal samples from the son, persisting clonotypes albeit with fluctuating frequencies (clonal drift); and, (iv) shared (‘public’) clonotypes between father and son. In the T-LGL leukemia of donor origin, the immunodominant clonotype was detected amongst the polyclonal donor repertoire and subsequently expanded in the recipient, persisting over time and accompanied by a few other considerably expanded, albeit smaller, clonotypes.

Summary/Conclusions: The borders between polyclonal oligoclonal versus monoclonal T-LGL lymphoproliferations are not sharply demarcated, but rather the transition from a polyclonal cytotoxic response to a clonal expansion of T-LGL leukemia is a gradual process. Repertoire restrictions, public clonotypes and clonal drift strongly indicate selection by restricted (perhaps also shared) antigens in T-LGL leukemia ontogeny and evolution.

E1408 MINIMAL RESIDUAL DISEASE (MRD) EVALUATION IN LYMPHOMAS WITHIN THE FIL (FONDAZIONE ITALIANA LINFOMI) MRD NETWORK: INTER-LABORATORY REPRODUCIBILITY ON BORDERLINE SAMPLES

I. Batsis2, I. Sakellari2, A. Anagnostopoulos2, N. Maglaveras3, I. Chouvarda3, M. Papaioannou4, K. Stamatopoulos1, A. Hadzidimitriou1

1Hematology Department and HCT Unit, G. Papanicolaou Hospital, 3Laboratory of Immunogenetics and Hematopathology, S. Orsola-Malpighi Hospital, University of Bologna, Bologna, 2Department of Cellular Biotechnologies and Hematology, Hematology, Sapienza University, Rome, 4Department of Medical Biotechnologies, University of Siena, Siena, 5Department of Experimental, Diagnostic, and Speciality Medicine, Hematopathology Section, S. Orsola-Malpighi Hospital, University of Bologna, Bologna, 6Department of Molecular Medicine, Hematology, Sapienza University, Rome, 7Division of Hematology, Azienda Ospedaliera SS Antonio e Biagio e Cesare Arioto, Alessandria, Italy

Background: In B-cell non-Hodgkin lymphomas, minimal residual disease (MRD) is a highly valuable tool for the direct assessment of the reduction of the disease burden. In 2009, the four laboratories of the Fondazione Italiana Linfomi (FIL) - FIL MRD network - started a collaborative effort to harmonize and standardize their methodologies, performing QC (Quality Control) rounds twice a year for follicular lymphoma (FL) and mantle cell lymphoma (MCL) MRD assessment.

Aims: We evaluated the molecular results of bone marrow (BM) samples analysis performed during the QC rounds, to determine how borderline samples (i.e. those with a low MRD level) challenge the inter-lab reproducibility and data interpretation.

Methods: Between February 2010 and November 2016, in the context of 14 QC rounds, the FIL MRD Network labs received 188 BM samples: 167 were analyzed by both nested polymerase chain reaction (PCR) and real-time quantitative PCR (RQ-PCR). BCL2/IGH rearrangement was analyzed by nested PCR (Gribben, 1993) and by RQ-PCR (Ladetto, 2000). Clonality assessment was performed using an IGHV multiplex consensus PCR (Ladetto, 2003) and, in some cases, carried out as described previously (Ladetto, 2000; Donoval, 2000). All analyses were conducted and interpreted according to the “EuroMRD Consortium” guidelines (van der Velden, 2007).

Results: The sensitivity and the accuracy of each molecular analysis was tested, reaching a uniform sensitivity of 10−2 and a quantitative range for RQ-PCR of at least 10−5. Ninety-three percent of analyses of all QC rounds were carried out as described previously (Ladetto, 2000; Donoval, 2000). All analyses were conducted and interpreted according to the “EuroMRD Consortium” guidelines (van der Velden, 2007).

Discussion: The sensitivity and the accuracy of each molecular analysis was tested, reaching a uniform sensitivity of 10−2 and a quantitative range for RQ-PCR of at least 10−5. Ninety-three percent of analyses of all QC rounds were carried out as described previously (Ladetto, 2000; Donoval, 2000). All analyses were conducted and interpreted according to the “EuroMRD Consortium” guidelines (van der Velden, 2007).

Results: The sensitivity and the accuracy of each molecular analysis was tested, reaching a uniform sensitivity of 10−2 and a quantitative range for RQ-PCR of at least 10−5. Ninety-three percent of analyses of all QC rounds were carried out as described previously (Ladetto, 2000; Donoval, 2000). All analyses were conducted and interpreted according to the “EuroMRD Consortium” guidelines (van der Velden, 2007).
samples analyzed by both methods, 83% (139/167) of these were classified as a+/− or −/− by all the FLR labs. The remaining 28/167 (17%) were the samples that showed discordant results in the inter-lab assessments: while in 17 cases the “borderline status” was defined alternatively by only one method, 11 resulted brd samples by both techniques (11/167, 6.6%) (Fig.). Given that the 167 samples were tested in three replicates across the 4 labs, a total of 12 replicates/sample were analyzed: 31 brd samples were thus identified, 13 of which brd by both approaches. Of 156 evaluations performed on the 13 brd, 69/156 (44%) resulted PCR-positive and 87/156 (56%) PCR-negative, 58/156 (37%) were RQ-PNQ and 98/156 (63%) RQ-negative.

Figure 1.

Summary/Conclusions: Despite the high inter-lab reproducibility in the MRD analysis that can be obtained and maintained by the QC round strategy, samples with the lowest MRD levels can still represent a challenge: 17% (28/167) of our series resulted brd, showing discordant results in inter-lab assessments; 39% of them (11/28) remained brd even applying both methods. The results did not change even increasing the number of replicates/sample. Thus, although representing a minority, brd samples are still problematic, especially when a clinically oriented interpretation is required. As the combined use of standard methods does not totally solve this problem, alternative, novel, methods such as digital PCR and NGS need to be tested in this context.

ROHA GLY17VAL MUTATION AND T-CELL CLONALITY ANALYSIS IN PATIENTS WITH ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA

Y. Sidorova1, N. Chernova2, I. Yakutik1, S. Smirnova1, N. Ryzhikova1, E. Nikulina1, M. Alekseenko2, O. Glinshchikova1, M. Siinitsyna1, A. Kovrigina1, E. Zvonkov2, A. Sudankov1

1Department of Molecular Hematology, 2Department of Lymphoma Chemotherapy, 3Department of Pathology, National Research Center for Hematology, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a rare subtype of T-cell lymphoma, characterized by generalized lymphadenopathy, hyperglobulinemia, and autoimmune manifestations. Interpretation of histological and immunohistochemical data can be difficult due to the small number of tumor cells, as well as by abundant polymorphocellular infiltrate. AITL could often be misdiagnosed as reactive processes and other lymphomas, including Hodgkin’s lymphoma. T cell clonality assessment plays an important role in AITL diagnosis. However, ambiguous clonality results may be obtained. Recently discovered somatic ROHA Gly17Val mutation is present in 53-71% of angioimmunoblastic T-cell lymphomas. We compared the efficacy of T-cell clonality testing and quantitative allele-specific PCR ROHA Gly17Val mutation assay in different tissues for AITL diagnosis.

Aims: To correlate the number of ROHA Gly17Val mutated cells in lymph nodes, bone, bone marrow and skin of AITL patients with corresponding T cell clonality results.

Methods: Lymph nodes (LN), skin biopsies, blood and bone marrow (BM) samples were studied for 40 patients with AITL. The male/female ratio was 25/15, median age was 65 years (36-92). To evaluate T-cell clonality rearranged TCRG and TCRB gene rearrangements were PCR-amplified according to BIO-MED-2 standardized protocol and analyzed by capillary electrophoresis on ABI PRISM 3130 (Applied Biosystems). Sensitivity of T-cell clonality assay was limited to 10% of clonal T-cells of the total T-lymphocytes in the sample. Gly17Val mutation was analyzed by quantitative allele-specific (qAS) TaqMan Real-Time PCR assay. The detection level of this method was 1% of mutated cells in the total cell population.

Results: The clonal TCR gene rearrangements in LN were found in 37 of 40 patients (92%). ROHA (Gly17Val) mutation in LN was revealed in 60% (24 of 40) patients. T-cell clonality was detected in 26 of 28 primary samples of BM, but in 12 of 26 patients (46%) clonal TCR rearrangements were not matched in length with rearrangements detectable in LN. Number of cells with ROHA mutation was highest in the LN (in average 26.7% of the total cells), while in the bone marrow ROHA mutation was undetectable (in 7 patients), or detected in 10 patients in a small amount (in average 2% of the total cells). Combined histochemical investigation, T-cell clonality and ROHA (Gly17Val) testing showed BM lesion in 76% of patients (13 of 17) with at least one of the methods. Blood and bone marrow samples examined simultaneously showed slightly higher numbers of ROHA positive cells in the blood than in the BM in 5 of the 7 ROHA positive patients. Significant percentage of cells with a ROHA mutation (in average 25% of the total cells) was revealed in 5 of 6 skin samples from ROHA positive patients. We have found good correlation (Spearman’s Rho=0.8198, p-level <0.00001) between T-cell clonality (matching with LN clonal peaks) and the number of ROHA positive cells in the AITL samples (n 51). Skin, blood and bone marrow samples with the T cell clonality peaks that differ from those found in the LN were also negative for the presence of cells with ROHA (Gly17Val) mutation.

Summary/Conclusions: ROHA (Gly17Val) point mutation is detected in LN by allele-specific PCR in 60% of patients with AITL. The percentage of tumor cells in BM is low (averaging less than 2% of the total cells). However, combined molecular and histological data suggest that BM may be involved in most patients. Extent of T cell clonality (matching with LN clonal peaks) correlates with the amount of cells having a ROHA mutation. T-cell clonality in BM, skin, spleen, etc. with rearrangements not matching those identified for the LN should be considered reactive and possibly associated with autoimmune process or antiviral response.
Results:
We analyzed the data of 9 HLH patients; 4 females and 5 males. These findings.

Aims:
To assess the diagnostic utility of Chitotriosidase activity (ChT), CCL18/PARC, 7-ketocholesterol (7KC) and glucosylphosphatidylsphingosine (Lyso-Gb1) concentrations in previously mentioned LSDs.

Methods:
ChT activity, CCL18/PARC and 7KC concentrations were measured in 146 plasma samples from subjects with suspected LSD (32 GD, 7 NPA/B, 90 NP-C and 17 LALD) received in our laboratory. In addition, a new biomarker, the Lyso-Gb1 concentration, was evaluated in 83/146 of previous mentioned subjects, 19 of them with confirmed LSD diagnosis. ChT was evaluated using a fluorogenic substrate, CCL18/PARC concentration by ELISA and 7KC and Lyso-Gb1 by liquid chromatography followed by tandem mass spectrometry.

Results:
A total of 9/32 (28%) samples with suspected GD showed high ChT activity, whereas CCL18/PARC and 7KC were normal in the rest and high in 1/32. One of those patients was a twin sister. In 19/43 (44%) subjects with suspected NPA/B, ChT and CCL18/PARC were positive and 7KC and Lyso-Gb1 were normal. In the rest of the subjects, who were NPA/B and altered biomarkers were confirmed. Among the 23/90 (26%) with suspected NP-C and some elevated biomarker four were diagnosed as NP-C, and two carriers showed some biomarker higher than cutoff. Of the 8/17 (47%) referred to LALD suspicion with some elevated biomarker six were affected. All GD confirmed patients show high levels of Lyso-Gb1 whereas none of the other cases showed elevation for mentioned biomarker.

Summary/Conclusions:
The screening of three biomarkers: ChT activity, CCL18/PARC and 7-ketocholesterol concentrations (the latter not applicable in GD) is a powerful tool to identify patients at high risk of suffering from LSDs which should undergo confirmatory diagnostic tests. In this line we would have reduced the number of cases needing confirmatory diagnostic test from 146 to 43 (23%) and 19/43 (44%) were positive for LSDs. Lyso-Gb1 concentration can allow the unambiguous identification of all the GD patients but is not useful for the other LSDs.

E1412
GAUCHER DISEASE PATIENTS EXHIBIT A HIGH EXPRESSION OF LIPOICINE (LCN2) AS POSSIBLE BIOMARKER OF RESIDUAL DISEASE AND IMMUNE-RELATED ACTIVITY: AN EXPLORATORY STUDY AND CORRELATION WITH OTHER CYTOKINES
M. Andrade-Campos 1*, M.P. Garcia Sobreviela 2,3, B. Medrano Engay 3, P. Irun1, J. Gervas Arruga3, M. Arbones2,3, P. Giraldo1,4
1Translational Research Unit, IIS-Aragon, CIBERER, ISCIII, 2ADIPOFAT, Instituto Aragones de Ciencias de la Salud, 3Translational Research Unit, IIS-Aragon, 4FEETEG, Fundacion Española Estudio y Terapéutica Enfermedad de Gaucher, Zaragoza, Spain

Background: Gaucher Disease (GD) is characterized by a latent chronic inflammation in macrophages with a high activation status expressed by an upregulation of pro-inflammatory cytokines, hyperferritinemia, hypergammaglobulinemia, altered calcium homeostasis and metabolic syndrome. Even patients under ERT do not fully revert this status and their risk to develop bone crises, iron metabolism alterations, autoimmune disorders and neoplasm remain higher. This observation is explained by the creation of a chronic-inflammatory state associated with an increased risk of bone crisis. Monitoring of patients through chitotriosidase and CCL18/PARC has become essential because there are patients whom never normalize while others developed bone crisis/ complications after long-time under therapy and normal values. One of the key features for chronic inflammation is the anemia; this is characterized by hyperferritinemia a common feature diagnosed in GD1 patients. Lipocicline (LCN2), a cytokine released by adipocytes, mononuclear cells and neutrophils with expression on endothelial cells, hepatocytes and other cells, has been involved into the monocyte polarization and perpetuation of the inflammatory state. Based on this, we have performed an exploratory study assessing LCN2 expression in GD patients under different circumstances.

Aims: To explore the Lipocicline (LCN2) expression as biomarker for disease activity in type 1 Gaucher Disease patients under different circumstances.

Methods: We have performed an exploratory study on 18 GD1 patients distributed in two cohorts. Cohort A was composed by 6 patients: 2 naïve (N) patients under miglitol therapy; this patient’s data were part of a previous study QUELAFER and sere from baseline and after 4 months on chelation therapy were obtained. Cohort B included 12 patients on enzymatic replacement therapy (ERT), for this cohort sera samples were obtained for LCN2 determination and also a panel of cytokines (IL-10, IL-13, IL-4, IL-6, IL-7, Mip1a, Mip1b y TNFα), and other parameters such as calcium, hepcidin, MIP1α and total iron of the patients between the beginning of ERT and after one year on it. Data were incorporated into a database for this purpose including demographic and clinical available data. All patients have signed an informed consent for the use of their samples and ethical approval were obtained form institutional board of FEETEG foundation.

Results: Compared to resting patients, patients receiving ERT showed increased levels of serum LCN2, the overall mean value for the initial sample was 171, 86 (67,72-216,72). As cohorts the differences among individuals were significant (Cohort A, p = 0.02 and cohort B, p < 0.01). Naive

haematologica | 2017; 102(s2) | 579
patients exhibit the higher values. In general, 9 patients showed a reduction in ferritin and chitotriosidase, however a fully corr.

Comparison of demographics, clinical presentation, treatment and outcomes between acquired primary TTP and secondary TTP are shown in Table below.

Primary TTP using chi-squared for categorical data and non-parametric Mann-Whitney U test for continuous data. *P<0.1 **P<0.05.

Summary/Conclusions: Compared to primary TTP, secondary TTP had an initial poorer response to thrombocytopenia. Patients with autoimmune diseases required more immunosuppressive therapy and rituximab. Although the final response and mortality rates showed a trend towards poorer prognosis in secondary TTP, it was not statistically significant. Further studies are needed to improve the treatment of TTP, both primary and secondary.

E1414 EVANS SYNDROME IN CHILDHOOD: LONG TERM SINGLE CENTER EXPERIENCE

A. Teli1, E. Farmaki1, A. Taparkou1, D. Adamidou2, M. Economou1,1

1Aristotle University of Thessaloniki, 2Blood Bank, Hippokration General Hospital, Thessaloniki, Greece

Background: Evans syndrome (ES) is a rare entity in childhood, usually presenting with a course that is chronic and refractory to treatment. Aims: To report on the clinical and laboratory characteristics of pediatric patients with ES diagnosed and long followed at a single center. Methods: Data covering a 15 year period and concerning 14 ES patients were retrospectively studied. Clinical presentation, laboratory parameters, disease severity, therapeutic approaches, number of relapses, presence of complications, time of follow-up and final outcome were reported. Disease was consid-

E1415 LOW DOSE RITUXIMAB IS A USEFUL ADDITION TO CORTICOSTEROIDS FOR NEWLY DIAGNOSED PATIENTS WITH WARM AUTOIMMUNE HEMOLYTIC ANEMIA

A. Gomez-De Leon1, P. Colunga Pedraza1, P. Santana-Hernandez1, G. Sotomayor-Duque1, L.D.C. Tarin-Arzaga1, J.C. Jaime-Perez1, C.H. Gutierrez-Aguirre1, O.G. Cantu-Rodriguez1, D. Gomez-Almaguer1

1Hematology, Hospital Universitario Dr Jose Eleuterio Gonzalez Universidad Autonoma de Nuevo Leon, Monterrey, Mexico

Background: Warm autoimmune hemolytic anemia (wAIHA) is an infrequent autoimmune disorder with a high response rate to corticosteroids, albeit relaps-

Method: We performed a single-center, prospective, single-arm, open-label study in adult patients with newly diagnosed "primary" or idiopathic wAIHA from 2013-2016 using high-dose dexamethasone (40mg IV days 1-4) followed by IVIG (1 g/kg) on day 5 and rituximab (375mg/m²) on days 1 and 15. Results: 22 patients were included, median age was 32 years (range 18-

Results: Eight patients were included, median age was 32 years (range 18-

Summary/Conclusions: The rare entity of Evans syndrome in childhood seems to be associated with various immune manifestations and to carry complica-

References: 580 | haematologica | 2017; 102(s2)
after diagnosis. Two patients were diagnosed with systemic lupus erythematosus during follow-up, they remained in CR. Twelve-month CR rate was 80% (5 evaluable patients). One patient experienced grade 3 neutropenia two months after the last rituximab infusion that resolved without complications. Estimated relapse-free survival was 80% at 2 years (60% if it is considered). No patient had a splenectomy performed.

Summary/Conclusions: This small study reports favorable outcomes for patients with newly diagnosed wAIHA treated with low-dose rituximab, and adds 8 patients with similar responses to the 7 cases previously published by the Italian group in 2012 and 2016. These results may be comparable to standard doses of rituximab, with a lower cost, and deserves further inquiry. The emergence of additional autoimmune phenomena (SLE, Evans’ syndrome) is unpredictable and can be an obstacle for appropriate data analysis in prospective AIHA studies.

E1416
INFECTIONIC COMPLICATION IN PRIMARY AUTOIMMUNE NEUTROPHENIA OF CHILDHOOD
T. Palianopoulos1, A. Gkioutras1, N. Chaliasos1, A. Makis1
1Department Of Pediatrics, University Hospital Of Ioannina, Ioannina, Greece

Background: Primary autoimmune neutropenia (PAN) of childhood is caused by the action of antibodies against membrane antigens of neutrophils leading to their peripheral destruction. Despite the low neutrophil counts, it is characterized by minor intermittent infections with rare severe bacterial episodes, which can be a significant cause of morbidity.

Aims: The retrospective evaluation of the incidence and characteristics of infectious complications in children with PAN from one reference academic center in Greece.

Methods: The study included the clinical and laboratory findings of children with PAN, who were diagnosed in our department in the last eight years (2008-2016). When children had neutropenia lasting over 3 months with a positive test for neutrophil antibodies, using the granulocyte immunofluorescence test, the granulocyte agglutination test and the monoclonal antibody immobilization of granulocyte antigen test. Laboratory evaluation for nutritional deficiencies, infections, systemic autoimmune diseases or malignancies was negative. Clinical data related to the occurrence of bacterial infections and treatment, hospitalization and outcome were collected and analyzed.

Results: 48 children with PAN were enrolled; 28 were boys, the median age was 14.5 months (range 5-96) and median follow-up time was 20 months (range 4-93). 19 children (39.6%) all suffering from severe neutropenia (<0.5 x 10^9/L) had to be hospitalized 25 times for bacterial infections; 4 for pneumonia, 7 for acute otitis media, 1 for mastoiditis, 7 for urinary tract infections, 4 for bacterial infections of unspecified site, 1 for perianal abscess and 1 for cellulitis, all with good outcome with proper antibiotic treatment. The average number of hospitalizations due to infections was 0.52/patient and the rate was 0.56/1000 patient-days.

Summary/Conclusions: Although rare, infections are an important clinical issue in the management of children with severe PAN, sometimes requiring hospitalization. Early signs of infection should be promptly recognized and accordingly treated.

E1417
NEW EPO-RECEPTOR MUTATION IN A -17 YEAR OLD WOMAN WITH ERYTHROCYTOSIS
B. Robredo1, L. Lo Riso1, B. Lopez1, L. Fiorenza2, A. Benedini2, B. Belosillo2, C. Balestier1, A. Perez1, A. Sampoli1, M.A. Duran1
1Hematology, Hospital Universitario Son Espases, Palma de Mallorca, 2Laboratorio Citologia Hematologica. Servicio de Patologia. Grethne. Escuela de Citologia Hematologica Soledad Woessner., Hospital del Mar, Barcelona, Spain

Background: Erythrocytosis is defined when red cell, hematocrit (Hct) and hemoglobin (Hb), are elevated above normal limits. Causes of erythrocytosis can be primary and secondary. Secondary causes are divided into congenital and acquired. There is a group of patients with idiopathic erythrocytosis.

Aim: We present a case report of a novel EPO-Receptor mutation.

Methods: We present a case report of a 17-year-old woman with erythrocytosis. In the control blood test she had hemoglobin of 18.6g/dl and hematocrit of 62%.

Results: At diagnozation she referred chronic headache without other symptoms. The physical examination was normal. At that time, three possible diagnose were suspected.

Summary/Conclusions: The study of the patient with erythrocytosis must begin with a full medical history and confirmation of raised Hb and Hct. In the study of erythrocytosis, after ruling out primary and acquired causes we should always consider the possibility of congenital erythrocytosis, which often is under-estimated. When EPO binds to its receptor a signaling cascade is activated, which cause red cells to be produced. This process is switched off when sufficient red cells have been produced by binding of SHP-1. EPO-receptor mutation results in failure of bind of SHP-1, causing uncontrolled production of red cells and erythrocytosis. We describe a new EPO-receptor (c.1275_1290dup) (fig. 1).

E1418
FAMILIAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN CHILDREN
Z. Salcioglu1,*, G. Aydoğan1, F. Akici1, C. Bayram1, A. Ayçiçek1, G. Özdemir1
1Pediatric Hematology and Oncology Clinic, Istanbul Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Familial hemophagocytic lymphohistiocytosis (FHL) is an autosomal recessive disorder characterized with uncontrolled activation of T-helper lymphocytes and macrophages and over-release of inflammatory cytokines. The only curative treatment is hematopoetic stem cell transplantation (HSCT).

Aims: This study evaluates the clinical and laboratory data of children with FHL. Thirty five FEL cases followed and treated at our clinic between 2005 and 2017 were retrospectively evaluated in our study.

Methods: Information of patients were retrieved from patient files and from the records contained in the electronic information processing environment created after 2005. All patients were treated with HLH-2004 protocol. HSCT was performed in nine patients.

Results: Twenty one of the cases were boys and fourteen were girls. The age at presentation for patients was two week-three years (mean 6.2 months). There was a history of consanguineous marriage in 26 of the families(74%). Fever, anemia, and hypertriglyceridemia were present in all HLH cases. Hepatomegaly was detected in 74%. Splenomegaly was more frequent in patients (87.7%). Leukopenia was detected in 21 patients. All patients had neutropenia and thrombocytopenia. Hypoferritemia was present in 94% of patients. Only nine patients found to have hemophagocytosis in the cytological evaluation of the CSF(25.7%). Mutation analysis were performed in 18 patients and of these, 10 had PRF1, 5 had UNC13D, and 3 had STX11 gene mutation. All patients were treated with HLH-2004 protocol. Of the 22 children who were placed in first remission. HSCT was performed in 9 patients (%25.7). The overall mortality rate was 57% (20 cases) in our series. Twenty children died opportunistic infection (n=10) or of disease progression (n=10).

Summary/Conclusions: The study of the patient with erythrocytosis must begin with a full medical history and confirmation of raised Hb and Hct. In the study of erythrocytosis, after ruling out primary and acquired causes we should always consider the possibility of congenital erythrocytosis, which often is underestimated. When EPO binds to its receptor a signaling cascade is activated, which cause red cells to be produced. This process is switched off when sufficient red cells have been produced by binding of SHP-1. EPO-receptor mutation results in failure of bind of SHP-1, causing uncontrolled production of red cells and erythrocytosis. We describe a new EPO-receptor (c.1275_1290dup) (figure 1).

Figure 1.
Summary/Conclusions: In conclusion, FHL is a disease with high mortality rates and the only curative treatment is HSCT. Donor search for HSCT must be started and HSCT should be performed after the remission.

E1419

ABNORMAL MONOCYTE POPULATIONS IN THE PERIPHERAL BLOOD OF PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

M. Velegraki1,*, V. Kaliafentaki 1, H. Koutala 1, A. Damianaki 1, M. Ximeri 1, P. Kanellou 1, I. Mavroudi 1, C. Pontikoglou 1, H. Papadaki 1
1Department of Haematology, University of Crete School of Medicine, Heraklion, Greece

Background: Chronic idiopathic neutropenia (CIN) is an acquired disorder of granulopoiesis characterized by an unexplained, prolonged reduction in the number of neutrophils and a generally benign and uncomplicated course. Neutropenia in CIN has been mainly attributed to increased apoptotic death of the granulocytic progenitor cells due to abnormal production of pro-inflammatory cytokines and pro-apoptotic mediators. Activated T-lymphocytes with a skewed oligoclonal/monoclonal profile and myelosuppressive properties have also have a major role in the pathophysiiology of CIN.

Aims: Monocyte subpopulations display a prominent role in innate immunity but also mediate pro-inflammatory responses and T-cell activation. The monocyte subsets in CIN patients were studied in CIN. The aim of the present study was to evaluate the monocyte subsets, namely the classical CD14++/CD16-, intermediate CD14++/CD16+ and non-classical CD14+/-CD16++ cells as well as the monocytic CD14+CD15/DRreg/CD53+CD11b+ fraction of the myeloid derived suppressor cells (MDSC), in CIN patients.

Methods: We have studied 25 patients fulfilling the well-defined diagnostic criteria for CIN and 10 age and sex-matched healthy individuals. Three-colour flow cytometry was used to assess the peripheral blood monocytes subsets in the gate of CD14 positive cells and five-colour flow cytometry for the evaluation of the myeloid derived suppressor cells in the gate of cells with intermediates/high FSC/SSC properties.

Results: The mean number of neutrophils and monocytes in CIN patients was 1176±249/μl and 412±130/μl, respectively (range 200-1800/μl and 200-700/μl, respectively). The proportion of classical CD14++/CD16- cells was significantly decreased in CIN patients (79.6%±7.60%) compared to the healthy individuals (87.9%±3.70%) (P<0.0009). The increase was due to the higher proportion of the intermediate CD14++/CD16+ but not the non-classical CD14+/-CD16++ monocyte subsets in CIN patients (12.7%±5.28% and 4.05%±2.51%, respectively) compared to controls (7.05%±2.47% and 2.73%±1.39%, respectively) (P=0.0014 and P=0.1383, respectively). Furthermore, the proportion of CD14+CD15/DRreg/CD53+CD11b+ MDSCs was significantly increased in the patients (6.18%±3.92%) compared to the healthy controls (4.05%±2.47%) (P=0.0412).

Summary/Conclusions: CIN patients displayed increased proportion of circulating intermediate CD14++/CD16+ monocytes that may have a role in the aberrant inflammatory responses commonly seen in these patients. The increased proportion of the CD14+CD15/ DRreg/CD53+CD11b+ MDSC in CIN may simply reflect a compensatory reaction aiming to suppress the T-cell activation. Isolation of the above cell populations and transcription studies are currently in progress in our laboratory.

E1421

DIAGNOSTIC VALUE OF CELL BOUND AND CIRCULATING ANTI-FOLLICLE STIMULATING HORMONE ANTIBODIES IN PAIN, CIN, secondary autoimmune (sAAN), post-infection (PIN) and non-autoimmune (nAAN) neutropenia referred to this laboratory during 2002-2014, respectively.

Results: Using highly specific median fluorescence intensity cut-off values calculated by ROC curves, a positive D-GIFT was found in 49% of CIN patients, who showed similar clinical features as those included in the pAAN group. In 4.05% of 202 CIN patients I-GIFT was repeated 2-3 times in a year, resulting in positive in 12 (27%) and 2 (5%) patients at the second and third screenings, respectively. Interestingly, 10 (71%) of the latter 14 patients showed a positive D-GIFT at the first serological screening.

Summary/Conclusions: D-GIFT evaluation improves the diagnostic accuracy of pediatric neutropenia. This can reduce the need for expensive and invasive investigations in CBN patients.

RITUXIMAB IN AUTOIMMUNE HEMOLYTIC ANEMIA OF INFANCY

M. Economidou1,*, A. Teii1, D. Adamidou2, A. Taparkou1, E. Farmaki1
1Aristotle University of Thessaloniki, 2Blood Bank, Hipkropation General Hospital, Thessaloniki, Greece
Background: Autimmune hemolytic anaemia (AIHA) is not commonly seen in childhood, and is extremely rare in infancy. Absence of guidelines renders management of the disease difficult in children – and even more so in infants.

Aims: Aim of the report is to present a number of cases of infantile AIHA, refractory to conventional treatments, demonstrating response in administration of rituximab.

Methods: The report concerns four infants (3 baby girls and one baby boy) who presented with AIHA. Data regarding demographics, personal and family medical history, immunologic assessments, previous treatments and response to rituximab were studied.

Results: Age at diagnosis of AIHA was 4-6 months. In 3 cases (cases number 1, 2 and 3) personal and family history, as well as laboratory screening at diagnosis, did not reveal presence of any other hematologic, autoimmune or immunologic condition. In case number 4 AIHA followed the diagnosis of giant cell hepatitis. Hospitalization before rituximab administration ranged between 1 and 18 months and multiple transfusions, administration of intravenous immunoglobin (maximum dose 6g/kg), repeated doses of intravenous methyl-prednisolone (30mg/kg) followed by oral prednizolone (max 5mg/kg), all failing to achieve sustained response. Rituximab was administered at 370mg/m² in 4 weekly infusions. In 3 infants 5 monthly infusions followed. Stabilization of hemoglobin and improvement of hemolysis parameters were observed after the 3rd-4th weekly infusion in all infants. In 3 patients (no 1, 2, 3) CD19+ and CD20+B cell assessment before and after rituximab administration was performed. Complete elimination (<1%) were observed in all patients after the 1st-2nd infusion. Despite B cells returning to normal 11 months after treatment infant no 1 remained in clinical remission during follow-up (22 months post treatment). Infant no 2 remained in clinical remission for the 16 month post treatment follow-up, despite B cell normalization. Infant no 3 relapsed following B cell normalization, 11 months after rituximab administration. Infant no 4 did not undergo B cell measurements and relapsed one year after completing rituximab therapy. The 2 patients that relapsed were re-treated with 4 rituximab infusions: patient no 3 remained well for the 18 month follow-up, whereas patient no 4 remained well for 10 years – again relapsing and receiving her 3rd rituximab treatment with good response for the remaining 7 month follow-up. None of the patients presented with adverse reactions during the infusions or with severe infections as a result of immunosuppression. However, infant no 1 developed asymptomatic progressive IgG hypogammaglobulinemia 11 months after initial exposure to rituximab, eventually requiring IVIG administration.

Summary/Conclusions: Rituximab administration in refractory AIHA seems to be efficacious and safe in infants. However, close follow-up is warranted in order to ensure absence of long term complications, including the risk of post-treatment hypogammaglobulinemia, when the drug is administered at such young ages.

E1424
EARLY LESSONS FROM WHOLE-EXOME SEQUENCING IN THE CLINICAL DIAGNOSIS OF RAPIDLY PROGRESSING ANEMIAS
N. Roy1,2, C. Camps3, H. Dreau2, S. Knight3, E. Kvikstad3, M. Pentony3, C. Babbs4, C. Scott4, K. Wray4, A. Schuh2, J. Taylor3
1Molecular Haematology Unit, 2BRC Molecular Diagnostic Centre, Oxford University Hospitals NHS Trust, 3Comprehensive Biomedical Research Centre, Weatherall Institute of Molecular Medicine, University of Oxford, 4Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Targeted re-sequencing has recently been adopted for the rapid diagnosis of anaemia patients whose disease is likely to have a genetic basis, however, currently results remain inconclusive in 30-60% of cases. Whole-genome sequencing (WGS), provides more uniform coverage than amplification-based panels and is allied to an unbiased approach offering the opportunity to explore both coding and non-coding regions. It is also possible to use WGS data to detect copy number variation with high resolution and sensitivity. Therefore WGS has the potential to offer an accurate molecular diagnosis in a proportion of unsolved anaemia cases and may therefore be a superior initial approach. Furthermore, WGS is likely to lead to the identification of novel genes involved in pathogenic and normal erythropoiesis.

Aims: Aim of this study is aimed to undertake WGS in a set of patients in whom targeted re-sequencing had not been able to identify a molecular cause for the inherited anaemia, in an attempt to increase the diagnostic yield of the molecular analysis of such patients and provide novel candidate genes as causative of anaemia.

Methods: We performed WGS of 20 individuals (2 singletons and 6 trios) at 30x coverage where all the trios have a rare anaemia of suspected genetic origin. Probands were pre-screened with a targeted panel containing ~50 candidate genes, none of which had harboured likely causative variants. Analysis of WGS data involved Stampy for read alignment, Platypus for variant calling and Ingenuity Variant Analysis (Qiagen) for variant annotation and filtering, followed by manual validation and verification of candidate variants.

Results: Known causative variants in a gene absent from the targeted panel were detected in two patients (25%), whereas candidate variants in novel genes not previously associated with anaemia were identified across the other six cases. Familial segregation and functional studies are underway to provide further evidence of causality for these novel variants, of which 60% are in genes with previous evidence of a role in erythropoiesis and 40% in genes with no known role in erythroid development.

Summary/Conclusions: These results illustrate the overlap in phenotypic abnormalities existing among these conditions and the importance of an unbiased whole-genome molecular diagnosis to enable correct diagnostic and clinical management of anaemia patients. We also demonstrate the benefit of using WGS over targeted resequencing given the difficulty of designing comprehensive gene panels and keeping them up-to-date as new candidate genes are identified.

CONGENITAL ERYTHROCYTOSIS: DISCOVER OF A NEW MUTATION
J. Barradas1,7, P. Rocha1, C. Dantas Rodrigues1, C. Constanço1, M. Reis Andrade1, C. Bento2, H. Matos Silva1
1Serviço de Hematologia Clínica, Centro Hospitalar Tondela-Viseu, Viseu, 2Serviço de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Congenital erythrocytosis (CE) is a rare hereditary disorder of red cell production, characterized by an absolute increase in red cell mass with elevated hemocrit and hemoglobin levels not accompanied by increased hematocrit increases that can be caused by defective in platelet ADAMTS13 induced signaling pathway (primary), defects in the control of EPO synthesis by the oxygen sensing pathway (secondary) or synthesis of high oxygen affinity hemoglobins. EPO transcription is regulated by Hypoxia Inducible Factor (HIF), the 3 prolyl hydroxylase domain proteins (PHD1, PHD2, PHD3), active in the oxygen carrying pathway, are able to hydroxylate key prolines in oxygen dependent degradation domains of HIF alpha subunit and it is degraded by the proteosome. Mutations in those proteins are linked to CE.

Aims: Describe a new mutation in PHD2 gene associated to CE.

Methods: Clinical process consultation and search in Blood, European Hematology Association and Pubmed websites of keywords: “congenitalfamilary erythrocytosis” “phd2”.

Results: We described a portuguese family followed by hematology service because of an isolated but sustained erythrocytosis, affecting 3 generations - grandfather, father (propositus) and son. Propositus referred headache and presented plethoric face and hypertension. Analytically, it was confirmed erythrocytosis (haemoglobin>18g/dL and hemocrit>50%), without any other changes, except an indirect hyperbilirubinemia. Secondary causes of erythrocytosis was excluded, with normal EPO and partial oxygen pressure. Bone biopsy only showed an erythroid hyperplasia, no JAK2 mutations identified, and normal hemoglobins electrophoresis, HBB and EPO gene sequencing. We then proceeded to sequencing of gene included in EPO-induced signaling pathway and it was detected a new mutations in PHD2 gene (F366L), in heterozygosity. Despite it has never been described, other mutations in PHD2 were found to be associated to cells increased that can be caused by defective in platelet ADAMTS13 antiplatelet aggregation therapy and phlebotemies. Additionally, they were diagnosed with Gilbert syndrome by a mutation in UGT1A1 gene promoter region (ATA/TTAA).

Summary/Conclusions: An unknown mutation of PHD2 has been detected in 2 generation of a family with erythrocytosis and it was co-segregated with the erythrocytosis phenotype. That gene plays an important role in the regulation of EPO production and subsequently in erythropoiesis. Furthermore family studies have to be performed to better understand its pathogenesis and management.

A RETROSPECTIVE STUDY OF THE THROMBOTIC MICROANGIOPATHIES DIAGNOSED IN THE LAST 17 YEARS IN ONE SINGLE CENTRE
A. Esteban Figuerola1,*, M.M. Olona Cabases2, R. Vallansot1, C. Talarn Forcadell1, L. Escoda Teigell1
1Hospital Joan XXIII Tarragona, Tarragona, Spain, 2Preventive Medicine Unit, Nefrology, 4Intensive Care Unit, Hospital Joan XXIII Tarragona, Tarragona, Spain

Background: Thrombotic microangiopathies (TMA) are characterized by the formation of platelet thrombi that obstructs vital organ microcirculation. The presence of the 5 classic parameters (haemolytic anaemia, thrombocytopenia, fever, oliguria and neurological affection) is rare. ADAMTS13 determination allows a more accurate diagnosis than the presumption based on clinical and biochemical parameters.

Aims: To retrospectively analyze 44 TMA patients diagnosed in our centre in the last 17 years and characterize TTP, HUS and secondary TMA (sTMA) by their clinical data, correlate with ADAMTS13 level and identify predictors for survival and relapse.

Methods: TMA was defined as microangiopathic hemolytic anaemia with thrombocytopenia under 150x10^9/L. All cases were classified as: 1. TTP (TMA with
Results: A total of 13 patients (56.5%) had single-lineage cytopenias and 10 (46.5%) had multi-lineage cytopenias. Shows last diagnosis of all the patients. In 9 of the patients, first cytopenias were diagnosed more than the primary diseases were diagnosed after median 2 months (between 0 and 77 months). Only one patient firstly had diagnosed as CVID, cytopenia has developed after years. All of the patients were treated with corticosteroids or intravenous immune globulin (IVIG) as first-line treatment. Ten patients needed second or further-line immunosuppressive therapies including rituximab, mycophenolate, ciclosporin, chloroquine, and cyclophosphamide. A total of 8 patients (34.7%) recovered from autoimmune cytopenias after the treatment of primary disease. That diseases were diagnosed as systemic lupus erythematosus in 4 patients, pyogenic glomerulonephritis in 3 patients, and celiac disease in 1 patient. Cytopenias have coexisted in 14 of the patients. One patient complicated with CVID died.

Summary/Conclusions: Cytopenia may be the first finding of an immunodeficiency or autoimmune disease and primary disease may be diagnosed in the clinical course. Early diagnosis is important because of beginning to the early treatment of underlying disease.

CHILDREN WITH CHRONIC-REFRACTORY AUTOIMMUNE CYTOPENIAS: A SINGLE CENTER EXPERIENCE

T.H. Karapınar,1* E. Dungu,1 Y. Cymak1, N. Güleș2, Y. Ay1, A. Geneli2, S. Gözmen1, E. Serdaroğlu3, S. Aydın Kocker1, E. Töret1, C. Vergin1
1Pediatric Hematology and Oncology, 2Pediatric Immunology, 3Pediatric nephrology, Dr. Behçet Uz Children Training and Research Hospital, Izmir, Turkey

Background: Autoimmune cytopenias are a group of heterogeneous disorders characterized by immune-mediated destruction of one or more hematopoietic lineage cells. They can be idiopathic or occur as a manifestation of other underlying diseases, such as autoimmune diseases, immunodeficiency, autoimmune lymphoproliferative syndrome, tumors, medications or infections.

Aims: The aim of this study was to evaluate the clinical course and significance of autoimmune cytopenias due to immunodeficiency or autoimmune diseases in children followed up at our hospital.

Methods: A total of 337 files of information belong to patients with chronic or refractory autoimmune cytopenias were evaluated retrospectively at our hematology department between February 1997 and September 2015. Ultimately, patients with immune deficiency or autoimmune diseases (23 patients) were included in this study. Data were analyzed using SPSS 15.0. The results are presented as the mean, SD, median, absolute number, or percentile.

Results: Two-thirds of the children with chronic or refractory autoimmune cytopenias (6.8%) had an immune deficiency or an autoimmune disease. The median age of diagnosis was 3.1 years (between 6 months-16 years) and the ratio of male/female was 1.3. The median duration of following was 2.6 years (between 4 months and 18.5 years). A total of 13 patients (56.5%) had single-lineage cytopenias and 10 (46.5%) had multi-lineage cytopenias. Shows last diagnosis of all the patients. In 9 of the patients, first cytopenias were diagnosed more than the primary diseases were diagnosed after median 2 months (between 0 and 77 months). Only one patient firstly had diagnosed as CVID, cytopenia has developed after years. All of the patients were treated with corticosteroids or intravenous immune globulin (IVIG) as first-line treatment. Ten patients needed second or further-line immunosuppressive therapies including rituximab, mycophenolate, ciclosporin, chloroquine, and cyclophosphamide. A total of 8 patients (34.7%) recovered from autoimmune cytopenias after the treatment of primary disease. That diseases were diagnosed as systemic lupus erythematosus in 4 patients, pyogenic glomerulonephritis in 3 patients, and celiac disease in 1 patient. Cytopenias have coexisted in 14 of the patients. One patient complicated with CVID died.

Summary/Conclusions: Cytopenia may be the first finding of an immunodeficiency or autoimmune disease and primary disease may be diagnosed in the clinical course. Early diagnosis is important because of beginning to the early treatment of underlying disease.
**Background:** Hemophagocytic lymphohistiocytosis (HLH) is a rare, potentially fatal hyperinflammatory syndrome, which in its most common, secondary form, can be induced by infection, malignancy or autoimmune disease. Diagnosis of HLH is made when at least five of eight clinical and laboratory HLH-2004 criteria are met. However, diagnostic criteria were established based on studies from pediatric patients, and it is debated if they can be applied to adults. Assessment of these criteria can be subjective (microscopic identification of hemophagocytes), time-consuming or not easily available (e.g. molecular analyses, functional tests of NK-cells).

**Aims:** The aim of the study was to evaluate phenotypic findings from flow cytometric (FC) analyses of bone marrow (BM) and other tissue samples from patients with hematological malignancies (hM) who developed HLH. The study was intended to investigate potential utility of a rapid phenotypic screening in diagnostics of suspected HLH.

**Methods:** Flow cytometric files for 42 patients with hM were retrieved from archive of the Department of Clinical Pathology and Cytology, Karolinska University Hospital. The patients were diagnosed and treated for hM-HLH at the Hematology Center of the same hospital, between 2009 and 2016. Tissue samples (bone marrow, peripheral blood, lymph nodes) were analyzed according to standard procedures, using monoclonal antibodies (BD, DAKO, Beckman Coulter, BioLegend). Cells were acquired using 4-color Canto A or 8-color Canto II cytometers (BD), and analyzed with BD FACSDIVA software. Neoplastic clones of myeloid or lymphoid character were excluded from reanalysis for the purpose of this study. Bone marrow samples were obtained from 31 patients shortly before and from 24 patients following HLH-diagnosis; in 13 patients paired BM samples were available.

**Results:** Patient characteristics are presented in table 1. Bone marrow B-cell lymphopenia was observed in 67% patients before and 74% after HLH diagnosis. Decreased amounts of NK-cells were noted in 48% persons at both time points. T-cell lymphopenia before HLH diagnosis was noted in 60% patients with myeloid malignancy but in only 25% cases of lymphoid malignancy, whereas in established HLH the respective figures were 27% and 46%. CD4/CD8 ratio was skewed-to-normal in both myeloid and lymphatic tumors before HLH was diagnosed. In cases of confirmed hyperinflammation, patients with myeloid tumors showed dominance of CD4+ cells but no such difference was noted in lymphoid disease. Loss of lineage specific markers of non-neoplastic T-cells was a constant feature in lymphoid malignancy, whereas aberrant expression of lymphatic markers (CD2, CD7, CD56) on myeloid cells was uniform in patients with myeloid tumors. Monocytosis was more often observed in myeloid as compared to lymphoid tumors. Monocytosis was more often observed in myeloid as compared to lymphoid tumors at HLH onset (40% vs 31%), although it was of non-neoplastic character. However, monocytopenia was also noted in cases of established HLH, in 10% of myeloid malignancies and 15% of lymphatic malignancy cases.

**Summary/Conclusion:** In the presented cohort, quantitative shifts could be observed in BM samples around the time of HLH onset. However, different patterns were observed between patients affected by lymphoid or myeloid malignancies, which may indicate disease-specific impact on BM microenvironment. Further study will be carried out to confirm findings in a large, possibly prospectively collected patient group. Control group of patients with respective malignancies but without HLH will be included.

**FLOW CYTOMETRIC ANALYSIS OF TISSUE SAMPLES IN 42 ADULT PATIENTS WITH MALIGNANCY-ASSOCIATED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS**

**BLEEDING IN PRIMARY IMMUNE THROMBOCYTOPENIA: WHO ARE MOST AT RISK?**

U. Doobare1,2, S. Hodges1, R. Nandigam1, A. Newland1, D. Provan1

1Haematology, Barts and The London School of Medicine and Dentistry, London, United Kingdom

**Background:** Primary Immune Thrombocytopenia is rare disorder in which patients are at risk of bleeding due to autoimmune-mediated platelet destruction. Until now, no studies have focused on describing the prevalence and types of bleeding events around the time of ITP diagnosis and after, as well as identify any factors that can potentially influence the risk of bleeding.

**Methods:** Data from the United Kingdom Immune Thrombocytopenia Registry were analysed for this study. The registry obtained its data from about 70 centres around the UK. Descriptive and logistic regression statistical techniques were used for this study.

**Results:** This analysis was based on 2365 (57.8% females) participants who are part of the Registry. The median age at diagnosis was 50 years (IQR 32, 66) and 77% of these patients were of European ethnicity. The commonest comorbid conditions was hypertension (23%). Median platelet count was 19 (IQR: 5, 53). Eighty percent had a platelet count below 30x10^9/L around ITP diagnosis. The most common bleeding events were skin-related (46.5%) and to the oral cavity (14.4%). About 70% of the cohort experienced at least one bleeding event at some point after diagnosis. After ITP diagnosis the most common bleeds were again skin-related (34.3%) and oral cavity bleeding (14.8%). Epistaxis had risen from 11.6% before diagnosis to 17.7%. Bleeding at other sites did drop. However, the prevalence of intracranial haemorrhage rose from 0.9% pre-diagnosis to 1.2% after diagnosis. Prednisolone (79%) and IVig (43%) were the most used drugs followed by rituximab (28%) among those who were treated. Romiplostim (15%) and Ertrombopag (9%) are used too but not anything more than mycophenolate (18%) and azathioprine (22%). Fourteen percent of the cohort had a splenectomy at some point. Age but not gender or ethnicity were found to be associated with having a bleeding event around the diagnosis of ITP. Patients older than 60 years (OR 1.8) are less likely to experience bleeding than older adults (>70 years), who were most at risk. Platelet counts, expectedly, was associated with bleeding with those presenting with a platelet of <30x10^9/L were at higher risk. No comorbid illness or cotherapies were found to be associated with bleeding events.

**Summary/Conclusions:** The frequency of bleeding decreased for most sites but for some others a slight increase has been observed since ITP diagnosis. It is possible that bleeding events may have been recorded more accurately or observed more closely and over a longer period of time since diagnosis. However, control of bleeding was an issue after the diagnosis of ITP. Future analysis stratifying its findings by time periods would be beneficial in describing if bleeding events were better controlled over the last few years, especially after the introduction of new therapeutic agents and the publication of the internal consensus report on the diagnosis and management of primary ITP.

**A MULTICENTRE, SINGLE ARM, OPEN LABEL STUDY EVALUATING THE EFFICACY AND SAFETY OF ERTOMPOBAG IN PATIENTS WITH SEVERE PERSISTENT IMMUNE THROMBOCYTOPENIC PURPURA (ITP) WITHIN SIX MONTHS OF DIAGNOSIS**

H. Tran1,2, R. Bird3, S. Chunliah3,4, T. Brightson5, J. Reynolds6, S. He7, C. Mazis1, R. Hall7, P. Shuttlworth7, A. Grigg7

1Clinical Haematology, The Alfred Hospital, 2Clinical Haematology, Monash University, Melbourne, 3Clinical Haematology, Princess Alexandra Hospital, Brisbane, 4Clinical Haematology, Monash Health, Melbourne, 5Clinical Haematology, Prince of Wales Hospital, Sydney, 6Clinical Epidemiology and Preventative Medicine, Monash University, 7Clinical Haematology, Austin Hospital, Melbourne, Australia

**Background:** Patients with acute ITP who fail or are dependent on steroids or intravenous immunoglobulin (IVIg) are often committed to splenectomy or prolonged immunosuppression. Splenectomy is potentially curable but may not be without operative risk with many patients reluctant to undergo surgery, while the response to immunomodulation is often suboptimal with significant side effects. Although effective, to date, there is no published studies evaluating the benefit of ertomopag among steroid dependent or resistant, non-splenectomised ITP patients diagnosed within 6 months.

**Aims:** To evaluate the efficacy and safety of ertomopag in patients with severe “acute” and persistent ITP within 6 months of diagnosis.

**Methods:** A multicentre, single arm open label study involving 39 patients with refractory ITP (oral and/or skin bleeding with platelet counts of >30x10^9/L), despite a daily dose of prednisolone of 1mg/kg for at least 2 weeks from diagnosis OR (b) requiring prednisolone ≥10mg daily and/or recurrent doses of IVIg to maintain a platelet of ≥30x10^9/L within 6 months of diagnosis. Prior splenectomy was not a requisite.
Patients with platelets <10x10^9/L will commence on eltrombopag 75mg daily while those with a count ≥10x10^9/L will commence on 50mg. A loading dose is used for subjects of East Asian heritage. The dose of eltrombopag can be progressively increased by 25mg increment every 2 weeks to maximum of 150mg daily (patients of East Asian heritage should have a maximum eltrombopag dose of 100mg daily) if the platelet count remains ≤30x10^9/L or there is clinically significant bleeding every 2 weeks. The steroid can be progressively weaned to zero over the subsequent 6 weeks if clinically appropriate. The primary endpoint was overall response rate (ORR) at week 12, defined as the proportion of patients achieving complete response (CR; platelet >100x10^9/L), partial response (PR; platelet >50x10^9/L) or minor response (MR; platelet ≥30x10^9/L with ≥25% reduction in the dose intensity of concomitant ITP therapy compared with screening). The protocol specified a 1-sided 5% level binomial test of the null hypothesis that ORR at week 12 ≤30% and reporting of a 90% two-sided confidence interval (CI).

**Results:** Of the 39 patients enrolled, 46% were women, median (Q1, Q3) age was 52 (42, 61) years, median (Q1, Q3) disease duration was 2.2 (1.1, 4.5) months, and median (Q1, Q3) screening platelet count was 21(13, 34) x10^9/L. Prior treatments included steroids (95%), IVIG (58%), and immunosuppression (28%). 35 patients (90%) completed 12 weeks of treatment, 4 (10%) discontinued eltrombopag prior to week 12 (3 required new ITP therapy; 1 developed pulmonary embolism (PE)). The median (Q1, Q3) dose eltrombopag at week 12 was 50 (50, 100)mg daily. The median (Q1, Q3) dose of steroid at week 12, zero (0, 5)mg daily. At week 12, the ORR was 64% (p<0.001; 90% CI: 51-77%); CR, PR, MR rates were 41%, 15% and 8% respectively and the median (Q1, Q3) platelet count among responders was 168 (58, 252)x10^9/L. At the end of 12 weeks, 45.4% (90% CI: 40-57%) CR, PR, MR rates were 28%, 21% and 5% respectively.

Two patients had serious adverse events (SAEs) with two episodes of venous thromboembolism (one deep vein thrombosis at platelet 97x10^9/L; one pulmonary embolism at platelet 240x10^9/L).

There were no other adverse events or deaths.

**Summary/Conclusions:** The majority of patients with ITP diagnosed for ≥6 months had a favourable overall response rate to eltrombopag and the drug was generally well tolerated. Longer-term follow up data (beyond 6 mos) will be presented at the meeting.

E1432

A NOVEL RUNX1 MUTATION IN FAMILY WITH FAMILIAL PLATELET DISORDER WITH PREDISPOSITION TO ACUTE MYELOGENOUS LEUKAEMIA L. Krupkova1, M. Divoka2, B. Ludikova2, J. Kucerova2, M. Holzerova1, A. Hlusi1, T. Papajik1, D. Pospisilova2

1Department of Hemato-oncology, 2Department of Pediatrics, University Hospital Prague and Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic

Background: Familial platelet disorder with predisposition to acute myelogenous leukaemia (FPD/AML) is a clinically heterogeneous group of rare disorders characterized by isolated thrombocytopenia and increased risk of bleeding. The development of autoantibodies against platelets and megakaryocytes results in decreased platelet production and insufficient platelet production remains central to the pathophysiology of ITP. Platelets contain high levels of miRNAs and a substantial fraction of circulating miRNAs originates from platelets. Circulating miRNAs are stable and relatively easy to measure and considered as potential disease biomarkers. The role of miRNAs in the pathogenesis of ITP has not been well explored.

**Aims:** Determine the expression profile of circulating miRNAs in ITP patients in aim to identify miRNAs that can be used as disease biomarkers and to explore the potential biological pathways that might be involved in the pathogenesis of ITP.

**Methods:** Exiqon Serum/plasma Focus microRNA PCR panel was used to determine the expression profile of 179 miRNAs in plasma acquired from 8 ITP patients with low platelet count and who failed to respond to various treatment for ITP, and from 8 age- and sex-matched controls. In addition, next generation sequencing (NGS) for miRNAs was performed in 2 pooled plasma samples (pool 1 from 4 ITP patients, and pool 2 from 4 matched controls), on the Illumina NextSeq 550 system. Statistical analyses were performed with the GenEx software and SPSS. Pathway analysis was performed using DIANA-miPath v3.0 to explore the probable pathways involved in the pathogenesis of ITP.

**Results:** Comparing the expression profiling from the PCR panel between ITP patients and matched controls, 81 circulating miRNAs were differentially expressed (p<0.05), of those 17 miRNAs had a high statistical significance (FDR correction). Among 17 differentially expressed miRNAs, miR-191-5p and miR-222-3p were down-regulated and miR-486-5p and miR-222-3p were up-regulated in ITP compared to controls. Interestingly, 15 of the 17 differentially expressed miRNAs from PCR panel were also differentially expressed in NGS. Using the 17 differentially expressed miRNAs in the miRPath analysis, we uncovered some immune system related pathways, including MyD88-independent toll-like receptor signaling pathway and TRIF-dependent toll-like receptor signaling pathway, as enriched pathways in target genes of miRNAs differentially expressed between ITP patients and controls.

**Summary/Conclusions:** We identified a large number of miRNAs that were differentially expressed in ITP patients compared to controls that might be associated with the pathogenesis of ITP. Pathway analysis uncovered some possible biological pathways that might be involved in the pathogenesis of ITP. Further validation of these miRNAs in a larger patient cohort and preferably in comparison to patients with other causes of thrombocytopenia such as aplastic anaemia to explore the role of these miRNAs in the pathogenesis of ITP. Future studies of these miRNAs in relation to initiation of treatment with defined clinical outcomes as treatment response/ remission after initiation of treatment will clarify their potential as biomarkers for treatment response.
NORDIC COUNTRY PATIENT REGISTRY FOR IMMUNE THROMBOCYTOPENIA (NCPRITP): A COHORT OF PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA IN DENMARK, SWEDEN, AND NORWAY

C. Christiansen1, S. Bahmanyar2, W. Ghaniama3, N. Kristensen1, S. Stryker4, J. Acuávella5, K. Nargaard1, H. Sörensen1

1Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark. 2Clinical Epidemiology Unit & Center for Pharmacoepidemiology, Department of Medical and Clinical Pharmacology, Karolinska Institutet, Stockholm, Sweden. 3Department of Medical and Clinical Pharmacology, St Olof Hospital Trust, Fredrikstad, Norway. 4Center for Observational Research, Amgen Inc, San Francisco. 5Center for Observational Research, Amgen Inc, Thousand Oaks, Utah, United States

Background: Immune thrombocytopenia (ITP) is a rare disease characterized by isolated platelet counts and an increased tendency to bleed. As yet, there have been no large, multi-country, population-based cohorts established to describe its long-term clinical course and investigate the effectiveness and safety of related therapies.

Aims: To describe the establishment of the NCPRITP and the characteristics of patients enrolled.

Methods: Encompassing Denmark, Norway, and Sweden, the NCPRITP started as a population-based post-authority authorization study to assess the long-term safety of romiplostim in treating ITP. It includes patients with prevalent chronic ITP (cITP – ITP lasting >6 months) from 01/01/2009 and a history of a cITP diagnosis from 04/01/2009-12/31/2014, confirmed through medical record review. Since the start of the registry, guidelines have changed to define cITP as ITP lasting >12 months. For consistency, incident cases of ITP for a duration of >6 months will continue to be accrued through 2019. Through linkage of datasets of the national health registries and medical record review, the registry has rich clinical information for all enrolled ITP patients, such as comorbidities (including scores according to the Charlson Comorbidity Index [CCI] – a validated tool developed to predict 1-year mortality), treatments, lab values (e.g., platelet counts), and complete follow-up for several clinical outcomes of interest (e.g., clinically significant bleeding, the need for rescue therapies, and thromboembolic/thrombotic events). Additionally, available bone marrow samples are stored and reexamined for reticulin and collagen content to assess Thiele’s myelofibrosis (MF) grading.

Results: The NCPRITP includes 3,749 patients with confirmed cITP (35% Danish, 51% Swedish, and 14% Norwegian), with a female preponderance (58%) and median age of 56 years at cITP diagnosis. Forty-one percent of the cohort was prevalent at study inclusion; 59% represent incident cITP patients. Median follow-up time thus far is 4.3 years. At study enrollment, 24% had a platelet count <50×10^9/L, 16% were splenectomized, and 41% had at least one previous cITP therapy (mainly oral glucocorticoid steroids). The majority (68%) of the cohort had no underlying conditions included in the CCI at study enrollment, but 8% had a CCI score of 3 or higher, indicating severe comorbidity. Of note, based on hospital diagnoses of specific comorbidities recorded within 5 years before study enrollment, 20% had a history of diabetes, 9% had a history of cancer, and 18% had a history of hypertension. Currently, 718 bone marrow samples from 566 patients have been retrieved.

Summary/Conclusions: The NCPRITP provides an example of how, within the Nordic countries’ uniform health care systems, registries can be established to study the clinical course of rare diseases such as ITP and the safety of drugs used to treat these patients.

ELTROMBOPAG (EPAG) FOR THE TREATMENT OF PATIENTS AGED ≥65 YEARS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP): SAFETY AND EFFICACY RESULTS FROM THE EXTEND STUDY

A. Salama1,*, R.S. Wongi1, K. Althoff2, M.N. Salesh3, B. Meddeb4, O. Cakir5, E. Quebe-Fehling6, J.B. Bussel7

1Charité-Universitätsmedizin, Berlin, Germany. 2Sir YK Pao Centre for Cancer & Department of Medicine and Therapeutics, Chinese University of Hong Kong, Shatin, Hong Kong. 3Hôpital Farhat Hached, Sousse, Tunisia. 4Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, United States. 5Hôpital Aziza Othmana, Tunis, Tunisia. 6Novartis Pharma AG, Basel, Switzerland. 7Pediatric Hematology/Oncology, Weill Cornell Medicine, New York, United States

Background: ITP is an acquired autoimmune disorder characterized by isolated platelet reduction, which is considered chronic when it persists for >12 months. Evidence suggests that age may influence both the hemorrhagic manifestations of ITP and also response and adverse events (AEs) associated with some therapies. Changes in drug metabolism can contribute to increased AE rates in patients (pts) ≥65 yrs compared with younger adults. The oral thrombopoietin-receptor agonist, EPAG, is approved for the treatment of previously treated (eg corticosteroids, immunoglobulins) cITP pts, but limited data are available in pts ≥65 yrs old. The EXTEND study was a global, open-label, extension study that evaluated long-term efficacy, safety and tolerability of EPAG in adults with cITP who had participated in prior EPAG studies.

Aims: To describe the efficacy, durability of response, and safety of EPAG use in pts with cITP aged ≥65 yrs.

Methods: All pts on EXTEND started EPAG at 50mg/day, titrated to 25–75mg/day or less often as required, based on individual platelet count responses: to achieve counts in the range ≥50–200×10^9/L. Maintenance dosing continues until the maximization of the persistent platelet response. Median follow-up time was 51 weeks (range 8-152 weeks). Mean increase in platelets was ≥50×10^9/L with rescue therapy. 74 (74%) achieved platelet counts ≥50×10^9/L, for ≥50% of assessments: 26 (52%) maintained platelet counts continuously ≥50×10^9/L for ≥22 weeks (Figures). Median time maintaining platelet counts >50×10^9/L and twice BL values,
while not receiving rescue treatment, was 78 (range, 0–350) weeks. Incidence of bleeding symptoms (WHO grades 1–4) decreased from BL (86%) to 1 yr (15%). AEs were reported in 47 (94%) pts, most frequently nasopharyngitis (n=13, 26%), constipation (n=12, 24%), fatigue (n=12, 24%), diarrrhea, urtiaria, respiratory tract infection, cataract and cough (all n=11, 22%). Serious AEs occurred in 24 (48%) pts, most frequently (>5%) cataracts (n=7, 14%), pneumonia (n=3, 6%); respiratory tract infection (n=3, 6%). The most frequent AEs with suspected relationship to study drug were cataracts (n=4, 8%), headache, fatigue, and increased ALT, AST and bilirubin (all n=3, 6%).

Summary/Conclusions: The efficacy of EPAG in cITP pts ≥65 yrs was consistent with that seen with the overall EXTEND study population (Bussel et al. Haematologica 2016;101[1];SS17), with sustained platelet increases and reduced bleeding. EPAG was well tolerated; AE rates were similar to that reported in the overall EXTEND study population, but an apparent increase in cataracts was observed in pts ≥65 yrs old (cataract incidence was 7% and 22% in <65 and ≥65 age groups, respectively). Further outcomes in patients <65 yrs old will be presented. Results should be interpreted with caution as almost half of the pts withdrew from the study. EPAG is an effective treatment option for certain cITP pts ≥65 yrs; its use should incorporate baseline cataract screening and regular monitoring.

E1438
SAFETY AND EFFICACY OF THROMBOPOIETIN RECEPTOR AGONISTS IN PATIENTS WITH PREVIOUSLY TREATED CHRONIC IMMUNE THROMBOCYTOPENIA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Y. Yamada1, T. Fuji1, C. Cromwell2, L. Shapira3
1Medicine, Mount Sinai Beth Israel, New York, 2Internal Medicine, University of Hawaii, Honolulu, 3Hematology, Mount Sinai Beth Israel, New York, United States

Background: The current American Society of Hematology guideline recommends the use of thrombopoietin receptor agonists, eltrombopag or romiplostim as second-line agents after failure of rescue therapies for chronic immune thrombocytopenia (ITP). The efficacy and safety of those drugs have been tested in several clinical trials. However, the safety profile was consistent throughout trials and is not yet well understood.

Aims: We herein conducted a meta-analysis of randomized controlled trials to compare the safety and efficacy of thrombopoietin receptor agonist: eltrombopag and romiplostim versus placebo in patients with previously treated chronic ITP. Our primary outcome was drug-related adverse events greater than CTCAE grade 3.

Methods: We performed a literature search in MEDLINE, EMBASE, Cochrane library, and the American Society of Hematology website up to September, 2015 by two independent authors according to PRISMA guideline. We included only randomized clinical trials comparing eltrombopag or romiplostim versus placebo. Random-effects model was used to estimate pooled Odds Ratio (OR). Results: 6 studies with a total of 874 patients were included in the analysis. There was no significant difference of grade 3 or higher adverse events between placebo and treatment group (OR=1.01, CI 0.57-1.78). Thromboembolism (OR=0.59 CI 0.20-1.73), elevated ALT (OR=0.68 CI 0.26-1.74), headache (OR=1.26, CI 0.90-1.78), nausea (OR=0.82 CI 0.43-1.55), fatigue (OR=1.13 CI 0.65-1.91) did not show a significant difference between groups, either. Clinical response, which is defined as platelets ≥50,000/μL at least once on treatment was significantly better in treatment group than in placebo group (OR=0.10 CI 0.07-0.15). Bleeding symptoms (WHO Grades 1–4) were significantly more frequent in the placebo group (OR=1.6, CI 1.14-2.24) during treatment.

Summary/Conclusions: Although several studies have suggested clinically significant treatment-related adverse events, such as thromboembolism, this meta-analysis showed that thrombopoietin receptor agonists are safe, well-tolerated, and effective in patients with previously treated chronic ITP.
MMF treatment. Therefore, it can be considered as an alternative therapeutic option in the setting of ITP non only for patients with an underlying diagnosis of ALPS but also for the ones with primitive disease or with an ALPS-like disorder.

ASSESSMENT OF ROMIPLOSTIM SELF-ADMINISTRATION BY PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA AND CAREGIVERS FOLLOWING RECEIPT OF HOME ADMINISTRATION TRAINING (HAT) MATERIALS: A PROSPECTIVE SECTIONAL STUDY

M. Schipperus1,*, G. KairafA, L. Taylor2, S. Wetten3, J. Bennett4, G. Kreuzbauer5, A. Boshier6, A. Seesaghur4

1Department of Haematology, Haga Teaching Hospital, The Hague, Netherlands, 2AHEPA University Hospital, Thessaloniki, Greece, 3Royal London Hospital, London, 4Amgen Limited, London (Uxbridge), United Kingdom, 5Amgen (Europe), Zug, Switzerland, 6Amgen Limited, Cambridge, United Kingdom

Background: A HAT pack was designed as an additional risk minimization tool to support healthcare providers (HCPs) in selecting patients and training of patients/caregivers to mitigate medication error risk when self-administering romiplostim subcutaneously, a thrombopoietin-receptor antagonist which is approved in the European Union (EU) to treat chronic immune thrombocytopenic purpura (ITP) refractory to other treatments.

Aims: To estimate the proportion of adult patients and caregivers who administer romiplostim correctly at a voluntary subsequent visit.

Methods: This non-interventional, cross-sectional study enrolled 40 patients/caregivers and was conducted at 12 centres in Austria, Belgium, France, Germany, Greece, The Netherlands, Spain, and The United Kingdom, from 7 July 2014 to 20 November 2015. HCPs directly observed adults (≥18 years of age) with chronic ITP or caregivers new to administering romiplostim in the act of product administration at the first standard-of-care (SoC) 4-week visit after HAT pack training. Correct administration of romiplostim (primary endpoint) was defined as dose accuracy within 10% margin of error between prescribed and administered romiplostim doses, and correct romiplostim reconstitution and successful injection, and no HCP intervention during administration to correct patient/caregiver error. All analyses were descriptive and no formal hypothesis was tested.

Results: At the first SoC visit, 4 weeks (range: 2-8 weeks) after HAT pack training, 35 patients/caregivers (87.5%) administered romiplostim correctly. The dose accuracy was within 10% margin of error for all patients. HCP intervention was required in 5 instances: 1 patient did not ensure all romiplostim was dissolved, 1 patient and 1 caregiver needed verbal encouragement, 1 patient needed nursing intervention to read the correct dose from the vial due to poor eyesight, and 1 caregiver needed guidance with syringe and vial connection. Further follow-up data was available for only 2 of these 5 patients/caregivers; they both administered romiplostim correctly at a voluntary subsequent visit.

Summary/Conclusions: Given that this study was conducted on a convenience instead of random sample of patients, generalizability of the results may be limited. Direct observation can be susceptible to observation bias and to the Hawthorne effect with the patients/caregivers acting differently when observed. Nonetheless, the success of most patients and caregivers in correctly administering romiplostim after HAT pack training suggests that self-administration of romiplostim is a feasible option for suitable romiplostim-treated ITP patients.

E1442

FCγRIA 131 H/R (A>G) RECEPTOR GENE POLYMORPHISM IN PATIENTS OF PRIMARY IMMUNE THROMBOCYTOPENIA (ITP)

A. Tripathi1,*, D. Yadav1, A. Kumar2

1Clinical Hematology, 2K.G. Medical University Lucknow India, Lucknow, India

Background: Primary Immune Thrombocytopenia (ITP) is an autoimmune hematologic disorder characterized by isolated thrombocytopenia (<100,000/cmm) in the absence of other causes or disorders that may be associated with thrombocytopenia. The predominant mechanism is enhanced peripheral destruction of autoantibody coated platelets through binding of Fc portion of antibody with the Fcy receptors on cells reticuloendothelial system mainly monocytes/macrophages.

Aims: This study was aimed to investigate the association of polymorphisms in FCγRIA 131 H/R (A>G) gene with Primary Immune thrombocytopenia (ITP).

Methods: Genotyping for the FCγRI A 131 H/R (A>G) was performed using polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP) in 70 ITP patients and 70 healthy controls.

Results: The mean age of patients and control was 29.5±13.86 yrs and 27.90±8.89 yrs respectively. Male/Female ratio in patients and control was 1:2. Under additive model, the heterozygous genotype (AG) of the FCγRI A 131 H/R (A>G) polymorphism shows the significant association with ITP. (Odds Ratio 2.41 (95% CI, Lower - 1.19 Upper 4.90 P-value 0.0149)) whereas the homozygous mutant genotype (GG) had no significant association with ITP (Odds Ratio 2.47 (95% CI, Lower - 0.63 Upper 9.72 with P-value 0.2976). Under dominant model, the Odds Ratio was 2.42 (95% CI, Lower - 0.34 Upper 9.94) with the significant P-value 0.0167. Mutant allele (G) frequency was 37.85% in patients and 25.71% in controls (Odds ratio 1.76 1.05-2.93 with the p-value 0.0397).

Summary/Conclusions: The study shows the association of heterozygous genotype (AG) of FCγRI A 131 H/R (A>G) with ITP. The dominant model also shows significant association with ITP. We conclude that mutant allele (G) in FCγRI A 131 H/R (A>G) gene polymorphism may have impact on susceptibility to ITP.

E1443

SHORT- AND LONG-TERM RESULTS OF FIRST LINE THERAPY WITH PULSED HIGH-DOSAGE DEXAMETHASONE IN ADULT IMMUNE THROMBOCYTOPENIA PATIENTS: A RETROSPECTIVE SINGLE-CENTER REPORT

L. Crucitti1,*, S. Cantoni1, R. Cairoli1

1Hematology and Oncology, Niguarda Cancer Center, Ospedale Niguarda Ca’ Granda, Milano, Italy

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder mediated by clearance of antibody-opsonized platelets (pt) by spleen macrophages. Pulsed high-dose dexamethasone (HD-DXM) has proved to be effective in adult patients (pts) with primary ITP resulting in controlled studies in 89% short-term response and a relapse-free survival (RFS) of 58% at 50 months (mos) (Mazzocioni, Blood 2007).

Aims: To assess the short-term and sustained response rates of adult ITP pts receiving pulsed HD-DXM in everyday clinical practice.

Methods: Charts of pts with ITP - as defined by Rodeghiero, Blood 2009 - treated with HD-DXM were reviewed. DXM was administered according to the schedule of 40mg/day for 4 consecutive days to be repeated every 21 days for a maximum of 6 courses. A reduced-dose schedule of 20mg/day for 4 days was preferred for elderly/diabetic pts. Pts who had completed at least 3 courses were included in the analysis. Response to HD-DXM was classified according to IWP definitions (Provan, Blood 2010); therefore, steroid-dependent pts were considered as non-responders even if plt counts increased to safe levels during HD-DXM and were included only in the analysis of short-term response, but not evaluated for long-term response. Short-term response rate was determined at completion of the whole course of treatment. Relapse was defined as a plt count decrease ≤20x10^9/L after initial response achievement and RFS was defined as the time interval between last course administered and the date of relapse, censoring pts alive or dead without relapse. Follow-up was defined as the time between diagnosis and last available assessment. The probability of RFS was calculated using the Kaplan-Meier method.

Results: A total of 45 pts (M: 21) were eligible for analysis; median age at treatment was 60 yrs (range 18-87) and median time between diagnosis and treatment start was 3 days (range 0-4686). Pts received a median of 5,15 courses (range 3-6); 27/45 completed 6 courses; 21/45 received the full dose of 40mg/day (=960mg total dose) while 6/45 received the reduced dose of 20mg/day (=480mg total dose). Median total DXM dose was 800mg (IQR: 600-1200) along with 1st DXM course were required in 11/45 pts. In between courses, no bleeding complications were observed and no emergency therapies were required. Short-term response was achieved in 39/45 (87%); complete response (CR) in 28/45 (62%), response (R) in 7/45 (16%); 4/45 (9%) pts were classified as steroid-dependent ITP and excluded from subsequent analysis. Long-term response off therapy, lasting for a median time of 28 mos (range 5-80) without relapses was observed in 25/35 responding pts (71.5%; CR in 18/25, R in 7/25 at last follow-up) with a RFS of 51% at 50 mos (Fig. 1). Median plt count at last

Figure 1.
follow-up was 102x10^9/L (range 54-336). Disease duration of less than 3 mos prior to therapy start was associated with better outcome (log rank p=0.049, Fig.2) with a median RFS not reached; median RFS for pts treated after 3 mos of diagnosis was 31 mos [OR: 3.8 (CI 95% 0.9-16.3), p=0.067]. No significant association between gender (p=0.87), age at treatment (more or less than 60 yrs) (p=0.85), DTX total dose (more or less than 480mg) (p=0.35) was found.

Summary/Conclusions: Pulsed HD-DXK is a well tolerated and highly effective first line treatment for ITP in every day clinical practice. The role of a reduce-dose schedule needs to be explored in a larger cohort of pts. Treatment of newly diagnosed ITP pts - i.e. within 3 mos of diagnosis (Rodeghiero Blood 2007) - seems to lead to longer RFS.

EFFECT OF OSELTAMIVIR TREATMENT ON PLATELET COUNTS

N. Revilla1,*, I. Heras2, M.E. de la Morena-Barrio3, P. Iniesta2, J.B. Nieto2, J. Corral1, V. Vicente3, M.L. Lozano4

1Servicio de Hematología y Oncología Médica, 2Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, 3Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca. Grupo de Investigación CB15/00055 del CIBERER, ISCIII, Murcia, Spain

Background: As platelets lose sialic acid during aging and circulation, they are cleared by the hepatic Ashwell-Morell receptor (AMR) (1). A recent study suggests that inhibition of sialidase by oseltamivir, a commonly administered anti-influenza medication that inhibits viral sialidase, could associate with an increase in platelet counts (2).

Aims: The aim of this study was to analyze the effect of oseltamivir treatment in platelet count.

Methods: We performed a retrospective single-center study. From November 2009 until March 2015, a total of 168 patients from our Hematology Unit were prescribed oseltamivir due to clinical suspicion of influenza. A total of 120 patients were excluded because they had received myelotoxic chemotherapy within 30 days (n=82) or platelet count was not available before treatment (n=38). The direct immunofluorescent antigen test was carried out with nasopharyngeal aspirate specimens. Those specimens that were negative by the antigen detection assay underwent RT-PCR testing for influenza virus types A and B. Platelet count was available before and after treatment (median of 5 days) in 48 patients and in 44 patients also when the infection was cleared (median of 30 days).

Results: Patients were divided into those with proven influenza (n=34) and without influenza (n=14). Median age was 58.0 and 59.5 years; respectively. Treatment consisted of 75mg oseltamivir bid for 5 days, with the exception of 3 patients in the proven influenza group receiving 150mg bid for 10 days (allo- geneic stem cell transplant recipients). We observed a significant increase in the mean platelet count after treatment with oseltamivir (170±95 x10^9/L vs 190±103 x10^9/L, p=0.04). As in the previous study (2), this effect was independent of whether influenza was diagnosed (Table 1). In addition, we did not discern significant fluctuation in platelet counts when treatment was immediately interrupted after a 30-day time lapse (184±100 x10^9/L vs 182±91 x10^9/L).

Table 1.

<table>
<thead>

<td>After: 234 ± 80</td>
<td>Before: 209 ± 87</td>
<td>After: 234 ± 80</td>
</tr>
</tbody>
</table>

Summary/Conclusions: Our study confirms the effect of oseltamivir on increasing platelet counts regardless of influenza infection. Although an increase in platelet counts related to the viral syndrome healing is not ruled out, the lack of long-term fluctuations after the end of treatment may indicate a late inhibition that contributes to reduction in platelet clearance via the hepatic receptor.

CLINICAL UTILITY OF CARDIAC MRI IN IMMUNE MEDIATED THROMBOCYTOPENIC PURPURA

F. Alwan1,*, D. Mahdi1, S. Mc Guckin1, J. P. Westwood1, M. Thomas1, J. Moon2, M. Scully1

1Haematology Department, University College London Hospital, 2Cardiac Imaging Department, Barts Heart Centre, London, United Kingdom

Background: Immune Mediated Thrombotic Thrombocytopenic Purpura (ITP) is a life threatening thrombomicroangiopathy caused by acquired antibody mediated inhibition of ADAMTS13. Cardiac complications are a common cause of death, with delayed proposed transfusion and high early mortality in ITP. There is scant evidence on the best investigations for patients suspected of being at risk of cardiac complications with no evidence on the clinical utility of cardiac magnetic resonance imaging (MRI) in acute ITP episodes.

Aims: A retrospective review evaluating the value of cardiac MRI scanning in ITP. Median age of patients underwent cardiac MRI between September 2008 and November 2014 whilst being treated for an acute episode of immune mediated TTP. All patients had troponin-t measurement on admission and a transthoracic echocardiogram within 72 hours of presentation. All patients were treated for their TTP episode with plasmapheresis, steroids and Rituximab. Two cardiologists reported each MRI scan and only agreed, unequivocal findings were considered.

Results: The median age of patients was 49 (range 13-75), 71% of whom were women. Two patients had a diagnosis of hypercholesterolaemia prior to TTP diagnosis but otherwise there was no previous cardiac history. 71% of patients had a raised troponin-t at presentation (normal <14ng/ml). Two patients developed bradycardia and one atrial fibrillation during their acute admission. One patient had symptoms of heart failure. Three patients had transient ST depression suggestive of ischaemia on EKG monitoring and a further four had non-specific T-wave inversion. There were no incidences of cardiogenic shock or MACE. There were no cases of myocardial ischemia or infarction in any of the patients. 33% of patients died within 3 mos of diagnosis.

Discussion: Reduced-dose schedule needs to be explored in a larger cohort of pts. Treatment of newly diagnosed ITP pts - i.e. within 3 mos of diagnosis (Rodeghiero Blood 2007) - seems to lead to longer RFS.
group and 56 (24-76) in the control group. Overall MEFV mutation prevalence was%25.9 (21/81) in the study group and%24.7(46/186)in the control group, (p=0.963). MEFV mutation distribution prevalence was similar in both gender groups among ITP patients and their presence did not alter the age of disease onset, (p=0.05). Similarly, presence of mutations did not change the platelet count at diagnosis, the number of treatment courses, the rate of patients undergoing splenectomy and primary steroid resistance. Although statistically not significant, there was a trend towards a better overall response to steroids in patients carrying MEFV mutations,%94.7 vs%82.8,(p=0.28) respectively. The median time to loss of response to steroids was 60 (10-124) months in patients with mutations and 42 (19-2-68) months in patients without MEFV mutations, (p=0.038). The median time to splenectomy was 101 (42.5-159.5) months in the MEFV mutation carriers and 51 (46-56) months in the non-carriers, (p=0.48). Time to loss of response to splenectomy was 38 (12-90.9) months in mutation carriers and 54 (14-93.9) months in non-carriers, (p=0.42).

Summary/Conclusions: To the best of our knowledge, our study is the first to address a possible effect of MEFV mutations on MEFV mutation carrier rates were similar in both ITP and control groups. Although MEFV carrier state had no impact on clinical features of ITP, mutation carrier tended to have a better overall response to steroid treatment, stayed longer in remission, had a longer time to splenectomy and relapsed earlier after splenectomy.

PD-1 AND CTLA-4 POLYMORPHISMS AFFECT THE SUSCEPTIBILITY AND CLINICAL FEATURES OF CHRONIC IMMUNE THROMBOCYTOPENIA

R. Io1, T. Kasamatsu1, Y. Kitamura1, K. Homma1, T. Nagashima1, N. Takahashi2, N. Gotoh1, M. Takizawa3, A. Yokohama2, H. Hands3, T. Salt0n1, H. Murakami1

Department of Medicine, Gunma University Graduate School of Health Sciences, 2Gunma University, 3Department of Hematology, 4Blood Transfusion Service, Gunma University Hospital, Maebashi, Gunma, Japan

Background: The programmed death-1 (PD-1) and cytotoxic T lymphocyte-associated antigen-4 (CTLA-4) play a central role in immune checkpoint pathways. The PD-1 negatively regulates self-reactive T and B cells in peripheral immune tolerance. The CTLA-4 antagonizes the binding of CD80 to its ligands including CD80 and CD86, and inhibits T cell activation. Previous studies have shown the lower expression of serum soluble PD-1 and CTLA-4 mRNA in patients with chronic idiopathic thrombocytopenic purpura (cITP) than healthy individuals. Single nucleotide polymorphisms (SNPs) of PD-1 and CTLA-4 have been reported to be associated with susceptibility of some autoimmune diseases; however, the possible association between these immune checkpoint SNPs and cITP risk remain controversial and obscure.

Aims: In order to explore the role of PD-1 and CTLA-4 in the pathogenesis of cITP, we investigated the impact of PD-1 and CTLA-4 SNPs on the susceptibility and clinical features of adult cITP.

Methods: We extracted the genomic DNA from 141 cITP patients and 223 healthy controls, and determined, 3 PD-1 SNPs (-606G/A, +7209C/T, A215V) and 2 CTLA-4 SNPs (+49 AA genotype (high producer) was significantly associated with low bleeding tendency than AG & GG genotype (low producer) (94.4% vs 71.5%, τ=0.358, p<0.0001), higher PC on the 7th days after splenectomy (56×109/L, ρ=0.502, p<0.0001) and on the 7th days after splenectomy (387×259/L vs.25×109/L, ρ=0.522, p<0.0001) and splenic platelet destruction (86% vs 0%, τ=0.358, p<0.0001). Using ROC analysis, cut-off prognostic values of PC were reevaluated: PC before splenectomy >47×109/L, (AUC 0.86, sensitivity 63.6%, specificity 83.2%, 95% CI 0.785-0.943, p<0.0001), PC on the first day after splenectomy >50×109/L (AUC 0.956, sensitivity 44.4%, specificity 83.2%, 95% CI 0.912-0.999, p<0.001 ) and PC on the 7th day after splenectomy >300×109/L (AUC 0.951, sensitivity 91.7%, specificity 45.6%, 95% CI 0.855-0.999, p<0.0001). By multy 112 molsay, rapl 2-beta-destruc-

tion, PC >47×109/L on the day of surgery (p=0.043) and PC >300×109/L on the 7th day after splenectomy (p=0.0013) were identified as predictive favorable response. Patients who relapsed frequently were older >60 years (31% vs 23%, p<0.030) and had lower PC three months after splenectomy (130×109/L vs 278×109/L, p=0.230, p<0.001). However, ROC values could not be calculated.

Summary/Conclusions: Splenectomy is effective in approximately two thirds of patients with ITP. Our study suggests that splenectomy might be considered in the patients younger than 60 years, with splenic platelet destruction and PC >20×109/L on the splenectomy day.

E1448
IS THE SPLENECTOMY OUTCOME PREDICTABLE IN PATIENTS WITH ITP?

M. Mitrovic1,2,*, S. Matic2,3, J. Bodrozic1, M. Smiljanic1, J. Jelicic1, D. Antic1,2, M. Todoric - Tiranic2,4, D. Tomin1,2, I. Elezovic1,2, N. Suvajdic1,2

1Clinic of Hematology, CCS, 2Faculty of Medicine, University of Belgrade, 3Clinic for Digestive Surgery, 4Center for Nuclear Medicine CCS, Belgrade, Serbia

Background: Splenectomy may lead to a good response in 60-80% of adults with corticosteroid resistant idiopathic immune thrombocytopenic purpura (ITP). However, in the era of news drugs the proper selection of patients for splenectomy is essential to optimizing treatment outcomes. Accordingly, it is important to identify pre- or post-operative parameters that are able to predict the response to splenectomy.

Aims: To identify the pre- and post-operative parameters predictive of successful splenectomy in ITP.

Methods: We retrospectively analyzed 130 ITP patients (median age 43 years, range 19-74; 84/39 female/male; median time from diagnosis to splenectomy 19 months, range 2-132; median number of pre-splenectomy therapies 2, range 0-6). Two cutoffs were defined after discontinuing corticosteroids Complete response (CR) and partial response (PR) were defined as platelet count (PC) >100×109/L and 30×109/L one month after surgery, respectively. The patient was considered refractory if his PC remained <30×109/L after splenectomy. Relapse was defined as a loss of response to steroids.

Results: CR and PR were achieved in 105/130 (79%) and 12/130 (7.5%) of the splenectomised patients, respectively. However, 13/130 (11.2%) patients were refractory. Twenty-nine of the 117 (24.8%) responsive patients relapsed. Predictors of good response after splenectomy identified by univariate analysis were: initial response to steroids (89.5% vs 22.7%, τ=0.358, p<0.0001), higher PC on the surgery day (90×109/L vs.37×109/L, p=0.353, p<0.001), on the first (387×259/L vs 56×109/L, p=0.502, p=0.0001) and on the 7th days after splenectomy (387×259/L vs 25×109/L, p=0.522, p=0.0001) and splenic platelet destruction (86% vs 0%, τ=0.358, p<0.0001). Using ROC analysis, cut-off prognostic values of PC were reevaluated: PC before splenectomy >47×109/L, (AUC 0.86, sensitivity 63.6%, specificity 83.2%, 95% CI 0.785-0.943, p<0.0001), PC on the first day after splenectomy >50×109/L (AUC 0.956, sensitivity 44.4%, specificity 83.2%, 95% CI 0.912-0.999, p<0.001 ) and PC on the 7th day after splenectomy >300×109/L (AUC 0.951, sensitivity 91.7%, specificity 45.6%, 95% CI 0.855-0.999, p<0.0001). By multy 112 molsay, rapl 2-beta-destruc-

tion, PC >47×109/L on the day of surgery (p=0.043) and PC >300×109/L on the 7th day after splenectomy (p=0.0013) were identified as predictive for favorable response. Patients who relapsed frequently were older >60 years (31% vs 23%, p<0.030) and had lower PC three months after splenectomy (130×109/L vs 278×109/L, p=0.230, p<0.001). However, ROC values could not be calculated.

Summary/Conclusions: Splenectomy is effective in approximately two thirds of patients with ITP. Our study suggests that splenectomy might be considered in the patients younger than 60 years, with splenic platelet destruction and PC >20×109/L on the splenectomy day.
drug reactions (ADRs), and other clinically relevant parameters. We report results from a full data analysis.

Results: A total of 59 patients were enrolled (49.4% male; 54% aged 65 years or above) from 38 sites; 22 of them were excluded due to protocol violations (e.g. incomplete documentation, inclusion criteria not met). Of the 137 remaining patients (the full analysis set, FAS), 102 completed the 2-year observation period for neuropsychological testing. Of the rest, 48 dropped out due to loss to follow-up (10 patients), deaths (6 patients) and ADRs (3 patients). Median (Q1-Q3) time from ITIP diagnosis to romiplostim initiation was 21.7 months (4-85 months) in the FAS. 123 FAS patients received prior ITIP therapies; most of them received corticosteroids (104 (75.9%)). 117 patients (85.4%) were non-splenectomized before romiplostim therapy, for reasons such as refusal of splenectomy, comorbidities, or age. Over the observation period, romiplostim was injected at a median (Q1-Q3) dose of 3.11 mcg/kg bw (1.8-4.8; FAS) over a median (Q1-Q3) treatment period of 103 weeks (33-104). The median platelet count rose sharply from baseline (29.0 x 10^9/L) to two weeks of treatment (62.5 x 10^9/L). From week 3 to 12 months, the median platelet count was maintained in a range of 50 x 10^9/L and 145.5 x 10^9/L. Since the start of the romiplostim therapy, 59 patients out of 137 (43.1%) received concomitant therapies, mostly corticosteroids (49 patients (35.8%)). The overall number of ADRs was 112 in the FAS, affecting 57 patients (27.0%). The most frequent ADRs were gastrointestinal (10.2%) and neurological (11.7%) ADRs, followed by constitutional symptoms (10.9%). Adverse drug reactions pertaining to bone/blood marrow affected 2.9% of patients (vascular/thrombotic events, bone marrow fibrosis), whereas bleeding as an ADR was seen in 0.7% of patients. The exposure-adjusted rate of bleeding events (grade 3 or 4) per 100 patient-years was 7.2 before treatment vs. 0.04 after starting the treatment. The rate of ITP-related hospitalization per 100 patient-years decreased from 23.3 before the start of therapy to 15.5 since the start of therapy.

Summary/Conclusions: This study of routine clinical practice in Germany showed that treatment with romiplostim in ITP patients resulted in a rapid increase in platelet counts to levels maintained between 50 and 250 x 10^9/L over time, regardless of the spleenectomy status of the patients; most of them were non-splenectomized. The product was well tolerated and achieved a decrease in the rate of ITP-related hospitalization.

THE CLINICAL UTILITY OF NEUROPSYCHOLOGY TESTING IN IMMUNE MEDIATED THROMBOTIC THROMBOCYTOPENIC PURPURA
F. Alwan1,*, S. Tayabali1, D. Mahdi1, M. Thomas1, J.P. Westwood1, L. Cipolotti2, M. Scully1
1Haematology Department, University College London Hospital, 2Neuropsychology Department, National Hospital for Neurology and Neurosurgery, London, United Kingdom

Background: It is well recognized that neurological manifestations are common in thrombotic Thrombocytopenic Purpura (TTP) however research into the neuropsychological impact of the disease is lacking despite evidence suggesting patients who experience critical illnesses are at high risk for long-term cognitive impairment.

Aims: To review the clinical utility of neuropsychology testing in thrombotic thrombocytopenic purpura.

Methods: Between 2010 and 2015, all patients within a single tertiary haematology center with a confirmed diagnosis of TTP were reviewed as outpatients after their acute episode. Those with persisting, non-physical neurological or psychological symptoms underwent cerebral MRI scanning and were referred for neuropsychological assessment. The Wechsler Adult Intelligence Scale III (WAIS-III) IQ test was used to assess factors including verbal IQ and performance IQ.

Results: 18 patients were included. 89% were female with a median age of 51 (16-67 years), 56% were Caucasian, 33% Afro-Caribbean and 11% of South Asian ethnic origin. 33% had experienced TIA or stroke-like symptoms during their acute episode. Those with persisting, non-physical neurological or psychological symptoms (n=7) were non-splenectomized. The product was well tolerated and achieved a decrease in the rate of ITP-related hospitalization.

Summary/Conclusions: HTS facilitates genetic confirmation of HPS diagnosis, and may help investigating phenotype-genotype relationships in HPS. The novel p.Leu91Pro variant in HPS4 associates with severe clinical phenotype. Funding: JMB: Gerencia Regional de Salud [GRS 1370/A/16]; JR: ISCIII & Feder (PI14/01956), Ciberer CB15/00055, Sociedad Española de Trombosis y Hemostasis

Background: Hermansky-Pudlak syndrome (HPS) is an inherited platelet disorder characterized by bleeding diathesis, oculoctaneous albinism and sometimes serious clinical complications. Heterogeneous clinical symptoms and a large numbers of possible genetic culprits (9 HPS genes, >118 exons) complicate unequivocal HPS diagnosis.

Aims: To assess the clinical and platelet phenotype in five patients with HPS suspicion and to identify their genetic defects through high-throughput sequencing.

Methods: We studied 5 patients from 3 families (2 Spanish, 1 Turkish) presenting with oculocutaneous albinism. Clinical records were reviewed and bleeding scored using ISTH-BAT. Platelet phenotyping (only Spanish patients) included: platelet aggregation, GPV expression and granule secretion.

Results: Clinical and laboratory findings in these patients are shown in Table 1. The Spanish patients (P1,P2,P5) showed impaired platelet aggregation to mild agonists and reduced platelet dense granules. In family 1 (F1), HSTS identified a heterozygous, potentially harmful, c.2054delC (p.Pro685Leu fs*17) variant in HPS4. One sister (P1) had Crohn’s disease and severe gastrointestinal (GI) bleeding. This variant had been reported in a 46yr Asian patient with pulmonary fibrosis (Bachi EB, Am J Med Genet 2004). A novel missense homozygous HPS4 variant, c.272T>C (p.Leu91Pro), was found in two Turkish siblings (F2). One had severe GI bleeding requiring colectomy (P4) and the other developed pulmonary fibrosis. Patient 5, suffering from mild GI bleeding, bears a heterozygous novel variant in HPS3 (c.2464C>T, p.Arg822X) and, most likely, an additional unrevealed mutation.

E1452
CHARACTERIZATION OF PLATELET ACTIVATION MARKERS IN EARLY ONSET PREECLAMPSIA
D. Angelovi1,2,*, K. Egan1,2, F. Ni Aline1,2,3,4,5
1UCD Conway SPHERE Research Group, 2School of Medicine, University College Dublin, 3Department of Haematology, Rotunda Hospital, 4Department of Haematology, Mater Misericordiae University Hospital, 5School of Molecular and Biomedical Sciences, University College Dublin, Dublin, Ireland

Background: Preeclampsia is a serious pregnancy complication with potentially life-threatening consequences for both mother and baby, diagnosed when new onset hypertension and proteinuria develops after 20 weeks gestation. Early onset preeclampsia (EOP; onset <34 gestational weeks), is associated with higher maternal and fetal risks than late onset preeclampsia. At the extreme end of the severity spectrum, HELLP syndrome is characterised by

Summary/Conclusions: Persisting psychological symptoms after an acute TTP episode are highly suggestive of underlying cognitive impairment as a result of cerebral sub-acute infarction or microhaemorrhages.

Summary/Conclusions: Persisting psychological symptoms after an acute TTP episode are highly suggestive of underlying cognitive impairment as a result of cerebral sub-acute infarction or microhaemorrhages.
hemolysis, elevated liver enzymes, and low platelets. Previous studies have demonstrated enhanced platelet activation in pregnant women with pre-eclampsia, using cell surface markers and platelet microparticles. Although severe pre-eclampsia is associated with increased inflammatory markers in vitro, levels of platelet activation do not necessarily correlate with severity of disease. 

Aims: To assess the prevalence, and degree, of platelet activation in a cohort of patients with early onset preeclampsia (EOP), HELLP syndrome, and to correlate this with evidence of in vivo coagulation activation using D-dimers. 

Methods: Plasma samples from patients with EOP were accessed from a clinical biobank. Platelet activation markers were characterized using ELISA assays measuring platelet factor 4 (PF4), soluble glycoprotein VI (sGPVI) and neutrophil activating peptide-2 (NAP-2). Platelet microparticles (CD42a+ microparticles) were measured by flow cytometry. Platelet activation biomarker levels were adjusted by platelet count and expressed as /10⁹ platelets/ml. All data was analysed using GraphPad Prism 7. Parameters were reported as mean±SEM.

Results: Plasma samples from 19 individual patients were included. Patients with HELLP syndrome demonstrated significantly greater numbers of CD42a+ microparticles when corrected for platelet count compared with those without HELLP syndrome (598x10⁹±220x10⁹ versus 297x10⁹±37x10⁹, CD42a+ microparticles/10⁹ platelets/ml, p=0.04). Similarly, patients with HELLP syndrome demonstrated increased levels of sGPVI than those without HELLP; corrected for platelet count (2.576±0.9667 versus 1.22x±0.124 x 10⁹ /10⁹ platelets/ml, p=0.0334). There was no difference in NAP-2 or PF4 levels between those with HELLP and those without HELLP, nor between severe and moderate pre-eclampsia patients. Severe pre-eclampsia patients in this cohort had a D-dimer level of 3.7±10.7472 µg/ml compared with non-severe patients 1.85±20.3510 µg/ml versus 3.53±21.1377 µg/ml, D-dimer levels (Spearman Rank correlation coefficient, r =0.532, p=0.04).

Summary/Conclusions: The results of this study demonstrate a positive correlation between severity of pre-eclampsia and platelet activation, as measured by levels of platelet-derived microparticles and platelet GPVI expression. A number of studies have concluded the role of low-dose aspirin therapy as prevention for pre-eclampsia, and there is Grade 2B evidence for its use in those at risk of severe pre-eclampsia. The evidence of enhanced platelet activation in our study provides rationale for the efficacy of aspirin in this setting, and the potential for novel antithrombotic agents to be studied for the same indication.

E1453 PRIMARY ITP IN ADULTS TREATED WITH ELTROMBOPAG: A RETROSPECTIVE STUDY USING DATA FROM THE UNITED KINGDOM ADULT IMMUNE THROMBOCYTOPENIA REGISTRY.
D. Provan1,2,*, U. Doobare3, A. Newland4, J. Fleming2,1
1Hematology, Barts and The London School of Medicine and Dentistry, London, UK. 2Haematology, Novartis, Camberley, Surrey, United Kingdom

Background: Primary ITP is an autoimmune disorder associated with a reduced peripheral blood platelet count. Although many patients are relatively asymptomatic, many suffer with bruising, mucosal bleeding and quality of life issues. Current management and first-line treatment has remained unchanged for decades and until recently, second-line therapy has been unsatisfactory, using empirical treatments. The recently approved thrombopoietin receptor agonists eltrombopag and romiplostim have transformed patient care and these agents are licensed second-line therapies in adults. 

Aims: To describe the adult patients receiving eltrombopag using data from the UK Adult ITP Registry. In particular we were interested in understanding the mean dose used, number of prior therapies, median length of treatment with eltrombopag, median counts at baseline before treatment and at six months following treatment, and sustained response in patients who have received eltrombopag.

Methods: The UK Adult ITP Registry involved more than 70 UK collaborating centres, coordinated by The Royal London Hospital. In this study we analysed data from all patients receiving eltrombopag and analysed these using various statistical techniques.

Results: The total number of patients evaluable was 129. The median age at diagnosis was 49.4 years (26.9-66.4). There were 74 males (57.4%) and 55 females (42.6%), 29 patients (22.4%) had undergone prior splenectomy. The median age at eltrombopag initiation was 59.5 years (37.0-70.7 years). The median time from ITP diagnosis to eltrombopag initiation was 1.6 years (0.7-2.3 years). The majority of patients started eltrombopag between 2013 and 2016 (93%), and 4% (8) started eltrombopag within the first 6 months and between 6 to 12 months of ITP diagnosis, respectively. Most patients had received prior ITP therapies. Some 10 patients (7.8%) had received one prior ITP therapy and 99 patients (77%) had received three or more prior therapies before starting eltrombopag. The commonest prior therapies were corticosteroids in 110 patients (87%), IVIg 51 patients (72%); rituximab 88 patients (54%); romiplostim 47 patients (37%); and immunosuppressants 71 patients (56%). At baseline, prior to starting eltrombopag, the median platelet count was 21x10⁹/L (10-54) and the majority of patients (64.5%) had platelets less than 30x10⁹/L. The mean platelet count at 6 months was 206.2±10⁹/L and at 1 year was 288±10⁹/L. The median dose of eltrombopag used was 50mg/day. The median course length on eltrombopag was 14.7 (IQR: 4, 67) weeks. After initiation, 53 (41%) remained on eltrombopag as a monotherapy whereas 27 (21%) had other ITP treatment concurrently with eltrombopag. Forty nine (38%) changed treatment after eltrombopag, of which prednisolone (47%), IVIg (33%), and monoclonal antibodies (31%) were used. Thirty six (27%) underwent a splenectomy. Response to eltrombopag was assessed for 106 patients with adequate follow up time and platelet counts. 81 (76%) had a response, of which 54 (51%) were above 100x10⁹/L and 27 (25%) had a partial response (platelet counts between 30 to 100x10⁹/L). Among those that had a response, 15 (14%) became unresponsive after some time whereas 22 (2%) patients were unresponsive soon after a brief episode of response. In short, 64 (60%) had a sustained response to eltrombopag (among patients who remained or came off eltrombopag).

Summary/Conclusions: The patient characteristics of those receiving eltrombopag appear to be typical of adult ITP. Only 10 patients (7.8%) had stopped 1st line therapy.

E1454 EFFICACY OF TPO-MIMETICS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA
F. Bachiani1,2, V. Carrai3, C. Biagioti1, A. Bosi1
1Hematology, AOU Careggi, Firenze, Italy.

Background: Immune thrombocytopenic purpura (ITP) is an autoimmune disorder in which antibodies are produced to circulating platelets. The two currently available agents (Romiplostim and Eltrombopag) have similar efficacies and only slightly different safety profiles, being effective in restoring a safe platelet count in 70%-80% of cases with chronic ITP failing one or more lines of treatment, including splenectomy.

Aims: We evaluated the efficacy of TPO-RAs in patients with ITP.

Methods: From November 2008 and February 2017 65 patients (33 M; 32 F) were treated with a median follow-up of 29 months (1-96); 39 underwent therapy with Romiplostim and 26 to Eltrombopag. Median age was 69 years (range 39-94 years). In the group of patients treated with Romiplostim, 21 had already received two lines of therapy, while 18 patients had one line of therapy. 13/26 patients who received Eltrombopag were at the 3rd line of therapy. 1 at the second, and the others were at least at the 4th line. The median platelet count was 21x10⁹/L (3-52) at the start of Romiplostim, with a median starting dose of 1µg (1-2) and 17x10⁹/L (1-53) in patients treated with Eltrombopag, with a median starting dose of 50mg (25-50).

Results: Patients treated with Romiplostim and observed complete responses and 10 responses, with a 82% response rate, while 7 patients were no responders. In our study 26 (66%) patients stopped Romiplostim after a median time of 16 months (1-93): 9 for stable response, 5 for no response, 3 for loss of response, 3 for adverse events (2 for bone marrow fibrosis, 1 for headache), one patient died due to a cerebrovascular event and one patient discontinued treatment due to new malignancies. 7 patients (17%) who did not interrupted treatment are still receiving therapy with a median of 29 months (3-96). Several studies report Romiplostim and Eltrombopag to be highly effective against chronic ITP, with average immediate responses exceeding 80% in our study. We observed that therapeutic response was influenced by the starting platelet count. In particular platelets count before therapy influenced the first response observed. In particular in patients treated with Romiplostim PLT pre-treatment directly correlated with the first response and the maintainance of response during treatment at month 1°, 2° 3° and 6. Patients with a median starting platelet count of 15x10⁹/L obtained a response (CR + R), while almost all patients who started therapy with PLT+15x10⁹/L at baseline can obtain an initial response, but the majority is only short-lived response.

Summary/Conclusions: TPO-mimetics have proved efficacy in patient with ITP and their use can be applied in several conditions (bridge to splenectomy; sustained response; switch and discontinuation). Future study on large series of patients are needed to best correlate baseline platelets with hematological response and to identify the optimal agents (Romiplostim vs Eltrombopag) that have similar efficacies and only slightly different safety profiles, being effective in restoring a safe platelet count in 70%-80% of cases with chronic ITP failing one or more lines of treatment, including splenectomy.

PREVALENCE AND RISK FACTORS FOR THROMBOSIS IN ADULT ITP PATIENTS
C. Moret1, A. Ticheli2, A. Wieland-Greguare-Sander3, A. Angelillo-Scherrer3, A. Rovó3,4
1Faculty of Medicine, University of Bern, Bern, 2University Hospital of Basel, Basel, 3University Hospital of Bern, Bern, Switzerland

Background: Immune thrombocytopenia (ITP) is characterized by severe thrombocytopenia due to autoantibody- and cell-mediated peripheral platelet destruction and attenuated thrombopoiesis. Despite a higher risk for bleeding, thromboembolic events (TEE) have been observed.

Aims: We aimed to investigate the prevalence and type of TEE and the potential risk factors in adult ITP patients.

Methods: Retrospective cohort study, including all ITP patients followed in our clinic between 01/1990 and 05/2016. Information on gender, age, date of ITP diagnosis, platelets count, type and clinical form of ITP, type of ITP treatments and its response, severe bleeding and follow up time were collected. Furthermore we evaluated date of first appearance, number and type of thromboembolic events, cardiovascular risk factors, date and cause of death. We assessed and compared risk factors of ITP patients with and without TEE in univariate and multivariate analysis.

Results: Medical files of 480 patients registered as ITP were reviewed; 42 patients were excluded from the analysis (not fulfilling the ITP criteria according to Rodeghiero et al. Blood 2009). In total 438 patients were retained for analysis, 10% out of them (44 patients) presented ≥1 TEE after ITP diagnosis. Within these patients, in total 54 TEE occurred: 34 venous (61%), 19 arterial (34%) and 3 arterial and venous (5%) thrombotic events. The most frequent venous TEE were pulmonary embolism, deep vein thrombosis, and superficial vein thrombosis; arterial TEE were cerebrovascular insults, myocardial infarction and peripheral artery thrombosis. At time of TEE, 43% of patients were on treatment with corticosteroids, 14% with thrombopoietin receptor agonists (TPO-ra) and 18% were off-treatment. In the univariate analysis, older age at diagnosis (≥50 years, P=0.015), poorer platelet recovery, persistent or chronic ITP (versus acute, P=0.009), ≥2 treatment lines (P=0.0002), TPO-ra at time of thrombosis (P=0.027), non-response to first-line treatment (P=0.010), smoking (P=0.011), arterial hypertension (P=0.005), and obesity (P=0.041) revealed to be significant. The multivariate analysis model showed an increase in platelet counts in 2 patients with primary immune thrombocytopenia (ITP) (1.2). A previous study has suggested a mechanism of Fcγ receptors (FcγR)-independent platelet clearance with primary immune thrombocytopenia (ITP) (1,2). A previous study has suggested a mechanism of Fcγ receptors (FcγR)-independent platelet clearance in ITP patients with anti-Glycoprotein (GP) Ibα autoantibodies (3). However, little is known about the exact response mechanism of this drug in ITP patients with anti-GP Ibα autoantibodies and TPO-ra at time of thrombosis

Methods: We performed a prospective study in 4 ITP patients who exhibited no response to standard therapies (steroid, IVIG and/or splenectomy) and showing relevant platelet desialylation levels. Patients were given off-label oseltamivir at the referring physician’s discretion. Desialylation of GP platelet surface was examined via flow cytometry (FC) analysis, with fluorescein-conjugated Ricinus Communis Agglutinin I (RCA-1), which binds galactose residues only if the terminal sialic acid has been removed. FC data are expressed as fold change compared to control samples. Additionally, patients' sera were incubated with normal human platelets to analyze the ability to induce desialylation of normal platelets. Analysis of plasma proteins was performed with Western blot (FXI, FXII) and HPLC (carboxylin I). Platelet autoantibody specificity was detected by a solid-phase modified antigen capture ELISA test (MACE).

Results: Patients' characteristics are summarized in Table 1. Two patients achieved complete platelet response (>100x10^9/L) after oseltamivir treatment. The oral dose was 75mg twice daily, for a variable duration (5 days in one case and 4 months in the other) showing relevant response criteria since the third week of from start) combined with low doses of other treatments (azathioprine or romiplostim). A sustained platelet response was observed after 4 weeks of the sial-

E1457
BORTEZOMIB THERAPY IS ASSOCIATED WITH SIGNIFICANT RESOURCE IMPLICATIONS FOR BOTH PATIENTS AND PROVIDERS: RESULTS OF A TIME-IN-MOTION STUDY

M. Tatarczuch1, K. Ramasamy1, A. Peniket1, M. Sultanova1, G. Vallance1, F. Panitsas1
1Haematology, Oxford University Hospitals NHS Trust, Oxford, United Kingdom

Background: Bortezomib is a proteasome-inhibitor, which has improved outcomes in multiple myeloma (MM). Its use is approved within the UK NHS. Bortezomib is frequently administered as a subcutaneous injection in a hospital day treatment unit. Whilst the administration of a subcutaneous injection is brief, the process for the patient travelling to hospital, assessment and waiting for the delivery of the injection can take considerable time. From a patient perspective, significant amount of time spent without economic activity and travel costs add up during the course of therapy. From the health-care provider the process of safely administering bortezomib has significant resource implications beyond those of drug procurement.

Aims: We set up a time-in-motion study to evaluate the costs to health care provider and patients during bortezomib therapy to estimate the ‘real-world’ cost of delivering bortezomib therapy.

Methods: Retrospective data collection was undertaken, using electronic prescribing records for patients treated between July 2014 - August 2016. Travel distance and time was estimated using Google maps and costed using HMRC mileage (an approved costing of mileage used for taxation purposes). The NHS schedule of service costs was used to estimate the cost of bortezomib administration. Cost of delivery of Bortezomib for healthcare providers is a sum of these individual costs.

Results: We identified 127 patients who incurred a total of 2,134 visits whilst receiving Bortezomib therapy at the Churchill Hospital in Oxford during this 2 year period. Median age was 70 years-old (yo) (39-95); Male 74 patients (58%); 53 patients (42%). We restricted the analysis to 110 patients who started and completed therapy during the study period. Median number of patient visits was 16 (range 11-52). The median travel distance (return journey) for each patient was 33 miles (53 km) (range: 1.2-224 mi; 1.9-360 km). Median travel time was 90 min (range: 8-300 min). The range travel cost per patient was £8.35-£13.20. Twenty-seven patients (21%) required use of specialist hospital transport services, which resulted in 295 transport-episodes (14%) in total. In order to assess the time spent in the day therapy unit, a subgroup of 589 patient-episodes were analysed to assess time from arrival to administration of Bortezomib: the median time from patient registration to bortezomib administration was 63min (range: 5-433min). Pharmacy cost for preparation of Bortezomib was £50 per dose. The cost of delivery of bortezomib (not including cost of drug) was £1,160 per cycle, which equated to a total median cost of £4,640 per patient (range: £290-£15,080). Drug procurement costs for Bortezomib is estimated at an additional £12,261 per course of therapy (BNF 2016). Delivery costs therefore added an additional 38% to the procurement costs.

Summary/Conclusions: We provide the first time-in-motion data on myeloma patients treated with Bortezomib. The ‘real-world’ cost of delivering therapy is 37% higher than the drug-costs alone. In addition the impact on patients is substantial: over a two year period 127 patients required 2,134 visits with a median time in the day unit of 63 minutes and a median travel time of 90 minutes per visit. Our data highlights the burden of both time and economic costs to patients during therapy. Novel oral proteasome inhibitors offer the potential to reduce this resource impact in the future. This data could be used by health care providers and reimbursing agents for economic modeling of the potential benefits of oral proteasome inhibitors.

Our data highlights the burden of both time and economic costs to patients during therapy. Novel oral proteasome inhibitors offer the potential to reduce this resource impact in the future. This data could be used by health care providers and reimbursing agents for economic modeling of the potential benefits of oral proteasome inhibitors.
Background: In France, azacitidine (AZA) is indicated for the treatment of adult patients affected by Myelodysplastic Syndrome with intermediate-2 or high risk according to the International Prognostic Scoring System (IPSS), Chronic Myelomonocytic Leukemia (CMML) with 10-29% medullary blasts and Acute Myeloblastic Leukemia (AML) with 20-30% blasts. It’s also a drug treatment of adult AML patients over 65 years with>30% of medullary blasts, Azacitidine is a cytidine nucleoside analog administered intravenously or subcutaneously as an effective, treatment cycles require frequent hospital visits which could decrease patient comfort and increase medical personnel workload. Limousin is a region with the oldest population of France and with a very low population density. There is one university hospital and two local state-run hospitals each with a hematology department. In 2009, HEMATO, the Limousin hematology network, set up a protocol called ESCADHEM (externalization and securitization of injectable chemotherapy at home for malignant hematological diseases) that facilitates chemotherapy administration via local hospital at Home (HaH) establishments, which is an alternative to conventional hospitalization in France (www.fnehad.fr). The aim was to minimize the frequent hospital visits that these treatments require. This organization includes the three previously mentioned hospitals, four HaH structures, and three central pharmacies with an integrated preparation unit for cancer treatments. From 2009 to 2015, a total of 11,367 infusions were administered at home for 464 pts. In 2016, we demonstrated the feasibility of ESCADHEM and the medico-economic interest of such care with Bortezomib, another injectable chemotherapy at home (Touati et al. Bortezomib, another injectable chemotherapy at home (Touati et al. 2016 Dec; 24(12):5007-5014). In 2014, we have conducted a satisfaction survey with a cohort of 84 pts who received treatment in HaH structures via ESCADHEM (20% pts with AML/MDS were treated by AZA). The overall satisfaction rate was 95%.

Aims: Our work aimed to demonstrate that HaH administration of AZA is feasible and well preferred by patients compared to hospital administration.

Methods: Chemotherapy at home obeys to strict rules. The first chemotherapy cycle (C1) and the first infusion (D1) of subsequent cycles were administered at the outpatient care unit. The following injections were administered at the patient’s home and carried out by HaH, according to a predefined procedures (Fig 1) to comply with safety rules essential to the protection of the professional, the patient, the entourage and the environment. Subcutaneous AZA injections were administered at 101 pts with median age of 75 years (range 41-92) there are 88 (52%) MDS patients and 81 pts (48%) with AML. Patients received a median number of 5 cycles (1-41) and 26 injections of AZA (1-244) at home. The total duration of HaH management lasted from less than 1 day to more than 3.4 years with a mean of 6.3 months. During the period of HaH administration of AZA, 101 pts of 169 pts (60%) had to return to the hospital for a non programmed rehospitalization: 90% of the time the patient needed a transfusion, 4% because of infection and 6% for other reasons.

Results: From 2009 to 2015, a total of 6369 subcutaneous injections of AZA were administered at home for 169 pts with AML/MDS received AZA therapy. Among all pts, 110 were men and 59 females. The median age was 75 years (range 41-92) there are 88 (52%) MDS patients and 81 pts (48%) with AML. Patients received a median number of 5 cycles (1-41) and 26 injections of AZA (1-244) at home. The total duration of HaH management lasted from less than 1 day to more than 3.4 years with a mean of 6.3 months. During the period of HaH administration of AZA, 101 pts of 169 pts (60%) had to return to the hospital for a non programmed rehospitalization: 90% of the time the patient needed a transfusion, 4% because of infection and 6% for other reasons.

Summary/Conclusions: Administration of oral analgesia and anxiety is a safe and feasible option to be used in outpatient setting: sedo-analgesia is very effective in reducing pain during the biopsy and diminishes the anticipatory anxiety related to a painful procedure. Patients should have the possibility to choose between local anesthesia alone or sedo-analgesia plus local anesthesia.

E1460 ASSESSMENT OF THE ECONOMIC IMPACT OF HORSE-ATG IN SWEDEN FOR APLASTIC ANAEMIA
1Hematology, Tallaght Hospital, Dublin, Ireland, 2Hematology, Saint Louis Hospital, Paris, France, 3Hematology, Department of Clinical Medicine and Surgery, Karolinska University Hospital, Stockholm, Sweden, 4Hematology, Department of Clinical Medicine and Surgery, Federico II University of Naples, Naples, Italy, 5Modeling & Simulation, Evidera, London, United Kingdom, 6Modeling & Simulation, Evidera, Budapest, Hungary, 7Pfizer, Philadelphia, United States, 8Pfizer, Paris, France

Background: Aplastic anemia (AA) is a rare, potentially fatal haematopoietic stem-cell disorder that can either be inherited or acquired. AA is graded according to disease severity, from non-severe to very severe and is linked to immune-related responses such as the generation of anti-marrow. Cases of severe and very severe AA are considered to be a haematological emergency requiring urgent treatment. Extended hospitalisations and the cost of treatments and disease management are associated with the economic impact of AA.
Aims: To assess cost-effectiveness of ATGAM (horse antithymocyte globulin) in comparison to rabbit antithymocyte globulin (r-ATG) in the treatment of moderate to severe aplastic anaemia (sAA) patients in Sweden.

Methods: A nested case-control study was conducted. The initial population consisted of 122 consecutive patients with sAA received ATGAM or r-ATG. The study included 60 patients in each group. The patients were divided into three groups based on the severity of the disease: mild, moderate, and severe. The severe group was further divided into two subgroups based on the duration of treatment: short-term (1-6 months) and long-term (greater than 1 year).

Results: Response to treatment was calculated to be seen in 67% of ATGAM patients' vs 35% in r-ATG (accounting for mortality). Over 2 years, the model estimated that patients gained 4.15 life-years (3.28 quality-adjusted) on ATGAM vs 3.52 (2.56) on r-ATG. Short-term disease management costs were estimated to be SEK 80,144 (€69,816) in responders vs SEK 1,264,016 (€139,041) in non-responders. Medium and long-term costs also followed the same pattern. Overall costs (drug plus disease management), were significantly lower for patients receiving ATG AM vs r-ATG; making ATGAM cost-saving by being both more effective and less costly than r-ATG. When considering treatment costs (only (including cyclosporine and HSCT), the model estimated a cost of SEK 107,097/life-year gained (€11,781) and SEK 135,655/quality-adjusted life-year (€14,922), showing ATGAM is highly cost-effective. The analysis showed that when treatment and disease management costs are considered, ATGAM dominates r-ATG as the gain in QALYs and LYS are achieved at a lower cost. Therefore making ATGAM cost-saving with greater health benefits in comparison to r-ATG.

Summary/Conclusions: Due to improved treatment response, survival, and quality of life outcomes, the model shows that ATGAM is at least more cost-effective, if not cost-saving, in comparison to r-ATG for the treatment of patients with aplastic anaemia.

A CLINICAL AUDIT OF NUTRITIONAL SCREENING AND SUPPORT OF HOSPITALIZED PATIENTS WITH HEMATOLOGIC DISEASES

A. Stamo1, A. Liaskas1, I.-G. Tzaniniris1, E. Kaniouira1, D. Politis1, L. Poulla2, N.-A. Viniou1, K. Konstantopoulos1, P. Diamantopoulos1.*

11st Department of Internal Medicine, Hematology Unit, Laikon General Hospital, National and Kapodistrian University of Athens, 2Clinical Nutrition Department, Laikon General Hospital, Hematology Department, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece

Background: Poor food intake is a common problem in patients with hematologic diseases. Recurrent infections and chemotherapy complications are some of the possible causes. Malnutrition is correlated to slow recovery, prolonged hospitalization, and higher mortality. Audits about the nutritional support of hospitalized patients may detect significant failures in patient care and help towards the correct application of the international guidelines.

Aims: We performed a prospective observational audit on hospitalized patients with hematologic diseases to investigate their nutritional status and whether they received the appropriate nutritional support.

Methods: The initial population consisted of 122 consecutive patients with hematologic diseases admitted from March 31, 2016 to June 8, 2016 in two Hematologic Units of a Tertiary University Hospital in Athens, Greece. We designed a special questionnaire based on the Malnutrition Universal Screening Tool (MUST) with additional questions on demographic, somatometric and medical data (Table 1). The questionnaire was applied by 6th-year medical students to all patients within 48 hours of admission. Patients were classified as high, intermediate, and low-risk per the MUST score and were reassessed at prede- fined intervals. During re-assessment, we examined the food intake and the nutritional interventions (nutritional supplements, enteral or parenteral nutrition) applied.

Results: Ninety-three patients were included in the final analysis (5 refused to participate, 22 were excluded due to short-term hospitalization, 2 were absent during reassessment). Forty-one (38%) patients had a MUST score ≥2 (high risk) but none of them received nutritional supplements. One patient was supported with parenteral nutrition (Table 1).

Summary/Conclusions: Our audit revealed a lack of nutritional support of the hospitalized patients. A meeting with the involved health professionals was organized and an oral presentation of the results and the possible causes (lack of sensitization of the staff, high regimen cost, shortness of staff) was performed. Proposals to change the current situation were made such as detection of high risk patients upon admission and further assessment by a nutrition specialist. A brief MUST-based questionnaire was also proposed to be used for all patients upon admission. A re-audit was programmed and is already in progress.
E1463
ASSESSING REAL-WORLD TREATMENT PATTERNS, OUTCOMES AND RESOURCE USE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) POST AUTOLOGOUS STEM CELL TRANSPLANT ACROSS EUROPE
J. Ashcroft1, G. Taylor-Stokes2, S. Dhansini3, D. Judge4
1Mid-Yorkshire Hospitals NHS, Wakefield, 2Adelphi Real World, Bollington, United Kingdom, 3Celgene International, Boudry, Switzerland

Background: Autologous stem cell transplant (ASCT) is the standard of care for first line (1L) treatment (tx) for patients (pts) with MM deemed of suitable fitness to safely undergo the procedure. More recently introduced tx options have significantly increased the life expectancy of pts with MM and continue to provide further promise for the future in this devastating disease. The increasing therapeutic armamentarium the MM pathway allows for varied tx patterns providing both potential differences in outcomes and healthcare resource use (HCRU).

Aims: The aim of the analysis was to determine current management of pts in the post ASCT setting, assess outcomes of pts and HCRU.

Methods: A retrospective chart review was conducted in France, Germany, Italy, Spain and the UK. Data collection took place in Q1 2017. Physicians provided data on consecutive pts with MM who had undergone an ASCT as part of 1L tx or on or after 1st January 2014, to specifically examine the HCRU post 1L ASCT. Data collected pertained to pt characteristics, b patterns, duration of tx and outcomes (including time to progression (TTP) and best response achieved (IMWG updated criteria), HCRU in terms of hospitalizations, additional supportive drugs prescribed and healthcare professional (HCP) visits. Pt records included in this interim analysis were completed by Feb 17th 2017, with data collection continuing in all countries.

Results: 214 record forms have been reviewed to date. Pts' mean age at diagnosis was 59 (±7.8 SD) years; 43% female and 57% male. Mean duration from diagnosis, to receiving an ASCT was 9.6 months (±13.3 SD). Of the pts included in the study, 62%, 28% and 8% had received 1st, 2nd and 3rd line tx respectively. In the 1L setting, 72% of pts did not receive any drug therapy post 1L ASCT, 21% received consolidation and 8% maintenance therapy. Of the pts who did not receive maintenance therapy, 42% and 34% went onto receive 2L and 3L drug therapy respectively; whereas, only 24% of pts who received maintenance therapy went onto 2L, and none onto 3L. The most frequently prescribed regimens at 1L maintenance were Lenalidomide (82%), Bortezomib (12%) and Thalidomide (12%).

Table 1. The emergence of targeted therapies with high efficacy in small populations such as TKI-refractory CP-CML has challenged decision makers.

Aims: To demonstrate a simple and intuitive approach to assessing the value of available TKIs (nilotinib, dasatinib, ponatinib and bosutinib) in this setting.

Methods: Using synthesized efficacy data from a published meta-analysis (Lipton 2014), we calculated NNT to achieve one additional response, defined as complete cytogenetic response (CCyR), for CP-CML patients treated with a TKI after failing ≥2 prior TKIs. NNT represents the expected number of treated patients required to achieve one additional response – i.e., the multiple of treat-
ed patients to responders. We assumed response is not evaluated prior to 3 months, per National Comprehensive Cancer Network (NCCN) guidelines. Therefore, the cost of achieving an additional response was estimated as the product of NNT and 3-month cost, based on US Wholesale Acquisition Costs (WAC) and recommended dosing for each TKI from US prescribing information (USP).

Results: To achieve one expected response, the NNT is 1.7 (95%CI: 1.5-1.9) patients for ponatinib, 3.8 (3.4-11) for nilotinib, 4.2 (2.2-11.1) for dasatinib, and 4.5 (3.4-6.7) for bosutinib (based on CCyR of 60%, 26%, 24% and 22%, respectively). With a 3-month WAC for ponatinib of $49,683, nilotinib; $33,892, dasatinib; $33,897 and bosutinib; $36,045, the estimated 3-month cost per response achieved is $82,000 ($73,100-$95,500) for ponatinib, $130,000 ($108,000-$161,000) for nilotinib, $141,000 ($75,300-$377,000) for dasatinib, and $164,000 ($124,000-$240,000) for bosutinib.

Summary/Conclusions: Using published, synthesized efficacy estimates, the NNT to achieve response with ponatinib in TKI-refractory CP-CML is less than with other TKIs. Despite a higher WAC for ponatinib, the lowest estimated 3-month cost per response achieved. Therapy choice should, however, consider both treatment cost and the benefit-risk profile of the individual patient.

THE COST-EFFECTIVENESS OF PEGASPARAGATE FOR FIRST-LINE TREATMENT OF ACUTE LYMPHOBLASTIC LEUKAEMIA: A COST-UTILITY ANALYSIS
S. Basu1, P.L. Lin2, C. Rowntree3,*, V. Sahai4
1Shire, London, United Kingdom, 2Shire, Cambridge, United States, 3University Hospital of Wales, Cardiff, 4University of Manchester, Manchester, United Kingdom

Background: Asparaginase is a key component in the multi-agent chemotherapy regimens for the treatment of children, adolescents, and adults with acute lymphoblastic leukemia (ALL). Compared to native asparaginase (native ASP), pegaspargase (PEG-ASP) has a longer half-life, can be given less frequently, and is less immunogenic, which leads to fewer hypersensitivity reactions. In the UK, patients with newly diagnosed ALL are treated with PEG-ASP followed by Erwinia-derived asparaginase (ERW-ASP) in cases of hypersensitivity, based on the UKALL protocols. Although native ASP is no longer used as the first choice of asparaginase therapy, it was the standard of care before PEG-ASP was available. A cost-utility analysis (CUA) was conducted to evaluate overall cost-effectiveness of PEG-ASP in comparison to native ASP when utilized as part of antineoplastic combination therapy for treating newly diagnosed ALL in children, young people, and adults.

Aims: To evaluate the cost-effectiveness of a treatment strategy including PEG-ASP in a multi-agent in patients with newly diagnosed ALL compared to regimens that include native ASP.

Table 1.

Methods: In line with accepted National Institute for Clinical Excellence (NICE) methodology, a combined decision tree and health state transition Markov model was developed to compare treatment sequences starting with PEG-ASP versus native ASP, followed by ERW-ASP in case of hypersensitivity. Although ERW-ASP is not used first-line in the United Kingdom, alternative switching scenarios could be clinically possible, and therefore all scenarios were modelled. Paediatric, young adult (≤25 years), and adult (26-65 years) patients were modelled separately using the UKALL 2003 and UKALL14 protocols, respectively. Further splits were made between high-, intermediate-, and standard-risk patients in the paediatric model, between patients aged ≤40 vs >41 years and patients eligible or not eligible for transplant in the adult model. Key model parameters (survival, risk of hypersensitivity) were based on published data and clinical expert input. In the base-case analysis, overall survival and event-free survival were assumed to be equivalent for PEG-ASP, native ASP, and ERW-ASP, with 1,000IU/m2 dosing (per UKALL protocols) used for all APIs. The 2,200 IU/m2 dosing (per German SmPC) of PEG-ASP was examined, as well as variations in comparative survival and hypersensitivity rates. Incremental cost-effectiveness ratios (ICER; defined as incremental costs/quality-adjusted life years [QALYs] gained) were produced.

IMPACT OF VENETOCLAX ON THE QUALITY OF LIFE OF PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA: RESULTS OF A PHASE 2, OPEN-LABEL STUDY OF VENETOCLAX (ABT-199/ GDC-0198) MONOTHERAPY

W. Weitzel1, 2, K. Saull, L. Noe2, R. Kamalakar2, J. Gdovin2, M. Verdugo2, S. Kim2, R. Humerickhouse2, S. Stilgenbauer3
1The University of Texas MD Anderson Cancer Center, Houston, 2AbbVie Inc, North Chicago, United States, 3Department of Internal Medicine III, Ulm University, Ulm, Germany

Background: Chronic lymphocytic leukemia (CLL) is associated with reduced health-related quality of life (HRQoL), with progressive severe fatigue being a particularly relevant burden. Disease-related symptoms, toxic effects of therapy, and the awareness of living with an incurable disease can have a profound impact on HRQoL. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.

Aims: To assess whether Venetoclax has a sustained impact on health related quality of life among patients with relapsed/refractory CLL based on a second interim analysis (first interim results through week 24) of patients treated with VEN monotherapy.

Methods: Patients ≥18 years of age with R/R CLL received VEN monotherapy until disease progression, unacceptable side effects, or discontinuation for any other reason. Patient-reported HRQoL measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), at 4 weeks and every 12 weeks thereafter. Change in the HRQoL measures from BL to each assessment are reported. Clinical relevance was based on minimum important difference (MID) of values from BL at different assessment points. The lower bound of 5–10 point changes, considered a “little” change for EORTC-C30 and a “moderate” change for EORTC-CLL16, was used for MID acceptance for both measures.

Results: Clinically meaningful improvements from BL were observed early and were sustained through week 96 in VEN treated patients in the EORTC-QLC30 global health status and the role, social, and emotional functioning scales. Improvements in VEN treated patients in EORTC-QLC-CLL16 based on a second interim analysis (first interim results through week 24) of patients treated with VEN monotherapy.

E1467
WHICH HAEMATOLOGICAL CONDITIONS CAN THIRD YEAR MEDICAL STUDENTS RECOGNISE INTERPRETING FULL BLOOD COUNT RESULTS?

S. Lovato1, 2, J. Arnold1, 2

Summary/Conclusions: This group of medical students found it difficult to correctly diagnose some of the haematological conditions presented, even though they had studied all the conditions before, however the use of a “Team Based Learning” approach where students could discuss the cases in small groups did improve their results. Interestingly for two conditions, for CML and Multiple myeloma the number of correct answers was the same for i-RAT and t-RAT, possibly the students who responded correctly during the i-RAT were each in a different group during the t-RAT and worked as peer-to-peer teachers for the other students. The i-RAT results for AML were actually worse than for the other students who replied correctly in the i-RAT were concentrated in fewer groups. To the author’s knowledge this is the first study on the effect of applying the Team Based Learning method to haematology teaching. This study showed that TBL could be a useful teaching tool to improve teaching of haematological conditions in medical schools, however the size of the sample was small and the results should be validated with a bigger study.

Summary/Conclusions: These updated interim results suggest that patients receiving VEN monotherapy experienced early and sustained clinically relevant improvement in several key aspects of functioning and HRQoL for up to 96 weeks in a very symptomatic and difficult to treat patient population. These results are important to consider when making treatment decisions in the R/R settings.

E1468
LONGITUDINAL ASSOCIATIONS BETWEEN HEALTH-RELATED QUALITY OF LIFE AND HEALTHCARE UTILIZATION IN AL AMYLOIDOSIS

M. Baylis1, T.P. Quock2, S.D. Guthrie3, M.K. White1, K.L. McCausland1, 4
1Optum, Lincoln, 2Prothena Biosciences Inc, South San Francisco, United States

Background: Light chain (AL) amyloidosis is a rare, complex disease associated with significant organ dysfunction, disability, and death. AL amyloidosis patients interact with the healthcare system in a myriad of ways, however, few studies have quantified healthcare utilization (HCU) in this condition.

Aims: To prospectively examine the association between health-related quality of life and healthcare utilization among patients with AL amyloidosis.

Summary/Conclusions: These updated interim results suggest that patients receiving VEN monotherapy experienced early and sustained clinically relevant improvement in several key aspects of functioning and HRQoL for up to 96 weeks in a very symptomatic and difficult to treat patient population. These results are important to consider when making treatment decisions in the R/R settings.

Results: The base-case scenario demonstrated that PEG-ASP followed by ERW-ASP dominated (i.e., was both less costly and more effective than) native ASP followed by ERW-ASP in adults, children, and the whole (combined) population (Table). Scenario analyses highlighted the robustness of the cost-effectiveness results. Differences in total QALYs between PEG-ASP and native ASP were driven primarily by the difference in hypersensitivity rates.

Summary/Conclusions: This analysis demonstrates that PEG-ASP, as part of multi-drug chemotherapy, is a cost-effective treatment option compared to native ASP for treating ALL in children, young people and adults with newly diagnosed ALL.
Methods: A non-interventional, longitudinal online study was conducted among patients with AL amyloidosis who were recruited with assistance from patient advocacy groups. Initial (n=341) and six-month follow-up (n=226) surveys assessed demographics, disease and treatment characteristics, and health-related quality of life (HRQoL), measured by the SF-36v2® Health Survey physical and mental component summary scores (PCS and MCS). HCU (e.g., outpatient visits, inpatient admissions, and days to myeloma-related death or progression) was assessed during the six-month follow-up. Prevalence of HCU and its bivariate associations with patient characteristics were evaluated. Multivariable logistic regression models were used to test for associations between HRQoL and having an ER visit or hospitalization in the past six months.

Results: Overall, visits with specialists and other healthcare providers during the previous six months were nearly ubiquitous (92.0% and 94.6%, respectively). Collectively, 56.0% of patients reported having ≥1 ER visit or hospitalization. ER visits and hospitalizations were not associated with the numbers or types of organ systems affected by the disease or the duration of disease. There were significant associations between PCS and ER visits (p<0.05) and between both PCS and MCS and hospitalizations (p<0.05 for all) based on multivariable analyses.

Summary/Conclusions: There is a lack of real-world evidence regarding HCU among patients with AL amyloidosis. This research identified longitudinal associations between HRQoL and HCU, indicating there is potential for using HRQoL surveys as screening tools to predict future HCU for AL amyloidosis patients. The development of prediction models for HCU in AL amyloidosis should consider incorporating HRQoL, as well as disease staging and treatment type.

MYELOMA PATIENT VALUE MAPPING: A DISCRETE CHOICE EXPERIMENT

J. Galinsky1,2, S. Fife3, S. Richard1
1Research, Myeloma UK, Edinburgh, United Kingdom, 2Research, Community and Patient Preference Research, Sydney, Australia

Background: Myeloma is a life threatening haematological cancer. Although myeloma is responsive to treatments, there remains no cure. In recent years, there have been improvements in survival due to the use of high dose therapies, stem cell transplant, and other novel therapies. However, while myeloma patients are living longer, they are also living with symptoms and treatment related adverse events. Therefore, myeloma patients face difficult decisions about the benefits and risks of treatment. The purpose of this study was to assess myeloma patient preferences for treatment.

Aims: The study aimed to answer the following questions: What treatment attributes do myeloma patients value? What is the relative importance of different treatment attributes to the patient? What level of risk are they willing to accept? What risk-benefit trade-offs characterise patients’ decision-making around treatment options, including not to treat? What, if any, influences and predictive factors are found in the way patients assess benefits and risk?

Methods: Participants were 475 Myeloma patients in the UK. Data were collected using discrete choice experiments (DCEs) through an online survey. The DCEs presented patients with a traditional treatment choice experiment (e.g., treatment A vs treatment B), focusing on the clinical benefits of treatments and the associated risks. The attributes and levels of the attributes were selected based on previous research, literature review and expert opinion. The DCE data were modelled using a Latent Class Model (LCM), and the effect of demographic characteristics were also examined.

Results: Findings revealed two classes (groups) of patients with different preferences for treatment attributes. Patients in class one placed greater importance on overall survival and mild-to-moderate side effects, whereas patients in class two placed greater importance on how the treatment was administered and the associated risks. The attributes and levels of the attributes were selected based on previous research, literature review and expert opinion. The DCE data were modelled using a Latent Class Model (LCM), and the effect of demographic characteristics were also examined.

Summary/Conclusions: Findings from this study suggest that not all myeloma patients value the same treatment features equally. This finding has important implications for the development of patient healthcare policy decisions and could be used to develop patient decision aids, tailored to the specific needs of the patient group. For example, there may be a need to offer different patient decision aids to patients who place greater importance on overall survival and those who place greater importance on how the treatment is administered and the associated risks.
E1472
QUALITY OF LIFE AND ABILITY TO WORK OF PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA TREATED WITH THYROSINE KINASE INHIBITORS
B. Sidi Mohamed El Amine1,*, H. Asma1, Z. Zahia1, M. Naima2, M. Nemra3
1Hematology department, Universitary hospital of Sidi Bel Abbes, Sidi Bel Abbes, 2Hematology department, Universitary hospital of Tiemenen, Tiemenen, 3Hematology department, Hospital of Mascara, Mascara, Algeria

Background: Thyrosine kinase inhibitors (TKIs) are now standard treatment for chronic myelogenous leukaemia (CML), but little is known about quality of life (QoL) of the patients.

Aims: The purpose of this study is to evaluate QoL of CML patients receiving TKIs, a disease requiring strict daily compliance with taking these drugs orally, as well as regular clinical and biological controls.

Methods: The study included patients with CML followed in three hospitals in west Algeria between 2004 and 2016. The measure of QoL was performed by the tool of functional assessment of chronic illness therapy (Functional Assessment of Chronic Illness Therapy, FACIT) for leukaemia. We have established QoL scores given by the questionnaire. FACIT, consisting of three levels: TOI for leukaemia trial outcome index, FACT-G for general score, and FACT-LEU for the total score of leukaemia. Specific areas of the questionnaire were associated with QoL of patients such as fatigue and ability to work. The correlation between these data and QoL scores was assessed using Spearman’s test. The test is significant if p<0.05.

Results: 67 patients with CML have agreed to answer to the questionnaire of QoL, medications in use, and their side effects. The mean QoL of the patients was 93.7 (out of 124 total points) for the TOI, 77.2 (out of 108) for the FACT-G, and 128.9 (out of 176 total points) for the FACT-LEU. Patients who presented with TKIs side effects had a low score of QoL (p=0.0006), especially when these effects are severe (p=0.003). Stopping TKIs medication was noted in 41.3% of patients with severe side effects. Severe fatigue was observed in 14 (22.9%) patients, having low QoL scores in all scales (p<0.0001). 44 (65.8%) patients were able to work with higher QoL scores in the three FACIT scales (p<0.0001, Spearman correlation).

Summary/Conclusions: QoL is an important aspect in the management of CML, its assessment is necessary and must be regular. The ability to work and fatigue are important components of QoL of patients receiving TKIs and should be specifically taken into account during the treatment. Adverse effects of TKIs can interfere with QoL of patients and can lead to discontinuation of CML therapy.
