1Psicología y Salud, Universidad Nacional Autónoma de México., 2Hematology, National Cancer Institute, Mexico City, Mexico, 3Health psychology, Harvard University, Massachusetts, United States, 4Oncology, National Cancer Institute, Mexico, 5Psicología, Universidad Nacional Autónoma de México., Mexico City, Mexico

Background: Hematopoietic stem cell transplantation (HSCT) is a consolidation therapy for multiple hematological malignancies and its goal include patients achieve levels of quality of life (QOL) similar that general population. However, studies developed in Europe and United States have shown that patients on long-term follow-up after HSCT reported lower levels of QOL, more unemployment and lower household income than before the procedure. These relationships have not been examined in Mexican HSCT patients.

Aims: To describe the QOL (EORTC-QLQ), level of employment and household income in Mexican patients on follow-up after HSCT

Methods: This was a cross-sectional study with patients ≥18 years old with at least one year of follow up after HSCT at the National Cancer Institute, Mexico.

Results: 30 participants were included, with a median age of 34 years (range 24-59), 56% male, and 41% married. Regarding educational level 68.7% had basic education, 25% had a college education and 6.3% postgraduate education. Mean time after HSCT was 36 months, 10% had active chronic graft versus host disease (GvHD). Patients reported moderate to high levels of QOL (Table 1). With respect to employment, 52% had a job (56% had a full time job, 13% work part-time and 31% had an informal job) and 48% were unemployed (50% could not find a job and 50% did not want to have a job). Finally, 56% had lower household income than before HSCT.

Summary/Conclusions: Mexican patients showed similar or higher levels of QOL in comparison with samples from other countries, with the exception of higher impact in emotional QOL and better social QL in our sample. Additionally, a substantial minority of patients were unemployed and over half had lower household income after HSCT. More work is needed to identify risks associated with changes in QOL, employment status and income among long-term survivors of HSCT.

E1474
ANTHRACYCLINE INCREASES THE RISK OF DEVELOPING DIABETES IN B CELL LYMPHOMA
H.-C. Lin1,*, W.-L. Hwang1, C.-L. Teng1
1Division of Hematology/Medical Oncology, VTaiichung Veterans General Hospital, Taichung, Taiwan, Republic of China

Background: Treatments of R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone) or R-CHOP like regimens have made B cell lymphoma to be one of the most curative hematological malignancies. Among the effective chemotherapeutic agents in B cell lymphoma treatment, anthracycline plays an important role. However, anthracycline associated bone marrow suppression and cardiotoxicity limit its clinical application. Whether anthracycline would further increase the risk of developing diabetes in B cell lymphoma remains unclear.

Aims: The aim of this study was to compare the cumulative incidences of diabetes in B cell lymphoma patients treated with and without anthracycline. We also investigated the dose effect of anthracyline on diabetes development. Additionally, whether anthracyline would increase the severity and complication of diabetes in B cell lymphoma patients were also studied.

Methods: We conducted this population-based study by using Taiwanese National Health Insurance Research Database. From 2004 to 2011, medical records from a total of 3984 B cell patients were analyzed. To understand whether anthracyline therapy was associated with more diabetes in B cell lymphoma, we compared the cumulative incidence of newly diagnosed diabetes between patients with (n=3147) and without (n=937) anthracyline treatments.

Impact of anthracyline on diabetes was further studied by multivariate Cox proportional hazard regressions in a dose-dependent manner.

Results: Log-rank test did not show the difference of cumulative incidences of newly diagnosed diabetes between B cell lymphoma patients with and without anthracyline treatments (p=0.1446). However, anthracyline remained associated with more diabetes [hazard ratio (HR): 1.59; 95% confidence interval (CI): 1.05–2.39; p=0.0278] after adjustment for age, gender, and comorbidities. Moreover, cumulative anthracyline doses of 253–400mg (HR: 1.94; 95% CI: 1.05–2.39; p=0.0278) increased the incidence density of diabetes in a dose-dependent manner.

Summary/Conclusions: Anthracycline therapy was responsible for more dia-
betes and b cell lymphoma in a dose-dependent manner. More intensive blood sugar monitoring and control should be recommended to b cell lymphoma patients, especially those who received anthracycline treatment.

E1475
THE COST-EFFECTIVENESS OF LENALIDOMIDE PLUS DEXAMETHASONE FOR THE TREATMENT OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA IN CHINA
J. Lu1, S. Hu2, P. Xu3, Y. Feng4
1Peking University People’s Hospital, Peking University Institute of Hematology, Beijing, 2Fudan University School of Public Health, Shanghai Health Development Research Center, 3Celgene China, Shanghai, 4Department of Pharmacy, Beijing Hospital, Beijing, China

Background: The introduction of lenalidomide plus dexamethasone (RD), and bortezomib-containing regimens, has improved the management of relapsed or refractory multiple myeloma (MM) in China. However, due to the absence of both head-to-head (direct) comparative efficacy and local economic data, stakeholders still face hard choices to make when choosing one therapy over another. Indirect treatment comparisons and health economic modeling can help support local decision-making by enabling the incorporation of country-specific unit cost data, in the comparison of cost-effectiveness of one treatment vs another when treatments have not been directly compared in clinical trials.

Aims: To assess the cost-effectiveness of RD relative to bortezomib/dexamethasone (VD) and bortezomib/cyclophosphamide/dexamethasone (VCD) for rMM in Chinese patients.

Methods: The Markov-based decision analytic model was constructed to simulate lifetime health benefits and direct medical costs associated with RD, VD, and VCD for rMM in Chinese patients. A systematic literature review was conducted (in both Chinese and English databases, from 2005 to 2016) to obtain efficacy data of the three treatment regimens. The risk of progressive disease associated with RD and VD were estimated from available Chinese trials. The efficacy of VCD and the mortality associated with progressive disease after treatments with RD and VD were lacking in China, therefore were estimated from the published international randomized clinical trials. Published quality of life data was adapted to Chinese rMM patients with health utility adjustment.

The model took into account (i) drug acquisition costs, (ii) treatment administration costs, (iii) Chinese urban hospital costs, (iv) serious adverse events management costs based on a survey of seven MM centers across China, and (v) rMM management costs estimated from a Chinese real-world hospital setting. Quality-adjusted life years (QALY) and direct medical costs in the model were discounted at 3% per annum. Base case analysis calculated incremental cost-effectiveness ratios (ICERs) per QALY for RD relative to VD and VCD, respectively from the Chinese healthcare payer’s perspective. One-way sensitivity analysis and probabilistic sensitivity (PSA) with 5,000 Monte Carlo simulations assessed the impact of the model uncertainty on the cost-effectiveness of RD. A scenario analysis was conducted by meta-analyzing the published international randomized trials for the efficacy associated with RD, VD, and VCD, to verify the base case analysis.

Results: Based on the model simulation without discounting survival outcomes over a lifetime horizon, RD could obtain longer average PFS years than VD (2.37 vs 0.78) and VCD (2.37 vs 1.36). RD was associated with longer disease-free survival (DFS) than VD (1.41) and VCD (1.41) after 6 months. The ICERs costs ($494,060 vs $272,135 and $272,135 vs $244,220) both than VD and both VCD. The ICERs per QALY for RD relative to VD ($149,706) and VCD ($150,774) were less than the cost-effectiveness threshold of China (three times of estimated 2016 China GDP per capital $166,920/QALY, $1= $6.130). The cost-effectiveness of RD is 1.38 times lower than VD and 1.41 times lower than VCD. The mortality risk associated with the progressive disease after treatment. The scenario analysis generated comparable ICER per QALY associated with RD relative to VD ($120,974) and VCD ($117,191), therefore supports the robustness of base case analysis.

Summary/Conclusions: The local data-based health economic model estimates that RD could gain longer PFS and OS with acceptable cost-effectiveness, when compared to VD and VCD in Chinese rMM patients.

E1477
OVARIAN TISSUE CRYOPRESERVATION IN PEDIATRIC AND ADOLESCENT PATIENTS UNDERGOING CANCER CHEMOTHERAPY AND/OR HEMATOPOIETIC STEM CELL TRANSPLANTATION
A. Kinoshita1, R. Ooyama1, D. Keino1, Y. Matsuoka1, Y. Koto1, T. Mori1, N. Suzuki1, S. Takae2, N. Suzuki2
1Pediciatric Hematology/Oncology, 2Department of Obstetrics and Gynecology, St. Marianna University School of Medicine, Kawasaki, Japan

Background: Ovarian tissue cryopreservation (OTC) and subsequent re-
implantation is the only option available for fertility preservation in prepubertal females, but this approach remains unestablished in pediatric and adolescent patients with cancer. After the experience of OTC for more than 200 patients with primary ovarian failure and more than 50 patients with breast cancer in our center over 5 years, we have started OTC for pediatric and adolescent cancer patients since 2015. Aims: To define safety and benefits of OTC in pediatric and adolescent patients with undergoing cancer chemotherapy and/or hematopoietic stem cell transplantation.

Methods: From December of 2015 to February of 2017, OTC was performed in 6 girls (median age 14 years, range 11-15): 2 patients with myelodysplastic syndrome, 2 with lymphoma, 1 with acute lymphoblastic leukemia, and 1 with myelodysplastic immuno-deficiency. Indications for OTC were 5 hematopoietic stem cell transplantation and 1 sterilizing chemotherapy. Two patients with myelodysplastic syndrome and 1 with immunodeficiency received no previous chemotherapy and the other 3 had received prior chemotherapy. Laparoscopy was used to collect a one of ovarium that was frozen by vitrification method.

Results: Ovari xenotissue in a total of 6 patients was collected and analyzed without major postoperative complications and this procedure did not delay chemotherapy or hematopoietic stem cell transplantation. Histological analysis of ovarian tissue revealed primordial follicles, even in the patients with previous cancer chemotherapy. No malignant cells were identified. Median post-harvest
follow-up was 9 months (0-14) and all patients were alive. Hormonal results were evaluable for 3 patients; 2 patients were in premature ovarian insufficiency. Re-implantation of ovarian tissue has not yet been performed.

**Summary/Conclusions:** Although OTC and subsequent re-implantation is experimental, this approach may be the best method for restoration of ovarian function and fertility preservation in pediatric and adolescent cancer patients. A risk of re-seeding malignant cells is a problem still to be conquered.

**Methods:** Between October 2016, and January 2017, we did a cross-sectional survey of individuals receiving at least 3 months of ongoing treatment for MM at our department. The survey included the 11-item COST measure (financial toxicity score range 0-44). A paper survey was offered to eligible patients on arrival for routine follow-up visits or treatment, and participants were asked to complete the survey before their visit or treatment. If the survey was not returned home & waited for a call from the Clinical Nurse Specialist (CNS) to confirm if blood results were appropriate for chemotherapy administration. If a dose adjustment was required the drug was wasted & patients needed to return to hospital for another prescription. Pharmacy waiting times for oral outpatient chemotherapy or supplementary medications are approximately 30 minutes. Aims: We introduced a weekly multi-disciplinary chemotherapy prescribing meeting in 2013 with the aims of improving prescribing safety; minimising time spent prescribing in clinic & reducing patient waiting times. Present at each meeting is a Haematology Specialist Pharmacist, Haematology CNS, Consultant & Specialist Registrar. Chemotherapy is planned a week in advance on ChemCare (an electronic chemotherapy prescribing package). Chemotherapy is prescribed & immediately screened by the pharmacist; oral chemotherapy is collected from pharmacy by a CNS prior to clinic. All prescription queries are resolved during this meeting. Deferred oral chemotherapy can be returned to pharmacy stock, minimising waste. Intravenous chemotherapy is pre-planned with authorisation on the day of treatment if the patient is fit to proceed.

**Results:** In this pathway we allowed patients to come to care of myeloma patients receiving oral chemotherapy, including setting up a nurse-led clinic. Data have been collected to assess service impact, particularly on patient satisfaction. The latter was assessed using a patient survey. Between July-Dec 2014, 66 patients received oral chemotherapy in the Myeloma Consultant-led clinic, Lenalidomide based regimens accounted for 86% of the oral regimens prescribed. On average, 7 patients per week were on maintenance therapy. During this period 8% of chemotherapy courses were deferred due to low blood counts or side-effects. Drugs were not wasted due to the pharmacy agreement.

**Summary/Conclusions:** The approach to prescribing & dispensing oral chemotherapy & supportive medication has streamlined our way of working & led to greater efficiency for both staff & patients. The new model has changed how patients are seen & assessed and minimised drug wastage, an issue incurred in the old system. However, it must be noted that during Jan-June 2015 the cost of wasted drug, due to patients being unfit for treatment on the day, potentially incurred by pre-prescribing was £57,775. It is, therefore, critical to ensure that medication that has not yet been given to patients can be returned to pharmacy if this type of pre-prescribing model is to operate efficiently.
Sickle cell disease

**E1481**

**DISEASE SEVERITY AND SLOWER PSYCHOMOTOR SPEED IN ADULTS WITH SICKLE CELL DISEASE**

E. Novelli,1,2, J. Dorgensen1, A. Metti2, M. Butters2, C. Rosano2

1Medicine, Vascular Medicine Institute, University of Pittsburgh, BST E1240, 200 Lothrop St., Pittsburgh, United States
2University of Pittsburgh, Pittsburgh, United States

**Background:** Psychomotor slowing is common in children with sickle cell disease (SCD), but little is known about its severity in adult patients. While the primary risk factor for psychomotor slowing is stroke, there has been mounting evidence that cognitive impairment also occurs in patients without a history of overt or silent stroke. Risk factors for cognitive impairment in patients with SCD without stroke are, however, not completely known, particularly in relationship to the SCD genotype.

**Aims:** We conducted a cross-sectional study to quantify psychomotor slowing, measured with the Digit Symbol Substitution Test (DSST), and a pencil and paper test of executive function, in relationship with disease severity in adult patients with SCD attending an outpatient clinic. We also examined whether demographic, behavioral, physiologic, and pathologic factors that are known to be related to SCD severity and cognitive function in other settings are also related to psychomotor speed in these patients.

**Methods:** Genotype was used to group patients with SCD (n=88, age: 36.3 years, 33 males) in “severe” (homozygous for the mutated sickle hemoglobin HbS [HbSS], or compound heterozygous with β0thalassemia [HbS/β0]) or “moderate” groups (compound heterozygous for HbS, with either HbC [HbSC], or βthalassemia [HbS/β+]). Standardized DSST scores based on published norms were used to define mild cognitive impairment, defined as ≤1.5 standard deviations (SD) below the DSST T-score (T-scores had a mean of 50 and SD of 10).

**Results:** Among our patients, 56 (63%) had a “severe” genotype and 32 (27%) a “moderate” genotype. Mild cognitive impairment was detectable in both the “severe” and the “moderate” group (30% and 9%, respectively, age-adjusted p=0.15). Compared to the “moderate” group, those in the “severe” group, had significantly lower DSST scores (age, sex and education adjusted p-value=0.006), independent of adjustment for factors that differed between groups: hemoglobin, ferritin, hydroxyurea use, blood pressure parameters and stroke history. Results were similar after excluding patients with stroke.

* Mean (SD) unless otherwise noted. † Age-adjusted. P1 includes SBI.

**Summary/Conclusions:** Psychomotor slowing in SCD differs in relationship to genotype; this difference appears unrelated to history of stroke or severity of anemia and other risk factors examined cross-sectionally. Although relatively infrequent, mild cognitive impairment was detectable in patients with a less severe genotype. Longitudinal studies of SCD should include all diseases genotypes, and examine factors that would reduce the risk of cognitive impairment in each subgroup.
Summary/Conclusions: Early identification of chronic hepatic disease sometimes pauci-symptomatic in terms of VOCs but able to lead to advanced stage and progressive fibrosis is crucial for suitable clinical management to avoid cirrhosis in SCD patients. The combination of TE with specific serum markers (GGT, ALP, albumin) is a valid tool to early detection of sickle hepatitis.

Background: Retinopathy is one of the ophthalmological complications of patients with Sickle cell disease (SCD), due to microvascular occlusions; occasionally, proliferative sickle cell retinopathy (PSR) can lead to severe vision loss. Aims: a. to analyze macular alterations in patients with Sickle Cell Disease (SCD) by spectral-domain optical coherence tomography (SD-OCT), using the automated software for retinal segmentation; b. to investigate relationship between OCT abnormalities and the severity of proliferative sickle cell retinopathy (PSR); c. to elucidate the role of potentially contributory systemic factors on the development of macular thickening.

Methods: This is a prospective, observational case-control study. Ophthalmological evaluation, fluorescein angiography and SD-OCT were performed. Central and temporal retinal layers were measured by the SD-OCT Automatic Segmentation software. SCD eyes were divided into two groups based on the presence of visible macular thickening areas. Clinical data and blood samples were collected.

Results: Thirty consecutive adult SCD outpatients were studied (median age 38.7±9.89 (M:F 12:18), including 9 patients with Sickle Cell Anemia (SCA), 17 with Sickle Cell β°-Thalassemia and 4 HbS/HbC. One HbS/HbC eye failed to complete the study. Need of chelation, ferritin (p=0.0187) and the HbF (p=0.0775). More specifically, the odds of retinal thinning increased when the need of chelation (p=0.0089) and the ferritin levels (p=0.0187) and the HbF levels (p=0.0775). Congruently, we observed a significant correlation between patchy areas of macular thinning on OCT and SCD need for transfusions, need for chelation, HbF, ferritin, and transferrin saturation (p<0.05).

Conclusion: The role of potentially contributory systemic factors on the development of macular thickening in SCD patients needs to be further investigated in larger studies.

E1484
SILENT CEREBRAL ISCHEMIA AND THROMBOEMBOLIC EVENTS IN SICKLE CELL DISEASE: ANALYSIS OF COAGULATION PARAMETERS AND THROMBOELASTOGRAPHY
M. Dimopoulou1,*, M. Politou2, K. Stavroula1, D. Koutsouri2, P. Tsioutsias1, P. Flevai1, E. Voskaridou1
1Thalassemia and Sickle Cell Disease Center, Laikon General Hospital, 2Hematology Laboratory, Blood bank, Aretaieion Hospital, Athens, Greece

Background: The complications of Sickle Cell Disease (SCD) include stroke and silent cerebral events (SCI). The increased incidence of thromboembolic events in SCD has only recently been recognized. Apart from red cell sickling other pathogenetic mechanisms have been proposed but they have not been clarified completely. Coagulation factors have been analysed in several studies in SCD but very limited data exist about global coagulation assays such as thromboelastography, which evaluates the contribution of platelets, coagulation factors and cellular elements in clot formation.

Aims: The aim of the present study was to assess the incidence of cerebral ischemia and TEs in SCD patients and to investigate their pathophysiology with analysis of coagulation parameters, including thromboelastography.

Methods: 61 adult SCD patients were included in the study and underwent brain MRI. Measurements of fibrinogen, D-Dimers, antithrombin III, proteins S and C were performed (SIEMENS BCS) and thromboelastography ROTEM® was performed in order to analyse NATTE CT(Closure Time), MCF (Maximum Clot Firmness), EXTEM CT, MCF and FIBTEM CT, MCF. Brain imaging was analyzed as well as all clotting assays were performed in steady state and not during the course of an acute thrombotic or ischemic event.

Results: The median age of the patients was 51 years (range 27-70), 40 of them were female and 21 male. Abnormal findings were revealed in the brain MRI of 37 patients (57.4%). The most frequent finding was silent retinal lesions affecting the visual function and can lead to irreversible visual loss, regular ocular checkups are essential for SCD patients.
4161 (1.6%) positive D-Dimers in 5759 (96.6%), decreased protein S in 1061 (16.3%) and decreased protein C or 13/61 (21.3%), NATEM MCF was increased in 27/61 (44.3%) patients while EXTEM MCF was increased in 3/61 (50.8%) patients. Patients with a history of TEE had higher mean values of NATEM-MCF and EXTEM–MCF and those differences were statistically significant (p=0.023, and p=0.011 respectively). There was a statistically significant association between the presence of ischemic lesions in brain MRI and the history of TEE (p=0.01). On the contrary the history of ACS was not correlated with the presence of ischemic lesions in MRI. Chronic Hydroxyurea treatment did not correlate with the absence of ischemic findings in brain MRI. Among patients with ischemic lesions those who were already on chronic hydroxyurea treatment had a shorter NATEM-CT compared to patients without treatment. In patients with ischemic lesions in MRI and a history of TEE NATEM-MCF and EXTEM MCF were higher (p=0.03, and 0.03, respectively).

Summary/Conclusions: The presence of microschemic encephalopathy is very common in SCD patients and is associated with a history of TEE, which is also frequent in SCD. There seems to be a permanent activation of the coagulation mechanism in SCD. In SCD patients with SCIs and a history of TEE, apart from clotting factors and natural inhibitors there seems to be a contribution of platelets and cellular elements, possibly sickle cells. The impact of chronic hydroxyurea treatment on the pathogenesis of silent infarcts and TEEs needs further evaluation.

E1487
INVASIVE BACTERIAL INFECTIONS IN GAMBIAN PATIENTS WITH SICKLE CELL ANEMIA IN AN ERA OF WIDESPREAD PNEUMOCOCCAL AND HAEMOPHILUS INFLUENZA TYPE B VACCINATION
G. Soothill1,2, S. Darboe2, G. Bahr3, L. Bolarmah4, A. Cunnington5, S. Anderson2
1Royal Free Hospital, London, United Kingdom, 2Medical Research Council Unit Gambia, Fajara, Gambia, 3Imperial College London, London, United Kingdom

Background: Bacterial infections cause significant morbidity and mortality in patients with sickle cell anemia, especially in populations without reliable access to antimicrobial prophylaxis and treatment. The limited understanding of penicillin prophylaxis and vaccination for Streptococcus pneumoniae and Haemophilus influenzae type b in resource-rich settings has minimised the additional risk of invasive bacterial infections associated with sickle cell anemia. However, these interventions are not routinely implemented in much of Africa, despite this region having the greatest burden of disease, with over 80% of people with sickle cell anemia born on the continent. The Gambia has well established vaccination programmes for pneumococcal and Haemophilus influenzae type b, which is rare in the region. There is little data on the incidence of bacterial infections in African sickle cell anemia populations, and we believe (until this study) there were no data from countries with comprehensive vaccination programmes against Streptococcus pneumoniae and Haemophilus influenzae type b.

Aims: Primary: to determine the predominant pathogens causing invasive bacterial infections in a population of sickle cell anemia patients admitted to the Medical Research Council Unit Gambia. Secondary: to review the characteristics of this sickle cell anemia population.

Methods: A retrospective analysis of the clinical and laboratory records relating to 161 admissions of 126 patients with sickle cell anemia admitted to the Medical Research Council Unit Gambia over a five-year period (between April 2012 and April 2013). Patients were divided into two groups; Group 1: Patients who had a painful crisis during the study (41 patients, mean age: 11.5 years) and Group 2: Patients who were in steady state during the study (30 patients, mean age: 11 years). Blood samples were taken from the patients for complete blood count, serum levels of C-reactive protein (C-RP), interleukin-1 β (IL-1β), interleukin-6 (IL-6), tumor necrosis factor-alpha (TNF-α), IGF-1, IGFBP-3 and IFG-1, IGFBP-3 gene expression.

Results: The patients in both groups were compared in terms of serum IGF-1 level; serum IGF-1 levels were normal in all patients (100%) in group 2 and 33 patients (80.5%) in group 1, and the difference was considered to be statistically significant (p <0.001). When the groups were compared in terms of serum IGFBP-3 level; serum IGFBP-3 level in Group 2 was found to be significantly lower in Group 1 (p <0.001). Also, when the patients were examined for IGF-1 and IGFBP-3 gene expression, no significant difference was found between the groups (Table 1). A negative correlation was found between leucocyte level and IGF-1 in group 1, and IGF-1 gene expression and C-RP in group 2. Serum IGFBP-3 and IL-6 levels were found to be significantly lower in patients without any painful crisis than those with painful crisis in the last year (p <0.05).

Table 1.

Figure 1.
Summary/Conclusions: The clinical manifestations of SCD were thought to be associated only with hemoglobin polymerization for a long time. However, recent studies have shown that SCD is a chronic inflammatory disease. The pro-inflammatory cytokines and IGF are in a state of equilibrium in the human body. It has been reported that IGF-1 plays a major role in the production of NO, which is produced in the endothelium and causes a vasodilatory response, and that it increases antioxidant systems and reduces oxidative stress, thereby decreasing inflammation by reducing pro-inflammatory cytokines. In our study, we found that the serum levels of IGF-1, an important growth factor that has not been studied previously in SCD and has recently been evaluated on the effects of inflammation, decreased in SCD patients with painful crisis compared to patients in steady state. It was also found that the serum levels of inflammatory cytokines, evaluated during the same period, such as IL-6 and TNF-α, were increased. In conclusion, IGF-1 was thought to play a role especially in the pathogenesis of acute inflammation in SCD.

UNIVERSAL NEWBORN SCREENING FOR SICKLE CELL DISEASE: PRELIMINARY RESULTS OF THE FIRST YEAR OF A MULTICENTRIC ITALIAN PILOT PROJECT

M. Martella1, L. Cattaneo2, G. Viala3, S. Azzena1, A. Capellani1, E. Baraldi3, C. Zorloli2, N. Maseri2, A. Biondi2, G. Basso1, R. Colombatti1, L. Sainati1
1Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy, Padova, Italy
2Pediatric Clinic, Università degli studi Milano-Bicocca-Fondazione MBBM, Monza, Monza, 2Neonatal Intensive Care, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy, Padova, Italy

Background: Sickle cell disease (SCD) is the most common monogenic disease worldwide. Although it is most prevalent in Africa, in parts of the eastern Mediterranean area and to a lesser extent in the southern USA, SCD is also continuously increasing in central and northern Europe. It is established that early detection and appropriate prophylactic measures prevent potentially fatal complications and many European countries have already introduced newborn screening programs for SCD. In Italy it is estimated that 6.5% of the total population is represented by carriers of hemoglobinopathies, nevertheless, there isn’t a national newborn screening program for SCD nor a plan to establish it. Selective newborn screening programs for SCD are currently active in three regions of Italy, and a pilot universal newborn screening terminated due to lack of funding. The primary aim of this investigation was to assess the feasibility and acceptability of a universal newborn screening program for SCD.

Methods: Two families in Padova and 19 in Monza refused the test. The ethnic origin of newborns was similar in the two sites: 64.08% were children of Italian couples, 8.21% of mixed couples and 27.71% of foreign couples in Padova. And 69.45% were of Italian couples, 19.31% of mixed couples and 13.24% of foreign couples in Monza. Two families in Padova and 19 in Monza refused the test. The ethnic origin of newborns was similar in the two sites: 64.08% were children of Italian couples, 8.21% of mixed couples and 27.71% of foreign couples in Padova. And 69.45% were of Italian couples, 19.31% of mixed couples and 13.24% of foreign couples in Monza. Two families in Padova and 19 in Monza refused the test. The ethnic origin of newborns was similar in the two sites: 64.08% were children of Italian couples, 8.21% of mixed couples and 27.71% of foreign couples in Padova. And 69.45% were of Italian couples, 19.31% of mixed couples and 13.24% of foreign couples in Monza.

Results: The incidence of S abnormality is in agreement with the only previous Italian screening program for SCD. In Italy it is estimated that 6.5% of the total population is represented by carriers of hemoglobinopathies, nevertheless, there isn’t a national newborn screening program for SCD nor a plan to establish it. Selective newborn screening programs for SCD are currently active in three regions of Italy, and a pilot universal newborn screening terminated due to lack of funding. The primary aim of this investigation was to assess the feasibility and acceptability of a universal newborn screening program for SCD.

Summary/Conclusions: These preliminary data indicate the feasibility and effectiveness of a multicentric universal newborn screening program in Italy. The implementation of the SCD newborn screening program in Padova during the first year showed high acceptance, that the program will help to identify affected newborns and to provide genetic counseling for the family. To reduce morbidity and manage complications of children with SCD.

E1491
EXTENDING ACCESS TO CARE FOR CHILDREN WITH SICKLE CELL DISEASE THROUGH TELEHEALTH

J. Kanter1,*, J. Mcelligott1
1Pediatrics, Medical University of South Carolina, Charleston, United States

Background: Sickle Cell Disease (SCD) is the most common inherited blood disorder in the United States and is highly prevalent in South Carolina. Previous work using administrative databases have shown that 25% of affected individuals live in the more rural PeeDee region and seek acute care from community hospitals. As a result, many of these patients have travel >90 minutes for routine SCD care. Due to the difficulty in travel, many patients from this region were seen at frequent intervals with limited access to comprehensive care. In order to provide care continuity, 16 patients were referred from the difficult-to-reach rural region to our academic center. Hydroxyurea, the only drug FDA-approved to modify the course of SCD, requires monthly laboratory assessments in the first year and every 3 months in subsequent years. In addition, in consideration of medicadt side effects, the frequency of visits limits this option for individuals in rural areas with SCD.

Methods: The primary aim of the study was to assess the feasibility and acceptability of using a telehealth clinic to provide SCD care for children living in a designated rural area. The secondary aims were to improve the clinic adherence for patients living in the rural PeeDee region, increase the burden of care and the expense of travel for affected families and improve hydroxyurea acceptance and uptake.

Results: The Pediatric SCD telehealth clinic was initiated in November 2014, and data reflects the first 16 months of practice. There were originally 21 patients identified from MUSC of which 4 families declined interest in participating. Additional children with SCD were referred from the local pediatric group for the telehealth clinic who had been designated as “lost to follow up (LTFU).” The clinics were originally scheduled monthly however three clinics were cancelled during the first 16 months and a total of 13 clinics were conducted. There were 64 total visits scheduled of which 56 visits were completed. The overall no-show rate was 14% (range 0-34%) and six clinics had a no-show rate of 0%. The scheduling rate was 76% (range 60-100%). The primary aim was to assess the feasibility and acceptability of a telehealth clinic measured by patients’ and families’ adherence to scheduled appointments. Of the 19 patients, 18 (90%) (9) and six clinics had a no-show rate of 0%. The scheduling rate was 76% (range 60-100%). The primary aim was to assess the feasibility and acceptability of a telehealth clinic measured by patients’ and families’ adherence to scheduled appointments.

Summary/Conclusions: The pediatric SCD telehealth clinic met its primary aim and has continued monthly operations. Hydroxyurea initiation has improved and decreased travel has been welcomed by participating families. Challenges have included equipment issues, difficulties in post-clinic care coordination and assuring participating families received discharge information. Future directions include a tele-tele-dual clinic visitation program from children with SCD at risk for stroke and additional telehealth clinics for adults with SCD that will be utilized for both routine care as well as acute care through the state sickle cell network (SC2). This approach will both harness the resources of the state to approach SCD and will also use a technology-based approach to increase education of providers.
Background: The incidence of the Sickle Cell Disease (SCD) has increased in Europe because of the high rate of migration from areas in which carriers of the sickle cell allele account for 19-27% of the entire population. Although SCD is endemic in Southern Italy, the recent migration fluxes spread SCD all over Italy with the number of carriers at about 6.5% of the whole population. The distribution of SCD patients has dramatically changed. The large part of resident immigrants are young with a high fertility rate. Neonatal screening combined with timely diagnostic testing, parental education and comprehensive care management may reduce morbidity and mortality of SCD. Up to now, a national newborn screening program for SCD is not active in Italy and only few pilot studies have been carried out (Ballardini E et al. Blood Transfus. 2013 Apr; 11(2): 245-9; Venturelli D et al., Blood Transfusion 2014; 12: 346-51; Rolia R et al. Clin Lab 2014; 60 (12): 2089-93).

Aims: To provide recommendation for newborn screening program for SCD in Italy.

Methods: A panel of experts was identified by Italian Society of Thalassemia and Hemoglobinopaties (SITE) and Italian Oncohematology Pediatric Association (AIEOP).

The panel has rigorously reviewed the literature (from 1990 to 2016), the existing recommendations/guidelines of other countries where newborn screening for SCD already exists and the most recent recommendations of the AIEOP and other international organizations. The panel reviewed the literature in order to develop a guideline to support the implementation of newborn screening for SCD in Italy, setting the standards of care and the follow-up of the newborns that are diagnosed with SCD.

Summary/Conclusions: The panel includes five sections: (i) to establish the need for newborn screening for SCD in Italy, (ii) to provide a summary of the current literature and experience, (iii) to discuss the current newborn screening programs in other countries, (iv) to provide recommendation for the newborn screening program for SCD in Italy, and (v) to discuss the implementation of newborn screening programs for SCD in Italy.

E1492
GENETIC HEMOLYTIC MARKER IN SICKLE CELL ANAEMIA
P. Pereira Nascimento1, L. Souza Torres1, D. Grunig Humberto da Silva 1, J. Viviane Okumura1, E. Belini Junior2, C. Lopes de Castro Lobo3, C. Regina Bonini-Domingo1
1 Departamento de Biologia, Instituto de Biociências, Letras e Ciências Exatas - IBL/UNESP - São José do Rio Preto, São José do Rio Preto, SP, Brazil
2 Medicina - UFMS/CPFL, Universidade Federal de Mato Grosso do Sul, Três Lagoas, MS, Brazil
3 HEMORIO, Instituto de Hematologia Arthur de Siqueira Cavalcanti, Rio de Janeiro, Brazil

Background: The heterogeneity and complexity of the phenotypic profile among individuals with sickle cell anemia (SCA) is one of the principal factors of current research. The SCA, a homozygous condition for Hb S, is a hereditary haemolytic anemia with severe clinical consequences. The intravascular hemolysis is a chronic clinical subphenotype and has been associated as an independent risk factor related to complications such as pulmonary hypertension, leg ulcer and more recently with progression of vasculopathies. Researches has already shown that the heterogeneity of the hemolytic profile can be due to the presence of different beta S-globin gene cluster haplotypes among the individuals, which suggests the participation of genetic factors in the characterization of this subphenotype. Thus, search for genetic variants has been a promising strategy to assist in the individualization of treatments, and favoring clinical evolution. Recent studies showed that the presence of at least one rs7203560 SNP allele (G) of the NPRL3 gene plays a protective role at hemolysis in individuals with SCA, suggesting this variant as a genetic marker of hemolysis.

Aims: Our objective were to evaluate the association between different genotypes of the SNP rs7203560 and the intravascular hemolysis in patients with SCA.

Methods: We evaluated 76 Brazilian people with SCA, all with a Bantu / Bantu haplotype profile, and in a steady state. The patients were divided into two groups according to the presence of the rs7203560 SNP allele (HC): 22 patients were homozygous (Bantu / Bantu + HC) and 54 without (Bantu / Bantu + HC). The association between categorical variables (with or without use of HC and genotypes SNP genotypes) and cell-free Hb levels was performed by univariate covariance analysis (GLM), followed by Fisher’s Post hoc, considering the gender and age covariables. Statistic software was used and assumed p <0.05 as significant.

Results: Evaluating the recessive model (GG / GT versus TT), we found a significant difference between the different genotypic patterns (p=0.026), and not confirmed the association. Therefore, we performed an analysis of the association of SNP in the variation of cell-free Hb levels and hemolysis markers commonly used as hemolysis parameters (relative reticulocytes, the enzymes lactate dehydrogenase and aspartate aminotransferase and unconjugated bilirubin), and we found that the individuals genotypic profile was responsible for 50.7% of the variability in HbK level (p<0.050), suggesting that the SNP may play a role in characterizing the hemolytic profile of our patients with SCA.

Summary/Conclusions: The SNP here studied is located in the intronic region of the NPRL3 gene, where the main regulatory elements of the alpha globin gene cluster (HS-48, HS-30 and HS-33) are also found. Studies have already suggested that the protective effect of the G allele of the SNP on the hemolytic profile may be probably related to the role of this genetic variant in the expression of the alpha globin genes. Its promising that aditional analyzes in other ethnic groups and models of hemolytic anemia, such as those of an acquired character are realized. This is one of our next step in the attempt to suggest this variant as a genetic marker capable of assisting in the characterization of the hemolytic and prognostic profile of people with SCA.
Summary/Conclusions: This is the first study highlighting key healthcare practice data for the small but significant number of SCD Day Hospital/Infusion Units around the globe. Our data suggest that among institutions with SCD-DH/IU there is no consensus regarding clinical practice or data collection. We conclude that there is a significant need to further evaluate SCD DH/IU patient-based value, and to develop operational standards / benchmarks to ensure dissemination, adaptability, and sustainability of these alternative care models.

E1494
REDUCED SERUM HAEMOPEXIN LEVELS IN HAEMOGLOBIN SC DISEASE OCCUR INDEPENDENTLY FROM THE DEGREE OF HAEMOLYSIS

F. Vendrame1,*, L. Marani1, S. Saad1, F. Costa1, K. Fertrin1
1Hematology and Hemotherapy Center, Unicamp, Campinas, Brazil

Background: In intravascular haemolysis, saturation of haptoglobin leads to haemoglobin oxidation and the release of free haem, whose main scavenger is haemopexin. In sickle cell mice, excess free haem has been shown to cause vaso-occlusion that can be reversed by haemopexin, implicating that knowledge on how haemolysis changes haemopexin production may influence the applicability of clinical use of haemopexin for sickle cell disease and other haemolytic states. Recent studies have reported reduced haemopexin levels in children with sickle cell disease (Santiago et al., 2016) and adults with beta thalassemia (Vinci et al., 2016) in association with elevated haem levels, thus suggesting haemopexin decreases due to chronic haemolysis. No data are available in adults with milder sickling disorder haemoglobin SC (HbSC) disease.

Aims: In this study, we examined haemolytic markers, haem, and haemopexin levels in samples from HbSC patients with varying degrees of haemolysis in comparison with healthy subjects with no abnormal haemoglobins (HbAA group).

Methods: Forty HbSC patients (age range 25-68 years, 15 men) and forty HbAA controls (age range 18-66 years, 28 men) participated in this study. Exclusion criteria were pregnancy, other cause of haemolysis, history of blood transfusion or sickle cell pain crisis in the past 3 months. Venous blood samples were collected for complete blood counts (Advia 2120, Siemens) and measurement of lactate dehydrogenase (LDH), bilirubin (Roche Hitachi), and haemopexin (Abcam) levels. Statistical analysis was performed with GraphPad Prism v.5 and data are expressed as mean±standard deviation.

Results: As expected, serum LDH, total and indirect bilirubin, and reticulocyte counts were increased in HbSC patients (P=0.0001). Despite this, no significant difference in total circulating haem was found between HbSC and HbAA (39±2.6 vs 35±1.8 μM, respectively, P=0.30), contrary to what has been reported in other haemolytic diseases. Haemoglobin (Hb) was higher in the HbAA group when compared to the HbSC group (15±0.2 vs 12±0.3 g/dL, respectively), contrary to what has been reported in other haemolytic diseases. Haemoglobin (Hb) was higher in the HbAA group when compared to the HbSC group (15±0.2 vs 12±0.3 g/dL, respectively), contrary to what has been reported in other haemolytic diseases.

Discussion: These results show that in adults with HbSC disease, haemopexin decreases due to chronic haemolysis. No data are available in other haemolytic states. Recent studies have reported reduced haemopexin levels in children with sickle cell disease and adults with beta thalassemia in association with elevated haem levels, thus suggesting haemopexin decreases due to chronic haemolysis. No data are available in adults with milder sickling disorder haemoglobin SC (HbSC) disease.

E1495
ASSOCIATION OF TOLL-LIKE RECEPTOR 2 GENE POLYMORPHISM WITH THE INCIDENCE OF BACTERIAL INFECTIONS IN SICKLE CELL DISEASE

K. Tozatto-Maio1,2,3,*, R. Girot4, C. Manaselvim5,6, M. Bennabi5,6, A. Ruggieri1,2, B. Cappelli1,2, R. Krishnamoorty7, B. Pinto Simões8, I. Diagne9, E. Gluckman1, R. Tamouza10
1Eurocord, Université Paris 7, Paris, France, 2Monacord, International Observatory on Sickle Cell Disease, Centre Scientifique de Monaco, Monaco, 3Monaco, 4Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, Brazil, 5Hôpital Tenon, 6Inserm U1160, Université Paris 7, Paris, 7Hospital Henri Mondor, Créteil, France, 8Pediatrics Unit, Centre Hospitalier National d’Enfants Albert Royer, Dakar, Senegal

Background: Despite antimicrobial prophylaxis and immunization, bacterial infection remains a leading cause of morbidity and mortality in sickle cell disease (SCD) patients. Functional hyposplenism/asplenia partially explains their susceptibility, since even young SCD children with functional spleen are at raised infectious risk. Toll-like receptors (TLR), that recognize pathogen molecular patterns, are at the forefront of immune protection. The interaction between TLR and infectious diseases in SCD patients has never been explored.

Aims: To evaluate if functional polymorphisms in TLR confer susceptibility/resistance to infections in SCD.

Methods: 160 SCD patients followed either in France (n=104) or Senegal (n=56) with recorded history of infections were tested for SNPs in TLR-1, TLR-2, TLR-4, TLR-6 and TLR-10 by TaqMan S-nuclease assay for their association with infectious history. Comparisons between groups were evaluated by x² or Fisher exact T-test with Bonferroni corrections of P-value (Pc); associations were measured by odds ratio (OR).

Results: 70 patients were positive for at least one bacterial infectious episode (IP) and 84 had no infection (NIP). Eleven IP had more than one episode of infection. Median age was 25 years (range 4-49) for IP and 23 years (range 3-52) for NIP with no distribution bias in gender (P=0.24). All patients had vaccinations against Streptococcus pneumoniae and Haemophilus influenza B, and patients under 10 years had received penicillin prophylaxis. Endotoxigenic agent was identified in 58 cases with encapsulated bacteria (EB) occurring in 35; the most common agents consisted of Mycobacterium tuberculosis, Streptococcus pneumoniae, Salmonella spp, Escherichia coli and Klebsiella pneumoniae. Sites of infection included respiratory tract (n=24), bone and joints (n=21), blood stream (n=17), urinary tract (n=11), central nervous system (n=8) and abdominal (n=5). TLR-2 rs4696480 TA genotype was less represented in IP than in NIP (45% vs 98%, OR=0.02, 95%CI=0.01-0.09, Pc<0.003) and in particular TLR-2 rs4696480 TA genotype was significantly less frequent in the group of patients infected by EB as compared to NIP+IP with other known endotoxigenic agents (51% vs 85%, OR=0.19, 95%CI=0.08-0.44, Pc=0.003). Other TLR SNPs, genotype and haplotype showed no significant difference between groups.

Summary/Conclusions: rs4696480 TA genotype apparently confers protection against infections especially for EB. Given the previously demonstrated association of AA genotype with exacerbated expression of inflammatory cytokines as well as association of T allele with lower expression of cytokines it is tempting to postulate that TA genotype can be considered as a compromise between deleterious effects of over inflammatory response (TLR-2 AA genotype) and under response (TLR-2 TT genotype) to infectious agents. Such balanced selection effect is probably reflected by the observed deviation from HWE.
Stem cell transplantation - Clinical

E1496
HIGH PROGNOSTIC VALUE OF PRE- SCT MOLECULAR MINIMAL RESIDUAL DISEASE ASSESSMENT BY WT1 GENE EXPRESSION IN AML TRANPLANTED IN CYTOLOGIC COMPLETE REMISSION
A. Candoni1, M. Zaninier1, E. Bertoli1, F. De Marchi1, E. Simeone1, C. Fili1, D. Lazzarotto1, G. Venturelli1, E. Tofolletti1, N. Rabassi1, C. D’Odonco1, C. Comuzzi1, R. Fanin1
1Division of Hematology and SCT, University Hospital, Udine, Udine, Italy

Aims: We analyzed the outcome of allogeneic Stem Cell Transplantation (allo-SCT) in AML patients according to molecular Minimal Residual Disease (MRD) at the pre transplantation (pre-SCT) workup, assessed by the quantitative expression evaluation of the panleukemic marker Wilms’ tumor gene (WT1), according to LeukemiaNET validated method.

Methods: 122 consecutive AML patients received allo-SCT while in cytotropic Complete Remission (cCR), between 2005 and 2016, at our Center. The median age at SCT was 53 years (18-70). The quantitative analysis of the WT1 gene expression (bone marrow samples) was available in 100% cases, both at diagnosis (100% overexpressing WT1 with a mean of 8607±187 copies/10⁶ leukocytes) and before allo-SCT (81/122; 66.6% MRD-WT1-negative and 41/122; 44% MRD-WT1 positive cases at the pre-SCT workup). We evaluated post-SCT Overall Survival (OS), Disease Free Survival (DFS) and Relapse Rate, according to MRD-WT1 pre-SCT status.

Results: Both pre-SCT OS and DFS were significantly better in patients who were MRD-WT1 negative (WT1<250 copies) at the time of SCT compared with those who were MRD-WT1 positive (WT1>250 copies), with a median OS and DFS not reached in the MRD-WT1 negative group and 9 and 8 months, respectively, in the MRD-WT1 positive group (OS log-rank p=0.0001; hazard ratio 0.19, 95% confidence interval [0.12-0.30]; DFS log-rank p<0.0001; HR=0.73, 95% CI=0.6-0.73). The relapse rate after allo-SCT was 15% (12/81) in pre-SCT MRD-WT1 negative cases and 44% (18/41) in MRD-WT1 positive cases (p=0.0073). At univariate analysis, MRD-WT1 negativity before allo-SCT and grade <2 acute GVHD were significant prognostic factors for improved OS and DFS. However, at multivariate analysis, MRD-WT1 negativity before allo-SCT was the only independent prognostic factor for improved OS and DFS.

Summary/Conclusions: These data show that pre-allo-SCT molecular MRD evaluation through WT1 expression is a powerful predictor of post-SCT outcome (OS, DFS, relapse rate). Patients with both cCR and a MRD-WT1 negative status before allo-SCT have a very good outcome with a very low relapse rate and better survival. The pre-SCT MRD-WT1 stratification in AML is a valuable tool to identify patients, transplanted in cCR, who are at high risk of relapse and who could be considered for conditioning regimen intensification and/or additional immunomodulatory approaches to improve outcomes.

E1497
GOOD IMMUNOLOGICAL RECONSTITUTION IN ADULTS WITH ACUTE LEUKAEMIA AFTER ALFA-BETA TCR/CD19+ DEPLETED HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT)
L. Prezioso1,*, S. Bonomini1, C. Schifano1, A. Monti1, I. Manfra1, A. Spolzino1, G. Sammarelli1, L. Craviotto1, M. Sassi1, M. Soli1, F. Aversa1
1Hematology and BMT Unit, 2Immunohematology and Transfusion Unit, Parma, Italy

Background: Haplo-HSCT based on the infusion of high numbers of T cell depleted (TCD) hematopoietic progenitor cells and no post-transplant immunosuppression controls both graft rejection and GVHD in patients with acute leukemia. One major remaining issue is the delay in the post-transplant immunological reconstitution because of the minimal residual T lymphocytes in the graft and in vivo ATG-linked T cell depletion. Current studies are focusing on rebuilding postransplant immunity to improve clinical outcomes separating GVHD from favourable donor immune responses. Selection of β+ T cells retains in the graft NK, dendritic cells, monocytes and γδ T lymphocytes. Under this approach, a rapid immunological reconstitution and very promising outcome have been reported in pediatric patients.

Aims: With the aims of confirming these results in adults, we tested this approach in adults with acute leukemia.

Methods: Thirty-two patients, median age 51 years (range 19-74), with AML (n=28) and ALL (n=5) entered to study. Twenty were in CR (12 CR1; 8 CR2), 12 in advanced-stage disease at transplant. Consisting of ATG 1.5mg/kg from day -13 to -10, Treosulfan 12 gr/sqm from -9 to –7, Fludarabine 30mg/qm from -6 to -2 and Thiopeta 5mg/Kg on days -5 and -4. PBPCs from haplo-donor (3 mothers, 9 siblings, 13 sons/daughters and 7 cousins) under-went αβTCR/CD19+ depletion by CliniMACS. No post-transplant immunosuppression was given. Ganciclovir was given over the conditioning regimen in the 22 patients who were CMV seropositive; L-AmB was used as anti mold active prophylaxis over the neutropenic phase.

Results: Grafts contained a median of 11x10⁶/kg (range 5-19) CD34+ cells, 4.3x10⁶ CD3-Tcells/kg (range 1-36), 4.9x10⁵/kg (range 0.4-62) αβ-T cells, 4x10⁹/kg+Tcells/kg (range 1-34), 5x10⁴/kg B cells/kg (range 1.5-32) and 22x10⁶CD56+NK cells/kg (range 5-91). All patient achieved a full donor sustained engraftment. Median time to reach 500 neutrophils and 20,000 platelets was 13 (range 10-18) and 11 days (range 6-30), respectively. Two patients developed and died from severe acute GVHD. One of them had received the highest dose of αβ+T cells (3.7x10⁶/kg) and the second one affected by 6GPDH deficiency experienced a late onset hepatic GVHD. Eight patients had skin limited grade II aGVHD that required short course steroids. Only two patients have so far developed mild cGVHD that recovered completely after steroid and cyclosporin treatment. Tending to confirm our working hypothesis, there was a rapid, sustained increase in peripheral blood T-cell subpopulations (Fig. 1). Naive and memory T-cell subsets increased significantly over the first year after transplantation. B-cell reconstitution was rapid and sustained and immunoglobin serum levels normalized within 3 months. CMV reactivation and/or reactivations). One with unfavorable serology (donor negative into recipient positive) developed and died of CMV disease 8 months after transplant. Relapse was the main cause of failure (8/12 in relapse, 3/20 in CR). NRM was 15% (4/12 in relapse, 4/20 in CR), 13 patients survive at a median follow-up of 29 months (range 5-53).

Figure 1.

Summary/Conclusions: The infusion of αβ/CD19-depleted grafts confirmed a fast immunological reconstitution also in adults. Relapse is still a major concern in patients already in relapse at transplantation.
23 patients showed prompt recovery of neutrophils and platelets. So far, despite...hematopoietic transplantation-specific comorbidity index (HCT-CI) score of ≥3 was significantly associated with a worse 3-year survival outcome (86.0% vs. 50.0%, P=0.035, Hazard ratio [95% Confidence interval]: 6.266 [1.139-34.463]).

**Summary/Conclusions:** Haplo-identical transplantation without in vitro T-cell depletion condition including BU/CY+ATG is a feasible strategy for adult SAA patients, with successful engraftment, acceptable GVHD, and inspiring survival outcomes. HCT-CI might be an outcome predictor in these patients.

**E1499**

**PLERIXAFOR EFFICIENTLY AND SAFELY MOBILIZES PERIPHERAL BLOOD STEM CELLS: HOVON-107 RESULTS IN HLA-IDENTICAL SIBLING DONORS AND TRANSPLANTED RECIPIENTS**

G. De Greef¹,², B. van der Holt³, E. Braakman³, J. Janssen², E. Petersen³, V. Vucinic⁴, N. Thuss¹, M. Groots¹, J. Cornelissen¹

¹Hematology, Erasmus Cancer Institute Rotterdam, Rotterdam, ²Hematology, Vu University Hospital, Amsterdam, ³Hematology, UMCU, Utrecht, Netherlands, ⁴Hematology, University of Leipzig, Leipzig, Germany

**Background:** Plerixafor (PFX) is a reversible inhibitor of stem cell-stroma cell interactions, by interrupting SDF-1 binding to CXCR4. A single subcutaneous (sc) injection given results in direct release of hematopoietic stem and progenitor cells (HSPC) with limited side effects and therefore could be of advantage for allogeneic stem cell donors.

**Aims:** We set out to address the feasibility of sc PF in family donors and their recipients. Feasibility was defined by the percentage of HLA-matched sibling donors with ≥10⁶/kg CD34⁺ cells/kg recipient weight could be harvested after 1 or 2 gifts of PFX (320μg/kg).

**Methods:** Currently, data of 23 donors and 23 transplanted patients are available. All donors (16 male; 7 female, median age: 47, range: 24-60) received PFX sc 9-11 hours before stem cell collection. The median age in patients was 50 (range: 21-64), diagnoses included: AML/MDS RAEB (n=9), ALL(n=3), MM (n=4), Hodgkin/NHL (n=3), CLL (n=2), other (n=2). Transplant conditioning regimen was non-myeloablative in 17 patients and myeloablative in 6. Grafts obtained after the first gift PFX were analyzed for the total number of CD34⁺ cells, CD34⁻ subsets: CD34⁺CD45RA⁻/CD90⁻ and 90⁻ cells, T-cells and distinct CD4⁺ T cell subsets including regulatory T cells (Treg), Th1, Th2, and Th17 cells. Median cell numbers assessed in 10 G-CSF-mobilized grafts were used as controls.

**Results:** Criteria for feasibility were met as in 22 out of 23 donors ≥2×10⁶/kg CD34⁺ cells were collected. PFX was administered twice in 10 donors. Side effects CTC grade 2 occurred in 39% of donors and included gastrointestinal (17%), headache or tingling (17%), fatigue/myalgia (17%). CTC grade 3 fatigue was observed in 1 donor; in 2 donors grade 3 clotting occurred during the leukapheresis procedure. All side effects resolved. The median number of CD34⁺ cells in the graft was 189 x 10⁶ (range:108-548) per PFX, G-CSF mobilization with non-frozen peripheral blood stem cells, on an outpatient basis and conditioning. Additional information is needed to assess the efficacy of these procedures in the treatment of patients with MS.

**Summary/Conclusions:** It is possible to conduct autotransplants for patients with MS employing non-frozen peripheral blood stem cells and outpatient condition. Additional information is needed to assess the efficacy of these procedures in the treatment of patients with MS.
Patients were endoscopically evaluated at time of GvHD diagnosis and follow-up. Treatment characteristics are provided in Table 1.

Results: All 13 patients experienced clinical responses, which were confirmed by endoscopies and in mucosal biopsies. 10 patients (77%) achieved clinical response within 28 days, and of these were complete responses. 1 patient (8%) had responded to treatment. Median time to complete response was 12 (range 2-162) days and 14 patients (73.7%) achieved a complete resolution of symptoms. 4 patients (30.8%) were associated with significant mortality and early initiation of treatment with steroids was warranted. The causes of death were transplantation related toxicity, GvHD in other target organs and infectious complications. Increased relative counts of CD25++ CD127low regulatory T-cells prior to treatment were observed in peripheral blood of 7 of 9 evaluable patients, and the relative counts decreased in all 7 patients during follow-up.

Summary/Conclusions: Our results indicate that vedolizumab may effectively treat steroid refractory cases of intestinal GvHD and is well tolerated. The mechanism of action is believed to be inhibition of allo-reactive T-cells interacting with intestinal endothelial cells. It is unclear why regulatory T-cells were initially increased in our steroid refractory GvHD patients and subsequently normalized. This might indicate a response to the alloreactive inflammation and subsequent redistribution to affected tissues and/or its resolution after successful treatment.

RISK FACTORS, OUTCOMES AND CHARACTERIZATION OF ‘AUTOLOGOUS GRAFT VERSUS HOST DISEASE’: THE MAYO CLINIC EXPERIENCE

T. Arangustou1, J. Paludo1, M.M. Patnaik1, M.R. Litzow1, D.A. Gastineau1, N. Dumal1, F.K. Buad1, N. Corrada1, W.J. Hogan1, G. Goyal1, J.S. Lehman1, S.K. Hashmi1, S.S. Kenderian1

Hematology/Medical Oncology, Mayo Clinic, Rochester, United States

Background: Graft versus Host Disease (GvHD) is a common complication of autologous stem cell transplantation (SCT) which is caused by the recognition of recipient antigens by the donor T lymphocytes. Acute GvHD remains a major cause of morbidity and mortality and half of the cases are refractory to steroids. The development of GvHD after autologous SCT (ASCT) is a poorly understood phenomenon. While some experts suggest that such an entity does not exist, some ASCT recipients develop clinical and histo-pathological changes similar to GvHD after autologenic S.

Aims: In this analysis, we aimed to elucidate the factors that affect the outcomes of patients with autologous GvHD.

Methods: This is a retrospective analysis of patients that received ASCT at Mayo Clinic between January 2006 and December 2015. Autologous GvHD was defined as the development of clinical and histo-pathological findings indicative of GvHD in ASCT recipients, as determined by pathology review. Survival was estimated and compared using the Kaplan Meier and Log Rank tests. This study was approved by the institutional review board.

Results: Between 2006 and 2015, 3,891 consecutive patients underwent ASCT. Of these, 35 patients (0.9%) developed symptoms suggestive of GvHD warranting biopsies. In 19 of these 35 patients (54%), the histopathological changes were consistent with GvHD. The most common underlying disease in patients with developed GvHD was multiple myeloma (14 patients, 73.7%) and the most common conditioning regimen used was melphalan (16 patients, 42.1%) and liver involvement in 2 patients (10.5%). The median time to symptom onset was 11 (range 2-80) days and the median time to GvHD diagnosis was 12 (range 2-162) days. Most patients (14, 73.7%) had grade 3 or 4 GvHD and liver involvement in 2 patients (10.5%). The median time to symptom onset was 11 (range 3-80) days and the median time to GvHD diagnosis was 12 (range 2-162) days. Most patients (14, 73.7%) had grade 3 or 4 GvHD and the clinical grading correlated with the histopathologic grading in all patients. 1 patient (8%) suffered disease progression. 7 patients (54%) were alive after a median follow up of 35 weeks. The causes of death were transplantation related toxicity, GvHD in other target organs and infectious complications. Increased relative counts of CD25++ CD127low regulatory T-cells prior to treatment were observed in peripheral blood of 7 of 9 evaluable patients, and the relative counts decreased in all 7 patients during follow-up.

Summary/Conclusions: Our findings suggest that autologous GvHD is associated with significant mortality and early initiation of treatment with steroids results in improved outcomes. Further studies into the mechanisms of the disease are warranted.

CNS DEMYELINATION AFTER HAPLO-HSCT AND ITS ASSOCIATION WITH THE IGG INTRATHECAL SYNTHESIS INDEX AND ANTI-MYLIN OLIGODENDROCYTE GLYCOPROTEIN ANTIBODY IN CEREBROSPINAL FLUID

X. Zhao1, Q. Wang1, J. Zhang1, X. Zhu1, Y. He2, L. Xu1, W. Han1, H. Chen1, Y. Chen1, F. Wang1, J. Wang1, Y. Zhang1, M. Xie1, Y. Chen1, Y. Wang1, Y. Chang1, L. Xu1, K. Liu1, X. Huang1, X. Zhang1

1Peking University Institute of Hematology, Peking University People’s Hospital, Beijing, China

Background: Haplidential haemopoietic stem cell transplant (haplo-HSCT) is an upfront and effective therapy for haematological patients, but it usually has many complications such as neurological complications. As one of the neurological complications following haplo-HSCT, immune-mediated demyelinating diseases of the central nervous system (CNS) seriously affect the patient quality of life. However, the incidence, risk factors and pathogenesis of CNS demyelination are not very well understood.

Aims: To analyse the incidence, risk factors, and prognosis of CNS demyelination after haplo-HSCT.

Methods: A study was conducted in 1,526 patients who underwent haplo-HSCT between January 2013 and June 2016. The definition of CNS demyelination during haplo-HSCT was confirmed by neurologic signs, MRI abnormality corresponding to the neurologic signs, abnormal CSF studies and the presence of systemic GvHD or the response to immunosuppressive therapy (Grauer O et al. Brain. 2010; 133(10): 2852-2865, Chronic graft versus host disease.
Background: The course following allogeneic hematopoietic stem cell transplantation (HSCT) varies between individuals. Baseline comorbidities, commonly scored by the Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI), are important determinants of transplant risk. However, their prognostic utility varies and only partially accounts for transplantation-related mortality (TRM). Standard pre-HSCT laboratory carries objective physiologic information which can be used for TRM risk estimation.

Aims: Determine the value of pre-HSCT estimated creatinine clearance (CrCl), albumin, and alkaline phosphatase (Alk-p) for TRM prediction.

Methods: The study population included 1,217 patients from two European centers. Indications for transplantation and conditioning regimens were diverse. Donors were either HLA-matched sibling donors (54%), matched unrelated donors (30%), or 9/10 HLA-mismatched unrelated donors (15%). The impact of donor type, cytomegalovirus serostatus, and conditioning intensity was evaluated by WT1 expression and MFC. Median age at transplant was 45 years. Disease phase was CR2 in 63 patients (68%) and CR3 in 29 (32%).

Results: We retrospectively analyzed the outcome of 92 consecutive AML patients receiving allo-BMT in 2nd (CR2) or 3rd (CR3) CR. Pre-BMT MRD was assessed by WT1 expression levels and multicolor flow cytometry (MFC) are the most common tools to evaluate MRD.

Aims: Here, we analyzed the role of pre-BMT MRD assessment as predictor for the post-transplant relapse risk in patient transplanted beyond first CR.

Methods: We retrospectively analyzed the outcome of 92 consecutive AML patients receiving allo-BMT in 2nd (CR2) or 3rd (CR3) CR. Pre-BMT MRD was evaluated by WT1 expression and MFC. Median age at transplant was 45 years. Disease phase was CR2 in 63 patients (68%) and CR3 in 29 (32%).

Aims: Here, we analyzed the role of pre-BMT MRD assessment as predictor for the post-transplant relapse risk in patient transplanted beyond first CR.

Methods: We retrospectively analyzed the outcome of 92 consecutive AML patients receiving allo-BMT in 2nd (CR2) or 3rd (CR3) CR. Pre-BMT MRD was evaluated by WT1 expression and MFC. Median age at transplant was 45 years. Disease phase was CR2 in 63 patients (68%) and CR3 in 29 (32%).

Results: Patients had a median age of 55 years and HCT-CI scores of 0 (24%), 1-2 (39%), and >3 (37%). A cut-off of CrCl<60 ml/min, albumin<3.5 g/dl, and Alk-p>180 IU/l corresponded with 8.8%, 8.3%, and 6.5% of the population, respectively. CrCl and albumin were associated with increased risk and higher cumulative incidence of TRM (CIR) (77.0%, 12.5-89.5% and 2.00 [1.37-2.95] and 2.02 [1.39-3.14], respectively). Interestingly, age did not make statistical significance in models incorporating these biomarkers, suggesting they strongly reflect patients' physiological status. Alk-p was dropped out in the multivariate analysis. Prediction models for day-100 and 2-years TRM, based only on HCT-CI, had AUCCs of 56.4 and 58.6, respectively. The introduction of both albumin and CrCl, separately or combined, resulted in incremental improvement in AUC, topping at 66.1 (+17% increase) and 63.2 (+8% increase), for day-100 and 2-years TRM, respectively (Figure-panel b). The improvement was maintained in all conditioning and donor subgroups.
number/Abl copy number 250x10^4 was used as cut-off value for abnormal WT1 expression.

Results: Relapse occurred in 30 patients (33%) and two years non-relapse mortality was 29%. Three-year estimate of OS was 47.9% (median 19 months). The survival probability was significantly affected by donor source (better for HAPLO, p < 0.05), ELN risk at diagnosis (better for ELN low risk, p < 0.01), MRD status, p < 0.03 for WT1-based MRD, p < 0.03 for MFC based MRD) and CR status at BMT (better for CR2, p < 0.05). Specifically patients transplanted in a MRD negative status had comparable OS irrespective of ELN risk at diagnosis (2-years OS of 62.2% and 52.7% among MFC MRD negative patient with ELN risk low or intermediate/high, respectively, Fig.1). The predictive value of MRD resulted independent from all other analyzed variables, although patients with positive MRD undergoing HAPLO BMT had a slightly better outcome. Multivariate OS analysis revealed that MRD status (evaluated by any method) was the only independent predictor of OS (p < 0.05 for both). Pre BMT MRD was also a strong predictor of cumulative incidence (CI) of relapse in competitive risk analysis (p < 0.01 and p < 0.03, respectively, for WT1 and MFC MRD). Multivariate CI of relapse analysis showed that donor source and MRD significantly influenced relapse risk (p < 0.05 and < 0.01, respectively).

Figure 1.

Summary/Conclusions: Pre transplant MRD evaluated by both WT1 and MFC on bone marrow samples is a reliable predictor of relapse risk and OS which can overcome the ELN risk stratification at diagnosis. Pre BMT MRD negative patients had a significantly better OS, compared with MRD positive ones. MRD positive patients showed an increased risk of relapse, irrespectively of having a low ELN risk at diagnosis. In patients undergoing BMT beyond CR1 pre-BMT MRD status confirms its prognostic relevance and may help in selecting stem cell source. Pre-BMT MRD evaluation may also help in choosing pre-emptive therapeutic strategies.

E1506 IMPACT OF ALLELE SPECIFIC PATIENT:DONOR HLA DISPARITY ON OUTCOME OF REDUCED INTENSITY TRANSPLANTS PERFORMED USING HLA MISMATCHED UNRELATED DONORS: ON BEHALF OF THE ALWP OF THE EBMT
C. Creddock1, L. R. Mabopin2, D. Niederwieser3, J. Cornelissen4, B. Afansayev5, P. Jindra6, J. Maertens7, D. Blaise8, P. Ljungman9, M. Gramatzki10, A. Ganser11, B. Savani12, M. Motty13, A. Nagler14

Background: Allelogeneic stem cell transplantation (allo-SCT) represents an increasingly important curative treatment strategy in adults with acute myeloid leukemia (AML), consequent upon both the increased availability of unrelated donors and the advent of reduced intensity conditioning (RIC) regimens. Although optimal outcomes are achieved in patients transplanted using an unrelated donor matched at 10/10 HLA-A, B, C, DRB1, DQ alleles it remains the case that many undergo transplantation using a donor matched at only 9/10 HLA alleles. Aims: There are limited data concerning the impact of specific HLA mismatches on patient outcome and we therefore interrogated the EBMT database in order to characterize the impact of mismatch on transplant outcome

Methods: 937 patients with AML in CR1 or CR2 underwent transplantation utilizing a RIC regimen using a 9/10 mismatched unrelated donor between 2001-2015. Of these 264 were transplanted using a donor mismatched at HLA-A, 127 were mismatched at HLA-B, 292 mismatched at HLA-C, 180 mismatched at HLA-DQ and 74 mismatched at HLA-DRB1. 85% of patients received in vivo T cell depletion.

Results: The 2 year leukemia free survival (LFS) for the whole cohort was 45% and the 2 year overall survival (OS) was 50%. The corresponding non-relapse mortality was 26% and relapse incidence 29%. Among 30% of patients developed Grade 2-4 acute GVHD and 14% chronic extensive GVHD. In Cox analysis age, adverse karyotype and patient CMV seropositivity were correlated with decreased LFS and OS. There was no significant difference in LFS or OS between patients transplanted from donors mismatched at HLA-A, B, C, DRB1 side effects. During the time of IFN-α treatment, the median time of IFN-α treatment was 60 days (range: 22–240 days). Of note there were no significant differences in disease characteristics including: bone marrow smear, leukemia-associated immunophenotype (LAIP), leukemia specific or related fusion genes, and donor chimerism through mult-parametric parameter to evaluate disease status. Patients were given IFN-α 2b 3–9 million units / day by subcutaneous injection for preemptive treatment once a relapse tendency was detected, such as: increasing proportion of blast in bone marrow between 3–5%, or MRD>1.0×10^−3, or leukemia specific gene transact from negative to positive, or dynamic increasing copy number of fusion gene. In patients undergoing BMT beyond CR1 pre-BMT MRD status confirms its prognostic relevance and may help in selecting stem cell source. Pre-BMT MRD evaluation may also help in choosing pre-emptive therapeutic strategies.

E1507 PRE-EMPTIVE THERAPY WITH IFN-A-2B FOR ACUTE LEUKEMIA PATIENTS WITH HIGH RISK OF RELAPSING TENDENCY POST ALLO-HSCT
X. Lin1, A. Wang1, F. Chen1, X. Ma1, A. Sun1, X. Zhu1, H. Qiu1, Z. Jin1, S. Xue1, D. Wu2, X. Tang1,2,3
1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Relapse still remains the most frequent cause of treatment failure and mortality. According to the data of CIBMTR, relapse has become the leading cause of death following allo-HSCT. The high risk patients with more advanced disease, have a relapse rate of 40–80%. Therefore, prevention and treatment of relapse post allo-HSCT is the most likely approach to improve survival of these patients. It is well known that IFN-α had been widely used in the field of antitumor. Recently it is shown that IFN-α also play an important role in immune modulation to enhance the effect of GVL. Aims: To determine the efficacy and safety of IFN-a-2b pre-emptive therapy for acute leukemia(AL) patients with relapsing tendencies after allogeneic hematopoietic stem cell transplantation (allo-HSCT).

Methods: Retrospectively analyzed 948 acute leukemia patients undergoing allo-HSCT from Jan. 2006 to Mar. 2014 in our hospital. After allo-HSCT, 948 AL patients were periodically monitored the minimal residual disease(MRD) including: bone marrow smear, leukemia-associated immunophenotype (LAIP), leukemia specific or related fusion genes, and donor chimerism through multi-parameter diagnosis to evaluate disease status. Patients were given IFN-α-2b 3–9 million units / day by subcutaneous injection for preemptive treatment once a relapse tendency was detected, such as: increasing proportion of blast in bone marrow between 3–5%, or MRD>1.0×10^−3, or leukemia specific fusion gene transform from negative to positive, or dynamic increasing copy number of WT1 more than 200 copies/10^4 abl, or decreasing of donor chimerism(≤90%). There were 98 patients who were presented increasing tendency of MRD and were enrolled in this study. Among them, 31 patients received IFN-α-2b pre-emptive therapy, and 67 patients received non-IFN-a-2b therapy such as: withdrawal immunosuppressant, traditional DLI or DC-CIK immunotherapy.

Results: There were no significant differences in disease characteristics between two groups. For the 31 patients who received IFN-a-2b pre-emptive therapy(IFN group), the median time of IFN-α treatment was 60 days (range: 5–720 days), Twenty five patients had responded to the treatment without progressing to hematological relapse (response rate 80.6%). 2 patients developed to hematological relapse again after temporary response; 3 patients had no response and eventually progressed to hematological relapse. Regarding 67 patients who received non-IFN-a-2b therapy, 45 patients failed to the treatment and progressed to hematological relapse at a median time of 35 (range: 6–940) days. There was significant difference of RR between two group(P=0.0001). 31 patients of IFN group tolerate well and no patient terminated therapy due to adverse effect. Among them, 31 patients received IFN-alpha-2b pre-emptive therapy, 6 patients 19.4% with aGVHD and 14-45.2% with limited cGVHD. The median follow-up time was 21.4-78.5 months. 22 of 31 cases of IFN group maintained disease-free survival. The 5-year overall survival rate (OS) and the leukemia-
free survival rate (LFS) of IFN group were 47.0%±13.9% and 38.7%±13.1% respectively. However, the 5-yr OS and LFS of non IFN group were 14.5%±10.7% and 12.5%±9.4% respectively. The difference were significantly (P=0.000, P=0.002 respectively). Patients with GVHD had significantly better response than patients without GVHD (88.9% vs 53.8%, P=0.043, P = 0.05).

**Summary/Conclusions:** IFN-α-2b pre-emptive therapy can effectively prevent high-risk patients with relapsing tendencies for disease progression post allo-HSCT. Further large-scale investigation is warranted.

**E1508**

**PREDICTING SURVIVAL AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION. THE GATMO SCORE**

1Hematology, Transplant Unit, Hospital Universitario Austral, Derqui, Buenos Aires, 2Hematology, Transplant Unit, Instituto Alexandra Fleming, 3Hematology, Transplant Unit, Fundacion Favaloro, 4Hematology, Transplant Unit, Hospital Italiano de Buenos Aires, 5Hematology, Transplant Unit, Hospital Italiano de La Plata, 6Hematology, Transplant Unit, Hospital Italiano de Cordoba, 7Hematology, Transplant Unit, Sanatorio Anchorena, 8Hematology, Transplant Unit, Hospital Britanico, Buenos Aires, 9Clinica Medica, Hospital Universitario Austral, Derqui, Argentina, 10CIBMTR, Department of Medicine, Medical College of Wisconsin, Milwaukee, United States

**Background:** Several attempts to predict mortality after autologous stem cell transplantation (ASCT) have been made, like Hematopoietic Stem Cell Transplant Comorbidity Index (HCT-CI) score, originally described by Sorror for allo-geneic HSCT. There is no score applicable to the clinical practice that integrates comorbidities with other patient characteristics.

**Aims:** To describe a comprehensive score that combines comorbidities with other factors and analyse the impact of this score in OS and NRM after ASCT in a cohort of patients transplanted in Argentina.

**Methods:** We retrospectively reviewed a cohort of 1453 medical records of adult patients who received an ASCT in our centres between October 2002 and August 2016, for Multiple Myeloma or Lymphoma. We compared NRM and Relapse with CI, OS with KM and long term MVA with fine-Gray or Cox regression.

We included in the score all the factors that remained significant after MVA for NRM, and assigned a score of 1 if the Hazard ratio (HR) was around 1 (1.5-2.5) and 2 if it was around 3 (2.6-3.5).

**Results:** Mean age was 50.7 years (range 15-74); 57% were male, 52% had Multiple Myeloma, 29% Non Hodgkin Lymphoma and 19% Hodgkin Lymphoma. Forty-seven percent were in CR, 50% in PR and 3% SD/PD; 14% received three or more chemotherapy lines before transplant (heavily pre-treated). Regarding comorbidities, 62% had low HCT-CI score (score 0), 26% intermediate risk (1-2) and 12% high risk (≥3). Median follow up was 1.1 years (range 5-85), with all patients having a neutrophil count <1x109/l. The reasons included. Data cut off was 1st February 2017. Electronic patient records were used to collect data on baseline patient characteristics, comorbidities and performance status. The Charlson comorbidity index (CCI) and hematopoietic cell transplantation comorbidity index (HCTCI) were calculated. Univariate analysis of variables was performed using Graph Pad Prism version 5.03. A p value <0.05 was considered significant.

**Results:** 689 patients received HDC-ASCT. The median age was 58 years (23-74). Patient characteristics are shown in the table (See Image). Thirteen patients (7.6%) required ICU admission at a median of 14 days post cell infusion (range 5-85), with all patients having a neutropel count <1x109/l. The reasons for ICU admission included sepsis (n=12), severe mucositis/colitis (n=11), renal failure (n=8), hypotension and arrhythmias (n=7), respiratory distress (n=4), liver failure (n=1). The median number of days spent in ICU was 9 (range 2-16). Five patients required single organ support (non-invasive ventilation, 2; intoropue support, 2; haemofiltration; 1) and 2 required only management of

**Summary/Conclusions:** We found that GATMO score had a significant association with long term OS due to an increase in NRM. All end-point risks increased proportionally with the score. This observation should be confirmed in larger series.

**E1509**

**A RETROSPECTIVE ANALYSIS OF PATIENT CHARACTERISTICS AND RISK FACTORS FOR ADMISSION TO THE INTENSIVE CARE UNIT (ICU) FOLLOWING HIGH DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION (HDC-ASCT)**

L. Jeyara Raj Nallathambi1,*, T. Freeman1, S. Williams1, V. Potter1, R. Benjamin1, K. Cuthill1, S. Devereux1, P. Patten1, D. Yallof1, S. Kassam1

1Haematology, Kings college hospital, London, United Kingdom

**Background:** HDC-ASCT is a standard treatment modality for patients with myeloma and lymphoma. It carries a low, but significant risk of morbidity and mortality. Given that the upper age limit for patient selection continues to increase, it is important to have an objective way of assessing patient suitability for HDC-ASCT. Admission to the ICU is an ominous clinical event post HDC-ASCT and carries a high risk of mortality. There are currently no standard assessment tools to predict the risk of morbidity and mortality.

**Aims:** To review the incidence and cause of ICU admission in patients receiving HDC-ASCT and identify pre-transplant factors that may be predictive of transplant morbidity and mortality.

**Table 1.**

**Methods:** All patients receiving HDC-ASCT for myeloma and lymphoma at King’s College Hospital, London between July 2015 and December 2016 were included. Data cut off was 1st February 2017. Electronic patient records were used to collect data on baseline patient characteristics, comorbidities and performance status. The Charlson comorbidity index (CCI) and hematopoietic cell transplantation comorbidity index (HCTCI) were calculated. Univariate analysis of variables was performed using Graph Pad Prism version 5.03. A p value <0.05 was considered significant.

**Results:** 689 patients received HDC-ASCT. The median age was 58 years (23-74). Patient characteristics are shown in the table (See Image). Thirteen patients (7.6%) required ICU admission at a median of 14 days post cell infusion (range 5-85), with all patients having a neutrophel count <1x109/l. The reasons for ICU admission included sepsis (n=12), severe mucositis/colitis (n=11), renal failure (n=8), hypotension and arrhytmias (n=7), respiratory distress (n=4), liver failure (n=1). The median number of days spent in ICU was 9 (range 2-16). Five patients required single organ support (non-invasive ventilation, 2; intoropue support, 2; haemofiltration; 1) and 2 required only management of
fluid balance. Six patients required multi-organ support (non invasive ventilation/ventilation, hemofiltration and isotropic support) and all died. Four patients died within 30 days of HDC-ASCT and had not engrafted neutrophils at the time of death. Two patients died late at day +120 and day +93 post HDC-ASCT. The latter had both successfully engrafted neutrophils but subsequently became neutropenic. Causes of death were neutropenic sepsis (3), cerebrovascular accident (1), acute renal failure (1) and acute respiratory distress syndrome (1). By univariate analysis none of the baseline parameters, comorbidities or conditioning regimens were predictive of ICU admission. The only parameter for which there was a trend for significance was baseline cardiac ejection fraction (EF) (<50% (p=0.05)). Three patients that required ICU had an EF <50% and 2 were on heart failure medications prior to HDC-ASCT. Two of these 3 patients died.

Summary/Conclusions: In this retrospective series, the risk for ICU admission and death following HDC-ASCT was 7.6% and 3.5% respectively. All patients requiring more than one organ support died. The only predictor of ICU admission was neutropenia but this would need confirmation in a larger series. Patient selection remains challenging with no definite tool to predict ICU admission or death.

E1510
AUTOLOGOUS STEM CELL TRANSPLANTATION WITH BENDA-EAM (BENDAMUSTINE, ETOPOSIDE, CYTARABINE, MELPHALAN) IN AGGRESSIVE NON HODGKIN AND HODGKIN’S LYMPHOMA
T. Noesslinger1, R. Simanek1,*, M. Panny1, E. Koller1, M. Moestl1, F. Keil1
1Hematology and Oncology, Hanusch Krankenhaus, Vienna, Austria

Background: Autologous Stem Cell Transplantation (ASCT) is standard of care in relapsed diffuse large B-cell lymphoma (DLBCL) and other lymphoproliferative disorders (relapsed Hodgkin’s disease, 1st line mantle cell lymphoma (MCL) or T-cell lymphoma). BCNU, Etoposide, Ara-C, Melphalan (BEAM) is a standard conditioning regimen, but BCNU is known to be associated with interstitial pneumonia (range 2 to 20%) and an increased risk of death compared with other regimens.

Aims: Therefore a less toxic conditioning protocol might improve the results in lymphoma patients. Bendamustine showed promising results in B- and T-cell lymphoma and dose escalation is safe and feasible. Here we report promising results with bendamustine replacing BCNU in the BEAM regimen described as Benda-EAM, previously published in a phase two dose finding study (Visani, Blood 2011).

Methods: Forty-one patients with Hodgkin’s (HL) n=9) or Non-Hodgkin (n=32) lymphoma were consecutively treated with Benda-EAM (bendamustine on two consecutive days at a dose of 200 mg/m² per day). Eleven patients were diagnosed with DLBCL, ten patients with MCL, six patients with follicular lymphoma (FL), three patients with T-cell lymphoma (TCL) and two patients with greyzone lymphoma (GZL). Twenty-seven patients were male and fourteen female with a median age of 52 years (range 22-71) and 25% were above the age of sixty. The median lines of previous therapies were 2 (range 1-4).

Figure 1.

Results: All patients had chemosensitive disease and before transplantation, 34 patients (83%) were in complete (CR) and 7 (17%) in partial remission (PR).

A median number of 4.20*10^6CD34+ cells/kg (range: 1.60-13.30) were infused. Eleven patients were diagnosed with DLBCL, ten patients with MCL, six patients with follicular lymphoma (FL), three patients with T-cell lymphoma (TCL) and two patients with greyzone lymphoma (GZL). Twenty-seven patients were male and fourteen female with a median age of 52 years (range 22-71) and 25% were above the age of sixty. The median lines of previous therapies were 2 (range 1-4).

Fourty-one patients with Hodgkin's (HL)(n=9) or Non-Hodgkin (n=32) lymphoma were consecutively treated with Benda-EAM (bendamustine on two consecutive days at a dose of 200 mg/m² per day). Eleven patients were diagnosed with DLBCL, ten patients with MCL, six patients with follicular lymphoma (FL), three patients with T-cell lymphoma (TCL) and two patients with greyzone lymphoma (GZL). Twenty-seven patients were male and fourteen female with a median age of 52 years (range 22-71) and 25% were above the age of sixty. The median lines of previous therapies were 2 (range 1-4).

year PFS are 73.2% and 57.9% and the 1- and 2-year OVS 85.4% and 79.4%, respectively.

Summary/Conclusions: In conclusion Benda-EAM is feasible with a quite promising outcome. Currently an international randomized phase II trial comparing Benda-EAM with BEAM is recruiting. So far fifty-five of 110 planned patients are randomized and first results are expected for 2018.

E1511
THROMBOTIC MICROANGIOPATHY WITH CONCOMITANT AGVHD AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: RISK FACTORS, SEVERE OUTCOME AND TREATMENT EXPERIENCE
X. Liu1, Q. Wang1, Y. He1, X. Zhu1, J. Zhang1, L. Xu1, W. Han1, H. Chen1, Y. Chen1, F. Wang1, J. Wang1, Y. Zhang1, X. Mo1, Y. Chen1, Y. Wang1, Y. Chang1, H. Xiu1, X. Hu1, X. Zhu2, and Z. Zhang1
1Peking University Institute of Hematology, Peking University People’s Hospital, Beijing, China

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT)-associated thrombotic microangiopathy (TA-TMA) is a significant complication after allo-HSCT. acute graft-versus-host disease (aGVHD) is one of the risk factors for the occurrence of TA-TMA, and some patients may develop both. Although there has been sufficient information available on aGVHD and TA-TMA, TMA with concomitant aGVHD after allo-HSCT remains not well understood.

Aims: To explore the possible risk factors for the occurrence and mortality of TMA with concomitant aGVHD and to investigate outcomes and treatments of this disorder after allo-HSCT.

Methods: This study was based on patients who underwent allo-HSCT at Peking University People’s Hospital from January 2008 to December 2016. We included patients who showed refractory diarrhea and underwent endoscopy and biopsy. The diagnosis of TA-TMA and aGVHD were mainly based on the probable-TMA criteria (Byung-Sik Cho et al. Transplantation 2010;90:918-926) and endoscopic appearance and histologic findings (Thomas Hematopoietic Cell Transplantation, Fifth Edition, 2016, respectively).

The potential factors affecting TMA with concomitant aGVHD occurrence and markers associated with the death of these patients were identified using univariate and multivariate Cox analysis. The cumulative incidence of relapse, non-relapse mortality (NRM), overall survival (OS) and disease-free survival (DFS) were estimated using the Kaplan-Meier method and were compared by the log-rank test.

Results: Among all 3,992 allo-HSCT recipients, 276 patients showed refractory diarrhea and underwent endoscopy; of these patients, 50 (1.93%) were diagnosed with TMA with concomitant aGVHD and were enrolled in the case group, and 150 (5.80%) were enrolled in the control group. The two groups matched well with regard to baseline characteristics. Based on the nested case-based control study, grade III-IV aGVHD (P=0.000), AKI (P=0.033) and hypertension (P=0.028) were significant independent risk factors associated with the occurrence of TMA with concomitant aGVHD. Considering the case group only, our data suggested that a haptoglobin level below normal (P=0.013), a maximum volume of diarrhea .2500 ml/d (P=0.015) and bloody diarrhea (P=0.049) were significant markers for death in both univariate and multivariate analysis. Among the case group and control group, the 9-year OS rates were 52% and 81% (P=0.001), respectively; the 9-year DFS rates were 50% and 65% (P=0.345), respectively; the 9-year cumulative incidence rates of NRM were 44% and 16% (P<0.001), and those of relapse were 6% and 19% (P=0.010), respectively. To further study the treatments of patients with TMA and aGVHD, we calculated the OS and found that plasma exchange (PE) use (PE=0, 62.5%; PE=1, 37.5%; P=0.156) had no significant influence on the patient outcome.

Summary/Conclusions: This study demonstrated that patients diagnosed with TMA with concomitant aGVHD after allo-HSCT had a significantly lower OS, higher NRM, and a lower incidence of relapse. The risk factors associated with the occurrence and mortality of TMA with concomitant aGVHD may help us assess the prognosis of patients. The findings also suggested that PE use may be ineffective to these patients.

SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE MONITORING BY QUANTITATIVE RT-PCR IN CORE BINDING FACTOR AML ON TRANSPLANTATION OUTCOMES
B. Oran1,*, K. Patel2, D. Marin1, Q. Bashir1, S. Ahmed1, A. Aoulos1, S. Ciurea1, J. Chen1, K. Rezvani1, U. Popat1, E. Shpall1, R. Champlin1
1Stem Cell Transplantation and Cellular Therapy, 2Hematopathology, The University of Texas MDACC, Houston, United States

Background: Despite the well-defined role of minimal residual disease (MRD) monitoring in core binding factor (CBF)-AML after intensive chemotherapy, it has been, to date, a paucity of data assessing the clinical utility of MRD monitoring before allogeneic stem cell transplantation (HSCT).

Aims: We investigated the prognostic impact of MRD monitoring by real-time quantitative polymerase chain reaction (RT-PCR) for RUNX1/RUNX1T1 and
CBFB-MYH11 transcript levels at HSCT on transplant outcomes in AML patients with CBF abnormalities.

**Methods:** We included 61 AML patients with CBF at diagnosis that underwent their first HSCT in complete remission (CR) from January 2007 through May 2016. Of 61, 19 (31%) had t(8;21) chromosomal translocation and 42 (69%) inv(16)(p13q22). Disease status at HSCT was CR1 in 19 (31%) and CR2 in 42 (69%). Cytogenetic and molecular analyses were done on peripheral blood (n=5), bone marrow (n=22) and cord blood (n=7). Conditioning regimen was myeloablative in 38 (62%) and reduced intensity in 23 (38%) patients. Donors were matched related (MR) in 24 (38%), unmatched unrelated (MUD) in 26 (43%), and haploidentical in 4 (7%). Quantitative real-time PCR analysis was performed on reverse-transcribed RNA for the CBFB-MYH11 (Type A) and RUNX1/RUNX1T1 fusion transcripts. Fusion (RUNX1/RUNX1T1 and CBFB-MYH11) and internal control (ABL1) transcript levels were detected simultaneously and quantitative results were expressed as the percent ratio of fusion to ABL1 transcript levels (fusion/ABL1 f-test=100).

**Results:** MRD by RT-PCR at HSCT was evaluable in 43 patients (70%) and 36 of 44 (84%) had evidence of MRD (MRDpos). RT-PCR was <0.1% in 22 patients, ≥0.1% and <1% in 7 and ≥1% in 5 patients. Overall survival (OS) and leukemia free survival (LFS) at 4-years was 100% and 85.7% in 7 MRDneg and 65.4% and 61.6% in 37 MRDpos patients respectively (p=0.09 and p=0.3). The incidence of disease progression was comparable between MRDneg and MRDpos patients, 15% vs 16% at 4 years. There was no increase in the risk of progression with higher levels of MRD by RT-PCR (p=0.6). None of the other variables were prognostic for OS, LFS and disease progression.

**Summary/Conclusions:** Transplant-related mortality observed in MRDneg group while the incidence was 22.6% at 2 years in MRDpos group.

**E1513**

**LONG-TERM OUTCOME OF ALLOGENEIC STEM CELL TRANSPLANTATION IN ADULT SEVERE APLASTIC ANEMIA WITH ABNORMAL CYTOGENETICS AT DIAGNOSIS**

**Background:** Cytogenetic abnormalities (CAs) have been reported at the time of diagnosis of acquired aplastic anemia (AA), up to approximately 4-15%. Considering evolution into clonal hematologic disorders and difficulty between AA and hypoplastic MDS, clinical implications of CAs in AA is important.

**Aims:** In this study, we investigated long-term outcome of allogeneic stem cell transplantation (SCT) in adult severe AA (SAA) patients with abnormal CAs at diagnosis.

**Methods:** Total of 19 patients with abnormal CAs at diagnosis who underwent allo-SCT at our institution between 2003 and 2015. Morphologically hypoplastic bone marrow with dysplastic cells was considered as hypoplastic MDS and excluded. Clonal CAs were defined as 2 or more cells showing the same chromosomal gain or structural abnormality, or 3 or more cells with the same chromosomal loss.

**Results:** The most frequent abnormality was trisomy 8 (n=11), followed by inversion 9 (n=2). Other CAs included t(1;3), t(5;18), t(1;11), t(1;8), t(1;19), -Y, +Y, -7, +9. Two patients had two or more CAs. Seven male and 12 female patients with a median age of 41 years (range, 20-59 years) were included.

**Summary/Conclusions:** Durable complete remissions can be achieved in CBF AML patients with HSCT even if they are MRDpos at HSCT.

**E1514**

**PROGNOSTIC VALUE OF PET/CT PRIOR TO AUTOLOGOUS HCT IN RELAPSED / REFRACTORY LYMPHOMA**

**Aims:** After due IRB approval, patients who received autologous HCT at our institution for relapsed / refractory lymphoma between 2010 - 2016 were identified. All variables were retrospectively extracted. PET/CT reports were reviewed and metabolic activity was assigned per Deauville criteria. Patients with primary CNS lymphoma were excluded. Refractory disease indicates disease progression prior to starting planned first line therapy. Categorical and continuous variables were compared using Chi-squared and Wilcoxon tests, respectively. Time to end point analysis was computed using the method of Kaplan and Meier with log rank tests. Competing events were computed using Grey’s method considering non relapse mortality as a competing event for relapse. Analysis was computed using JMP software, version 11.

**Methods:** Prognostic value of PET/CT in relapsed / refractory lymphoma patients prior to HCT.

**Results:** A total of 47 patients had pre-HCT PET/CT. Median time to HCT for patients with PET/CT at 17 days (6-59). There were no significant differences between the cohorts based on age at HCT, gender, underlying diagnosis, relapsed/refractory status, time to relapse, number of salvage regimens, number of salvage cycles, use of immunotherapy as part of salvage and post-HCT immunotherapy use as maintenance. Considering Deauville ≤3 as complete metabolic response (CMR), 2-year CMR was 16.7% vs 60.5% for PET negative vs PET positive patients (p=0.0021). 2-year PFS was significantly higher in PET negative vs PET positive patients at 72% vs 39.5%, respectively (p=0.035). 2-year OS was similar irrespective of PET status (p=0.49). Considering Deauville ≤2 as CMR, there was only a trend towards decreased CIR for metabolically negative scans (p=0.096). Significance of these results remained unchanged after adjusting for NHL cases. B. Relapse post HCT: Median time to relapse post HCT for patients...
was 109 days (55-395) vs 271 days (55-440) for PET positive vs PET negative patients, respectively. Mortality post-relapse was 90% with the remaining patients achieving long term disease control with immunotherapy alone (54%), allogeneic HCT (29%) and combination chemotherapy (14%). Median follow up of patients with long term disease control was 1093 days (177-1271). Causes of death post HCT relapse was progression of disease in all cases.

Summary/Conclusions: Despite inherent limitations of this analysis, we present a number of important observations: 1. Deauville score ≤3 is an appropriate cutoff for metabolic activity pre-HCT and is associated with significantly decreased relapse and improved DFS. 2. PET positive status will better identify patients who may benefit from maintenance strategies post HCT. 3. Time to relapse in PET positive patients is significantly shorter highlighting the need for early initiation of pre-emptive maintenance therapy. 4. Long term disease control is possible in a high proportion of patients despite relapse post HCT. These important observations require further study.

COMPARISON OF OUTCOMES AFTER DONOR LYMPHOCYTE INFUSION WITH OR WITHOUT PRIOR CHEMOTHERAPY FOR MINIMAL RESIDUAL DISEASE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

X.-D. Mo1, X.-H. Zhang1, L.-P. Xu1, Y. Wang1, C.-H. Yan1, H. Chen1, Y.-H. Chen1, W. Han1, F.-R. Wang1, J.-Z. Wang1, K.-Y. Li1, X.-J. Huang1

1Peking University People’s Hospital, Institute of Hematology, Beijing, China

Background: Minimal residual disease (MRD) can predict impending relapse after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Thus, MRD-directed immunotherapy may be a reasonable option for relapse prophylaxis after allo-HSCT. However, there is limited data about the efficacy of allo-HSCT in patients with leukemia with relatively low tumor burden. Herein, we report the outcome of allo-HSCT in patients with MRD positive and might benefit from immunotherapy.

Methods: We enrolled 115 consecutive patients who received either DLI (n=20) or Chemo-DLI (n=39) during the same period. Three recipients matched for age at the HSCT, underlying diseases, and the year of the HSCT were randomly selected from the Chemo-DLI cohort (n=60).

Results: The 2-year cumulative incidence of severe acute graft-versus-host disease (GVHD) and chronic GVHD was comparable between the groups. Fifteen (10%) patients and 47 (78.3%) patients in the DLI and Chemo-DLI groups turned MRD negative, respectively. The 2-year cumulative incidences of relapse and non-relapse mortality after intervention were 30.7% versus 39.6% (P=0.582) and 10.3% versus 6.0% (P=0.508) in the DLI and Chemo-DLI groups, respectively. The 2-year probabilities of disease-free, overall, and GVHD-free/relapse-free survival after preemptive intervention were 58.9% versus 54.3% (P=0.662), 69.3% versus 78.1% (P=0.361), and 44.4% versus 35.1% (P=0.489) in the DLI and Chemo-DLI groups, respectively. In multivariate analysis, the intervention method did not significantly influence the clinical outcomes.

Summary/Conclusions: In summary, preemptive DLI alone may be effective for patients who are MRD positive and may be a potential alternative for patients who refuse or are unable to receive Chemo-DLI after HSCT.

E1516

DIFFERENTIAL PROGNOSTIC IMPACT OF HEMATOPOIETIC CELL TRANSPLANTATION SPECIFIC COMORBIDITY INDEX (HCT-CI) ON TRANSPLANT OUTCOMES BY STEM CELL SOURCES

Y. Adachi1, K. Sagou1, Y. Yamaga1, N. Fukushima1, K. Ozeki1, A. Kohno1

1Department of Hematology and Oncology, Konan Kosei Hospital, Konan, Japan

Background: The hematopoietic cell transplantation specific comorbidity index (HCT-CI) has been proposed to predict the probability of nonrelapse mortality (NRM) and overall survival (OS) in allogeneic hematopoietic cell transplantation (HSCT). However, the impact of HCT-CI on clinical outcomes in single unit umbilical cord blood transplantation (UCBT) has not been investigated extensively.

Aims: The purpose of this single-center retrospective study was to investigate the clinical impact of HCT-CI in UCBT.

Methods: We retrospectively analyzed a cohort of 144 consecutive adult patients who received first allogeneic HSCT between July 2008 and December 2016 in our hospital. One patient was excluded from this analysis due to inadequate data regarding comorbidities before HSCT. Patients were divided into the UCBT group (n=90) and the non-UCBT group (n=53). Two-year OS and 1-year NRM were defined as the primary endpoints.

Results: Pre-transplant parameters, such as gender, diagnosis, and the phase of disease, were comparable between the two groups. The median follow-up durations were 562 days and 627 days for the non-UCBT group and the UCBT group, respectively. The most frequent comorbidity was mild hepatic comorbidity (22%), followed by mild or severe pulmonary comorbidities and active infections (16%). For the non-UCBT group, 2-year OS rates for HCT-CI scores of 0, 1-2 and ≥3 were 70% (n=43), 63% (n=30), and 31% (n=17), respectively (P=0.014). For the non-UCBT group, 1-year NRM rates for HCT-CI scores of 0, 1-2 and ≥3 were 10%, 17%, and 35%, respectively (P=0.026). For the UCBT group, 2-year OS rates for HCT-CI scores of 0, 1-2 and ≥3 were 78% (n=26), 46% (n=13), and 69% (n=14), respectively (P=0.38). For the UCBT group, 1-year NRM rates for HCT-CI scores of 0, 1-2 and ≥3 were 9.0%, 15%, and 7.1%, respectively (P=0.75). In multivariate analysis, the HCT-CI score of ≥3 was significantly associated with lower OS (p=0.005; hazard ratio [HR] 2.6) and higher NRM (p=0.015; hazard ratio=3.1) for the non-UCBT group, but not for the UCBT group. There was no significant difference in the cumulative incidences of grade 2 to 4 acute GVHD between the non-UCBT group (41%) and the UCBT group (33%; P=0.51). Similarly, there was no significant difference in the cumulative incidences of grade 3 to 4 acute GVHD between the non-UCBT group (8.8%) and the UCBT group (6.1%; P=0.80). The cumulative incidence of extensive chronic GVHD was significantly higher in the non-UCBT group compared with the UCBT group (38% vs 3.8%; P=0.001). Although not significant, patients in the non-UCBT group were more likely to have the systemic steroid therapy compared with those in the UCBT group (54% vs 34%; P=0.084).

Figure 1.

Summary/Conclusions: UCBT showed good OS with the low incidence of NRM even in patients with high HCT-CI scores. These results indicate that a single unit umbilical cord blood might be a promising stem cell source for patients with multiple comorbidities. Further studies are needed in order to validate these results.

E1517

LOW DOSE POSTTRANSPLANTATION CYCLOPHOSPHAMIDE CAN ENHANCE THE PROTECTIVE EFFECT OF ATG/G-CSF ON GVHD: RESULTS OF A PHASE II PROSPECTIVE TRIAL

Y. Wang1,*, Y.-J. chang1, X.-J. huang1

1Peking university people’s hospital, beijing, China

Background: Anti-thymocyte globulin (ATG)/granulocyte colony-stimulating factor (G-CSF)-represented regimen produces essentially universal engraftment with limited relapse and favorable survival, albeit with relatively high rates of graft-versus-host disease (GVHD), especially after HCT from maternal donor or collateral relatives. While use of high-dose, post-transplant cyclophosphamide (PT/Cy) results in low rates of GVHD and favorable immune reconstitution, although with higher rates of relapse and somewhat high rates of graft failure. Thus, novel strategies are needed to refine each approach: under BCR protocol including ATG and G-CSF, reducing GVHD without abrogating GVF effect is a major priority.

Aims: In order to benefit patients at high risk of developing GVHD without abrogating engraftment and GVF effects, we sought to develop a novel procedure in TCR haplo-HCT with intensified conditioning containing ATG and G-CSF followed by lower-dose of PT/Cy. In addition, our current study attempt to establish a murine model and focus on Treg cells to clarify the immunological mechanisms for GVHD prevention by the new strategy.

Methods: We performed a prospective pilot study of HLA haploidentical cell transplantation from maternal or collateral relatives with intensified conditioning including G-CSF and ATG, followed by two lower doses of PT/Cy (14.5mg/kgx2 doses; designated as Group A). Outcomes were compared with those of 160 controls from matched-pair analysis who undergone haploidentical HCT from other donors than mother or collateral relatives at the same time period (Group B) as well as with those of 46 historical controls who underwent HCT from mother or collateral relatives at earlier time period (Group C). In addition, the current study attempt to establish a murine model and focus on Treg cells to clarify the immunological mechanisms for GVHD prevention by the new strategy.

P=0.005; hazard ratio=2.6) and higher NRM (p=0.015; hazard ratio=3.1) for the non-UCBT group, but not for the UCBT group.
the new strategy. Trial registration: The study is registered at www.clinicaltrial.gov as NCT02412423.

**Results:** We found that low dose PT/Cy combined with ATG could alleviate GVHD in mice and could increase the number of Treg cells while have no effects on CD4+ or CD8+ T cells. A total of 40 patients with myelodysplastic syndrome (MDS) and leukemia undergoing haploidentical HCT from maternal or collateral donors were enrolled in the study. The cumulative, 100-day incidence of acute GVHD, grades II-IV, in Group A (17%; 95% CI, 5%-29%) was significantly lower than both that in Group B (33%; CI, 25%-41%; P=0.04) and that in Group C (56%; CI, 42%-70%; P<0.001). The 1-year probabilities of NRM (5%; CI, 0%-12%), OS (84%; CI, 88%-100%), and LFS (83%; CI, 70%-96%) in Group A were similar to that in Group B, but was significantly lower than that of Group C (28%; CI, 15%-41%; P=0.006; 65%; CI, 51%-79%; P=0.02; and 65%; CI, 51%-79%; P=0.04; respectively).

**Summary/Conclusions:** Low dose PT/Cy can enhance the protective effect of ATG/G-CSF on GVHD. Conditioning with ATG/G-CSF and low-dose PT/Cy might be a feasible option for patients undergoing HLA haploidentical, T-cell replete HCT, in particular for those with high GVHD risk.

**E1518**

**HEPATITIS B REACTIVATION IN HEMATOPOIETIC STEM CELL TRANSPLANTED PATIENTS: 22 YEARS EXPERIENCE OF A SINGLE CENTRE**

**Background:** Reactivation of inactive viruses is an important complication of haematopoietic stem cell transplantation (HSCT). Suggestion of strategies to combat this problem will probably decrease transplant related mortality and morbidity.

**Aims:** Aim of this study is to evaluate the clinical progress and risk factors for reactivation in HSCT patients who were infected with hepatitis B virus (HBV) with the prospect of developing recommendations for a better clinical care.

**Methods:** Patient files and electronic records of 561 patients who received HSCT between 1994 and 2015 at the Bone Marrow Transplantation Center of Cerrahpaşa Medical Faculty were retrospectively evaluated. A total of 66 patients with HBsAg (n=15; 29 autologous, 3, allogeneic and anti-HBC IgG positivity (n=51; 29 autologous, 22 allogeneic) were included in the study. Cases were grouped according to transplant types (allogeneic or autologous) and anti-HBc IgG positivity (isolated anti HBc IgG positivity) to calculate relative risks and cumulative incidences of HBV reactivation.

**Results:** Four (%26) of the 15 patients with HBsAg positivity showed HBV reactivation in an average of 13 months following HSCT. While cumulative incidence of reactivation was 7% at day 60, it went up to 16% and 44% at days 270 and 730 following HSCT, respectively. In Anti HBC IgG positive group, allogeneic HSCT (n=22) was a higher risk factor for reactivation (31.8%) than autologous HSCT (n=29, 6.8%). Relative risk of reactivation in the allo-transplanted patients who were anti-HBc IgG positive and anti-HBs negative was 6.8 when compared to anti-HBs positive patients (n=9, 55% vs n=13, 10%) (95% CI: 1.3-46.5). Cumulative incidence of reactivation in anti-HBc IgG positive anti-HBs negative patients (isolated anti HBC IgG positivity) was 11% at day 10 day, 33% at day 133, 50% at day 400 and going up as high as 75% at day 940.

**Summary/Conclusions:** The results of our study indicate that HBsAg positive patients undergoing autologous or allogeneic HSCT should receive prophylaxis at least one year posttransplant. Anti-HBc IgG positive patients carry the risk of reverse seroconversion, with receivers of allogeneic HSCT having higher risk than those of autologous HSCT. Patients who are anti-HBc IgG positive and anti-HBs negative should receive prophylaxis for HBV if allogeneic HSCT is to be performed. However, close follow-up seems to be acceptable rather than a prophylactic treatment for anti-HBc IgG positive patients undergoing autologous HSCT.

**E1519**

**ALLOGENEIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION FROM HAPLOIDENTICAL DONOR WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE WAS RELATED TO LESS INPATIENT COST COMPARED TO CORD BLOOD TRANSPLANTATION**

**Background:** The number of allogeneic HSCT from alternative donors such as cord blood (CB) and haploidentical donor (haplo) is increasing especially after introduction of post-transplant cyclophosphamide (PT/ Cy) as GVHD prophylaxis for haplo. Although comparison of the survival benefit between CB and haplo with PT/CY has been made by several groups, there is little information about the medical cost and the hospitalization period of HSCT from alternative donors.

**Aims:** We evaluated the medical costs and the hospitalization period related to allogeneic HSCT in order to clarify the impact of donor sources and other clinical factors on these outcomes.

**Methods:** Patients (n=134) with hematological malignancies who underwent allogeneic HSCT between January 2013 and December 2016 in University of Tsukuba Hospital were included. The days of the initial hospitalization (from the beginning of the conditioning regimens to discharge), the whole initial inpatient costs and the costs of transfusion during the initial hospitalization was retrospectively analyzed.

**Results:** The median age of the patients was 46 (range, 16-67) years. The diagnoses were AML (n=66), ALL (n=31), MDS (n=17), lymphoma (n=11), and others (n=9). Twenty-seven patients were transplanted from MDR, 37 from MUD, 22 from haplo with PT/CY, and 48 with single-unit CB. The median initial inpatient cost was €49179 (IQR, 37030-66923), the median transfusion cost was €11500 (IQR, 9500-12525), and the median length of initial hospitalization was 55 (IQR, 44-75) days. CB showed significantly higher inpatient cost (median, €66852) than haplo (median, €49085, P=0.008 vs CB), MUD (median, €36998, P=0.001 vs CB), and MED (median, €39262, P=0.001 vs CB). The transfusion cost was highest in CB (median, €22750) compared with haplo (median, €12866, P=0.001 vs CB), MUD (median, €12699, P=0.001 vs CB), and MED (median, €13118, P=0.001 vs CB). The median hospitalization days were 67 in CB, 61 in haplo (P=1.0 vs CB), 46 in MUD (P=0.001 vs CB), and 49 in MED (P=0.01 vs CB). Among the clinical variables such as diagnoses (acute leukemia or others), refined disease-risk index (low/inter/highvery high), donor source (MUD, MED, haplo, or CB), age, first or second HSCT, intensity of conditioning (RIC or MAC), with or without morbidity, graft failure, GVHD III-IV, and admission to the intensive care unit (ICU), multiple regression models revealed CB (P=0.001), haplo (P=0.003), graft failure (P=0.001), admission to ICU (P<0.001), and MAC (P=0.05) were the factors that increased initial inpatient cost. The transfusion cost was increased by CB (P=0.001), graft failure (P=0.001), admission to ICU (P<0.001), and MAC (P=0.001). CB (P=0.001), haplo (P=0.003), and GVHD III-IV (P=0.01) were selected as factors associated with longer hospitalization period.

**E1520**

**THE ROLE OF PPARα EXPRESSION IN PATIENTS WITH aGVHD FOLLOWING ALLOGENIC HSCT**

**Background:** The acute graft versus host disease (aGVHD) is the main com-
Haploidentical transplantation with myeloablative conditioning regimen could serve as an optional salvage therapy for younger patients with refractory or relapsed non-Hodgkin lymphoma.

**Aims:** To evaluate clinical outcomes of haplo-HSCT in patients with R/R aggressive NHL.

**Methods:** 65 patients under allo-HSCT and 10 healthy controls were enrolled in study. Peripheral blood (PB) of patients was collected at 15 days, 30 days, 60 days, and 90 days after allo-HSCT. The mRNA expression of PPARγ, IFNγ, T-bet was detected by the real-time PCR. Furthermore, we conducted mixed lymphocyte reaction (MLR) to detect the proliferation of active lymphocytes under different concentration of PPARγ agonist.

**Results:** Among 65 patients after HSCT, aGVHD occurred in 45 patients. Expression of PPARγ mRNA in healthy controls was significantly lower than that in patients after allo-HSCT within 90 days (P<0.05). The expression of PPARγ mRNA held steady in non-GVHD patients within 90 days after allo-HSCT, and was significantly lower in GVHD group than in non-GVHD group (P<0.05). PPARγ expression in severe aGVHD (grade 3 to 4) was 41.7% and 35.5% (P<0.37), while non-relapse-mortality (NRM) was 21.7% and 35.0%, respectively (P<0.32). Collectively, these results showed no significant difference with respect to major allo-HSCT endpoints between the haplo-HSCT and HLA-matched-HSCT groups. On multivariate analyses, older age (> 45 years), primary chemorefractory disease and occurrence of grade III-IV aGVHD were associated with poor prognosis in both groups. Likewise, the most important factors that influenced the overall survival rate in the haplo-HSCT group were age and occurrence of grade III-IV aGVHD.

**Summary/Conclusions:** Low expression of PPARγ is associated with aGVHD occurrence and degree. PPARγ agonist can inhibit the proliferation of lymphocytes, which may be a new way to treat aGVHD.

---

**OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA HARBOURING INV(3)(q21;q26.2)/T(3;3)(q21;q26.2)**

**Aims:** To explore the role of PPARγ in aGVHD after allo-HSCT.

**Methods:** Of 15025 patients with AML who were aged ≥16 years and who underwent their first transplantation between January 2000 and December 2014. We analyzed outcomes of AML with inv(3)/t(3;3), who were aged ≥16 years and underwent their first allo-HSCT in patients with AML.

**Results:** Of 15025 patients with AML who were aged ≥16 years and who underwent their first transplantation, inv(3)(q21;q26.2)(t3;3)(q21;q26.2) was identified in 66 patients. The median age of patients who underwent allo-HSCT was 33 years (range, 16-58). Twenty-three patients had received transplant from haploidentical donors, while twenty-five patients received transplant from HLA-matched donors, of which included 13 ISD and 12 MUD. Chemorefractory disease at transplantation was more common in the haplo-HSCT group as compared to that in the HLA-matched HSCT cohort (P<0.005). No significant between-group differences were observed with respect to distribution of age and sex, histological subtype, bone marrow involvement, aaIPI score, chemotherapy regimen and relapse after ASCT.

**Conclusion:** Median age of patients at allo-HSCT was 33 years (16-58). Over a median follow-up of 23 months, 27 out of the 48 patients (56%) were alive. Progression free survival (PFS) rate at 2-years in the haplo-HSCT and HLA-matched HSCT groups was 52.1% and 56.6%, respectively (P<0.75); 2-year overall survival (OS) rate was 52.8% and 57.8%, respectively (P<0.83). Cumulative incidence of relapse (R) was 41.7% and 35.5% (P<0.37), while non-relapse-mortality (NRM) was 21.7% and 35.0%, respectively (P<0.32). Collectively, these results showed no significant difference with respect to major allo-HSCT endpoints between the haplo-HSCT and HLA-matched-HSCT groups.

---

**OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR YOUNGER PATIENTS WITH REFRACTORY OR RELAPSED NON-HODGKIN LYMPHOMA**

**Aims:** To evaluated clinical outcomes of haplo-HSCT in patients with R/R aggressive NHL.

**Methods:** 620 patients under allo-HSCT and 10 healthy controls were enrolled in study. Peripheral blood (PB) of patients was collected at 15 days, 30 days, 60 days, and 90 days after allo-HSCT. The mRNA expression of PPARγ, IFNγ, T-bet was detected by the real-time PCR. Furthermore, we conducted mixed lymphocyte reaction (MLR) to detect the proliferation of active lymphocytes.

**Results:** Among 65 patients after HSCT, aGVHD occurred in 45 patients. Expression of PPARγ mRNA in healthy controls was significantly lower than that in patients after allo-HSCT within 90 days (P<0.05). The expression of PPARγ mRNA hold steady in non-GVHD patients within 90 days after allo-HSCT, and was significantly lower in GVHD group than in non-GVHD group (P<0.05). PPARγ expression in severe aGVHD (grade 3 to 4) was 41.7% and 35.5% (P<0.37), while non-relapse-mortality (NRM) was 21.7% and 35.0%, respectively (P<0.32). Collectively, these results showed no significant difference with respect to major allo-HSCT endpoints between the haplo-HSCT and HLA-matched-HSCT groups. On multivariate analyses, older age (> 45 years), primary chemorefractory disease and occurrence of grade III-IV aGVHD were associated with poor prognosis in both groups. Likewise, the most important factors that influenced the overall survival rate in the haplo-HSCT group were age and occurrence of grade III-IV aGVHD.

**Summary/Conclusions:** Low expression of PPARγ is associated with aGVHD occurrence and degree. PPARγ agonist can inhibit the proliferation of lymphocytes, which may be a new way to treat aGVHD.
(HR, 2.03; 95% CI, 0.99-4.14; P=0.05) were risk factor with marginal significance for poor OS. Summary/Conclusions: These findings revealed that AML with inv(3)/t(3;3) had dismal outcome even after allo-HSCT. Multivariate analysis suggested that a myeloablative conditioning regimen might improve the transplantation outcome.

E1523
PHARMACOKINETICS (PK) OF PROPYLENE GLYCOL-FREE MELPHALAN HCL (PG-FREE MEL) IN MULTIPLE MYELOMA (MM) PATIENTS UNDERGOING AUTOLOGOUS TRANSPLANTATION (AHCT)

Background: Melphalan (MEL) is the most commonly used conditioning agent in AHCT for MM and exhibits a dose response relationship (Nath CE Br J Clin Pharmacol. 2010 May; 69(5):484). PG-free MEL (Evolena™) has longer stability in solution, results in a slightly higher systemic exposure compared with standard MEL and eliminates propylene glycol administration during high dose melphalan-based conditioning. This agent was shown to be bioequivalent to conventional melphalan leading to successful myeloablation and engraftment in MM pts receiving AHCT with no transplant related mortality or unexpected toxicity leading to its FDA approval (Hari P Biol Blood Marrow Transplant. 2015 Dec; 21(12):2100). Published studies thus far have used PG-free MEL in 2 consecutive daily doses of 100mg/m²/day while a single daily conditioning dose of 200mg/m² (MEL200) is most commonly used in clinical practice. Aims: Determine the safety and PK variability of high dose PG-free MEL 200mg/m² in patients undergoing AHCT for MM Methods: Open-label phase II study in which 10 serial blood samples at specific time points for the PK evaluation of melphalan were collected immediately prior to and after receiving single 200mg/m² dose of PG-free MEL on day -2 as a 2mg/ml solution. The primary objective was a descriptive analysis of melphalan PK while secondary objectives included the response rates, engraftment and the toxicity and safety profile of PG-free MEL conditioning. Results: As of Feb 2017, a total of 24 pts. were enrolled (63% male) with a median age of 67 years (range 46-72), including 23 (96%) who received upfront AHCT and 1 (4%) after relapse (Figure 1). High-risk cytogenetics was present in 6 (25%) pts 25% were in ISS stage 3. Disease status at transplant was complete remission (CR) in 2 (8%) and PR in 8 (33%). AHCT was performed entirely as outpatient in 25%. PK data are available for the first 12 pts at this time. Wide variability in MEL exposure was noted with maximum plasma concentration (Cmax) of 10,100 ng/ml, median Cmax 7750ng/ml (range, 5220-10,100) and median area under the concentration- time curve (AUC) of 561500 ng.min/ml (range, 771000-254000). Mean AUC was 549000 ±155000). No grade 4 non-hematologic toxicities or gastrointestinal toxicities were observed including in patients with Cmax >10,000 (upper quartile of distribution) or AUC>625000. All patients are alive and post-transplant responses in those with at least 100 days of follow up indicate sCR/CR in 60% and VGPR in 30%. Summary/Conclusions: PG-Free MEL can be safely administered as a single 200mg/m² dose in conditioning with a favorable toxicity profile. Considerable variability in the PK parameters of high dose MEL indicate that PK directed MEL dosing could be used to optimize MEL exposure. The safety profile of PG-free MEL indicates no increase in mucosal toxicity or adverse events seen even in subjects with highest levels of MEL exposure. For patients in the lowest quartile of AUC, increased PG-free MEL doses up to 20 to 40% over 200mg/m² may be safely attempted without additional toxicity if PK directed dosing is used to ensure adequate MEL exposure and utilize the dose response effect of MEL.

Figure 1.
remaining, both CD4+ and CD8+ subpopulations remained low and these patients were prone to develop relapse. These findings underscore a putative function of CD8+ T-cells in eliminating post-transplant residual disease and maintaining the patients disease free.

**E1525**

COMPARISON OF TEMAC AND BEAM HIGH-DOSE CHEMOTHERAPY FOLLOWED BY AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN LYMPHOMA: EFFICACY AND TOXICITY

F. Sahin1,*, P. Patir1, N. Akad Soyer1, R. Durusoy2, G. Saydam1, M. Tobu1, M. Tombuloglu1, F. Vural1
1Hematology, Ege University Hospital Internal Medicine, 2Public Health, Ege University, Bornova, Turkey

**Background:** High-dose chemotherapy conditioning regimens followed by autologous hematopoietic stem cell transplantation (AH SCT) generally provide good results in relapsed and refractory lymphomas.

**Aims:** Limited data are available to guide the choice of conditioning regimen before AH SCT for patients with lymphoma. We evaluated the efficacy and safety of TEMAC and BEAM regimens as conditioning with autologous stem cell support in patients with relapsed/refractory lymphomas.

**Methods:** From July 2011 to October 2016, 64 pathologically confirmed lymphoma patients underwent AH SCT with BEAM (n=32) or TEMAC (n=32) regimens in Hematology Division of Ege University Faculty of Medicine. Patients considered as high risk at diagnosis or with relapsed or refractory diseases were eligible for AH SCT. The two groups were well matched in terms of age, gender, histology. Patients were conditioned with TEMAC (thiotepa [40mg/m2 x four days], etoposide [200mg/m2 x four days], cyclophosphamide [60mg/kg x one day], cytarabine [200mg/m2 x four days] and melphalan [80mg/m2 x two days]) or BEAM (carmustine [300mg/m2 x one day], etoposide [200mg/m2 x four days], cytarabine [200mg/m2 x four days] and melphalan [140mg/m2 x one day]) regimens.

**Results:** The estimated 22-months overall survival for the TEMAC and BEAM groups were 53% and 63%, respectively (p=0.41). The estimated 22-months progression-free survival in the BEAM group (59%) was relatively inferior to the TEMAC (74%) group, but the differences were not significant (p=0.98). Cardiotoxicities were relatively more common in the BEAM group. No differences were observed in the time to hematopoietic recovery, the duration of hospitalization, hematological and nonhematological toxicities.

**Summary/Conclusions:** We conducted a single-center retrospective on lymphoma patients undergoing AH SCT, comparing efficacy and toxicity of TEMAC and BEAM conditioning regimens. These two regimens are all optional high-dose chemotherapy with favorable efficacy and acceptable toxicity.

**E1526**

GENETIC MARKERS OF THE NEUTROPHIL DURATION AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA

E. Nazarova1,*, M. Horobryh2, V. Shardakov3, V. Dem'janova1, V. Zorina2, N. Minaeva3, I. Paramonov3
1Laboratory of Immunology of Leukemia, 2Department of chemotherapy and bone marrow transplantation, 3Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

**Background:** The successes achieved in the treatment of multiple myeloma (MM) in the past few years, associated with the use of high-dose chemotherapy, and with the use of new drugs. Using high-regimes with subsequent autologous hematopoietic stem cells (auto-HSCT) has increased both overall and progression-free survival of patients with MM, as well as improved quality of life. In most cases, patients in the early post-transplant period have severe toxic and infectious complications of varying severity that requires resource-intensive supportive care. The duration of the period of hematopoiesis hypoplasia is dependent on many factors, and an average of 14-16 days. In turn, the attachment of infectious complications in some cases adversely affect the duration of neutropenia.

**Aims:** To evaluate the possible association of the immune response genes mutation status to the duration of neutropenia after autologous transplantation of peripheral blood stem cells in patients with multiple myeloma.

**Methods:** The study included 19 patients with multiple myeloma at the age of 32 to 67 years (median - 52 years) who underwent autologous transplantation of hematopoietic stem cells after conditioning regimen with high-dose melphalan. Among surveyed: 8 men and 11 women. In accordance with staging for Durie-Salmon (DSS) system in patients following stages of MM were installed: stage 1A in one patient (5.2%), stage 2A - in 12 patients (63.2%), stage 2B - in two patients (10.5%) and stage 3A - in four patients (21.1%). In the pre-transplantation period, partial remission of the disease was achieved in seven patients (36.8%), very good partial remission - in eight patients (42.1%) and complete response in four patients (21.1%). Genotyping of polymorphisms of the innate immune response genes TLR2 (rs5743708), TLR3 (rs3775291), TLR6 (rs5743810), TLR9 (rs5743836), IL1β (rs2856841), IL2 (rs2069762), IL4 (rs2245250), IL6 (rs1800795), IL10 (rs1800871), IL17A (rs2275913), CD14 (rs34424920), TNFa (rs1800629), FCGR2A (rs1801274) was performed by polymerase chain reaction with allele-specific primers (LifeTech, Russia) at the time of diagnosis.

**Results:** Depending on the duration of the neutropenia period all examined are divided into two groups. The first group included 10 patients with MM who have early observed recovery (within the first 13 days, 11-13 days), the number of leukocytes ≥1000 cells per ml after auto-HSCT. The second group consisted of nine patients with agranulocytosis held more than two weeks (≥14 days, 14-19 days). When comparing the genotyping data found that a longer period of neutropenia after autologous HSCT was significantly associated with the presence in genotype of MM patients homzygotic wild-type allele A gene IL17A at position -197 (OR 13.15, 95%CI: 0.60-288.34, p=0.03) and with a predominance of heterozygous mutant allele C of the gene IL1β at position -31 (OR 8.17, 95%CI: 1.03-67.94, p=0.04).

**Summary/Conclusions:** Our findings point to immune response genes involved in the rate of recovery of hematopoiesis in MM patients after autologous HSCT. Identification of the wild-type allele in intron gene IL17A (G-197TA) and mutant allele in intron gene IL1β (T-31C) will predict the risk of prolonging the period of agranulocytosis and, consequently, the risk of post-transplant complications, and develop a personalized strategy of managing them.

SUCCESSFUL TREATMENT WITH GRANULOCYTE TRANSFUSION AND EARLY NEUTROPHIL ENGRAFTMENT IN ALLOGENIC TRANSPLANT PATIENTS WITH FEBRILE NEUTROPHENIA

A. Ünal1,*, L. Kaynar1, N. Kem1, A. Birekül1, E.E. Turak1, S. Sivgin1, B. Eser1, M. Çetin1
1Erciyes University Medical School, Kayseri, Kayseri, Turkey

**Background:** Febrile Neutropenia is very severe and urgent early complication after bone marrow transplantation before engraftment. Infection delays engraftments. In this study we retrospectively evaluated the effect and outcome of Granulocyte transfusion on febrile neutropenia and neutrophil engraftment in patients receiving allogeneic transplantation.

**Aims:** Between 2015-2016, five patients receiving allogeneic bone marrow transplantation (BMT) were treated with granulocyte transfusion at the time of febrile neutropenia before engraftment. The reasons for the use of the granulocyte transfusion were prolonged febrile neutropenia episode.

**Methods:** Five AML patients underwent allogeneic transplantation. Three of them transplanted from match sibling donors, one from unrelated donor, and one from (7/10) mismatch mother (haploidentic transplant). They had febrile neutropenia after transplantation, before engraftment. They were given antibacterial and antifungal prophylaxis. Before the granulocyte transfusion, on the 13th-18th days of transplantation, their neutrophil counts were 0.03-0.08 x 10⁹/μl.

**Results:** We started Granulocyte transfusion for three days. Granulocyte was collected from unrelated and same blood groups donors. Mean infused gran-
unilocyte counts were 3.6x10^9/1 (1.3-4x10^9/1/day). Twenty-four hours after granulocyte transfusion, mean neutrophil counts were 0.6x10^9/3/dl (0.4-0.8x10^9/3/dl). Neutrophil counts were 2.6x10^9/3/dl (1.7-2.6x10^9/3/dl), after 48 hour. After 72 hours, neutrophil counts were 3.4x10^9/3/dl (2.1-4.5x10^9/3/dl). After 4th days of granulocyte transfusion, neutrophil counts were normal levels (>0.5x10^9/3/dl).

Summary/Conclusions: Granulocyte transfusions during the febrile neutrope-nia, helped to better overcome febrile neutropenia periods in allogeneic trans-plant patients before engraftment. In addition, granulocytes transfusion also may help early neutrophil engraftments.

E1528 DEFIBRITODE FOR THE PREVENTION AND TREATMENT OF HEPATIC VENO-OCLUSION DISEASE AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION; A SINGLE CENTER EXPERIENCE
B. Aitnmen1,2, I. Sasmaz2,2, B. Karagun1, M. Serbest1,2
1Pediatric Bone Marrow Transplantation Unit, Department of Pediatric Hema-tology, Adana Acibadem Hospital, 2Pediatric Hematology, Cukurova University, Adana, Turkey

Background: Hepatic veno-occlusive disease (VOD) is a common and serious complication of hematopoietic stem cell transplantation (HSCT) in children. We aimed to assess prospectively the use of prophylactic defibrotide in pediatric patients undergoing HSCT.

Aims: We aimed to assess prospectively the use of prophylactic defibrotide in pediatric patients undergoing HSCT.

Methods: In this study, 113 patients who underwent HSCT were given defibrotide prophylaxis as 25mg/kg per day in four divided intravenous infusions over 24h, starting on the same day as the pretransplantation conditioning regi-ment. The mean duration of use of defibrotide is 25 days as a prophylaxis.

Results: In this study, 113 patients were recruited, 66 male patients and 47 female patients, with the average of 9.1 years, range 1-20; 8% infants, 55% children and 37% adolescent. There were 50 patients with thalassemia major, 41 patients with leukemia, 11 patients with aplastic anemia, one patient with Diamond Blackfan anemia, two patients with congenital dyserythropoietic anemia, one patient with osteopetrosis, four patients with familial hemophagocytic lymphohistiocytosis, two patients with severe immune deficiency and one patient with Kostman syndrome. All transplants were allogeneic. No serious side effects of defibrotide patients developed clinical VOD (Seattle crit-e-ria). In these patients, defibrotide dose was increased to a treatment dose of 40-60mg/kg per day. One infant patient with Kostman syndrome died due to hepatic and pulmonary veno-occlusive disease. After 36 months of follow up, 7 patients who developed VOD are being well and no patient have transplant related complications.

Summary/Conclusions: Hepatic veno-occlusive disease, which is caused by hepatocyte and sinusoidal vessel endothelium damage, can occur early after HSCT, and in its severe form, may lead to liver failure, hepatorenal syndrome, portal hypertension, and eventually death from multorgan failure. In this prospective study, we demonstrated that the use of defibrotide is safe and effective in preventing and treating VOD in pediatric patients at high risk.

E1529 ACUTE RENAL IMPAIRMENT IN ALLOGENIC STEM CELL TRANSPLANT RECIPIENTS, A PREDICTOR OF MORTALITY
A. J. Mahdi1, D. Foxwell1, G. Scot1, D. Davies1, K. Wilson1, W. Ingram1, 1Department of Haematology, 2Department of Nephrology, University Hospital of Wales, Cardiff, United Kingdom

Background: Allogeneic stem cell transplant (ASCT) remains the only curative option in many malignant and non-malignant conditions. There remains however, an unmet need for improved morbidity and mortality. One risk, acute kidney injury (AKI), can result from drug toxicity and/or haemodynamic instability from sepsis and/or graft vs host disease (GVHD). Existing reports on the impact of AKI have focused mainly on patients undergoing mainly myeloablative (MA) conditioning regimens and improvements in supportive care, have allowed offering allogeneic transplantation to more and older patients (pts). A balanced risk-benefit approach of candidates for allo-HSCT is the key for maximized chances of cure with acceptable quality of life.

Aims: To investigate the incidence, causes and consequences of AKI in patients undergoing ASCT, including survival.

Methods: The prospectively maintained database of the South Wales Blood and Marrow Transplant programme which serves 77% of the Welsh population, was interrogated to identify patients undergoing ASCT from January 2010 to December 2015. Patients received ciclosporin as GVHD prophylaxis to 100 days post ASCT and weaned thereafter in the absence of GVHD. Serum creatinine and derived estimated glomerular filtration rate (eGFR) acted as the main assessment of renal function. The Acute Kidney Injury Network classification was used to grade acute kidney injury (AKI). Causes of AKI were assigned after independent review of clinical notes and relevant laboratory data. Patients undergoing second ASCT were excluded. Statistical analysis was carried out using SPSS, version 23 including COX regression and Kaplan-Meier survival analysis.

Results: A total of 229 patients were identified (MA=n=35, 15%;RIC=n=194, 85%). Acute myeloid leukaemia was the most common indication (n=103, 45%). Mean age at ASCT was 51 years (18-72 years). Median follow up after ASCT was 21.9 years (range 9-66.6 years). Overall survival to 100 and 365 days was 93% and 74% respectively. Pre-existing renal impairment was uncommon (mean eGFR 62ml/min, range 45-143ml/min). During the first 100 days, no dif-ferences were seen in mean eGFR in survival vs non-survival groups (75 and 80ml/min respectively, p=0.23). Amongst all patients, AKI incidence in the first 100 days was greater in the non-survival group (93.2% vs 80.6%, p=0.02). On multivariate analysis, AKI event in the first 100 days and HLA mismatch (<8/8) were independent factors predicting mortality (p=0.02 and p=0.04 respectively).

Figure 1.

A. Solé Magdalena1, S. González Muñiz1, A.P. González Rodríguez1, 1Pediatr. Hémato-oncología, 1Pediatr. Nefrología, 1Hospital Universitario Ramón y Cajal, 2Instituto de Investigación Biomédica de la Complexión Hospitalaria de Madrid, 3Madrid, Spain, June 22 – 25, 2017
in the low, intermediate, high and very high risk groups, respectively, showing a clear distinction by categories (p<0.038) (figure 1). Refraining realease, 44 (28.6%) of the patients in the defibrotide expanded-access program had VOD/SOS diagnosed by investigators using Baltimore criteria (bilirubin ≥2mg/dL and ≥2 of: hepatomegaly, ascites, ≥5% weight gain), modified Seattle criteria (≥2 of: bilirubin >2mg/dL, hepatomegaly, or ascites and/or ≥5% weight gain), or biopsy. The median age was lowest in patients with bilirubin <2 (20.4% of patients); median age in other groups ranged from 15 to 17 years. Kaplan-Meier estimated Day +100 survival in all HSCT patients was 58.9%, with 85.6% in patients with BR <2; other bilirubin groups were older and survival estimates decreased (Table 1). In the pediatric (aged ≤16 years) and adult (aged >16 years) patients, survival was similar (Figure 1). Estimated survival rates were lower for patients with MOD across all groups. Of all 1000 HSCT patients with confirmed VOD/SOS, 210 (21%) had treatment-related AE(S) (TRAE(S)). The TRAEs in ≥2% of patients were pulmonary hemorrhage (4.6%), gastrointestinal hemorrhage (3.0%), epistaxis (2.3%), and hypotension (2.0%).

Summary/Conclusions: This post-hoc analysis found that higher bilirubin levels were generally associated with lower Day +100 survival. These results should be interpreted with caution, as only 1 EBMT criterion was analyzed. MOD was also associated with lower Day +100 survival. The results suggest that diagnosis and treatment of VOD/SOS, before bilirubin becomes markedly elevated, may be associated with improved outcome.

Support: Jazz Pharmaceuticals.
Aims: In this analysis, we extended the follow-up of our trial.

Methods: SC was prospectively enrolled in a national multi-center prospective phase II trial to evaluate the efficacy of upfront consolidation of clinical response with autologous (auto) or allogeneic (allo) stem cell transplantation (SCT) in patients at diagnosis. The results were previously reported (4 year PFS of 70% and 69% for auto and allo SCT, respectively) (Corradi P. 2014).

Results: Only 37 patients underwent transplantation (autologous SCT (n=14), allogeneic SCT (n=23)) whereas 24 did not for toxicity (n=5), progressive disease (n=18) or clinical decision (n=1). In intention to treat analysis, at a median follow-up of 78 months, the estimated 7-years progression-free survival (PFS) and overall survival (OS) were 30% (95% CI, 21% > 40%) and 62% (95% CI, 48% > 72%) respectively. Despite auto or allo SCT consolidation was chosen based on donor availability, the majority of patients allografted had a diagnosis of PTCL-NOS (19 of 23 (83%) versus 6 of 14 (43%) autografted, p=0.02). The PFS for auto OS were not significantly different in patients transplanted with a related compared to unrelated donor (PFS: 48% (95%CI, 32% > 62%) versus 33% (16% > 51%) (p=0.26); OS: 50% (95% CI, 33% > 64%) versus 30% (13% > 49%) (p=0.36)). Considering only the patients who underwent a consolidation with an SCT after auto SCT, the PFS for auto allo SCT comparisons were too small to be conclusive (PFS: 32% (95% CI, 11% > 55%) versus 41% (95% CI, 28% > 53%), p=0.39) and 30% (95% CI, 17% > 45%) versus 38% (18% > 58%) (p=0.68). We did not observe a significant difference in OS between auto or allo consolidation 69% (95% CI, 51% - 88%) versus 63% (38% > 79%) (p=0.51), but 3 patients in relapse after auto SCT were allografted. The main cause of failure after auto SCT was relapse (6 of 14, last relapse occurring at 81 months after auto). The Cumulative Incidence of non-relapse mortality and relapse after allo SCT were 19% (n=4 deaths, one patient died of cardiac complication 62 months after allo SCT) and 17% (n=4 deaths, respectively).

Summary/Conclusions: The long-term outcome of patients receiving any transplantation strategy remains satisfactory. In the future, biological markers could help physician to select the better therapeutic option for the patients.

E1535

POLIMORPHISMG IN TGFBI GENE PREDISPOSES TO RELAPSE AND DEVELOPMENT OF ACUTE GRAFT-VERSUS-HOST DISEASE GRADES III-IV

N. Meggyesi1,*, P. Kovy1, V. Telek1, K. Balassa1,2,*, L. Varga1, A. Barta1, P. Kazár1, A. Batsai1, E. Topolygó1, L. Gopcsa1, L. Lengyel1, A. Barta1, A. Tor- da1, T. Masszsi2, H. Andrikovics1,2
1Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, 2School of Phd Studies, Semmelweis University, 3Department of Haematology and Stem Cell Transplantation, St. Istvan and St. Laszlo Hospital, 4Department of Pathophysiology, 3rd Department of Internal Medicine, Semmelweis University, Budapest, Hungary

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the most effective treatment option for certain hematological malignancies. Cytokines play a well established role in the mechanism of acute GvHD (aGvHD), which is one of the most significant complications allo-HSCT. rs6257 transforming growth factor B1 (TGFBI) is one of the inflammatory cytokines, which play a pivotal role in the development of aGvHD.

Aims: The aim of this study was to investigate the role of TGFBI -1347C>T polymorphism in the outcome of HSCT.

Methods: We examined the association of recipient and donor TGFBI -1347C>T and allo-HSCT outcome in a cohort of 419 adult patients who underwent first allo-HSCT between January 2007 and December 2013 at our single center. 217 patients received stem cells from their siblings, 202 patients from matched unrelated donors (MUD). For identification of TGFBI rs1800496 genotyping DNA LightCycler melting curve analysis (LightCycler 480II, Roche Diagnostics) was performed.

Results: We did not find any association between recipients’ TGFBI -1347C>T polymorphism and HSCT outcome. However, in patients whose unrelated donors carried homozygous TGFBI -1347TT variant, aGVHD grades III-IV occurred more frequently (aGVHD grade III-IV: 28.9% vs aGVHD grade 0-II: 9.6% p=0.006). Similar finding was observed on a subgroup of patients with acute leukemia: in aGVHD grade III-IV 37.5%, while in grade 0-II 11.5% of patients had TT genotype (p=0.022). Donor TT genotype did not influence the relapse rate significantly. Patients with MUD carrying TT genotype had lower overall survival (OS) that of donors bearing at least one C variant, but the difference did not reach the level of significance (OS at 40 month for CC and CT variant donors: 45.3% and for TT donors: 26.2%). In case of sibling donors, we did not find association between recipient or donor genotype and aGVHD, but relapse rate was increased if donor had at least one T variant (n=115, 67.9% vs 32.1%, p=0.028). Significant differences in OS between the subgroups with different genotypes were not observed.

Summary/Conclusions: Our findings suggest that TGFBI -1347C>T polymorphism in HSCT donors might influence the development of aGvHD in unrelated and the relapse rate in related HSCT.
Background: Live-vaccines should be avoided in the early period following allogeneic hematopoietic cell transplantation (HCT), due to a possible uncontrollable proliferation of the attenuated strains. The post HCT immune system is severely compromised by pharmacological immunosuppression and disruption of lymphoid tissues by conditioning and donor T cell alloreactivity. Patients frequently lost their antibody-based immunity against measles, mumps, and rubella after receiving allogeneic HCT.

Aims: Here, we studied the dynamics of antibody (AB) titers against measles, mumps, and rubella post-HCT.

Methods: We retrospectively analyzed serologic AB titers in 240 patients who underwent allogeneic HCT from related and unrelated HLA-matched donors from 2002-2014 at our center. AB titers against measles, mumps and rubella were measured prior to HCT, at 6 months (m), and every year (y) post-HCT.

Results: Most patients had protective AB titers (measles 90%, mumps 86%, rubella 92%) prior to HCT. AB protection against mumps was lost in a substantial proportion of patients after HCT (protective AB titers in 72%@1y, 56%@5y, 50%@8y), comparing to AB against measles, which persist more frequently (protective AB titers in 85%@1y, 74%@5y, 73%@8y). We found a faster loss of protective AB in the first years for patients given a myeloablative conditioning (MAC) in comparison to patients with reduced condition (RIC), but the proportion of seropositive patients became more equal over time (Figure 1 displays the percentage of seropositive patients to Measles AB given MAC or RIC during 8 years post-HCT). The proportion of patients who retained protective AB titers at 5y post-HCT was higher in recipients of mobilized peripheral blood compared with bone marrow (BM) grafts (measles p=0.01, mumps=0.06, rubella p=0.08). For rubella, absolute AB titers were available. Patients with lymphoid malignancies, ongoing GVHD and pharmacological immunosuppression had a steeper decline of rubella AB titers as compared to patients with myeloid malignancies.

Summary/Conclusions: We found a marked decline of AB titers post-HCT with loss of protection in a substantial proportion of patients. Surprisingly, BM grafts did not provide better AB protection post-HCT, despite their higher content of (donor) plasma cells. Together with the observations that (i) patients with lymphoid malignancies (who have received (B-) lymphocyte targeted therapies prior to HCT) had lower AB levels, while (ii) those given reduced intensity conditioning have a higher percentage of protective AB levels in the first years, our data suggest, that residual host plasma cells significantly contribute to AB levels in the first years post-HCT. In opposite, the loss of protective AB levels in later years after transplantation was independent of the toxicity of the conditioning regime and may be a effect of weakening signaling for host plasma cells or late donor alloreactivity.

**Figure 1.**

Summary/Conclusions: We found a marked decline of AB titers post-HCT with loss of protection in a substantial proportion of patients. Surprisingly, BM grafts did not provide better AB protection post-HCT, despite their higher content of (donor) plasma cells. Together with the observations that (i) patients with lymphoid malignancies (who have received (B-) lymphocyte targeted therapies prior to HCT) had lower AB levels, while (ii) those given reduced intensity conditioning have a higher percentage of protective AB levels in the first years, our data suggest, that residual host plasma cells significantly contribute to AB levels in the first years post-HCT. In opposite, the loss of protective AB levels in later years after transplantation was independent of the toxicity of the conditioning regime and may be a effect of weakening signaling for host plasma cells or late donor alloreactivity.

**E1536 EARLY AND LATE LOSS OF PROTECTIVE ANTIBODY LEVELS AGAINST MEASLES, MUMPS AND RUBELLA IN PATIENTS GIVEN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION**

M.-J. Apithy1,*, A. Charbonnier2, J. Desoutter1, P. Morel2, J.-P. Marolleau2, N. Guillaume1

1Hematology, 2Pathology, University Hospital Zurich, Zurich, Switzerland

Background: Here, we evaluated, whether recipient MICA and donor NKG2D polymorphisms identified alleles associated with a low (NKC3 C/C and NKC4 C/C) or high cytotoxic activity (NKC3 G/G and NKC4 T/T).

Aims: In this study, we hypothesized that polymorphisms at the MICA and NKG2D loci are associated with adverse outcomes in HSCT.

Methods: We designed the MICA A5.1 alleles with a premature stop codon. Moreover, NKG2D polymorphisms have no significant impact on OS and RFS in our study (median of follow up=15 months; range 0.2-49 months).

Summary/Conclusions: Our data suggest that a MICA or NKG2D low activity status can be related to an increase of acute GVH according to a mechanism that remains to be elucidated, maybe by a low cytotoxic activity on recipient dendritic cells.

**E1537 MICA AND NKG2D POLYMORPHISMS HAVE A SIGNIFICANT IMPACT ON GRAFT VERSUS HOST DISEASE AFTER HLA-MATCHED HEMATOPOIETIC STEM CELL TRANSPLANTATION**

J. Sögehezli1,*, E. Haralambleva2, M.G. Manz1, U. Schanz1, A.M. Müller1

1Hematology, 2Pathology, University Hospital Zurich, Zurich, Switzerland

Background: Live-vaccines should be avoided in the early period following allogeneic hematopoietic cell transplantation (HCT), due to a possible uncontrollable proliferation of the attenuated strains. The post HCT immune system is severely compromised by pharmacological immunosuppression and disruption of lymphoid tissues by conditioning and donor T cell alloreactivity. **E1538 STEM CELL TRANSPLANTATION WITH MYELOABLATIVE CONDITIONING USING TIMED SEQUENTIAL BUSULFAN IMPROVES OUTCOMES IN OLDER AML AND MDS PATIENTS**

B. Ora1,*, R. Saliba1, S. Ahmad1, A. Alousi1, S. Ciurea1, C. Hosing1, I. Khouri1, D. Marin1, A. Olson1, Q. Bashir1, Y. Niel1, K. Rezvan1, P. Kebriaei1, B. Valdez1, E. Shpillar1, B. Andersson1, R. Champlin1, U. Popat1

1Stem Cell Transplantation and Cellular Therapy, The University of Texas MDACC, Houston, United States

Background: Here, we evaluated the outcomes of patients with AML and MDS who received a myeloablative Bu regimen, which is used as standard (ST) for older patients at our center.

Aims: To assess its impact on survival, we compared the outcomes of older patients treated with the ST Bu (ST cohort) and the reduced intensity conditioning with Flu/Bu regimen, which is used as standard (RIC cohort) for older patients at our center.

Methods: Patients in the ST cohort received Flu 40mg/m²/d followed by IV Bu daily for 4 days (day -6 to -3) to achieve a total Bu course AUC of 16,000μmol-min based on PK studies. Patients in the ST cohort received Flu 40mg/m²/d followed by IV Bu daily for 4 days (day -6 to -3) to achieve AUC of 16,000μmol-min. Patients with AML or MDS were eligible for the study if they had adequate organ function, had matched related or unrelated donor and were treated between Jan 2012 and Dec 2017.

Results: Patient characteristics including age, sex, disease status, cytogenetic risk group, donor type, graft source CMV status and comorbidity were similarly distributed between the two cohorts. Median age was 66 and 65 years in TS-MAC and RIC cohorts respectively. Overall survival (OS) and progression free survival (PFS) were significantly better in the TS-MAC cohort. This was due to a reduction in the disease progression without any increase in the TRM. After adjusting for other covariates, the multivariate analysis for PFS confirmed longer PFS with TS-MAC regimen (HR: 0.36; P=0.003). The benefit was mainly seen in patients with a comorbidity score ≤3.

**Summary/Conclusions:** The myeloablative timed sequential Bu regimen improves survival and appears promising in older patients with AML/MDS.
E1539

HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH DEPLETION OF TCR ΑΒ (+) IN CHILDREN: ERCIYES PEDIATRIC BMT CENTER

M. Karakuçu1, E. Unal1, E. Yılmaz2, A. Ozcın1, S. Kosel1, G. Ucan1, T. Patiroğlu1,* 1Department of Pediatrics, Division of Pediatric Hematology Oncology, Erciyes University, Faculty of Medicine, Kayseri, Turkey

Background: Recently, haploidentical hematopoietic stem cell transplantation (HSCT) poses an alternative option for patients without a suitable donor. Erciyes Pediatric BMT Center is the first pediatric center for haploidentical HSCT with depletion of TCr αβ (+) in Turkey.

Aims: We would like to share our pediatric experience with a follow up period of 7 years.

Methods: All children who underwent haploidentical HSCT in our center from December 2012 to February 2017 were included in the study. Total 51 haploidentical HSCT in 44 children (17 relapsed/refractory ALL, 9 relapsed/refractory AML, 4 SAA, 4 HLH, 2 Fanconi aplastic anemia, 2 Griscelli syndrome, 1 JMML, and 5 SCID) were performed. Transplantation-related mortality (TRM) was 13.7%. The regimen included ATG, Fludarabine, Thiotepa, Melphalan. Mycophenolate mofetil (MMF) was given as GvHD prophylaxis if the graft contained>5 x10^10/kg TCR αβ (+).

Results: The mean of collected CD34 cells were 18.60 (range 3.98-43.66) x 10^6/kg. The graft had a purity of 99.9% TCRαβ depletion with a median of 0,257 (range 0.003 to 1.47) x 10^5 TCRαβ cells. The median engraftment days for myeloid and platelet were both 12th day of HSCT (range 7 to 28, 9 to 33 day) respectively. Grade II skin GvHD was detected in 8 patients, and treated with steroids without any further complications. However grade III, and grade IV gastro-intestinal GvHD were observed in three patients. Although the patients with gastrointestinal GvHD were treated with steroid, buedoxon, cyclosporine, MSC; one patient did not respond and died. MMF was given as GvHD prophylaxis in 36 patients and 15 patients did not receive any immune suppressive drug. The mean day of discharge was 34th day of HSCT. The long term follow up revealing immunological reconstructions were performed in 18 patients.

The analysis of the immune reconstitution of the patients transplanted in haploidentical HSCT group showed a rapid immune reconstitution for CD3+ T cells 732 (range 126-2432)/mm3; for CD4+ helper T cells 92 (range 1-419)mm3; CD8+ cytotoxic cells 310 (range 95-2235)/mm3 at 28th day of HSCT. Twenty nine patients are currently alive, with a median follow up of 22 months (range 1 to 49 months). Overall survival was 65.9% in this group.

Summary/Conclusions: Our primary results underline that haploidentical HSCT with depletion of TcR αβ (+) can be an option in experienced center in countries which unrelated donor programs are not satisfactory, as in Turkey. The availability of a haploidentical donor in most families is a potential advantage. Moreover probably more potent graft-versus tumor effect can be induced with haploidentical HSCT.

E1540

SECONDARY MYELODYSPLASTIC SYNDROME AND/OR ACUTE LEUKEMIA INCIDENCE AFTER AUTOLOGOUS TRANSPLANTATION FOR LYMPHOMA PATIENTS IS CONNECTED WITH DECREASE OF HEMATOPOIETIC RESERVE

M. Tmínek1,2, M. Tmínková1, D. Pohlreich1, B. Vacková1, Z. Gasova1, R. Pytlík1, P. Blahova1,1
1Charles University General Hospital, 2Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Secondary myelodysplastic syndrome and acute myelogenous leukemia (sMDS/AML) is one of the most important long term complication of high dose therapy (HDS) with autologous stem cell transplantation (ASCT). The factors usually described to be associated with sMDS/AML development are pretreatment, HDS itself, radiotherapy, age and recently the evidence of TP53 mutations (Wong, Nature 2015) or clonal hematopoiesis (Gibson, JCO 2016) was reported as an independent risk factor for sMDS/AML.

Aims: The aim of the study was to analyse the incidence and risk factors for sMDS/AML after HDT and ASCT for lymphoma.

Methods: Patients who underwent HDT with ASCT for lymphoma in one centre since 12/1993 till 7/2016 were analysed. Pretreatment characteristic, graft quality, engraftment characteristics were included into analysis. Patients were censored at the time of death or alogeneic stem cell transplant. Pearson, Kaplan Maier, log-rank and Cox regression test were used.

Results: Altogether 728 pts underwent ASCT for lymphoma in given time period. 216 pts (29.9%) consisted of sMDS/AML (sMDS, 6%; T-NHL (n 43) and 16% HL (n 119), 58% were men, age median at the transplant was 49 years (18-71). The median of previous lines was 2 (1-9). The stem cell collection was performed after chemotherapy and G-CSF mobilization in most cases, 19 pts were mobilized by G-CSF only and bone marrow only was used in 4 pts. The target CD34 cells dose was 3 x10^6/kg. The median number of apheresis was 2 (1-12). At the time of ASCT 90.6% of patients had chemosensitive disease (51.1% CR) and 9.4% were transplanted for chemoresistant disease. Tandem HDT and ASCT was used in 36 pts, BEAM was the most frequent HDT regimen (92.5%, 15 pts received ibritumomab tiuxetan and BEAM), the total body irradiation was used only in 4 pts, the rest of the patients received other chemotherapy regimens (CPB, thiotepa based, ICE and others). All pts except 4 received peripheral blood progenitor cells (PBPC) with median CD34 dose 6.8x10^6/kg (0.4-115.5). BM was used in 22 cases (in 18 together with PBPC). G-CSF was administered from day +1. Involved or extended field radiotherapy either during pretransplant therapy or in the period after ASCT was used in 37.7% of pts. With median follow-up 7.2 years there were observed 19 cases of sMDS/AML. The cumulative sMDS/AML incidence was at 5, 10 and 15 years 2.7%, 4.0% and 5.3% (figure A) in all lymphoma pts, 3.3% at 5,10 and 15y in HL pts, and 2.6%, 4.3% and 6.3% in NHL pts (figure B). There was significantly increased sMDS/AML incidence in pts with 3 previous lines (7.7% vs 1.9% at yr 3, HR 3.9, p 0.005), in pt's group with chemoresistant disease (8.1% vs 2.3%, HR 3.5, p 0.05), in CD34+ dose<3.0x10^6/kg (14.3% vs 2.5% at 5y, HR 4.9, p 0.05), in BM reinfused group (13.7% vs 2.5% at 5y, HR 4.7, p 0.05), in patients with prolonged platelet engraftment above 20x10^9/l - ³15 days vs 5.4% vs 3.0% vs 0.9%, p 0.05). There was no difference between groups of NHL and HL, with and without radiotherapy, according to the apheresis number or neutrophil engraftment. In multivariate analysis in the whole cohort the independent risk factors were number of previous therapy lines, disease status at ASCT and the speed of platelet engraftment (p<0.05). For NHL only number of previous therapy lines (p<0.05), for HL number CD34+cell infused, use of BM as the progenitor cell source and disease status (p<0.05).

Figure 1.

Summary/Conclusions: The risk of sMDS/AML was 4.0% at 10y after ASCT and was connected with heavier pretreatment, which leads to the decrease of BM reserve, hematopoietic clonal development. The lower dose of CD34+ cell, and necessity to use BM progenitor cell and prolonged platelet engraftment could be considered as clinical markers of these biological processes.

E1541

USE OF DEFIBROTIDE TO TREAT TRANSPLANT-ASSOCIATED THROMBOTIC MICROANGIOPATHY

M. Martínez-Muñoz1,2, A. Lario G1, B. Gautista1, J. Bueno1, B. Navarro1, A. Mbadigela1, J. Cabrera1, R. Duarte1
1Hospital Universitario Puerta de Hierro Majadahonda (Madrid), Majadahonda, Spain

Background: Transplant-associated thrombotic microangiopathy (TA-TMA) is a severe early transplant complication which results from endothelial injury and it exhibits characteristics of an atypical hemolytic uremic syndrome. Beyond removal or treatment of precipitating factors and, more recently, treatment with eculizumab, TA-TMA remains a therapeutic challenge. Defibrotide, with marked protective effects on the endothelium and the potential to restore thrombin-fibrinolytic homeostasis in small vessels, may be considered a therapeutic option for TA-TAM.

Aims: To analyze our center’s experience in the treatment of TA-TMA with defibrotide.

Methods: We reviewed all cases of TA-TMA treated with defibrotide in our allogeneic transplant recipients between October 2008 and November 2016. All cases had non-immune hemolytic anemia with high LDH, low haptoglobin and negative Coombs test, 2>chistocytes per high-power field and thrombocytopenia (<50x10^9/L or <50% of normal baseline). Cases without signs of renal or neurological involvement were excluded.

Results: We identified 17 TA-TMA episodes treated with defibrotide in 16 allogeic transplant recipients: 9 men; median age 38 years old (16-57); 10 single-cord blood plus third-party donor cells [Bautista G, 2009], 3 HLA-identical siblings and 3 unrelated donors; 13 myeloablative conditioning regimen, 10 with total body irradiation (Table 1). Concomitant risk factors at the time of TA- TMA onset were: calcineurin inhibitor treatment in all cases (13 cyclosporin, 4 tacrolimus), acute GVHD grade III/IV in 8 cases, 3 CMV reactivations and 2 severe fungal (1 pulmonary aspergillosis, 1 Scedosporium Prolificans sep- ticemia) or bacterial (1 E Coli sepsis) infections. Median onset of TA-TAM was on day +43 after transplant (2-56); 11 cases of early onset (<2 months) and 6 of late onset. Nine episodes were probable TA-TMA without organ dysfunction, 8 had renal failure and 2 presented with concomitant diffuse alveolar hemorrhage. First line replacement of calcineurin-inhibitors for basiliximab or other
Summary/Conclusions: TA-TMA is a severe endothelial dysfunction syndrome for which, beyond the complement inhibitor eculizumab, treatment is not well established. Defibrotide has proven to be safe and effective in sinusoidal obstruction syndrome. Here, we provide encouraging evidence suggesting that defibrotide, as monotherapy or in combination with other agents, may be effective in capturing comorbidity and predict post-transplant outcomes. HSCT-cell transplantation-specific comorbidity index (HSCT-CI), which was modeled on the basis of pre-transplant comorbidity assessed by HSCT-CI. Post-transplant outcomes were evaluated in terms of overall survival (OS) and event-free survival (EFS). Event was defined as graft failure including primary and secondary, relapse, donor lymphocyte infusion, and death.

Results: The median age of including patients was 31 year-old (range, 31-61 year-old) and male was 81 patients (58%). HCT-CI score was 0 in 92 patients (65.0%), 1-2 in 34 (24.3%), and ≥3 in 14 (10.2%). The most prevalent comorbidity captured by the HCT-CI was infection (n=20, 14%) followed by moderate/severe hepatic comorbidity (n=10, 7%). During a median surviving post-HCT follow-up period of 45.5 months (range, 4-1-784.4 months), 32 patients (24%) died and 20 (14%) experienced primary or secondary graft failure. The 10-year probability of OS and EFS was 73.4% and 63.8%, respectively. OS and EFS was significantly different according to HCT-CI score; the OS for HCT-CI 0, 1-2, and ≥3 at 4 years was 84.1%, 68.6%, and 60.6%, respectively (P=0.007). The EFS for HCT-CI 0, 1-2, and ≥3 at 4 years was 76.5%, 60.0%, and 56.3%, respectively (P=0.019). Multivariate analysis after adjustment for other variables demonstrated that higher HCT-CI score were associated with increased OS and EFS as judged by increasing hazard ratio compared to patients with HCT-CI score of 0 (Table 1).

Table 1.

Summary/Conclusions: In conclusion, our data indicate that the presence of pre-transplant comorbidity assessed by HSCT-CI may predict worse outcomes after allo-HSCT in severe aplastic anemia.

E1543

EFFICACY AND SAFETY OF FILGRASTIM BIOSIMILAR COMPARED TO FILGRASTIM ORIGINATOR IN THE STEM CELL MOBILIZATION AND HEMATOPOIETIC ENGRAFTMENT IN PATIENTS UNDERGOING STEM CELL TRANSPLANTATION

M. López-Parra1,*, M. Baile1, J. Dávila1, J.C. Caballero1, Á. Veiga1, N. Arratibel1, F. López-Cadenas1, L. García-Martín1, M. Salinero1, N.C. Gutiérrez1, O. López-Villar1, M.D. Caballero1, R. García-Sanz1

1Hematology, University Hospital of Salamanca, Salamanca, Spain

Background: Neupogen® is the original Filgrastim used for peripheral blood stem cell mobilization (PBSC) in patients and donors selected for stem cell transplantation (SCT). Nivestim® is a Filgrastim biosimilar approved for the same indications as Neupogen®.

Aims: To evaluate the efficacy and safety of Nivestim® in the PBSC mobilization for harvesting and hematopoietic SCT.

Methods: Retrospective, controlled, observational study conducted at the University Hospital of Salamanca (Spain) between JAN08 and DEC15. Among PBSC SCS, 145 were mobilized with Nivestim® and 220 the originator Neupogen®. Patient characteristics between groups were similar; although lenalidomide was more frequently used in the Nivestim® group, as it corresponds to more recent transplants. The mean number of CD34+ cells/µl in the peripheral blood after 4 days of mobilization treatment was not significantly different (Neupogen®: 22,220 vs Nivestim®: 22,214). The mobilization failure rate was slightly higher with Nivestim® (22%) than with Neupogen® (13%, p=0.04), although it was attributed to a more frequent use of lenalidomide. Most patients underwent ASCT: 87% and 92% in patients with the Neupogen® and biosimilar groups, respectively. There were no statistically significant differences in hematopoietic recovery and trans-
plant-related toxicity. The median hospitalization time (20, range 14-70 vs 20, range 14-53, p=0.72) and the consecutive number of re-admissions after discharge (27% vs 35%, p=0.35) were also similar between Neupogen® and Nivestim® groups. In the group of HEALTHY DONORS, 95 were mobilized with Neupogen® and 122 with Nivestim®. Donor characteristics were equivalent between groups, and no severe adverse events were registered in any of them. Mean of CD34+ cells collected/kg of recipient body weight was 7.62x106 SD=3.45x106 for Nivestim® vs 6.26x106 SD=2.71x106 Neupogen® (p=0.002), but the minimal target cell dose (2x106/kg) was collected in all donors. 8.5% of donors mobilized with Nivestim® failed to achieve the optimal cell dose (4x106/kg) compared with 13% in the Neupogen® group (p=0.25). All recipients were successfully transplanted. All donors for haploidentical transplants (N=25) were mobilized with Nivestim®; none with Neupogen®. There were no other transplant differences. Platelet and neutrophil engraftment were comparable between the two groups, as well as transfusion requirements and infectious complications after transplant. The incidence of grade 1 to 4 acute graft-versus-host disease was not different (Nivestim®65.5% vs Neupogen® 67.7%; p=0.7). The hospitalization period was similar in Neupogen® and Nivestim® groups, (30 days, range 16-102; 30 days, 16-136, respectively).

**E1544**

**PERIPHERAL BLOOD STEM CELL DONATION IN OLDER SIBLING DONORS: IS IT SAFE?**

K. Balassa1, A. Peniket1, R. Danby1, R. Pawson1
1Department of Haematology, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

**Background:** The introduction of reduced intensity conditioning regimens has led to an increase in allogeneic haematopoietic stem cell transplantation (HSCT) in older patients with a consequent increase in age of family members who are asked to donate HSCs for them. Such donors are expected to have more comorbidities than younger donors and careful assessment of their suitability to donate is required.

**Aim:** Over 60 donors from family members were assessed to frequency and nature of issues concerning the eligibility of related peripheral blood stem cell donors seen at Churchill Hospital, Oxford between 2012 and 2016. We wished to examine the influence of age and the nature of any extra interventions required to establish donor suitability.

**Methods:** For clinical data collection donors’ notes were reviewed and analysed retrospectively. A similar template was used in all cases for sibling donor selection and screening.

**Results:** During the study period 90 related donors were screened, of whom 1 declined to proceed because of his concerns regarding G-CSF safety, 2 were excluded due to pre-existing medical conditions and 2 were defined medically inpatient during work-up, and finally 85 donors donated PBSCs to their relatives (36% of allogeneic HSCT performed at our centre). The median donor age was 51 years (range 25-71, n=17 over 60). Nearly half of the donors (44%) took regular medications. Two thirds (67%) suffered from at least one significant comorbidity (25% hypertension, 24% back problems, 16% asthma, 9% cardiovascular conditions, 9% diabetes mellitus, 8% autoimmune disease). The presence of comorbidities was significantly associated with age (p=0.033). 59% travelled abroad, of whom 14% visited a malarial area within a year of donation. Based on donors’ history or examination findings, 47% needed extra blood tests on top of the mandatory tests before the clearance, including malaria (31%) and haemoglobin and haematology investigations etc. BMA, molecular studies. Additional imaging studies were performed in 13%. In 16% specialist opinion was sought from other specialties with concerns regarding donor fitness or safety. 13 out of 85 cases were handled as planned deviation from our standard eligibility criteria.

**Conclusion:** With careful assessment and planning even individuals with significant co-morbidities can donate successfully. The demographic trend and its implications should be considered when planning resources in HSCT programmes.

**LONG-TERM RESULTS OF DONOR LYMPHOCYTE INFUSIONS IN RELAPSED AND MIXED CHIMERISM PATIENTS AFTER ALLOGENIC STEM CELLS TRANSPLANTATION**

O. Koroleva1, E. Parovichnikova1, L. Mendeleva1, L. Kuzmina1, M. Drokov1, V. Vasilyeva1, Z. Konova1, E. Mikhailova1, D. Dubrynk1, N. Popova1, V. Savchenko1
1BMT, National Research Center for Hematology, Moscow, Russian Federation

**Background:** Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a potentially curative treatment for patients with hematological malignancies. However, relapse remains the major cause of treatment failure after allo-HSCT. Mixed chimerism (MC) can induce immunologic tolerance and lead to relapse. One of the most effective approaches to treat these patients is donor lymphocyte infusion (DLI) with or without chemotherapy.

**Aims:** To analyze long-term results DLI in early posttransplant MC and in relapsed patients after allo-HSCT.

**Methods:** The study included 61 patients of whom DLI with interleukin 2 (IL-2) was administered at the National research center for Hematology from 2011 till 2016. DLI with IL-2 was administered for patients with MC, more than 10-15% recipient DNA (n=26). A median age was 33 years old (19-54 years). Eight were males, 20 – females. There were AML (n=17), ALL (n=4), MDS (n=2), CML/MPN (n=3). Before allo-HSCT complete remission had in 20 patients and 6 had relapse/progreSSION disease. Patients received allo-HSCT from related (n=20) or unrelated (n=6) donor. The intensity of conditioning was mainly reduced intensity (n=15) rather than myeloablative conditioning (n=11). Bone marrow (BM) as a graft source was used in 20, PBSC – 6. DLI was started at low dose 1*107 CD3+ per kg. Every following dose of infusion CD 3+ increased you by 5.03, p<0.001. Citrate related toxicity was the most common complication of the apheresis procedure (52%). The only documented serious complication affected a 69-year old donor who was hospitalized on 3rd day of G-CSF treatment with chest and abdominal pain and troponin rise, but investigations excluded acute coronary syndrome or other significant acute pathology and she managed to donate successfully with no further issues.

**Summary/Conclusions:** Peripheral blood stem cell collection seems to be safe among sibling donors, who are significantly older than unrelated donors. With careful assessment and planning even individuals with significant co-morbidities can donate successfully. The demographic trend and its implications should be considered when planning resources in HSCT programmes.
was 2 (1-5). There were 5 (19%) graft failures. Acute GVHD appeared in 8 (32%), all of them Grade 3; chronic GVHD occurred in 7 (27%). Patients with a MC had better overall survival 77.6% than patients with relapse after allo-HSCT (22%). Remission was achieved in 16 (48%) patients with relapses. However, 5 patients relapsed again. Acute GVHD was developed in 8 cases (22%). Nineteen patients died from relapse and 1 patient died from aGVHD in remission. Five patients relapsed in patients with MC and in patients with relapses was 78.6% and 26.2%, respectively.

Summary/Conclusions: The prognosis of hematological malignancies is poor if relapse is established after allo-HSCT. DLI protocol as preventive therapy must be created for improving long-term results in high risk patients. Prevention is better than cure.

E1546

MEMORY T CELLS DONOR LYMPHOCYTE INFUSIONS AFTER HAPLOIDENTICAL STEM CELL TRANSPLANTATION AS A SAFE PROCEDURE TO IMPROVE T-CELL RECONSTITUTION

S. Cortez 1,*, R. De Paz 1, M. Gasior 1, A. Martínez 1, Y. Mozo 2, B. Rosích 2, J. Valentín 1, A. Sastre 2, A. Pérez 2

1Hematology, 2Pediatric Hematology-Oncology, Hospital Universitario La Paz, Madrid, Spain

Background: Hematopoietic stem cell transplantation (HSCT) is a potential curative treatment for patients with hematologic malignant diseases. Haploidentical transplantation with extensive ex vivo T cell depletion of the graft, has demonstrated to prevent graft versus host disease (GVHD), but the major disadvantage has been the development of graft failure, relapse and infections due to delayed immune reconstitution. A selective T cell depletion method that removes T naïve cells expressing CD45RA+ in haploidentical donor lymphocytes, the CD45RA+ cells depletion was made using the cliniMACS system. These cells, which are responsible for GVHD, as well as preservation of memory T cells CD45RO, is a novel therapy that may provide functional T cells with anti-infection, anti-leukemia and anti-rejection properties.

Aims: We describe the outcome of CD45RA+ cell depletion of donor lymphocytes infusions, in patients with hematologic malignancies with mixed chimerism, severe infections and high risk of relapse after hematopoietic stem cell transplantation.

Methods: Patients with hematologic diseases with poor prognosis who lacked an HLA matched donor were included. The recipients received a CD45RA-depleted haploidentical transplantation, on day 0 they received a first graft with a median CD3+ cell dose of 8.4x10^6/Kg (range 0-5x10^6/Kg) in haploidentical donor lymphocytes, which are responsible for GVHD, as well as preservation of memory T cells CD45RO, is a novel therapy that may provide functional T cells with anti-infection, anti-leukemia and anti-rejection properties.

Results: We present the results of six patients with a median age of 11 years (range 1-18 years), diagnosis included B-Cell acute lymphoblastic leukaemia (n=2), T cell acute lymphoblastic leukaemia (n=1), acute myeloblastic leukaemia (n=2), aplastic anemia (n=1), these patients received a selective CD45RA-depleted haploidentical transplantation. The follow up after HSCT, three patients had persistent lymphopenia, four patients developed infections caused by CMV, norovirus, HHV-6, BK virus and toxoplasma, one patient had increasing levels of mixed chimerism and one had graft failure. These patients were treated with infections of 16 alleles of cryptopreserved CD45RA+ haploidentical donor lymphocytes, the CD45RA+ cells depletion was made using the cliniMACS system. The median dose of CD45RA+ cells was 1.02x10^6/ Kg, starting at a dose of 0.01x10^6/Kg, the median dose of 2x10^6/Kg was used every 21 days. The CD45RA+ cell dose was a median of 0.005x10^6/Kg (range: 0-1.6x10^6/Kg). All the procedures were well tolerated, neither adverse events nor GVHD were noticed. After the DLI, a progressive increase in T cells count was observed.

Summary/Conclusions: In our experience DLI enriched for CD45RO+ memory T Cell is a promising and safe strategy for patients with severe viral infections and risk of relapse after haploidentical HSCT, these cells have demonstrated to trigger the CD4 and CD8 T-cell reconstitution, which will help reduce risk infection with a low risk of GVHD. However further studies are needed in order to support this therapy.

E1547

FLAG REGIMEN WITH IDARUBICINE AS CYTOREDUCTION THERAPY BEFORE ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH REFRACTORY ACUTE MYELOID LEUKEMIA

L. Wang 1,*, R. Devillier 2, R. Fan 1, W. Tang 1, S. Harbi 2, N. Vey 2, J. Hu 1, D. Blaise 2

1Blood and marrow transplantation center, Department of Hematology, Rui Jin Hospital, Shanghai Second Medical University, Shanghai, China, 2Unité Transplantation et de Thérapie Cellulaire, Département d’Hématologie, Institut Paoli-Calmettes, Marseille, France

Background: Allogeneic hematopoietic stem cell transplantation (Allo-HSCT) is the only curative option for patients with refractory acute myeloid leukemia (AML). However, allo-HSCT with standard conditioning regimen could merely achieve a long-term survival of 20% and the key problem is the high relapse rate even after transplantation.

Aims: We have evaluated the safety and efficacy of new conditioning regimen with sequential intensive chemotherapy (FLAG-IDA) followed by conditioning of Flu-Bu(3).

Methods: The study was designed and developed in two separate transplanta

centers in Rui Jin Hospital (RJH, Shanghai) and Institut Paoli-Calmettes (IPC, Marseille) respectively. A total of 47 refractory AML patients with median bone marrow blast of 30% (1-90%) and median age of 63 (16-75) were enrolled. Thirteen patients received transplantation with mobilized peripheral blood stem cells (PBSC) from HLA-matched sibling donor while 18 and 16 with matched unrelated or haplo-identical donors. All patients received FLAG + 3-days idarubicin (12mg/m2 in RJH or 10mg/m2 in IPC) and then received Flu-Budarabine (5 days) with IV Busulfan (3-days) with a 7-day interval. The GVHD prophylaxis regimens were CsA+MMF+ATG (RJH) or post-cyclophosphamide (IPC).

Results: With a median follow-up of 8 months (1-70m), a total of 14 patients relapsed with a median time of relapse at 4.8 months (2.1-18.1) and most of the patients relapsed within first 6 months after transplantation. A total of 24 patients died due to relapse (n=12) or non-relapsed mortality (NRM, n=12). The estimated 3-year relapse rate (RR) and NRM were 42.9±9.2% and 25.9±6.5% respectively. The estimated 3-year OS and DFS were 43.6±7.8% and 42.2±8.7%. In the primary multivariate analysis (including age, cycles of pre-transplantation chemotherapy, bone marrow blasts, cytogenetics and treatment center), only bone marrow blast ≥25% and age over 40 were associated with disease-free survival and relapse respectively while there was no significant difference between RJH and IPC in terms of transplantation outcome in univariate and multivariate analysis.

Summary/Conclusions: Our primary data demonstrated a promising outcome with FLAG-IDA chemotherapy as debulking therapy sequential with Flu-Bu3 conditioning regimen in patients with refractory AML and clinical trial with larger patients cohort is warranted.

E1548

STUTTER PCR PRODUCTS MAY NOT INTERFERE WITH STR BASED CHIMERISM MONITORING AFTER ALLOGENEIC BONE MARROW TRANSPLANTATION

N. Kostritsa 1,*, N. Risinskaya 2, E. Parovichnikova 3, A. Sudarkov 2

1School of Medicine, Lomonosov Moscow State University, 2Department of Molecular Hematology, 3Department of Hematological Oncology and BMT, National Hematology Research Center, Moscow, Russian Federation

Background: Chimerism analysis is one of the main methods to monitor the bone marrow engraftment or disease relapse after allogeneic bone marrow transplantation. Routine test is based on differences in the length of short tandem repeats (STR) from the donor and the recipient. However, chimerism estimation is complicated by stutter PCR peaks appearing due to irregular DNA polymerase activity. Generally, these sequences are 4 nucleotides shorter than a specific marker and may concur with a specific sequence of recipient’s DNA hindering chimerism estimation based on that locus. This problem seems to be especially serious in case of a sex-matched sibling BMT when most of the alleles for donor and recipient are the same. One may suggest to limit the use of these markers for the cases with stutter-bands comparable with donor allele peak height. Thereby, the absence of “stutter-peaks free” markers hinders mixed chimerism estimation at the point of low recipient hematopoiesis output.

Aims: To identify the contribution of stutter-bands to the total amount of PCR-product and to derive universal formulas for the chimerism calculation excluding stutter percentage.

Figure 1.

Methods: Genomic DNAs of donors and patients were isolated from bone marrow samples. Chimerism was assessed by the STR-PCR analysis (polymerase chain reaction with a panel of primers for loci of short tandem repeats) with The OneStep® Plus multiplex kit for amplification of 19 polymorphic STR-markers and amelogenin loci. The fragment analysis was performed on a 3130 Genetic Analyzer. The data processing was accomplished using GeneMapper v4.0 software. Informative loci were chosen beforehand comparing pretransplant
patient DNA and donor DNA. The percentage of donor chimerism as well as stuffer percentage was calculated using standard formula.

**Results:** Fifty transplant cases with stuffer peaks were evaluated: 18 homoyzous; 15 heterozygous with both alleles showing detectable stuffer; 17 heterozygous with one stuffer visible only. Stuffer percentage and standard deviation were calculated in each case for donor DNA sample and for four bone marrow DNA samples from recipient with established complete donor chimerism taken during the time. It was found that the contribution of the stuffer-peaks into the total amount of product ranges from 1.2% to 11% (SD was no more than 1.5% for each locus) for markers with appreciable stuffer-bands and seems to be locus-specific constant for each patient. Assuming the stuffer percentage as a locus and 13.63% in the constant (for the same PCR conditions) we derived a formula for recipient DNA percentage: Actual recipient’s%=(apparent rec.×total DNA ratio - stuffer/total DNA ratio)×100% (specific formulas for hetero- and homoyzous on fig. 1). To test these formulae the panel of DNA samples with mixed chimerism from 50 to 97% estimated by independent “stutter-free” markers appeared to be the same (SD<1%).

**Summary/Conclusions:** The use of formulae described may circumvent the absence of the “stuffer-free” informative markers for mixed chimerism estimation.

---

**INTRODUCING PLERIXAFOR TO IMPROVE MOBILIZATION IN MULTIPLE MYELOMA PATIENTS WHO BEHAVIE AS POOR-MOBILIZERS IS COST-EFFECTIVE CONSIDERING THE WHOLE MOBILIZATION AND TRANSPLANT PROCEDURE**

C. Di Clemente1, A. Correllor-Soriaño2, R. Touzani3, A.-M. Stoppa4, C. Lemarie1, M. Debals-Gontier2, B. Calmets1, R. Bouabdallah1, A. Granata1, 1Centre de Therapie Cellulaire, Departement de Biologie du Cancer, Institut Paoli-Calmettes, 2SESSTIM, Inserm, 3Department d’Oncohematology, Institut Paoli-Calmettes, Marseille, France

**Background:** Plerixafor, a CXCR4-antagonist, is efficient to improve CD34+ cell mobilization and collection in candidates for autologous transplantation who behave as poor-mobilizers. The cost of the drug is however of concern. Published medic-economic studies were mostly conducted in the US, and few including detailed and comprehensive micro-costing of the collection and transplantation process; conclusions may thus not apply to European countries where cost structures are different.

**Aims:** To compare costs and effectiveness of plerixafor-free and plerixafor-replete management strategies for multiple myeloma patients who behaved as poor-mobilizers after adequate administration of a standard rHuG-CSF mobilization regimen.

**Methods:** Sixty patients diagnosed with multiple myeloma were consecutively identified during years 2009-2011, immediately before and after EMA granted marketing authorization for plerixafor. Poor-mobilizers were defined as having achieved the minimal target number of 2x10^6 collected CD34+ cells/kg. Achieving a minimal target number of 2x10^6 collected CD34+ cells/kg was identical (28/30). Length of hospitalization, times to neutrophil and platelet recoveries, costs were calculated in each case for donor DNA sample and for four bone marrow DNA samples from recipient with established complete donor chimerism. To test these formulae the panel of DNA samples with mixed chimerism from 50 to 97% estimated by independent “stutter-free” markers appeared to be the same (SD<1%).

**Summary/Conclusions:** The use of formulae described may circumvent the absence of the “stuffer-free” informative markers for mixed chimerism estimation.

**PERIPHERAL BLOOD STEM CELL (PBSC) HAPLOIDENTICAL TRANSPLANTATION VERSUS MISMATCHED UNRELATED DONOR TRANSPLANTATION: A SINGLE UK CD34+ CELL CENTER STUDY**

J. O’Sullivan1, K. Parmessar2, D. Mc Loran2, D. L. Hugues2, V. Potter2, M. Streetly1, M. Gallagher4, I. Walker4, M. Kazmi2, A. Kulasekaraar2, J. Marsh4, G. Muffi1, T. Pagliuca4, K. Raj3, 1Haematology, Guy’s and St. Thomas’ NHS Foundation Trust, 2Haematology, King’s College Hospital NHS Foundation Trust, 3Haematology, Guy’s and St. Thomas’ NHS Foundation Trust, 4Haematology, King’s College Hospital NHS Foundation Trust, London, United Kingdom

**Background:** Haploidentical (Haplo) and mismatched unrelated donor transplants (MMUD) are potential alternatives for those without a fully matched available donor. Recent collaborative and single centre studies suggest that haploidentical donor outcomes are comparable to unrelated donor outcomes in the T cell-replete setting.

**Aims:** In this single centre review, we aimed to compare outcomes of T cell-replete haploidentical allogeneic stem cell transplantation with mismatched unrelated donor allogenic stem cell transplantation.

**Methods:** From January 2010 to December 2015, 38 patients underwent T cell-replete HLA-matched haploidentical transplantation with post transplantation cyclophosphamide given on days +3 and +4 given as graft versus host disease (GvHD) prophylaxis. These were retrospectively compared with 45 patients underwent single HLA-locus mismatched unrelated donor transplantation with alemtuzumab as GvHD prophylaxis. Data was censored at time of last contact in 2016. Analysis was performed using SPSS v.23.0 and R 3.3.2 software.

**Results:** The median recipient age was similar in both groups; 51 (19-69) years in Haplo and 59 (28-74) years in MMUD transplants, p=0.012; 68.7% of all patients were male. Non-Caucasian ethnicity comprised 63.2% of Haplo versus (vs.) 15.6% of MMUD transplants, p<0.001. Myelodysplasia (MDS)/acute myeloid leukemia (AML) was the commonest disease for both groups (60.5% of Haplo and 93.6% of MMUD transplants). The disease risk index (DRI) in this subgroup was overall low/intermediate in 69.2% and high/very high in 26.2% (unknown in 4.6%). Reduced intensity conditioning was used in all but two Haplo (4.6%) and 4 MMUD transplants. Patients were followed up for a median of 544 days with a similar 2-year overall survival of 61.8% (95% confidence interval, CI, 52.4 – 69.3%) and 58.1% (95% CI 48.8-66%) and 3-year overall survival of 56.4% (95% CI 45.8 – 65.6%) and 48.9% (95% CI 41 – 56.2%) in Haplo and MMUD transplants respectively, p=0.67. Overall progression free survival (PFS) at 2 years was 53.3% (95% CI 44-61%) and 40.1% (95% CI 34-46%) in Haplo and MMUD transplants respectively, p=0.31. In those with MDS/AML, the 2-year progression-free survival was 62.4% (95% CI 49-75%) in Haplo vs 38.5% (95% CI 33-43%) in MMUD transplants, p=0.1. In Haplo and MMUD transplants, the 3-year cumulative incidences of non-relapse mortality were 25.5% (95% CI 12-41%) and 31.2% (95% CI 18-45%) respectively, p=0.61 and for relapse were 25.6% (95% CI 12-41%) and 34.8% (95% CI 20-49%) respectively, p=0.51. Median time to neutrophil engraftment was 18 and 12 days and for platelet engraftment 21 and 12 days in the Haplo and MMUD transplants respectively. Engraftment was successful in 89.4% (Haplo) and 95.5% (MMUD) of patients. The incidence of acute GvHD was similar in Haplo and 35% in MMUD transplants but severe grades 3/4 acute GvHD occurred in 7.9% (Haplo) and 8.9% (MMUD). Chronic GvHD occurred in 15.8% of Haplo and 33.3% of MMUD transplants, p=0.067. Chronic GvHD did not impact overall or progression free survival in either transplant group.

**Conclusions:** Haploidentical transplantation when compared with T cell-deplete mismatched unrelated donor transplantation showed high engraftment rates, low rates of severe acute and chronic GvHD and comparable overall survival, non-relapse mortality and relapse rates. We suggest that T cell-replete haploidentical transplantation is a safe and acceptable alternative when a matched unrelated donor is unavailable.

---

**IMPACT OF ABO BLOOD GROUP INCOMPATIBILITY ON THE OUTCOME OF RECIPIENTS UNDERGOING ALLOGENIC TRANSPLANTATION: EXPERIENCE IN OUR CENTER BETWEEN 2013 AND 2016**

G.A. Méndez Navarro1, G. Moreno Jiménez1, F.J. López Jiménez1, A. Jiménez Martin1, S. López González1

1Servicio de Hematología y Hemoterapia, Hospital Universitario Ramón y Cajal, Madrid, Madrid, Spain

**Background:** ABO blood group compatibility is not an essential requirement or priority in the selection of the allogenic bone marrow donor, unlike what happens in solid organ transplant; thereby, up to 30-50% of allogeneic transplantation shows ABO incompatibility1, but its clinical impact is controversial. It's accepted that it may provoke hemolytic reactions and delayed erythrocyte engraftment. Nevertheless, its influence on leukocyte and platelet engraftment, graft-versus-host disease (GvHD), and overall survival is not fully elucidated yet2.

**Aims:** To describe the experience in our center in allogeneic transplantation with ABO mismatching and its relation with hemolotic events (HE), red blood cell
Aims: Several biological mechanisms may contribute to graft failure. Immuno-
ological rejection of the graft is known as a major cause of graft failure. Graft
failure may also be caused by septicemia, viral infections, drug toxicity and so
on. These events have been frequently occurred just before engraftment, and
we often experience fluctuation of blood levels of immunosuppressive drugs.
Here, we analyzed an association between blood levels of Tacrolimus (Tac)
before neutrophil engraftment and neutrophil engraftment.

Methods: Between January 2011 and July 2016, 76 patients received single-
unit CBT at our institutions. We analyzed 59 patients for whom Tac was used for
GVHD prophylaxis including Tac and Mycophenolate mofetil (MMF) combi-
nation (n=26) and Tac with an additional short Methotrexate (sMTX) (n=33).
Sixteen patients who underwent second or third CBT and a patient for whom Tac
was not used for GVHD prophylaxis were excluded. We also excluded a
patient whose Tac concentration we didn’t check more than two times a week.
Tac was started at a dose of 0.02mg/kg/day by continuous i.v. infusion. Tac
blood concentrations were monitored at least three times a week before engraft-
ment, and dosages were adjusted to maintain serum levels around 10-20 ng/ml.

Results: Of the 59 patients, 48 patients achieved neutrophil recovery at a
median of 22 (range 13-35) days. Two patients died before engraftment from
severe PIR and active infection. Nine patients (18.6%) experienced graft failure.
Patients who could maintain Tac level above 12ng/ml during the second week
after CBT (Tac high group) had an incidence of graft failure of 4.8%, which was
significantly lower than the 26.3% seen in the other patients (Tac low group)
(p<0.01). Patients for whom Tac and MMF were used (MMF group) had an
incidence of graft failure of 3.8%, which was significantly lower than the 36.4%
seen in the other patients for whom Tac with an additional sMTX (MTX group)
for GVHD prophylaxis (p<0.01). Combined of these factors, the patients of Tac
low group and MTX group had had an incidence of graft failure 40.9%, which
was significantly highest than the 5.4% seen in the other patient including Tac
high group and MMF group even if the patient were included of Tac low group.

Summary/Conclusions: Low levels of Tac blood concentration were signifi-
cantly associated with the incidence of graft failure of the patient for whom Tac
with an additional sMTX were used for GVHD prophylaxis. Before engraftment,
frequent checks of the Tac blood concentration and maintaining the drug level
should be considered for these patients.

E1553

THE EXPRESSION OF TOLL-LIKE RECEPTORS GENES IN PATIENTS
WITH LYMPHOID MALIGNANCIES AFTER AUTOLOGOUS PERIPHERAL
BLOOD STEM CELL TRANSPLANTATION

J. Rybka1, B. Jaźwiec1, W. Wierzbicka1, K. Bieńkowska-Kowalska1, K. Kuliźkowska1, T. Wróblewski1
1Hematology, 2Internal Medicine, Wroclaw Medical University, Wroclaw, Poland

Background: Peripheral blood stem cell transplantation (PBSCT) is one of
the main strategies for the treatment of malignant hematological diseases. Toll
like receptors (TLRs) are present on various immune cells including natural
killer cells, monocytes, macrophages, T lymphocytes and B lymphocytes. Ten
different TLRs have been evaluated in humans. TLRs play a central role in
immune surveillance and in the initiation of the inflammatory response. The
expression of TLRs genes and their association with outcome in patients treat-
ted with PBSCT remains unclear.

Aims: The objective of the current study was to investigate association between
expression of TLRs genes and hematopoietic recovery and rate of infections
in patients treated with PBSCT.

E1552

LOW BLOOD CONCENTRATION OF TACROLIMUS CAN BE A RISK
OF GRAFT FAILURE AFTER CORD BLOOD TRANSPLANTATION
A. Fujimoto1, T. Ishikawa1
1Hematology, Kobe City Medical Center General Hospital, Kobe, Japan

Background: Cord blood transplantation (CBT) has recently emerged as an
attractive alternative donor. However, graft failure still remains potential threats
to morbidity and mortality.

Aims: The objective of the current study was to investigate association between
expression of TLRs genes and hematopoietic recovery and rate of infections
in patients treated with PBSCT.
Methods: The evaluation of TLRs expression genes were performed in 40 patients who underwent PBSCT. The median age of patients was 54 years (range: 25-66 years). There were 15 patients with multiple myeloma (MM), 20 patients with non-Hodgkin lymphomas (nHLs) and 5 patients with Hodgkin lymphoma (HL). Peripheral blood samples were taken before megachemotherapy with autologous stem cell transplantation and at time of hematopoietic recovery in patients with hematopoietic AEs. Relative expression of TLRs receptors was assessed by real-time PCR using inventoried TaqMan® Assays from Life Technologies/ThermoFishcer. Beta glucoronidase (GUSB) served as endogenous control. Reaction was performed in 7500 Real Time PCR instrument (LifeTechnologies) using Gene Expression MasterMix (LifeTechnologies/ThermoFisher). Comparative Ct method (***) was used to compare expression among patients with and healthy controls. Statistical analysis was conducted using STATISTICA 12 software (StatSoft, Polska). For quantitative variables arithmetic means (X) and standard deviations (SD) of estimated parameters were calculated in the analysed groups. Distribution of variables was examined using the tests of Lilliefors and W-Shapiro-Wilk. In cases of independent quantitative variables with the normal distribution the statistical analysis took advantage of t test for unlinked variables. In cases of variables manifesting distribution distinct than the normal one, for independent quantitative variables U test of Mann-Whitney was used. For dependent quantitative variables of the normal distribution, the test for linked variables was applied. In cases of quantitative dependent variables with the distribution distinct from normal, the pair sequence test of Wilcoxon was applied. In order to define a relationships between the studied variables, correlation analysis was performed. Results: The level of p<0,05 were assumed to be of statistical significance.

Results: The mRNA expression of TLR2 and TLR9 was significant higher in patients after PBSCT than before PBSCT procedure (∆Ct TLR2 1,4209±1,0461 vs 1,7877±1,4974 and ∆Ct TLR9 117,853±141,0870 vs 289,788±271,98) (p=0,05). We observed that expression of TLR9 was significant higher in patients with bacterial and viral infection after PBSCT in comparison to group without infection after PBSCT (∆Ct TLR9 117,853±141,0870 vs 289,788±271,98) (p=0,05). Moreover we found significant positive correlation between expression of mRNA of TLR9 and neutrophil recovery after PBSCT (r=0,4075; p=0,023).

Summary/Conclusions: In conclusion our findings suggest that TLRs could be useful markers in outcome in patients treated with PBSCT. This observation should be validated by larger study.

Support: Jazz Pharmaceuticals.

TIMING OF DEFIBROTIDE INITIATION POST-DIAGNOSIS OF HEPATIC VENO-OCCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION: EXPANDED ACCESS PROGRAM FINAL DATA

S. Grupp1, P. Richardson2,*, A. Smith3, N. Kernan4, J. Antin5, L. Lehmann6, S. Giralt7, W. Liang8, R. Hume8, W. Tappe8, R. Soiffer6

1Pediatric Oncology, The Children's Hospital of Philadelphia, Philadelphia, 2Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 3Division of Pediatric Blood and Marrow Transplantation, University of Minnesota, Minneapolis, 4Pediatric BMT Service, Memorial Sloan Kettering Cancer Center, New York, 5Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, 6Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 7Memorial Sloan-Kettering Cancer Institute, New York, 8Jazz Pharmaceuticals, Inc., Palo Alto, United States

Background: Hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is an unpredictable, potentially life-threatening complication of hematopoietic stem cell transplantation (HSCT). VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal and/or pulmonary dysfunction post-HSCT in the United States. Prior to approval in the United States, defibrotide had been available via an expanded-access program.

Aims: To perform an exploratory post hoc analysis of final data from the expanded-access program on the impact of timing of initiation of defibrotide after diagnosis of VOD/SOS in HSCT patients.

Methods: In an expanded-access study, patients diagnosed with VOD/SOS (per Baltimore criteria, modified Seattle criteria or biopsy) with or without renal/pulmonary MOD after HSCT or chemotherapy received defibrotide 25mg/kg per day divided in 4 doses. If the patient was planned to receive defibrotide for >14 days, a recommendation was provided for informed consent. For these exploratory analyses, Day +100 survival rates in HSCT patients were examined post hoc by time from VOD/SOS diagnosis to start of defibrotide for (1) all patients before/after days 1, 2, 3, 4, 7, and 14, using Fisher’s exact test and (2) patients starting defibrotide on a particular day, with Bonferroni correction. A trend test for particular initiation days also showed a significant trend over time for higher Day +100 survival with earlier defibrotide initiation post-diagnosis in both the overall HSCT group and MOD subgroup (P<0.001). Adverse events (AEs) and serious AEs occurred in 70.8% and 53.4% of patients, respectively. Other than VOD/SOS and MOD, the most common AE was hypotension (11.7%) and most common serious AE was respiratory failure (7.3%).

Results: In the final dataset, timing of initiation date was available for 1000 HSCT patients (512 with MOD) who received ≥1 dose of defibrotide. In 31.0% of all HSCT patients, defibrotide was started the day of diagnosis; in 92.9%, by Day 7. In the population-wide analysis of initiation before/after days 1, 2, 3, 4, 7, and 14 post-diagnosis in both the overall group and MOD subgroup (Figure 1), earlier initiation was associated with significantly higher Day +100 survival rates for all days (P<0.001), except Day 14 (2.6% of patients started defibrotide after Day 14). The trend test for particular initiation days also showed a significant trend over time for higher Day +100 survival with earlier defibrotide initiation post-diagnosis in both the overall HSCT group and MOD subgroup (P<0.001). Adverse events (AEs) and serious AEs occurred in 70.8% and 53.4% of patients, respectively. Other than VOD/SOS and MOD, the most common AE was hypotension (11.7%) and most common serious AE was respiratory failure (7.3%).

Figure 1.

Summary/Conclusions: In this exploratory analysis of final study data, earlier defibrotide initiation post-VOD/SOS diagnosis significantly improved Day +100 survival, confirmed by the Cochran-Armitage test (P<0.001). No specific day provides a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed.

RED BLOOD CELL DISTRIBUTION WIDTH (RDW) AS AN ACUTE GRAFT VERSUS HOST DISEASE PREDICTOR MARKER IN ALLOGENIC STEM CELL TRANSPLANTATION

B. Robredo1, F. Sartor1, M.A. Duran1, A. Gutierrez1, A. Sampol1, L. Lo Riso1, J.M. Sanchez-Raga1, B. Lopez Andrade1

1Hematology, Hospital Universitario Son Espases, Palma Mallorca, Spain

Background: The red blood cell distribution width (RDW) is a common parameter for measuring anisocytosis in the study of anemia. Recently it has been regarded as a surrogate marker of inflammation and adverse outcome in several diseases. Acute graft-versus-host disease (GVHD) is a common complication of allogeneic hematopoietic cell transplant (allo-HSCT) which is related to inflammation in the context of damage of the host tissue and the release of inflammatory cytokines. We decided to study the utility of this potential inflammatory marker in the setting of GVHD in the allo-HSCT.

Department of Medical Oncology, Dana-Farber Cancer Institute, 1Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 633

Summary/Conclusions: In this exploratory analysis of final study data, earlier defibrotide initiation post-VOD/SOS diagnosis significantly improved Day +100 survival, confirmed by the Cochran-Armitage test (P<0.001). No specific day provides a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed.

Support: Jazz Pharmaceuticals.

Table 1.
Aims: RDW values were evaluated at the day of infusion (RDW(0)), we choose this point in time to evaluate the tissue injury and inflammation secondary to the conditioning regimen, in order to evaluate if there is a major incidence of GVHD.

Methods: We retrospectively evaluated 103 patients who had underwent allo-HSCT for different indications at our center, with a median follow up of 12.8 months (0-235) at our center. The population consisted of 59 males and 44 females, the median age was 43.7 years. The RDW was collected from the hemogram at the day of the HSCT cell infusion, before it was performed (table 1). The IBM SPSS STATISTICS program was used for all statistical analyses. Differences were considered statistically significant when p<0.05. The median of RDW values in our study was of 16.4 (11.2-38.5). The areas under the receiver operating characteristic (ROC) curves of RDW were ≤18.4 and >18.4 for the selection of the increased RDW cutoff. We evaluated the association of increased RDW (>18.4) with the development of GVHD. A survival analysis of the association of different levels of increased RDW was performed. A subgroup analysis of the Haploidentical HSCT patients (N=13) was also evaluated.

Results: The presence of increased RDW >18.4 was strongly associated with an increased risk of developing acute GVHD (p=0.009) being present in 80% of the patients. In the haploidentical HSCT subgroup an increased RDW >16 was associated with acute GVHD. (p=0.044). There was no association of chronic GVHD with elevated RDW at day 0 (p=0.563). The survival analysis didn’t found an association of high RDW levels with mortality or survival (p=0.301) but a tendency to an increased survival was show between the RDW level subgroups. (figure2). Where a higher RDW seems to have a better survival, but this should be evaluated in a wider sample.

Summary/Conclusions: RDW at day 0 is a feasible predictor factor of Acute GVHD, most likely as a secondary surrogate marker of inflammation secondary to the conditioning regimen. The presence of other factors contributing to the RDW increase (secondary to other comorbidities) cannot be ruled out; but by itself RDW it’s an easy and affordable prognosis marker for aGVHD that should be further evaluated.

E1556

COMPARISON OF THE BEAM CONDITIONING REGIMEN AND THE BEAM CONDITIONING REGIMEN IN THE AUTOLOGOUS TRANSPLANTATION FOR HL AND NHL

S. Lozenov1,*, P. Ganeva1, B. Spassov1, Y. Petrov1, G. Arnaudov1, G. Mihaylov1

1NSHA THD, Sofia, Bulgaria

Background: The BEAM has established itself as a standard of care conditioning regimen in the autologous lymphoma HSCT setting for most transplant centres in Europe. Yet however various other regimens are being compared with it in order to achieved better safety profile, better OS and DFS, in order to improve results with chemoresistant and unfavourable patients. One such regimen is BeEAM (bendamustine, etoposide, cytarabine, melphalan).

Aims: We aimed to compare the efficacy of the BEAM and BeEAM conditioning regimens and to compare there myelotoxicity profile.

Methods: We evaluated retrospectively 114 patients, receiving auto-HSCT at the National Specialized Hospital for Active Treatment of Hematological Diseases in Sofia for relapsed/refractory HL or NHL for the period from 1.01.2013 to 1.07.2016 with a follow-up of patients up to 1.11.2016. 92 of the patients received BEAM and 22 received BeEAM. 2 and 3 year OS and DFS were compared, CR rates and the average time periods to hematological recovery.

Results: The OS at 2 and 3 years respectively was 86.1%, 86.1%, for BeEAM and 78%, 71% for BEAM. The DFS at 3 years was 76.4% in BeEAM and 73.2% BEAM, provided that the differences did not have statistical significance. The CR rate was 63.63% in the BeEAM group versus 50% in the BCNU group. 22.72% of the patients receiving BeEAM in SD or in diseases progression achieved CR versus 10.86% respectively for the BEAM group. The mean time to hematological recovery for neutrophils was 11.27 days (BeEAM) versus 10.24 days (BEAM) and 12.64 days (BeEAM) versus 11.12 days (BEAM) for platelets.

Figure 1.

Summary/Conclusions: BeEAM appears to be a non-inferior alternative conditioning regimen to the standard BEAM, it shows a trend towards higher myelotoxicity, but also a trend towards better short-term results in chemoresistant patients.

E1557

DOUBLE UMBILICAL CORD BLOOD TRANSPLANTATION IN ADULTS: CORRELATION OF ALLELE-LEVEL HLA MATCHING WITH OUTCOME AND WHICH CORD BLOOD UNIT WILL BECOME DOMINANT

M. Westendorp1,*, D. Hogge1, K. Song1, S. Narayanan1, S. Nantel1, R. Broady1, M. Barnett1, C. Toze1, A. Gerrie1, Y. Abou Mourad1, D. Sanford1, M. Power1, D. Forrest1, S. Heather1, N. Thomas1

1Leukemia/BMT Program of BC, Vancouver General Hospital, Vancouver, Canada

Background: Umbilical cord blood (UCB) has been used for alternative donor transplantation for the past 3 decades. Graft failure is not uncommon due to higher degrees of hemo-incompatibility between recipient and UCB units and fewer hematopoietic precursors in the product. To improve engraftment rates, especially in larger (i.e. adult) patients (pts), two UCB units can be used. Double UCB transplantation (DUCBT) is being utilized at many centres although it has been noted that, while both units may contribute to engraftment, only one unit becomes “dominant” – i.e. persists to provide long-term hematopoiesis. A variety of predictors of which unit will become dominant have been suggested, primarily the unit that is more closely HLA-matched or the unit with the highest total nucleated cell (TNC) count.

Aims: To determine the likelihood of engraftment, incidence of GVHD, influence of TNC count and HLA mismatch on survival and selection of the dominant cord following DUCBT in adults with high-risk hematologic disorders.

Methods: A retrospective review was performed of adult pts undergoing DUCBT at the referral centre for British Columbia. Recipients signed informed consents for all clinical trials in which they participated. HLA typing at A, B, C and DRB1 loci was done on all pts using high-resolution allele-level testing (HRT). RHT was available at these 8 loci for both UCB units in 25/31 pts; for the remaining units, class I typing was done by serology. UCB units selected had to be ≥4/6 match at A, B (serologically) and DRB1 (by HRT). Combined TNC count for the units had to be ≥30x10⁹/kg recipient weight. Conditioning was Fludarabine 40mg/m² x4 and TBI 150 cGy x8; GVHD prophylaxis was Tacrolimus/Mycophenolate. Pts received G-CSF 300 mcg s.c. daily from day +1. Outcomes were compared using Fisher’s exact test.

Results: Between 06/09 and 09/16, 31 pts underwent DUCBT - 11 males, 20 females with median age 50 years (range 19-59). Diagnosis was acute myeloid leukemia (AML; n=12), acute lymphoid/mixed phenotype leukemia (n=7), chronic lymphoproliferative disease (n=5), MDS (n=4) or other (n=3). All 31 pts recovered ANC>0.5x10⁹/L at median of 20 days (range 14-72). Platelet count reached >20x10⁹/L in 26/31 pts at median of 38 days (range 24-188). Acute GVHD developed in 26/31 pts (84%) and chronic GVHD in 17 of the 26 pts (65%) that survived to day +100. Seventeen pts (55%) remain alive, in contin-
uous remission at median follow-up of 3 years (range 0.5-7.0). Ten pts (32%) experienced non-relapse mortality from GVHD (5 pts), infection (4 pts) or unknown cause (1 pt). Four pts (13%) have relapsed at 3.5, 10 and 12 months. Outcomes for pts when the best cord unit match was 0-2 antigen-mismatched (Ag-MM) were superior (8/12 alive and well) to those pts when the best unit was 3 Ag-MM (3/9 alive and well; p=0.20). Unexpectedly, 6/9 pts whose best unit was >4 Ag-MM were alive and well. Information on the dominant cord was available on 19 pts (Table 1); in 15/19 pts, the dominant cord was the same or a better HLA match compared to 4/19 with a dominant cord that was an inferior HLA match (p<0.001). However, the TNC was of less importance with the lower TNC unit being dominant as frequently as the higher TNC unit for each HLA match category (Table 1).

Table 1.

Summary/Conclusions: DUCBT is effective in adults with life-threatening hematologic disorders. With current UCB inventories, conditioning therapies and supportive care, graft failure is rare - even in adults. HLA disparity between the UCB unit and the patient is a better predictor than the TNC regarding which unit will become dominant. Pts receiving well-matched UCB units (0-2 Ag-MM) may have better outcomes than pts receiving 3 Ag-MM units although successful outcomes can be seen even with a high degree (>4 Ag-MM) of HLA incompatibility.

E1558
CLINICAL ANALYSIS OF HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR 46 ACTIVE RELAPSED AND REFRACTORY ACUTE PEDIATRIC LEUKEMIA
L. Yuan1, S. Xue1, J. Wang1.
1Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Given the dismal prognosis for relapsed and refractory (R/R) acute leukemia, many physicians discourage offering hematopoietic stem cell transplantation to HSCT in adults with R/R acute leukemia. Many adults with R/R acute leukemia are not eligible for a bone marrow transplantation because of age or comorbidities. The outcome of utilizing HSC transplantation in adults with R/R acute leukemia has an urgent need for clinical analysis.

Aims: With no significant alternative managing options for these patients, more data are required to make an informed and patient tailored decision.

Methods: We retrospectively analyzed the preliminary outcome of 46 active acute R/R leukemia patients over the period from 2012 to 2016. Median age at HSCT was 13 years. Active R/R disease was all confirmed by cytogenetics/molecular genetics and aggressive clinical course. Median bone marrow blasts was 46.4% (5-99%). Of note, 27 patients had over 50% blasts in BM. The earliest 13 transplants were conditioned with conventional BuCy or TBI/Cy regimen, thereafter, all received intensified conditioning including FLAG/TBI (N=21), FLAG/Bu/Cy (N=2) and CLAG/Bu/Cy (N=10). Immuno-suppressive agents withdrawal started since day 30 if no acute GVHD occurred. Varieties of post-HSCT intervention including donor lymphocytes infusion and intrathecal-2 injection were performed to reduce relapse. Median follow-up of the whole cohort is 19 months (3–53 months).

Results: Forty-five (97.8%) achieved CR following HSCT. One died of infection before engraftment. All 3 death occurred before 90 day due to relapse. Transplant-related mortality at 1 year was 15.2%. Acute GVHD incidence was 49.3% (grade III 20.4%), chronic 59.5%. Relapse was the major cause of treatment failure and occurred in 28.3% of patients at a median of 1 year post HSCT. Two-year overall survival and leukemia-free survival were 44.8±9.5% and 44.6±8.9%, respectively. Survival of AML patients was superior to those of ALL. Failure and occurred in 28.3% of patients at a median of 1 year post HSCT. Two-year overall survival and leukemia-free survival were 44.8±9.5% and 44.6±8.9%, respectively. Survival of AML patients was superior to those of ALL. Failure and occurred in 28.3% of patients at a median of 1 year post HSCT.

OUTCOMES OF PATIENTS RELAPsing FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION FOR AML IN FIRST CR: SINGLE CENTER EXPERIENCE
D. Pastore1,2, P. Carluccio1, M. Delia1, A. Ricco1, A. Russo Rossi1, M.S. De Candia1, A. Mestice1, V. Carluccio1, V. P. Gagliardi1, S. D’Agostino1, C. Pasciolla1, G. Albano1, G. Specchia1.
1Hematology with Transplantation-University Policlinico, Bari, Italy

Background: Allogeneic stem-cell transplantation (SCT) is a curative therapy for patients with AML but disease relapse continues to be the most common relapse after SCT and treatment results are very poor. Treatment options range from supportive care through chemotherapy and donor lymphocyte infusion (DLI) up to a second SCT from the same or a different donor.

Aims: We report a retrospective study of 36 patients AML relapsed patients for autologous stem cell transplantation in first CR.

Methods: Between 2000 and 2016, 637 allogeneic patients with AML in first CR underwent allo-SCT. We identified 36/130 patients (27%) who had relapsed and proceeded to review the management and outcomes of these patients; the incidence of relapse was 20% and 54% after myeloablative and reduced intensity conditioning, respectively. The median time to disease relapse after allo-SCT was 11 months (range 5-48); 15/36 (41%) of relapsed patients suffered aGVHD grade II-IV or extensive cGVHD. At time of relapse 15/36 (41%) patients were still taking immunosuppressive treatment, which was immediately suspended.

Figure 1. Short-term reconstitution in BM and PBSC recipients with and without Post-HSCT-Cy.

Summary/Conclusions: Lymphocyte recovery was impaired for the PTCy groups in the immediate post-HSCT period but quickly recovered. The mechanism of induction of tolerance using PTCy on the +3, +4 day not limited to deletion of alloreactive T-cell clones, but also affects other leukocyte subpopulations (B cells, monocytes, granulocytes). The use of PTCy at +3, + 4 day is immunologically safe method for prevention of GVHD.
ALLOGENIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH CHEMOREFRACTORY HODGKIN LYMPHOMAS: A RETROSPECTIVE MULTICENTER EXPERIENCE OF THE RETE EMATOLÓGICO PUGLIESE (REP)

V. Pavone1,*, F. Gaudio2, G. Specchia2, P. Galieni1, N. Cascavilia4, P. Mazzu5
1Haematology, Panicò Hospital, Tricase, 2Haematology, Policlínico Hospital, Bari, 3Hematology, Mazzoni Hospital, Ascoll Piceno, 4Hematology, Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo (FG), 5Haematology, Moscati Hospital, Taranto, Italy

Background: Second-line salvage high-dose chemotherapy and autologous stem cell transplantation (SCT) have become the standard of care for refractory/hodgkin lymphomas (HL), leading to durable responses in approximately 50% of relapsed patients and a minority of refractory patients. Patients with refractory HL after autologous SCT generally have poor clinical outcomes with available therapies and by far, allogeneic SCT represents the only strategy with a curative potential.

Methods: 39 patients with HL who received allogeneic SCT in chemorefractory disease, from 2000 to 2016 were retrospectively studied. The median age was 34 years (range 16-57 years) and 23 (59%) were male. The majority of patients (80%) had prior autologous SCT. Most (90%) patients received reduced intensity conditioning, 59% received matched sibling donor and 41% matched unrelated donor grafts.

Results: 36 patients survived beyond 100 days and were evaluable for chronic GVHD of whom 22 (61%) remained free of cGVHD and 14 (39%) developed cGVHD. The disease status at day 100 post-transplant was reported in 36 out of 39 evaluable patients. 7 (19%) achieved a CR, 11 (31%) had a PR, 15 (42%) were stable disease and 3 (8%) had progressive disease. Following transplantation 30 (77%) patients have relapsed or progressed at a median time of 12.7 months (range 1- 39 months) following transplantation. The causes of death included infection (n=2), GVHD (n=3), multi-organ failure (n=1). The Kaplan-Meier estimates PFS at five years was 18%. 6 patients (18%) died of non-relapse mortality (NRM) at a median of 300 days (range 28 days- 40 months) following transplantation. The median of NRM and GVHD, disease relapse still represents the major issue in the setting of severe mucositis (grade III and IV) in the group in which cryotherapy was used against the cohort in which it was not (40% vs 72.9%, p<0.005). The need for morphine was also lower in the cryotherapy cohort (54% vs 72%, p=0.149). The use of parenteral nutrition was lower in the non-cryotherapy group (85.7% vs 13.5%, p=0.07). The prevalence of fever was predominant in the cryotherapy group (51% vs 43%, p=0.48), but and infection was documented on more occasions in cryotherapy group (27% vs 81%, p=0.04). The median number of days the patients were discharged from the cryotherapy group was lower (+14 vs +15 median days, p=0.39) and the mortality at day 100 was higher in the non-cryotherapy group (0% vs 8%, p=0.24).

Decreased mucositis degree was associated in both univariate and multivariate analysis only with cryotherapy (p= 0.01 and p=0.0003). Hazzar ratio was 0.81 (IC 95% 0.06-0.55).

Summary/Conclusions: In our center, cryotherapy reduces significantly the severity of mucositis. The use of morphine and parenteral nutrition and other complications do not present such a drastic decline, probably because they influence the gastrointestinal mucositis, which is not combated with cryotherapy. With these results, we are encouraged to continue to include cryotherapy in our protocols.

E1563
REDUCED INCIDENCE OF PRIMARY GRAFT FAILURE IN PATIENTS UNDERGOING HAPLOIDENTICAL STEM CELL TRANSPLANTATION: A SINGLE CENTER EXPERIENCE

A. Martínez-Velandia1, A. Gasoi1, R. de Paz1, S. Cortez1, D. Bueno2, A. Sastre2, M. Canales1, A. Pérez-Martínez2
Aims: Our objective is to describe the incidence and risk factors of PGF and treatments if needed.

Methods: We retrospectively analyzed 40 consecutive patients who underwent HSCT from 2014 to 2016: unmanipulated for 20 adults and graft engineering for 20 children (CD34 selection, n= 6; and CD34-CD45RA depletion, n=14). The stem cell source was mobilized peripheral blood in all cases. GCSF was systematically used from day 5 until engraftment. We used descriptive statistical methods for analysis.

Results: Patient characteristics are described in Table 1. Conditioning regimen was Bu-Flu-Cy (n=18, adults), Thio-Bu-Flu (n=2, adults), Flu-Mel-Thio for all pediatric patients. ATG was used in 6 children and TLI in 14 children. All adult patients were given PT-Cy. Only one adult patient had high titer donor specific anti HLA antibodies and was desensitized with plasma exchange, Rituximab and IVIG before transplantation. All patients engrafted before day 28 and no PGF diagnosis was established in our serie. We found that 4 patients (3 children, 1 adult) required a boost of CD34 selected graft from the same donor for secondary GF and poor graft function.

Summary/Conclusions: PGF incidence described in literature is 5-10%, we did not find any primary graft failure in our serie. Desensitization therapy appeared to be effective in one patient with anti HLA antibodies. All CD34 boosts were performed for secondary graft failure/poor graft function due to treatment toxicities or viral infections. Unfortunately, analysis of causes and risk factors for secondary GF requires a larger number of patients to be determined.

E1564

RESULTS OF HAPLOIDENTIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH LYMPHOMA: A SINGLE CENTER EXPERIENCE

Z. Gulbas1,*, D. Cekdemir1,2, I. Dora1,2, E. Er1,2
1Hematology and Hemotherapy, 2Pediatric Hemato-oncology, Hospital Universitario La Paz, Madrid, Spain

Background: Haploidentical stem cell transplantation (HSCT) is an alternative for patients without HLA matched donors. However, primary graft failure (PGF) and graft versus host disease are still limitations derived from alloreactivity due to HLA mismatch. T cell depleting approaches (in-vivo with post-transplant cyclophosphamide (PT-Cy) or ex-vivo with graft engineering) and surveillance for anti HLA antibodies are strategies intended to reduce these complications. PGF has a high mortality, and treatment with a second graft is not well defined in terms of donor, source, graft engineering or conditioning.

Aims: Our objective is to describe the incidence and risk factors of PGF and treatments if needed.

Methods: We retrospectively analyzed 40 consecutive patients who underwent HSCT from 2014 to 2016: unmanipulated for 20 adults and graft engineering for 20 children (CD34 selection, n=6; and CD34-CD45RA depletion, n=14). The stem cell source was mobilized peripheral blood in all cases. GCSF was systematically used from day 5 until engraftment. We used descriptive statistical methods for analysis.

Results: Patient characteristics are described in Table 1. Conditioning regimen was Bu-Flu-Cy (n=18, adults), Thio-Bu-Flu (n=2, adults), Flu-Mel-Thio for all pediatric patients. ATG was used in 6 children and TLI in 14 children. All adult patients were given PT-Cy. Only one adult patient had high titer donor specific anti HLA antibodies and was desensitized with plasma exchange, Rituximab and IVIG before transplantation. All patients engrafted before day 28 and no PGF diagnosis was established in our serie. We found that 4 patients (3 children, 1 adult) required a boost of CD34 selected graft from the same donor for secondary GF and poor graft function.

Summary/Conclusions: PGF incidence described in literature is 5-10%, we did not find any primary graft failure in our serie. Desensitization therapy appeared to be effective in one patient with anti HLA antibodies. All CD34 boosts were performed for secondary graft failure/poor graft function due to treatment toxicities or viral infections. Unfortunately, analysis of causes and risk factors for secondary GF requires a larger number of patients to be determined.

E1565

COLLECTION OF PERIPHERAL BLOOD HEMATOPOIETIC PROGENITOR CELLS (PBPC) FROM HEALTHY DONORS: 15 YEARS SINGLE CENTER EXPERIENCE

B. Aguado1,*, E. Jimenez Barral1, A. Arriero1, J. Cornago1, Y. Paz1, I. Vicuña1, V. Gomez1, R. de la Camara1, A. Figuera1, A. Alegre1
1Hematology, H.U. La Princesa, Madrid, Spain

Background: hematopoietic stem cell transplantation (HCT) is, nowadays, a consolidated therapy within the treatment of multiple hematological pathologies. In the last two decades, the main method of obtaining hematopoietic progenitor cells is blood leukapheresis after mobilization with granulocytic colony growth factors (G-CSF).

Aims: To describe the experience of our center in apheresis of healthy family donors in the last 15 years. Furthermore, analyze the influence of different variables on the procedure and the yields obtained.

Methods: retrospective analysis was performed on 189 hematopoietic progenitor cell collection (HPCC) from January 2002 to December 2016. The study was carried out at Apheresis Unit, Hospital de La Princesa, Madrid, Spain. Progenitor cells mobilization was performed with G-CSF in all cases at a dose of 10mg/kg b.w. Apheresis device was COBE Spectra in all cases and citrate was the anticoagulant used for all the apheresis procedures. All donors were carefully evaluated and informed on the donation procedure and signed an informed consent for apheresis. The venous access used was mostly peripheral venous access in antecubital veins, and in only 7 cases (3.7%) central venous catheter was required. Donor details studied were age, sex, AB0 group, number of apheresis, number of CD34+ per kilogram collected, and processed volume.

Results: among the 189 donors, 85 were females and 104 were males (45% vs 55%). The hematologic pathologies that motivated transplantation were, in order of frequency, Acute Myeloid Leukemia (AML) (40.2%), Myelodysplastic Syndrome (MDS) (13.8%), Acute Lymphoblastic Leukemia (ALL) (10.1%), Hodgkin’s Lymphoma (HL) (8.5%), Non-Hodgkin’s Lymphoma (NHL) (6.3%), Multiple Myeloma (MM) (5.3%), Chronic Myeloid Leukemia (CML) (4.2%); other 11.6%. Apheresis donors most of them AB0 group, 9 were women (65%) donor and recipient had the same group. Median weight of donors was 74 Kg and in recipients was 70.5 Kg. Median age of our donors was 50 and median age of recipients was 51 years. Twenty donors were >65 years (10.6%) and 10 were >70 years (5.3%). Median of processed volume was 13 liters, but if we stratify that volume by recipient’s weight, in those whose were heavier than 100 kg, median of processed volume was 18 liters. Two apheresis procedures were performed only in ten donors. Of these, 2 were older than 70 years (20% of total donors over 70 years of age) compared to 8 under 70 years of age (4.5% of all patients in that age range). The median of CD34+ /kg collected was 5 x 10⁶. Among the age ranges, median yield of CD34+ in patients older than 70 years was 3.55 x 10⁶, in patients between 31 and 69 years was 4.96 x 10⁶ and in patients younger than 30 years was 5.5 x 10⁶. The apheresis procedure was mostly well tolerated, with only mild symptoms of hypocalcemia and disturbances related to venous access in a minority of cases. No significant long term adverse effect has been observed in the blood donors reported to our centers during the five years of follow up after the donation.

Summary/Conclusions: donor age and weight discrepancy with recipient were the factors that significantly affected PBPC yields in our experience in healthy donors. These factors had also an impact in the amount of liters of plasma collected, although in most cases only one apheresis procedure was enough. Adverse effects of apheresis for PBPC collection were the same as for other apheresis procedures such as those related to venous access, almost always peripheral one and citrate toxicity.

Methods: A total of 81 lymphoma patients (Hodgkin and Non-Hodgkin) with a mean age of 42 years who underwent allo-HSCT (HLA matched n=46, haploidentic n=35) between July 2010 and July 2016 were analyzed. All patients received Cyclophosphamide (Cy) 50mg/kg i.v. on days +3 and +4. All patients initiated CsA day +5, and then adjusted according to the plasma levels. In addition to CsA, all haploidentical allo-HSCT recipients received MMF until day +35.

Results: There were no significant differences in age, sex, diagnosis, disease status up-front HSCT, or transplant characteristics between the groups except a higher median number of stem cells infused in haploidentical group (p=0.004). The median follow-up was 13 months for haploidentical group and 12 months for HLA-matched group. Outcomes of patients are summarized in Table 1.

Summary/Conclusions: Our results suggest that haploidentical allo-HSCT is a safe treatment modality in patients with relapsed lymphoma who lack HLA-matched siblings. The major problem are seems to be viral infections. Future challenges remain in improving post-transplant immune reconstitution and finding the best approach to reduce the incidence and severity of viral infections, while preserving graft-versus-lymphoma effect to prevent the recurrence of the underlying disease

ALLORESPONSES OF HUMAN T-CELLS FROM ADULT PERIPHERAL BLOOD AND UMBILICAL CORD BLOOD ARE DIFFERENTIALLY IMPACTED BY LENALIDOMIDE - IMPLICATIONS FOR AHSTC
C. Besley1, E. Kotsiou1, R. Petty1, A. Sangaranigam2, C. Chelala2, E. Ghazaly1, R. LeDieu1, J. Gribben1, J. Davies1
1Centre for Haematology-Oncology, 2Centre for Tumour Biology, Barts Cancer Institute, London, United Kingdom

Background: Immunomodulatory drugs (IMiDs), such as lenalidomide provide a tool to enhance both direct anti-tumor and graft-versus-tumor effects after allogeneic haematopoietic stem-cell transplantation (AHSTC). However, early clinical experience with IMiDs after AHSTC using adult peripheral blood (APB) as a stem cell source has been limited by induction of graft-versus-host disease. Characterization of the mechanisms by which IMiDs can modulate alloresponsiveness of T-cells from different cell sources could facilitate more effective use of these drugs in the setting of AHSTC.

Aims: To use in vitro modelling to identify changes in alloresponses of APB and umbilical cord blood (UCB) T-cells after exposure to the widely used IMiD lenalidomide.

Methods: We used multi-parameter flow cytometry and gene expression profiling to perform an in-depth characterisation of the phenotypic and genotypic effects of clinically relevant concentrations of lenalidomide treatment on T-cells during allogeneic co-culture. Using GCSF-mobilised APB (GMPB), steady state APB and UCB PBMC as responder cells in allogeneic co-culture we have been able to compare the differential effect of lenalidomide on these three cell sources. Allogeneic responder cells were labelled with CFSE (carboxyfluorescein diacetate succinimidyl ester) to allow quantification of allo-proliferation. Responder T-cell subsets including naive, memory, activated, cytotoxic and regulatory were interrogated. Functional effects of lenalidomide treatment including cellular capacity to produce cytokines, degranulate and exert direct cytotoxicity was also assessed. RNA was extracted from highly purified proliferative and non-proliferative CD8+ T-cell fractions following a combination of magnetic and flow-sorting and gene expression changes assessed by Affymetrix whole genome array and qRT-PCR.

Results: We demonstrate that lenalidomide increases net alloproliferation of APB T-cells by selectively enhancing allospecific proliferation of CD8+ T-cells. These CD8+ T-cells have enhanced effector memory differentiation, are enriched for polyfunctional effectors and have a distinct gene expression profile with altered expression of key immunoregulatory genes and pathways. This effect on CD8+ T-cell proliferation was seen across all 3 cell sources. Importantly a differential effect on CD4+ T-cell responses was observed depending on cell source. Lenalidomide treatment of APB results in no change in CD4+ T-cell proliferation overall, but leads to reduced frequencies of CD4+ regulatory T-cells (Treg). In contrast lenalidomide treatment of GMPB resulted in a significant increase in CD4+ T-cell proliferation, with no effect on Treg cell frequencies. Most strikingly, although lenalidomide treatment of UCB T-cells during allosimulation results in a similar increase in alloreactive effector CD8+ T-cells, it also reduces allospecific proliferation of CD4+ T-cells and selectively expands frequencies of Treg, resulting in a net reduction in UCB T-cell alloproliferation.

Summary/Conclusions: Our findings show that lenalidomide has a qualitatively different impact on alloresponses of T-cells from different cell sources, with a potentially tolerogenic effect on UCB T-cells. These findings have important implications for the future use of IMiDs in the setting of AHSTC.

USING MARKER GENES ANALYSIS INSTEAD OF MLR ASSAY FOR IDENTIFICATION OF FUNCTIONAL CD4+FOXP3+ REGULATORY T CELLS IN GVHD PROPHYLAXIS
1Division of Transfusion Medicine, Department of Medicine, Taipei Veterans General Hospital and National Yang-Ming University School of Medicine, 2Institute of Biochemical Science, National Taiwan University, Taipei, 3Department of Life Science, Fu-Jen University, New Taipei City, Taiwan, Republic of China

Background: There are two types of CD4+CD25+FoxP3+ regulatory T cells (Tregs), natural Treg cells (nTreg) developing in thymus, and induced Treg cells (iTreg) arising from CD4+ naïve T cells. The iTreg cells have been considered important for maintenance of immunological tolerance and correlate with the occurrence of GVHD in some studies. Establishing a quick method to identify the functional iTreg cells is worthy of focusing. Five to ten percent Tregs could be found in human CD4+ T cells and should be expanded via cytokine IL-2. TGF-β and retinoic acid. Then, the iTreg cells harvest time for clinical use. Therefore, using qPCR for marker genes analysis instead of MLR assay is an important issue.

Methods: Mouse splenocytes were prepared from mouse spleen. Human PBSC were prepared from peripheral blood (PB) of healthy donors by Ficoll-Hypaque density gradient centrifugation. All T cells were isolated by negative selection, then CD4+ naïve T cells were harvested. CD4+ naïve T cells were activated with anti-CD3/CD28 beads in the presence of IL-2, TGF-β and retinoic acid (RA) containing RPMI1640 medium. The protocol is showed in Fig. 1.

Results: Seven genes for qPCR analysis were used to identify the functional iTreg cells. We used the different proportions of iTreg cells in total naïve T cells for 7 genes expression analysis and MLR assay to investigate the relationship between gene expression and MLR assay. The iTreg cell gene expressions were evaluated by qPCR. The iTreg cells gene expression were shown in Fig 2. It indicated that the different proportion of iTreg cells could show the different expression profile of these genes. Obviously, the Foxp3 gene expression increased in a great level. Based on our previous

Figure 1. Methods: We have used multi-parameter flow cytometry and gene expression profiling to perform an in-depth characterisation of the phenotypic and genotypic effects of clinically relevant concentrations of lenalidomide treatment on T-cells during allogeneic co-culture. Using GCSF-mobilised APB (GMPB), steady state APB and UCB PBMC as responder cells in allogeneic co-culture we have been able to compare the differential effect of lenalidomide on these three cell sources. Allogeneic responder cells were labelled with CFSE (carboxyfluorescein diacetate succinimidyl ester) to allow quantification of allo-proliferation. Responder T-cell subsets including naive, memory, activated, cytotoxic and regulatory were interrogated. Functional effects of lenalidomide treatment including cellular capacity to produce cytokines, degranulate and exert direct cytotoxicity was also assessed. RNA was extracted from highly purified proliferative and non-proliferative CD8+ T-cell fractions following a combination of magnetic and flow-sorting and gene expression changes assessed by Affymetrix whole genome array and qRT-PCR.

Figure 1. Results: Seven genes for qPCR analysis were used to identify the functional iTreg cells. We used the different proportions of iTreg cells in total naïve T cells for 7 genes expression analysis and MLR assay to investigate the relationship between gene expression and MLR assay. The iTreg cell gene expressions were evaluated by qPCR. The iTreg cells gene expression were shown in Fig 2. It indicated that the different proportion of iTreg cells could show the different expression profile of these genes. Obviously, the Foxp3 gene expression increased in a great level. Based on our previous
experiments, iTreg cells induction could be TGF-β1 dependent. After different amount of TGF-β1 induction, the genes expression profile also showed the coincidence of the data in Fig.2 (Fig.3). Using the same iTreg populations, MLR assay have been investigated for 5 days. The T cell suppression percentage would be dependent on the iTreg cells proportion (Fig.4A and B). It indicated that the gene expression levels can represent the biological function of iTreg cells. It’s the better way to identify the iTreg cells. Further, we have used PBMCs for Treg cell induction, the marker genes expression analysis also showed in Fig.5. After comparing with IL-2 cultured T cells, the gene expressions revealed the difference in between iTreg cells and un-induced T cells.

Summary/Conclusions: Our study showed that MLR assay should spend 3 to 5 days for identification of the functional iTreg cells, however, the marker genes analysis took only one day for that. Besides, MLR assay is a more complicated method than qPCR analysis. Using simple analysis for human iTreg cells functional identification could save the time for clinical application and might prevent GVHD occurrence effectively.

OXIDANT-ANTIOXIDANT SYSTEM IN PATIENTS WITH MULTIPLE MYELOMA
L. Aleksandriani1, L. Rybakova1, S. Kapustin1, S. Gritsaev2, S. Bessmeltsev2
1Biochemistry laboratory, 2Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Multiple myeloma (MM) is one of the most widespread malignant B-cell lymphoproliferative disorders and is characterized by a clonal proliferation of atypical plasma cells in bone marrow or, less frequently, in extramedullary locations synthesizing monoclonal immunoglobulins. Currently, autologous hematopoietic stem cell transplantation (auto-HSCT) is recognized as the standard method of treatment for young patients (<65 years old) with MM. Moreover, the best auto-HSCT results are observed in patients who have received new medication (thalidomide, bortezomib, and lenalidomide) during induction therapy and who have achieved at least a very good partial response, which leads to a significant increase in overall survival. However, studies reflecting the impact of this kind of treatment on the dynamics of oxidant-antioxidant indicators are virtually non-existent. At the same time, the possibility of treating developing diseases by prescribing medication makes the problem highly relevant.

Aims: The aim of the study was to investigate the state of OS-AOS in patients with MM during auto-HSCT.

Methods: We studied 20 patients (11 men and 9 women, mean age 49 years) who followed auto-HSCT after high-dose melphalan. The control group consisted of 50 age- and sex-matched healthy persons. The plasma levels of malonic dialdehyde and ceruloplasmin as well as activities of superoxide dismutase and catalase were measured by standard biochemical techniques. In erythrocytes, the level of non-protein thiol groups was studied. The state of OS-AOS was investigated in each patient four times: before and after conditioning with melphalan, at the moment of maximal leukocyte decrease and after complete reconstitution from cytophenia.

Results: We have found the features of impaired balance in OS-AOS in MM patients before as well as in course of auto-HSCT. The level of malonic dialdehyde in MM patients was not significantly different from that in the control group. At the same time, ceruloplasmin plasma level as well as catalase activity were significantly increased in patient group (p<0.05), whereas the level of non-protein thiol groups was decreased in MM (p<0.05). The results of our study have shown, that an imbalance of OS-AOS is frequently seen in MM patients and, possibly, could influence the course of auto-HSCT.

Summary/Conclusions: The results of the study indicate a high frequency of occurrence of disturbance of the condition of OS-AOS in patients with MM. The imbalance in the functioning of this system is not entirely eliminated in the process of treating the patients with MM using auto-HSCT. The question of the necessity and methods of the possible correction of OS-AOS in patients with MM, particularly during auto-HSCT, requires further study.

SURFACE RECEPTOR EXPRESSION PROFILE DEFINES ALLOREACTIVE DONOR CD8+ T-CELLS AFTER MURINE ALLOGENIC HEMATOPOIETIC CELL TRANSPLANTATION
C. Bäuerlein1, M. Qureischi1,*, C. Brede1, A.-L. Jordán Garrote1, S.S. Riedel1
1Biochemistry laboratory, 2Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Acute graft- versus-host disease (aGVHD) is a severe and often life-threatening inflammatory complication of allogeneic hematopoietic cell transplantation (allo-HCT). aGVHD is mediated by alloreactive donor T cells attacking the gastrointestinal tract, liver, and skin of the host. Efficient strategies to improve aGVHD-related morbidity and mortality will rely on more precise methods than preemptive immunosuppression to consistently predict aGVHD and abrogate disease manifestation without exposing patients to an unwarranted risk for infectious complications. Recent insights into the multistep-pathophysicsiology of aGVHD provide a good basis for the development of new tests to identify individual patients at risk before the onset of aGVHD.

Aims: As pathologic T cell responses rely on spatiotemporally defined programs of T cell activation, acquisition of effector functions, and homing to GVHD target tissues it appeared attractive to assess receptor expression profiles of peripheral blood T cells as potential predictive markers.

Methods: Therefore, we characterized the surface receptor expression profile of peripheral blood donor lymphocytes early after allo-HCT in two independent murine models across minor histocompatibility antigens (miHAg) with multicolor flow cytometry. C57Bl/6 (H-2b, Thy1.1+) or B10.D2 (H-2d, Thy1.1+) T cells plus bone marrow cells were transplanted in conditioned (8Gy) miHAg mismatched BALB/C (H-2b, Thy1.2+) and syngeneic C57Bl/6 (9Gy) or BALB/c (H-2d, Thy1.1+) recipients. To identify suitable predictive markers, we compared the expression pattern of allo-HCT recipients to syngeneic HCT recipients and untreated wild type controls.

Results: Comparing a panel of T cell surface receptors, we found the homing markers CD45R0 integrin, and P- and E-selectin ligand highly up-regulated on allogeneic peripheral blood donor CD8+ T cells at peak time points of cell migration. The combination of these homing markers with the activation markers CD25 and CD69 at later time points and low expression levels of L-selectin allowed to define alloreactive donor T cells.

Summary/Conclusions: Based on this data we propose that alloreactive CD8+ T cells can be identified in miHAg allo-HCT recipients upon their homing receptor expression pattern as soon as six to ten days before the onset of aGVHD.

SOLUBLE FORM OF TRANSFERRIN RECEPTOR IS ASSOCIATED WITH AGE AT DIAGNOSIS AND RISK OF THERAPEUTICAL INTERVENTION AND IRON OVERLOAD IN PATIENTS WITH NON-TRANSFUSION-DEPENDENT THALASSEMIA

P. Ricchi, A. Meloni, S. Costantini, A. Spasiano, T. Di Matola, A. Pepe, L. Pistola, A. Filosa

Background: The soluble transferrin receptor (sTfR), that fully reflects the narrow erythropoietic activity, was found to have not only a striking diagnostic accuracy in predicting the risk of extramedullary haematopoiesis (EMH), but also in scoring disease severity in non-transfusion-dependent thalassemias (NTDT).

Aims: We retrospectively evaluated the relationship between sTfR and some fundamental events in the life and in the management of patients with NTDT.

Methods: We considered 111 NTDT patients with four genetic entities of NTDT: homozygous or compound heterozygous state for β-thalassemia, triplicated a β defect plus a β chain variant. sTfR was measured with a commercially available kit. A group of patients was enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) network and underwent hepatic iron overload assessment by the T2* Magnetic resonance Imaging (MRI) technique.

Results: The group with homozygous or compound heterozygous for β-thalassemia had the higher sTfR levels. sTfR values were negatively related to age at diagnosis (R=−0.462, P<0.0001), and to age at first transfusion (R=−0.703, P<0.0001). At ROC curve a sTfR>5.3mg/L discriminated the patients with a previous history of occasional transfusions. sTfR values were significantly higher in splenectomized patients. sTfR values were negatively related to age at splenectomy (R=−0.328, P=0.044) and in unsplenectomized patients a significant positive correlation was found between sTfR values and spleen diameter (R=0.572, P=0.0001). sTfR values were negatively related to age at starting chelation therapy (R=−0.564, P=0.044). Patients never chelated showed significantly lower sTfR values than patients under chelation therapy (see Figure). sTfR values were significantly correlated with serum ferritin levels (R=0.321, P<0.0001), but no with LIC values.

Figure 1.

Summary/Conclusions: The heterogeneity of patients with NTDT is an emerging cause of complex management and treatment of the disease. Our data indicate that the measurement of sTfR level, a common laboratory test, could contribute to correctly stratify the disease history and the chelation strategy in NTDT.

E1571

LOW SERUM FERRITIN LEVELS DO NOT PROTECT FROM CARDIAC AND HEPATIC IRON IN PATIENTS WITH THALASSEMIA MAJOR

Background: The estimation of serum ferritin levels is the most commonly employed test to evaluate iron overload in Beta Thalassemia Major (TM).

Aims: The aim of this multicenter study was to assess the distribution of serum ferritin levels in a cohort of well treated TM patients and the possible protective role of really low levels versus iron accumulation in the heart and in the liver.

Methods: We considered 1548 TM patients regularly transfused and chelated consecutively enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) Network. Myocardial and hepatic iron burdens were quantified by the T2* technique. For the heart a multislice approach was adopted in order to calculate segmental and global T2* values. Hepatic T2* values were converted into liver iron concentration (LiC) values.

Results: Among patients with serum ferritin ≤500 ng/ml and between 500 and 1000 ng/ml versus patients with serum ferritin ≥1000 ng/ml. Among patients with serum ferritin <500 ng/ml, 9.1% showed significant cardiac iron (global heart T2*<20 ms) and 21.6% showed hepatic iron (LiC ≥3mg/g dw). Cardiac and hepatic iron levels were significantly lower in patients with serum ferritin <500 ng/ml than in the other two groups and in patients with ferritin between 500 and 1000ng/ml versus patients with serum ferritin ≥1000 ng/ml (see Figure). Compared to patients with serum ferritin ≤500 ng/ml, the other two groups showed a significant higher risk of cardiac iron overload (odds ratio-OR=2.03, P=0.002 for patients with ferritin 500-1000 ng/ml and OR=5.96, P<0.0001 for patients with ferritin ≥1000 ng/ml) and of hepatic iron overload (OR=3.44, P<0.0001 for patients with ferritin 500-1000ng/ml and OR=25.43, P<0.0001 for patients with ferritin ≥1000ng/ml).

Summary/Conclusions: Low serum ferritin values, even in the normal range, do not per se exclude cardiac and hepatic iron overload, although decreasing the risk. Before to consider a reduction of the chelator dose in patients whose serum ferritin levels have reached the target, a MRI scan should be performed in order to measure iron levels in the different organs.

E1572

ISCHEMIA MODIFIED ALBUMIN AS A MARKER OF OXIDATIVE STRESS IN CHILDREN AND ADOLESCENTS WITH B-THALASSEMIA: RELATION TO LIPID PEROXIDATION, IRON OVERLOAD AND VASCULAR DYSFUNCTION

Background: Ischemia modified albumin (IMA) is an altered type of serum albumin that forms under conditions of oxidative stress and an independent predictor of major adverse cardiovascular events.

Aims: To measure the levels of IMA in 45 children and adolescents with β-TM compared with 30 healthy controls and assess its relation to lipid peroxidation, vascular complications and subclinical atherosclerosis.

Methods: β-TM patients without symptoms of heart disease were studied focusing on transfusion history, chelation therapy, serum ferritin, malondialdehyde (MDA) and IMA levels. Echocardiography was performed and carotid intima media thickness (CIMT) was assessed.

Results: IMA and MDA levels were significantly higher in β-TM patients compared with controls (p<0.001). IMA was higher among patients with heart disease and pulmonary hypertension (PH) risk than those without. Serum IMA and MDA levels were elevated among patients with serum ferritin ≥2500 µg/L compared with patients below this cutoff. TM patients compliant to chelation had a significantly lower IMA levels than non-compliant ones. Receiver operating characteristic (ROC) curve analysis revealed that a cutoff value of IMA at 75 U/mL could differentiate β-TM patients with PH risk with 90% sensitivity.
91.4% specificity and positive predictive value of 75% and negative predictive value 97%; area under the curve 0.883 (95% confidence interval 0.752-0.959). In addition, the cutoff value of IMA at 17.5 U/mL could differentiate β-TM patients with heart disease with 80.5% sensitivity, 88.9% specificity and positive predictive value of 96.7% and negative predictive value 73.3%; area under the curve 0.887 (95% confidence interval 0.750-0.962). Significant positive correlations were found between IMA levels and disease duration (r=0.311, p=0.045), white blood cell count (r=0.322, p=0.031), serum alanine aminotransferase (r=0.388, p<0.01) and aspartate aminotransferase (r=0.382, p=0.037). IMA and MDA levels were positively correlated (r=0.503, p<0.001) and there was a significant positive correlation between these two markers and mean serum ferritin (IMA; r=0.545, p<0.001 and MDA; r=0.567, p<0.001) among TM patients. IMA levels were positively correlated to TRV (r=0.62, p=0.008), while negatively correlated to ejection fraction (r=-0.412, p=0.014) and fractional shortening. Both IMA and MDA were positively correlated to CIMT (r=0.607, p<0.001 and r=0.615, p<0.001, respectively).

Summary/Conclusions: Our results highlight the role of oxidative stress in the pathophysiology of vascular complications in thalassemia. IMA could be useful for screening of β-TM patients at risk of cardiopulmonary complications and atherosclerosis because its alteration occurs in early subclinical disease.

E1573
SERUM N-TERMINAL PRO-BRAIN NATRIURETIC PEPTIDE LEVEL AND ECHOCARDIOGRAPHIC TISSUE DOPPLER ABNORMALITIES IN PATIENTS WITH BETA THALASSEMA MAJOR
M. El-Tagui1, I. Mahmoud2, H. Agha1, S. Mohamed1, M. El-Ghamrawy1,*
1Pediatrics, 2Clinical and Chemical Pathology, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Heart disease remains the major cause of morbidity and mortality in thalassemia patients. Multiple pathologies have been implicated in the development of cardiomyopathy in these patients including: cardiac iron overload leading to right ventricular diastolic then left ventricular systolic dysfunction, chronic anemia and tissue hypoxia. Because congestive heart failure is the main cause of death in these patients, early recognition of cardiac dysfunction may be useful in modifying therapy in a timely manner. Tissue Doppler imaging (TDI) and serum brain natriuretic peptide (BNP) level may be promising tools for such a purpose.

Aims: This study aimed to assess serum NT-proBNP level and echocardiographic tissue doppler abnormalities among a cohort of Egyptian beta thalassemia major patients and to detect possible associations between them as well as other disease variables including iron overload.

Methods: Thirty beta thalassemia major patients with a mean age of 12.93±2.07 years regularly followed up at Pediatric Hematology Clinic, Cairo University and thirty aged matched healthy control subjects were included. Conventional, M-Mode and TDI echocardiography were performed to all patients and control subjects in addition to cardiac magnetic resonance (CMR)for studied patients. Serum NT-proBNP level was measured using enzyme linked immunosorbant assay (ELISA).

Results: Tissue doppler imaging revealed a significant difference of ratio of the early (e') to late (a') right ventricle filling velocities (Rv e'/a' ratio) between cardiac iron overloaded patients reflecting early diastolic dysfunction in cardiac iron overloaded patients. Myocardial performance index of left ventricle (LV_TDI index) by TDI showed significant difference in cardiac iron overloaded patients compared to non cardiac iron overloaded patient (mean 0.39±0.04 vs 0.33±0.03) indicating decrease in ventricular relaxation due to iron overload and restrictive cardiomyopathy. SerumBNP level was significantly higher among patients compared to controls (mean 99.18±72.43pg/ml versus 18.93±9.65pg/ml respectively with p-value<0.001) and among cardiac iron overloaded patients compared to non cardiac iron overloaded (mean 212.3±57.18pg/ml versus 64.75±26.69pg/ml respectively with p-value<0.001). We found positive correlation between level of BNP and frequency of the blood transfusion/year, Rv'e/a' and LV_TDI index with (p value 0.006, <0.001 and 0.030 respectively) denoting early diastolic impairment in asymptomatic thalassemia patients.

Summary/Conclusions: Asymptomatic thalassemia major patients under chelation therapy may have diastolic and or systolic dysfunctions that could not be detected by conventional echocardiography but could be highlighted by TDI. CMR, TDI and serum BNP level measurement are promising tools for accurate assessment of cardiac functions and iron overload in thalassemia patients.

PRENATAL DIAGNOSIS OF HEMOGLOBINOPATHIES IN NORTHERN GREECE. 15 YEARS REPORT
S. Theodoroudi1, N. Prapas2, A. Sotiriadis2, A. Athanasiadis2, T. Daglis2, O. Diamandouli3, D. Adamidou1, M. Konstantinou1, A. Tei1, B. Delaki3, E. Boutou1, E. Yfanti1, A. Balassopoulou1, T.-A. Vyzantiadis4, T. Theodoridis1, E. Voskaridou3, B. Delaki3, E. Boutou3, E. Yfanti3, A. Balassopoulou3, T.-A. Vyzantiadis4, T. Theodoridis1, E. Voskaridou3
1Thalassemi Unit, 2Obstetric Department, Hippokration General Hospital, 3Thessaloniki Centre, Laikon General Hospital, Athens, 4Microbiology Department, 5Obstetric Department, Aristotelion University, Thessaloniki, Greece

Background: Hemoglobinopathies constitute the most frequent monogenic disorders worldwide and thalassemias are the most frequent genetic disorders of the blood. The impact of thalassemia is frequency dependent and varies from place to place, where 15% of the population are carriers of the Hb S mutation. The rate of β-thal carriers could be as high as 15-20% in some areas. The risk of giving birth to an affected child depends on the incidence of the thalassemic gene and this may vary from 1/24 to 1/150 in married couples. The National Program for prevention of Thalassemia was established in 1973. Through population screening and prenatal diagnosis programs Greeks and immigrants are screened and counseled.

Aims: We report our findings on prenatal diagnosis of thalassemias and hemoglobinopathies in Northern Greece over a 15 year period (2001-2015).

Methods: During the 15 year period, a total of 33.837 subjects were screened for thalassemia and as couples or as single individuals. We report 3.659 couples screened for hemoglobinopathies. In 371 couples both partners carried an abnormal Hb gene and counseling was offered and 329 pregnancies were found at risk of giving birth to an affected child. The genes interactions were in 245 pregnancies at risk for thalassemia major of which 84 for sickle cell disease ones. Prenatal diagnosis was offered for 12 weeks of gestation (n=298), in cases by amniotic fluid sampling (n=21) collected at 16-18 weeks. Few late comers were tested by fetal blood sampling at 20 week of gestation(n=5).

Results: Our findings on prenatal diagnosis of thalassemias and hemoglobinopathies in Northern Greece over a 15 year period are as follows: 76 fetuses (23%) were found to be homozygote or double heterozygote for clinical significant mutations. These couples were informed of the danger of having an affected child but the termination or continuation of the pregnancy was left to the couples to decide. Nevertheless all, except three couples, preferred to terminate the pregnancies so we had one case of thalassemia major major offspring and two cases of silent β-thal/O Arab offsprings born. Selective abortion of the affected fetus was performed in the cases of the twin pregnancies (n=6). There have been no cases of misdiagnosed pregnancies and only one obstetric complication (rupture of membrane that lead to miscarriage) was reported.

Summary/Conclusions: It is universally accepted that thalassemia prevention programs are successful in countries with a high frequency of Hb mutations, and prenatal diagnosis is mandatory in all at risk couples. The National Thalassemia Prevention Program has effectively decreased the incidence of thalassemia major and sickle cell syndromes in our country and in our region.

E1575
THE IMPACT OF LIVER STEATOSIS ON THE ABILITY OF SERUM FERRITIN LEVELS TO PREDICT LIVER IRON CONCENTRATION AMONG NON TRANSFUSION-DEPENDENT THALASSEMAIA PATIENTS: A CROSS-SECTIONAL EVALUATION
P. Ricchi1, A. Meloni2, L. Pistoia2, V. Positano2, P. Preziosi3, A. Filosa1, A. Pepe2
1AORN A. Cardarelli, Naples, 2Fondazione G. Monasterio CNR-Regione Toscana, Pisa, 3Ospedale “Sandro Pertini”, Rome, Italy

Background: Fatty liver is a common abnormality encountered in western countries among patients undergoing imaging of the abdomen and is associated to systemic inflammation and to increased ferritin levels, frequently unrelated to iron overload.

Aims: We analyzed the impact of the presence of fatty liver in the parameters of iron overload among our patients with Non Transfusion dependent Thalassemia (NTTD).

Methods: 111 patients with NTTD were cross-sectionally evaluated; the diagnosis of liver steatosis was ultrasound-based (US). In all patients, ferritin levels and serum alanine aminotransferase (ALT) to serum aspartate aminotransferase (AST) ratio were assessed. Liver iron concentration ( LIC) measurements were available for 64 patients (54%) who underwent a magnetic resonance Imaging (MRI) scan within the Myocardial Iron Overload in Thalassemia (MIOT) network.

Results: Liver steatosis was frequently (35.5%) encountered among our patients with NTTD and was significantly more prevalent in males with respect to females (49.0% vs 24.6%, p<0.008). Patients with liver steatosis had significantly higher levels of ALT/AST, ALT/AST ratio and ferritins than those without, but LIC values were comparable (Table 1). At ROC curve analysis, a ALT/AST ratio >0.89 predicted the presence of liver steatosis with a sensitivity=0.872 and a specificity =0.901 (P<0.001). Overall, ferritin levels positively correlated with LIC values (R=0.558, P<0.001) but in patients without steatosis there
was a strong relationship between ferritin and LIC values (R=0.656, P<0.0001) while in patients with steatosis the correlation was moderate (R=0.42, P=0.05).

Table 1.

Summary/Conclusions: Our data show that liver steatosis affected also patients with NTDT and should be suspected in presence of a ALT/AST ratio >0.89. Recently, serum ferritin thresholds to predict clinically relevant liver iron concentrations for guiding chelation therapy when MRI is unavailable in patients with (NTDT) have been provided. Our data show that the presence of liver steatosis may lead to overestimate the magnitude of iron burden and may be responsible for anticipating or exceeding chelation treatment in patients with NTDT in absence of a LIC evaluation.

E1576

CIRCULATING CELL-FREE DNA (CFDNA) AND INEFFECTIVE ERYTHROPOIESIS IN BETA-THALASSEMA INTERMEDIA

D. Tavazzi1, G. Graziaedi2, A. Marcon2, L. Duca2, I. Nava2, M.D. Cappellini1,2, M. Sampietro3
1Dip. Scienze Cliniche e di Comunità, Università degli Studi di Milano, 2Dipartimento di Medicina Interna, Fondazione IRCCS Cà Grande Policlínico di Milano, 3Dip. Igiene e Medica Generale, Università degli Studi di Milano, Milano, Italy

Background: Low concentrations of circulating cell-free DNA (cfDNA) are found in the plasma of healthy individuals and increase in a number of conditions: malignancies, to clinical severity, including cancer, chronic inflammation, autoimmune diseases and trauma. The mechanisms of release of cfDNA in the bloodstream are not well understood: DNA could originate from cells undergoing apoptosis/necrosis in tissues or from cells released in the blood and subsequently lysed. Also the tissue origin of cfDNA is mainly unclear. It has been suggested that cfDNA, at least after bone-marrow transplantation, could be mostly of hematopoietic origin. This finding prompted us to explore whether cfDNA is increased in patients with ineffective erythropoiesis (IE), a condition characterized by the over-proliferation and lysis/removal of erythroid precursors. This situation is common in thalassemias, mainly in non transfusion-dependent patients (NTDT). Aims: The present study was designed i) to evaluate the behaviour of cfDNA in IE caused by beta-thalassemia, and ii) to assess whether cfDNA could be useful to quantify IE.

Methods: We studied 49 beta-thalassemia intermedia (TI) patients (mean age 41 years, range 18-65), 23 of whom were splenectomized. No evidences of tumor, trauma or autoimmune diseases have been observed in any patient at time of the study. Eighteen healthy subjects were also included as control group. The study was approved by the local ethical committee. DNA was extracted by QIAgen silica-based micro-spin columns from 200 mL of K2EDTA plasma. cfDNA concentration determined fluorometrically using the fluorescent dye PicoGreen. Biochemical and hematologic parameters were determined in all patients as a part of laboratory routine. Reticulocytes and peripheral erythrocytes (EBL) were counted by automated procedures. Soluble transferrin receptor (sTfR) and growth differentiation factor 15 (GDF15) were also measured by immunometric ELISA assays.

Results: In the 49 patients studied, plasma cfDNA concentrations ranged from 6.3 to 93.1 ng/mL and are significantly higher than in controls (median 21.8 vs 10.4, p<0.0001). Comparing non splenectomised (non-SPX) with splenectomised (SPX) patients, we observed a significant increase of cfDNA in the SPX group (median 29.4 vs 19.3 ng/mL, p=0.0085). In the whole TI group, cfDNA concentration was significantly correlated with EBL (p<0.0001), LDH (r=0.52, p=0.0001) and AST (r=0.56, p<0.0001). Correlations of cfDNA were also observed with sTfR (r=0.45, p=0.0014) and GDF15 (r=0.56, p<0.0001). Notably, correlations with EBL (r=0.75, p<0.0001), AST (r=0.58, p<0.0036) and unconjugated bilirubin (r=0.54, p=0.0083) were observed only within the SPX group and not in non-SPX.

Summary/Conclusions: In this study we found that plasma cfDNA rises in TI patients compared to controls. Its concentration appears to correlate with both the amount of IE and based on high number of EBL and the lysing of circulating erythroid precursors (both increased after splenectomy). We obtained preliminary evidences that circulating cfDNA concentration may be a suitable indicator of erythropoietic activity in TI patients. Results need to be extended on larger samples of patients’ population to investigate the possible use of plasma cfDNA as a feasible and reliable biomarker to describe/monitor the severity of IE and TI complications.

E1577

LEFT VENTRICULAR HYPERTRABECULATION BY CARDIAC MAGNETIC RESONANCE IN THALASSEMA INTERMEDIA PATIENTS: FREQUENCY AND PROGNOSTIC ROLE

A. Melon1,2, F. Macione2, L. Pistoia3, S. Pulini3, V. Santamaria4, M. Benni5, L. Sardella5, A. Barison1, G. Peritore1, V. Postiano1, S. Novo2, A. Pepe1

Background: Differentiation of left ventricle non-compaction (LVNC) from hypertrabeculated LV due to a negative heart remodeling in thalassemia intermedia (TI) depends on the selected CMR criterion. The recently proposed Piga’s criterion (NC/C ratio threshold of >2.5, Am J Haem 2012) seems to have a low specificity to identify the true LVNC in TI. Anyway, the Piga’s criterion could easily detect a negative heart remodeling in TI patients.

Aims: The aim of our study was to prospectively assess whether the Piga’s criterion had a prognostic role for adverse cardiovascular outcomes in TI patients.

Methods: We studied prospectively 168 TI patients (81 males, mean age 38.32±11.61 years) consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network. Standard cine steady-state free precession sequences were acquired and used for the calculation of biventricular function parameters (short-axis) and for the calculation of the thickness of the non-compacted and the compacted myocardium (three diastolic long-axis views) in all 16 segments. The maximal NC/C ratio was considered. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.

Figure 1.

Results: Eight patients were excluded because a cardiac complication was present at the first CMR. The baseline mean age of the considered 161 TI patients was 38.32±11.61 years and 81 patients were males. The study population was divided into two groups: patients with Piga’s positive criterion (n=15, 9.31%) and with Piga’s negative criterion (n=146, 90.68%). No significant differences were found between the two groups in terms of demographic features and CMR parameters. The mean follow-up time was 57.50±21.87 months. Sixteen new cardiac events were recorded: 1 heart failure, 10 supraventricular arrhythmias and 5 pulmonary hypertension. Due to numerical reasons, it was possible to perform a Cox regression analysis only for arrhythmias and cardiac complications globally considered. Patients with Piga’s positive criterion had a significantly higher risk of developing arrhythmias (hazard ratio=HR=7.19, 95% CI=2.02-25.51; P=0.002) and cardiac complications (HR=3.86, 95% CI=1.18-11.36, P=0.025). The figure shows the Kaplan-Meier survival curves. The Piga’s positive criterion remained a significant prognosticator also in a multivariate models including previous and resolved events (14 cardiac complications, of which 7 arrhythmias) (HR for arrhythmias=23.67; HR for cardiac complications=7.09).

Summary/Conclusions: Based on our data a NC/C ratio >2.5 provides prognostic information for patients with TI about the risk of developing cardiac complications.

E1578

NITRIC OXIDE DYSREGULATION IN BETA-THALASSEMA MAJOR: RELATION TO PULMONARY HYPERTENSION

M. Elshinawy1,2, A. Elnegg3, A. Ghanem2, M. Wagdy4
1Pediatric Hematology, Sultan Qaboos University Hospital, Muscat, Oman, 2Pediatric Hematology, Faculty of Medicine, 3Hematology, Medical Research Institute, 4Clinical Pathology, Faculty of Medicine, Alexandria, Egypt

Background: Pulmonary hypertension (PH) is emerging as one of the most devastating complications of beta-thalassemia major. Chronic hemolysis and iron overload constitute a major source of strong oxidative stress. Free heme radicals and red cell membrane elements resulting from hemolysis have a negative effect on the intrinsic nitric oxide (NO) production and arginine availabil-

642 | haematologica | 2017; 102(s2)
ability. Deficiency of both biochemical mediators promotes vasoconstriction of the pulmonary vasculature resulting in further endothelial dysfunction, with subsequent intensified reduction of nitric oxide. The role of nitric oxide dysregulation is well-studied in non-transfusion dependent thalassemias and in sickle cell disease, but yet not well-characterized in beta thalassemia major.

**Aims:** The aim of our work is to study the relation between intrinsic nitric oxide level and the evolution of pulmonary hypertension in beta thalassemia major.

**Methods:** This is a case-control study, including all patients with beta thalassemia major above 12 years of age, undergoing follow up in pediatric hematology and medical research institute, University of Alexandria, Egypt throughout a period of 6 months from 1st of July till 31st of December 2016. All patients were screened for pulmonary hypertension by echocardiography, and those who have high tricuspid regurgitant jet velocity (TRV>2.5m/sec.) underwent cardiac catheterization.

**Results:** The present study included 52 thalassemic patients, 28 males and 24 females. The age ranged between 11 and 26 years. The patients were subdivided into two groups (17 patients with pulmonary hypertension (PH), proven by cardiac catheterization and 35 patients without pulmonary hypertension). Nitric oxide level (measured by ELISA) was significantly lower in patients as a whole compared to controls [median of 19 micromol/L versus 30 micromol/L (P=0.02)]. Similarly, nitric oxide was significantly lower in PH group compared to non-PH patients (p=0.001). In addition, there was a statistically significant negative correlation between serum NO level and serum ferritin level in all patients (r=-0.444, P=0.001).

**Summary/Conclusions:** In conclusion, NO reduction might contribute significantly to the development of pulmonary hypertension in patients with beta thalassemia major. This effect could be related to the degree of hemolysis, iron overload and the duration of disease. Further studies on the adverse pathophysiological effects of nitric oxide deficiency in beta thalassemia major e.g. its relation to coagulopathy and platelet aggregation are recommended.

**SPECKLE-TRACKING ECHOCARDIOGRAPHY FOR DIAGNOSIS OF EARLY MYOCARDIAL DISEASE IN EGYPTIAN BETA THALASSEMIA MAJOR PATIENTS**

A. G. C. Tantawy,1,2 N. M. Habeeb, N. H. Elsherif, E. M. Hasan, A. Abdelhameed1,2
1Pediatric Hematology & Oncology, 2Cardiology Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt

**Background:** The new parameters of cardiac function, derived from two-dimensional speckle-tracking echocardiography could be useful for an early diagnosis of cardiac involvement in transfusion dependent β-TM patients.

**Aims:** In this cross sectional study, our goal was to detect early myocardial disease in transfusion dependent β-TM patients using Echocardiography (Speckle Tracking) to assess its specificity and sensitivity in comparison with cardiac MRI T2*.

**Methods:** This cross sectional study included 30 transfusion dependent β-thalassemia patients aged between 11-20 years recruited from the Pediatric Hematology & Oncology Unit, Children Hospital, Ain Shams University. All included patients were subjected to detailed medical history including transfusion, chelation, hepatitis C Virus history with calculation of mean serum ferritin in last 2 years) Radiological investigation included Echocardiography (Tissue Doppler and Speckle Tracking), MRI T2* were done. Cardiac affection by speckled was defined as decreased longitudinal strain less than 11 percentage or affection of any segment less than 11 percentage.

**Results:** Cardiac affection by speckled echocardiography was found in 10 patients (33.3%), 8 of them (80%) had normal ejection fraction and normal shortening fraction, while 9 had iron overload by Cardiac MRI T2*. Patients with mean serum ferritin >2500 ng/mL in the last 2 years prior evaluation showed a significantly lower longitudinal strain (GLPSLAX) (P=0.043) which was further proved by a significantly negative correlation with the mean serum ferritin (P=0.002). No significant differences were found between both spelecmorized and non-splenec- tomized patients as regard speckle tracking echocardiographic measures. The ROC curve analysis revealed that GLPS A4C a cutoff value of ≤21% was able to detect β-thalassemia patients having myocardial disease by cardiac MRI T2* with a sensitivity of 87.50% and specificity of 63.64%. Patients with cardiac iron overload by MRI T2* had significantly lower GLPSLAX & GLPSA4C and higher Ao Diam than those without cardiac iron overload (P=0.016, P=0.008, P=0.047 respectively). No significant difference between beta thalassemia patients with cardiac affection and those without cardiac affection as regard the duration of the disease, type and compliance of chelation therapy.

**Summary/Conclusions:** Although, Magnetic Resonance Imaging T2* technique is a promising tool in cardiac iron overload detection, its routine use is limited by its high costs, poor availability. We demonstrated in this study an abnormal global longitudinal strain despite preserved LV systolic functions among BTM patients; thus speckle tracking echo techniques might be considered as an alternative effective method to detect early myocardial disease before evident systolic dysfunction.

**EFFICACY, SAFETY AND GENETIC BASIS OF VARIABILITY OF RESPONSE TO HYDROXYUREA THERAPY IN BETA THALASSEMIA: A SYSTEMATIC REVIEW**

S. Khalil1,2
1Pathology, faujii Foundation Hospital/Foundation University Medical College Rawalpindi, 2Hematology, Hemophilia Centre, Rawalpindi, Pakistan

**Background:** Pharmacological agents such as hydroxyurea promote fetal hemoglobin production via a reactivation of γgenes. In β-thalassemia there is an imbalance in globin chains which could be ameliorated by the newly synthesized γchains which neutralize the excess α-chains and therefore improves symptoms.

**Aims:** Systematic review of literature to evaluate the efficacy, safety and the genetic basis of variability of response to hydroxyurea therapy in beta-thalassemia patients.

**Methods:** Research sources used were: MEDLINE (PubMed), EMBASE (Ovid) and Cochrane from June 1993 till June 2016. Eligible articles were reviewed and data including patients characteristics, duration of treatment, outcome, toxicity and impact of genetic mutation on response to hydroxyurea therapy were extracted. Major responders were those who became transfusion independent after hydroxyurea treatment, partial responders had significant decline in transfusion requirements, poor responders did not respond to hydroxyurea therapy. Statistical analysis software package 16 was used for data analysis.

**Table 1.**

The percentage of diabetic patients diagnosed by CGMS was significantly higher than that with OGTT (p = 0.012). According to CGMS readings, 10 of the 13 patients with diabetes had abnormal HbA1c readings of diabetic range (6.5-9.9%) while 5 of the 7 patients with impaired glucose tolerance had HbA1c readings in the prediabetic range (5.5-6.1%). Serum ferritin was significantly higher among patients with RBG ≥140mg/dL (p<0.001). It was noted that 66% of those with RBG ≥140mg/dL were noncompliant and 75% of patients on desferrioxamine therapy had RBG≥140mg/dL. There was a significant positive correlation between HbA1C% and FBG among the studied thalassemia patients with elevated RBG≥ 140mg/dL, while HbA1C% was negatively correlated with fasting C-peptide. Serum ferritin was positively correlated with RBG. As regards GDF-15 data, HbA1C was positively correlated to maximum blood glucose, average blood glucose, SB blood glucose and area under the curve≥140mg/dL. The only significant independent factor for elevated RBG ≥140mg/dL was serum ferritin.

Summary/Conclusions: The use of CGMS in the diagnosis of early glycemic abnormalities (prediabetes) among patients with β-TM appears to be promising and superior to other known diagnostic modalities namely OGTT and HbA1c.

E1583
LEFT VENTRICULAR REGIONAL FUNCTION IN CHILDREN WITH BETA THALASSEMIA WITH NO CARDIAC MANIFESTATIONS (FOUR-DIMENSIONAL ECHOCARDIOGRAPHIC STUDY)
M. El-Shahawy1,2, M. El-Toba1, W. El-Shehaby1, A. Elshamia 2, A. Fayed3, A. ElKholy 4, E. Eldosoky 2
1Pediatrics, Faculty of Medicine, Tanta University, Tanta, 2Pediatrics, Ministry of Health, Basyun, 3Pediatrics, Ministry of Health, Kotor, 4Pediatrics, Ministry of Health, Zefta, 5Pediatrics, Ministry of Health, Alexandria, Egypt

Background: Early detection of myocardial dysfunction is essential for the management of patients with thalassemia. Four-dimensional echocardiographic imaging technique that analyzes the motion of tissues in the heart may be useful for detecting subclinical cardiovascular disease.

Aims: To evaluate the 4-dimensional echocardiographic strain in children with beta thalassemia major and correlate it with other echocardiographic parameters.

Methods: This is a cross sectional cohort Study included 200 children, 1-18 years-old. They were divided into: One hundred children with β-Thalassemia major with no clinical cardiac manifestations and 100 healthy children as a control group. They were subjected to the following investigations: Complete blood count, serum ferritin and Four-dimensional echocardiographic strains (Longitudinal, Circumferential, Radial and Area strains).

Results: There was no significant difference between the two groups as regard mitral annulus systolic velocity (S wave), E/A ratio and iso-volumetric acceleration but there was a significant difference as regard to ejection fraction, left ventricle mass, sphericity index and myocardial performance index. The mean values of Left ventricular Strains (Longitudinal, Circumferential, Radial and Area strains) were significantly lower in patients with thalassemia (-14.8±6.12±131, -8.0±3.829, 33.1±10.613, -19.4±6.866) than controls (-19.1±3.5102, -16.0±3.723, 37.2±10.094, -22.9±4.307) but there was a positive correlation with 2-Dimensional strain.

Summary/Conclusions: Strain parameters of the left ventricle obtained by four-dimensional echocardiography can be a novel and promising technique for early detection of left ventricular dysfunction in children with thalassemia.

E1584
THE IMPORTANCE OF SERUM GDF-15 LEVELS TO ASSESS IRON OVERLOAD IN PATIENTS WITH THALASSEMIA MAJOR
M. Ucman1, U. Caliskan2,3, H. Tokgoz2
1Necmettin Erbakan University Meram Medical Faculty, Konya, Turkey, 2Pedi- atric Hematology and Oncology, Necmettin Erbakan University Meram Medical Faculty, Konya, Turkey

Background: There is growing interest in noninvasive assessment of iron accumulation in patients with thalassemia major. Magnetic resonance imaging (MRI) have become widely available in recent times.

Aims: We aimed to evaluate the importance of serum GDF-15 levels for monitoring the iron overload in patients with beta thalassemia major.

Methods: Forty-six patients aged between 1 and 25 years were included in the study. Serum levels of GDF-15, ferritin, troponin, AST and ALT were studied.

Results: There was no significant difference between thalassemia patients and control group as regards serum levels of calcium, osteocalcin and alkaline phosphatase and DEXA among studied groups.

Summary/Conclusions: To study the relationship between SP1 polymorphism in the collagen type 1 alpha 1 gene and the development of osteoporosis in patients with Beta thalassemia.

E1585
ASSOCIATION OF SP1 POLYMORPHISM IN THE COLLAGEN TYPE I ALPHA 1 (COL1A1) GENE WITH OSTEOPOROSIS IN CHILDREN WITH BETA-THALASSEMIA
M. Hesham1, N. Khalifa2, M. Zakaria1, N. Elbax2, D. AbdElemonem2
1Pediatric, 2clinical pathology, Zagazig University Hospital, Zagazig, Egypt

Background: Osteoporosis is a progressive bone disease that is characterised by a decrease in bone mass and density that leads to an increased risk of fracture. Early detection of mutation at the Sp1-binding site on the COL1A1 gene is mandatory in order to initiate preventive therapy before the occurrence of fractures in children with Beta-thalassemia major.

Aims: To study the relationship between SP1 polymorphism in the collagen type 1 alpha 1 gene and the development of osteoporosis in patients with Beta thalassemia.

Methods: A prospective case control study was carried out in the Outpatient Clinic of Hematology Unit of Pediatric Department and Clinical Pathology Depart- ment at Zagazig University Hospitals on forty thalassemic patients (21 females &19 males) aged 6-18 years during their regular follow-up visits (22 patients with thalassemia major and 18 with thalassemia intermedia) and forty age- and sex-matched healthy children as a control group. All patients and control were subjected to full medical history, thorough clinical examination and laboratory investigations in the form of complete blood count, Hb electrophoresis, Calcium level Serum alkaline phosphatase, Bone Density by DXA, Serum osteocalcin level and COL1A1 gene polymorphism by using polymerase chain reaction-restriction fragment length polymorphism technique (PCR-RFLP).

Results: There was highly significant difference between thalassemia patients and control group as regards serum levels of calcium, osteocalcin and alkaline phosphatase and DEXA results but no significant difference between thalassemia major and thalassemia intermedia patients. As regard COL1A1 genotype there was high percentage of heterozygous Ss (G/T) and homozygous ss (T/T) genotype in beta thalassemia major 55.63%, 13.67% than thalassemia intermedia 50.6%, 0%, respectively. There was significant relation between COL1A1 genotypes and Calcium level (p=0.02). But there was no significant relation between COL1A1 genotypes and osteocalcin, alkaline phosphatase levels and DEXA among studied groups.

Summary/Conclusions: SP1 polymorphism in collagen gene could be of clinical value in identifying the thalassemic patients at risk of developing osteo- porosis.

Estefânia, Centro Hospitalar de Lisboa Central, 6Fac-
Results: sideropenic anemia, hemoglobin variants or alpha thalassemia. Sequencing of samples from January 2007 to January 2016. The inclusion criteria were the simultaneous presence of hypochromia and microcytosis (adjusted to the age) and HbA2 values between 3.2% and 3.4%. The exclusion criteria were the presence and/or clinical information of sideropenia, or sideropenic anemia, hemoglobin variants or alpha thalassemia. Sequencing of the entire HBB gene was performed by Sanger Sequencing.

Methods: Parameterized search of all the consecutive individuals evaluated in our laboratory from January 2007 to January 2016. The inclusion criteria were the simultaneous presence of hypochromia and microcytosis, with normal or slightly elevated RDW, without sideropenia, with HbA2 between 3.2-3.4%, should be screened for mutations in the HBB gene, in order to rule out beta thalassemia carriers due to Beta+ mutations. As HBB IVSI-6 (T>C) mutation is one of the most frequent beta thalassemia mutations in Portugal, and in Mediterranean basin, it is necessary to screen for this mutation. The classic rule of HbA2> 3.5% for the diagnosis of beta thalassemia minor may underdiagnose this pathology and lead to an incorrect genetic counseling.

Summary/Conclusions: We have identified 14/43 (32%) individuals as beta thalassemia carriers who, for the conventional cut-off of HbA2 ≥3.5%, would not have been diagnosed. Based on this data, we propose that individuals with hypochromia and microcytosis, with normal or slightly elevated RDW, without sideropenia, with HbA2 between 3.2-3.4%, should be screened for mutations in the HBB gene, in order to rule out beta thalassemia carriers due to Beta+ mutations. As HBB IVSI-6 (T>C) mutation is one of the most frequent beta thalassemia mutations in Portugal, and in Mediterranean basin, it is necessary to screen for this mutation. The classic rule of HbA2> 3.5% for the diagnosis of beta thalassemia minor may underdiagnose this pathology and lead to an incorrect genetic counseling.

DIAGNOSIS OF HEMOGLOBINOPATHIES BY CAPILLARY ZONE ELECTROPHORESIS: EXPERIENCE WITH 925 CASES

P. Tripathi1, H.P. Patil1, R. Saxena2

1Dept of Hematology, All India Institute of Medical Sciences, New Delhi, India
2Medicine, Hematology and Oncology, Centro Hospitalar de Lisboa Norte, Lisboa, Portugal

Background: Hemoglobin (Hb) is a protein responsible for oxygen transporta-

tion from lungs to the entire body. It is composed by four globular subunits - the
globins - each with a central core containing a heme molecule. Globins are
ecoded by the α- and β-globin gene clusters located at 16p13.3 and 11p15.5, respectively. The pattern of globin gene expression during development is pre-
cisely controlled by the interaction of cis-regulatory genomic regions (located
in close proximity to and far from genes) with trans-activating/silencing factors
within permissive chromatin domains. Distally upstream of the α-globin genes
there are four multispecies conserved sequences (MCS-R1 to R4) which are
critical for the expression of downstream globin genes. Deletions removing
the α-globin genes and/or their distal MCSs give rise to α-thalassemia, one of
the most common genetic recessive disorders worldwide, due to a reduced
rate of α-globin chain synthesis. The severity of the pathology is variable ranging
from a very mild microcytic hypochromic anemia to a moderately severe anemia
associated with the formation of αβ tetramers resulting in HbH disease or an
even higher reduction or complete absence of α-chains resulting in hemoglobin
Bart's hydrops fetalis, a condition generally incompatible with life.

Aims: The main objectives of this work were to characterize the molecular
lesions underlying ten Portuguese cases of unusual α-thalassemia/HbH disease
and to interpret their origin and functional consequences.

Methods: After exclusion the most frequent molecular lesions associated with
α-thalassemia, Multiplex Ligation-dependent Probe Amplification (MLPA) using
the SALSA MLPA P140B HBA kit (MCR-Holland) was used to search for DNA
deletions in the subtelomeric region of chromosome 16p. Additionally, specifi-
cally designed synthetic MLPA probes, as well as gap-PCR and Sanger
sequencing were performed for more accurate deletion breakpoint mapping.

Results: We have found five distinct deletions and one indel, all in heterozy-
gosity. The deletions range from approximately 3.3 to 323 kb and two of them are
novel. The three larger deletions remove the entire α-globin cluster whereas the
others remove totally or partially the distal regulatory elements keeping the α-
globin genes structurally intact. The indel comprises the deletion of the MCS-
R2 regulatory element and the insertion of a singular 39 bp DNA fragment pos-
sibly originating from a complex rearrangement involving chromosome 3. Final-
ly, no α-globin gene cluster deletion or point mutation were found in a patient
who presented a very unusual case of acquired alpha-thalassemia associated
with a myelodysplastic syndrome.

Summary/Conclusions: Our study widens the spectrum of molecular lesions
and unusual molecular mechanisms by which α-thalassemia/HbH may occur
and emphasizes the importance of diagnosing large αβ-deletions to provide
patients with appropriate genetic counseling.

RELEVANT ROLE OF VON WILLEBRAND FACTOR-ADAMTS13 AXIS IN HEPATIC ISCHEMIA- REPERFUSION INJURY

1Emergency and Critical Care Medicine, 2General Medicine, 3Surgery, Nara Medical University, Kashiwara, Japan

Background: Hepatic ischemia-reperfusion injury (I/R) is a liver damage occurring during liver surgeries such as hepatic resection or transplantation, and denotes the major basis for graft dysfunction after transplantation. Although detailed mechanisms of hepatic I/R injury remain to be clarified, an excessive inflammatory response is thought to play a role in this regard.

Aims: Since recent studies suggest that von Willebrand factor (VWF) plays a pivotal role in a cross-talk between inflammation and thrombosis, we assumed that VWF may be involved in the pathophysiology of hepatic I/R injury. To test this hypothesis, we have used a mouse experimental model of hepatic I/R injury.

Methods: Mice were anesthetized with sodium pentobarbital and a midline laparotomy was then performed on a heating pad. Blood supply for the left lateral and median lobes of liver (approximately 70% of the liver mass) was interrupted by cross-clamping the hepatic artery and portal vein with a microvascular atrumatic clip for 90 min. Then a clip was taken off to provoke the reperfusion of hepatic blood flow, which was monitored on the surface of left lateral lobe by Laser Doppler flowmetry (ALF21, Advance Co, Tokyo, Japan). The hepatic blood flow was measured again 24 h after reperfusion and mice were then sacrificed. The cell number and histological changes of liver tissue were observed. We also performed hepatic I/R injury in VWF-KO mice as causative.

Results: As compared to WT mice, restoration of hepatic blood flow was significantly greater in VWF-KO mice at 24 h after reperfusion (WT; 61±17% vs KO; 87±17%, expressed as the percentage of pre-ischemic value). Consistent with the hepatic blood flow, the time-course analysis of serum alanine aminotransferase (ALT) at several time points after reperfusion revealed the lesser liver damages of KO mice (WT, 698±3270 and 1313±621 IU/L vs KO; 3043±1320 and 478±330 IU/L, at 3 h and 24 h after reperfusion, respectively).

In addition, histological analysis confirmed that neutrophil infiltration in the liver tissue of KO mice was significantly reduced as compared to WT mice at 24 h after reperfusion. These impaired hepatic blood flow and ALT values as well as intensified neutrophil infiltration in WT mice were significantly improved to an extent comparable to those of KO mice by the bolus injection of recombinant human ADAMTS13 (3 μg/mouse equivalent to 2800 U/kg, n=12) just prior to the I/R operation.

Summary/Conclusions: Our results altogether indicate that VWF-dependent inflammatory responses with neutrophil recruitment at ischemic sites are involved in pathophysiology of hepatic I/R injury, and functional regulation of VWF by ADAMTS13 may serve as a promising therapeutic option for hepatic I/R injury.

THE IMPORTANCE OF THE FULL BLOOD COUNT, JAK II AND ADAMTS13 TESTING IN STROKE EVALUATION: A REVIEW OF 619 CONSECUTIVE YOUNG STROKE AND TIA PATIENTS

A. Taylor1, V. Alakbarzade2, A. Chandrathewa2, R. Simister2, A. Dados2, M. Dhan2
1Haematology, 2Neurology and Stroke Medicine, University College London Hospital, London, United Kingdom

Background: Young ischaemic stroke patients undergo extensive investigations yet around 40% remain of undetermined cause. Complex and costly thrombophilia testing is routinely sent despite limited evidence linking to arterial disease. A full blood count may be ignored but is potentially more helpful in suggesting myeloproliferative disease or thrombotic thrombocytopenic purpura (TTP) as causative.

Aims: We retrospectively reviewed full blood counts, specifically haematocrit and platelet count, and whether these were documented and further investigated if outside of the normal laboratory range. We examined whether less common primary haematological disorders known to cause stroke were considered and how justification for further investigation for myeloproliferative diseases such as polycythaemia vera (PV) and essential thrombocythaemia (ET), and ADAMTS13 analysis for TTP.

Methods: We retrospectively reviewed consecutive clinical and laboratory records for all stroke and TIA patients <60 years presenting to a regional hyper- acute stroke unit and daily TIA clinic from January 1st 2015- August 7th 2016. All those with thrombocytosis (defined as platelet count >400x10^9/L) and/ or raised haematocrit (defined as Hct >0.45) were reviewed to see if a cause could be determined, and if not, whether JAK II analysis was considered and tested. We similarly examined patients presenting with thrombocytopenia (defined as platelet count <150x10^9/L), and if no cause determined, whether ADAMTS13 testing was contemplated.

Results: 610 patients <60 years were included: 379 ischaemic stroke (62.1%), 193 TIA (31.6%) and 38 haemorrhagic stroke (6.2%). 161 (26.4%) had abnormalities in haematocrit or platelet count: 116 (19%) had a raised haematocrit, 19 (3.1%) thrombocytosis, and 26 (4.2%) thrombocytopenia. Of these, 7 patients demonstrated abnormalities of both cell lines. Of these initial 161 abnormal results, 119 (73.9%) were repeated but 42 (26.1%) were not. JAK II testing was deemed warranted in 17 (2.8%): a persistently raised or progressively raised haematocrit or platelet count respectively, with normal liver and renal function and no other explicable cause. JAK II mutational analysis was performed in 3 patients (0.5%). One was proven positive for the V617F mutation, hence diagnosed with polycythaemia vera. Of the 2 negative JAK II results, one patient was subsequently diagnosed with chronic myeloid leukaemia. Fourteen patients had no further testing or monitoring, 26/10 (4.3%) patients had thrombocytopenia. ADAMTS13 testing was not warranted in 17 of these (subsequent resolution of platelet count n=7, HIV n=2, liver derangement n=7, known ITP with no MAHA n=1). ADAMTS13 testing was indicated in 9 of these patients (34.6% of thrombocytopenic patients), defined as a persistent thrombocytopenia with no clear cause, normal liver and renal function and negative HIV status. Seven of these patients did not have ADAMTS13 considered, according to the clinical documentation, nor sent. Of the 2 tested for ADAMTS13, one result was normal, helping to resolve the clinical diagnosis of ITP. In the other patient, ADAMTS13 was <5%, confirming TTP and facilitating life-saving plasma exchange to take place.

Summary/Conclusions: In stroke patients <60 years, one quarter had abnormalities in haematocrit or platelets. Myeloproliferative disease or TTP was present in 3 patients of 5 specifically investigated in the cohort. From a haematological perspective, at least 21 further patients merited further investigation. However, this number may be higher since a quarter of those patients with initial discrepancies of haematocrit and or platelet count did not have repeated testing. Although primary haematological disorders are rare as a cause of stroke, a basic full blood count result should not be ignored in considering the aetiology of arterial thrombosis in a younger cohort.

A STUDY OF VENOUS THROMBOEMBOLISM SUSCEPTIBILITY LOCUS FACTOR XI, ABO AND FIBRINOGEN IN A PORTUGUESE POPULATION SAMPLE
L. Manco1,*, C. Silva2, P. Martinho3, T. Fidalgo3, A.B. Sarmento2,3, M.L. Ribeiro1,3
1Research Center for Anthropology and Health (CiA), 2Faculty of Medicine, University of Coimbra, 3Serviço Hematologia Clinica, Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal

Background: Venous thromboembolism (VTE) is a multifactorial disease caused by a combination of acquired required risk factors and complex gene–gene and gene–environment interactions. VTE results from the development of a thrombus, usually in the deep veins of the legs (deep vein thrombosis, DVT) that can subsequently embolise to the lung (pulmonary embolism, PE). Classical inherited risk factors for VTE in European-ancestry populations include protein C and S deficiencies, factor V Leiden and prothrombin gene mutation (FII G20210A). Several other common and low-frequency susceptibility variants, mainly single nucleotide polymorphisms (SNPs) in loci ABO, FXI, FII, FV, FGG, GP6, KNG1, PROCR, SLCA4A2, STXBPS, TSPAN15 and VWF, have been also found robustly associated with VTE. However, in the Portuguese population the genetic background for VTE for most of these genetic susceptibility variants remains to be evaluated.

Aims: To investigate the association of five SNPs in the loci ABO (rs2519093 and rs8176719), FXI (rs2036914 and rs2289252) and FGG (rs2066865) with VTE in a sample of Portuguese patients.

Methods: A retrospective (2012-2015) case-control study with 119 cases of unprovoked VTE and 148 healthy controls of Portuguese origin was conducted, to evaluate allele frequencies of the five risk VTE SNPs in the Portuguese population and to assess the association between these alleles and the risk for VTE. FXI (rs2036914 and rs2289252) and FGG (rs2066865) SNPs were genotyped by real-time PCR with TaqMan probes. ABO rs2519093 and rs8176719 SNPs were genotyped by restriction fragment length polymorphism (RFLP). PLINK software was used to determine the allelic frequencies, concordance with Hardy-Weinberg equilibrium and association between risk alleles and VTE through logistic regression, in the additive model, estimating OR with 95% confidence intervals (95% CI) and p-values. The association between the cumulative number of risk alleles and the risk of VTE was assessed through Pearson χ² using the Simple Interactive Statistical Analysis software (SISA).

Results: The estimated risk allele frequencies in the overall study population sample were: 0.212 for FGG rs2066865 (T), 0.62 and 0.50 for FXI rs2036914 (C) and rs2289252 (T), respectively, and 0.295 and 0.417 for ABO rs2519093 (T) and rs8176719 (C), respectively. The genotype distributions were in agreement with Hardy-Weinberg equilibrium (HWE) for all SNPs. The risk allele frequencies regression under an additive model showed that FGG rs2066865 was associated with VTE (nominal p=0.029; OR=1.57, CI 95% 1.05-2.37) as well as ABO rs8176719 (nominal p=0.0065; OR=1.65, CI 95% 1.15-2.36). Both SNPs remain significantly associated even after adjusting for age and sex (P<0.019 and P<0.005, respectively). ABO rs2519093 did not reach significant associations with VTE in our population sample (P=0.184) as well as FXI rs2036914 and rs2289252 SNPs (P=0.76 and P=0.16, respectively). In addition, there was an increased risk of VTE associated with the increment in the total number of risk alleles: 0 vs 1 risk allele: X²=58.5, p=0.015, OR=2.31; and 0 vs 2 or more risk alleles: X²=12.2, p=0.0048, OR=3.36.

Summary/Conclusions: Our data suggest that the alleles FGG rs2066865 T and ABO rs8176719 C may contribute to the VTE susceptibility in the Portuguese population. The absence of significant associations for the remaining loci could be the result of a limited statistical power, consequence of a modest effect size of polymorphisms or lower sample sizes, or because of differences in genetic backgrounds between populations.

PEdiatric vEnous ThROMboEmболism: incidence, risk factors and management of hospitalized patients in a tertiary care teaching hospital
P. Raheja1,2, P. Olivera1, V. Pons3, E. Johansson 1, T. Canals1, F. Bosch1, and Management of Hospitalized Patients in a Tertiary Care Setting

Background: Venous thromboembolism (VTE) is a rare event in childhood. In spite of this, the incidence of VTE is on the rise in hospitalized patients. Medical progress in the treatment of critically ill patients has increased the use of central venous catheters (CVC) and interventional procedures, especially in children with cardiac defects and malignant disease. Therefore VTE is increasingly recognized as a major secondary complication of advanced tertiary care in infants and children.

Aims: To study the incidence, demographics, risk factors, diagnostic tests, therapy, and complications of pediatric acute VTE in our tertiary care hospital.

Methods: A retrospective single-center study of patients<18 years of age who were discharged from January 2014 to December 2016 by using diagnostic codes for acute VTE from our hospital database. We studied demographic characteristics, clinical presentation, diagnostic tests, risk factors, treatment strategies and outcome.

Results: We report an incidence rate of 10.7 cases per 10,000 patient-years (70 acute VTE events / 21,892 discharge cases over a 3-year period). Patients were predominantly male (57%). Mean patient age was 3.5 years, with the greatest concentration of cases in children in the infancy and in early childhood, while children above 1 year comprised 37% and neonates (<1 month) formed 8.6% of our sample. Patients were mostly born at full term (71.4%), although 45.7% of the neonatal and infant cases were premature. Catheter-related (CVC-VTE) comprised 55.7% of VTE cases. On the other hand, non-catheter-related (NCTR) diagnoses were made in 35.5% of cases. VTE was uncommonly treated with LMWH at 29% and intracardiac in 19.3%. Only 3 cases of NCR-pulmonary embolism (PE) and 2 cases of NCR-upper extremity DVT were reported. Doppler ultrasound was the most common diagnostic test used (75.7%), followed by MRI, CT and CT angiography in equal proportions. Critically ill patients encompassed most of the cases (88%). Mean duration of hospitalization was 89 days (range 2-156) and time from admittance to VTE diagnosis was 25.6 days. A large proportion had congenital heart defects (32.9%) requiring interventional procedures. Half of the patients (51.4%) had surgery around the time of VTE diagnosis. Malignancy was identified in 5 cases (2 of which were CVC-VTE). Transient triggers, such as infection (12 cases) and use of aspiraginase (2 cases) were also reported. Most patients were not tested for thrombophilia (n=44, 62.9%) since they were classified as provoked VTE and from those who were tested 10% were diagnosed with a thrombophilia. ABO and factor V Leiden were the most common tested coagulant disorders (n=52) were initially treated with low molecular weight heparin (LMWH) and while most continued treatment with LMWH, 8.6% (n=6) received vitamin K antagonists and 8.6% received direct oral anticoagulants. LMWH dosing was adjusted using anti-Xa assays (AXA) in 85.7% of cases, documenting a median of 5 AXA per patient, out of which 3 were within therapeutic range. Mean duration of treatment was 5.8 months. Recurrence rate was 17%, half of which were in patients with CVC-VTE. On the other hand, bleeding rate was 15.7% most of which were mild (10%) or provoked bleeds (4.3%). Mortality was 10%, although cause of death was not directly related to VTE in any of the cases.

Summary/Conclusions: Pediatric VTE is a substantial complication arising from tertiary care hospitalization where critically ill infants are at greater risk. Potential risk factors of VTE include use of CVCs, patients with complex congenital heart defects, surgical procedures, infection and malignancy. Further studies on VTE prophylaxis and identification of VTE predictors in a critical care setting are required.

E1595
CELL-BASED EVALUATION OF CHANGES IN COAGULATION ACTIVITY INDUCED BY ANTIINFLAMMATORY DRUGS FOR THE TREATMENT OF ACUTE MYELOID LEUKEMIA
M. Tsunaka1, T. Koyama1
1Graduate School of Health Care Sciences, Tokyo Medical and Dental University, Tokyo, Japan

Background: Idarubicin (IDR), aminosidine (Acra), and lanatoxarine (Am80) are effective for treatment of acute myeloid leukemia (AML). In leukemic patients, the incidence of venous thromboembolism or disseminated intravascular coagulation is associated with induction chemotherapy.

Aims: How some drugs for the treatment of AML affect the procoagulant activity is unclear. Thereby, in this study, we investigated the procoagulant effects of IDR in comparison with Acra and Am80.

Methods: Procoagulant effects of IDR, Acra, and Am80 were investigated in a vascular endothelial cell line EaHy926 and AML cell lines HL60 (AML M2), NB4 (AML M3, APL), and U937 (AML M5), focusing on tissue factor (TF), phospholipase A2 (PLA2), and thrombomodulin (TM). Normal human plasma-based recalcification time assay, flow cytometric analyses, and RT-PCR are applied for the evaluation.

Results: IDR induced procoagulant activity on the surface of vascular endothelial and AML cell lines. Expression of TF antigen, TM antigen, and PLA2 were induced by IDR on the surface of each cell line, whereas expression of TF and TM mRNAs were unchanged. Increased TF and PS expression may overcame increased TM expression and the overall effect may be procoagulant. Conversely, Am80 decreased TF expression and procoagulant activity, and increased TM expression on NB4 cells. In NB4 cells, we observed downregulation of TF mRNA and upregulation of TM mRNA by Am80. But Am80 did not sufficiently downregulated TF and PS expression on NB4 cells when applied simultaneously with IDR.

Summary/Conclusions: These data suggest IDR may induce procoagulant activity in vessels by apoptosis through PS expression and/or TF expression on vascular endothelial and AML cell lines. Am80 may suppress procoagulant action of IDR through regulation of TF expression and induction of TM expression. Our methods could be useful to investigate changes in procoagulant activity induced by antiinflammatory drugs.

haematologica | 2017; 102(s2) | 647
DESCRIPTION OF THROMBOTIC EVENTS AND/OR PREGNANCY LOSS IN A COHORT OF HOMOZYGOUS CARRIERS OF THE F467 POLYMORPHISM IN THE F2 GENE

S. Martin-Dominguez1, L. D. Weiss, with meano, R. Vidal1, C. Blais 1, J. M. Alonso-Dominguez1, A. Garcia Raso2, P. Llamas1
1Haematology, 2Health Care Institute, Fundacion Jimenez Diaz, Madrid, Spain

Methods: We have identified the polymorphism in a cohort of 122 cases: 45 (36.88%) male and 77 (63.12%) female. Mean age: 46.2 years (±16.6). Risk factors: 46.2. One or more CVRF were found in patients with any thrombotic event. Presence of one or more CVRF was found in 66.7% of them. Familiar history of thrombosis was found in 13%. 16.7% had a recent or active malignant neoplasm. Among women, 28.8% and 12.9% had one and more than one pregnancy loss respectively. Additional thrombotic risk factors were present in 60% of women with recurrent losses. One (43%) or more than one (46.7%) other additional thrombotic risk factors were found in patients with any pregnancy loss. Presence of one or more CVRF was found in 30% of them. Familiar history of thrombosis was found in 34.4%, whereas none of them had a recent or active malignant neoplasm. Survivors of patients with a thrombotic episode had one or more additional risk factors. Nevertheless, up to 26.7% presented no other risk factor than homozygous F12 C467T, suggesting a relevant role in the pathogenesis of thrombosis. According to our results, the risk of abortion could be increased by the presence of homozygosity for F12 C467T, since it was the only thrombotic risk factor for women with recurrent losses. Additional studies are needed to clarify the real contribution of F12 C467T to thrombosis and pregnancy losses on prospectively selected patients.

ANALYSIS OF CHARACTERISTICS OF HOSPITAL ASSOCIATED THROMBOSIS

Neil Smith1, Charalempos Kartsonis1
1Haematology, University of England NHS Foundation Trust, Birmingham, United Kingdom

Background: Hospital associated thrombosis (HAT) is now commonly monitored but expected targets of HATs remains poorly reported.

Aims: To describe the occurrence of thrombotic events and/or pregnancy losses and the existence of other risk factors for thrombosis in a cohort of homozygous individuals for F12 C467T.

Methods: We retrospectively analyzed all the homoygous F12 C467T cases diagnosed in our laboratory from January 2015 to January 2017.

Results: 122 cases were evaluated: 45 (36.88%) male and 77 (63.12%) female. Mean age: 46.2 years (±16.6). One or more CVRF were found in 66.7% of them. Familiar history of thrombosis was found in 13% of them. 16.7% had a recent or active malignant neoplasm. Among women, 28.8% and 12.9% had one and more than one pregnancy loss respectively. Additional thrombotic risk factors were present in 60% of women with recurrent losses. One (43%) or more than one (46.7%) other additional thrombotic risk factors were found in patients with any pregnancy loss. Presence of one or more CVRF was found in 30% of them. Familiar history of thrombosis was found in 34.4%, whereas none of them had a recent or active malignant neoplasm.

Summary/Conclusions: Our study indicated that patients with homozygous F12 C467T had a higher occurrence of thrombotic events and/or pregnancy losses and additional thrombotic risk factors compared to the general population. Further studies are needed to clarify the role of this polymorphism in the pathogenesis of thrombosis.
Background: Soluble fibrin monomer complexes (SFMC) are the early marker of thrombophilia that represent the complexes of monomeric fibrin with fibrinogen or their products of degradation (FDp). SFMC levels are not directly affected by therapy with thrombolytic agents. Detection of SFMC formed due to the activation of blood clotting by thrombin reveals a pathological process in the early, preclinical stages.

Aims: We explored the quality difference between the SFMC fraction obtained from acute ischemic stroke patients and one year post acute phase of stroke in the absolutely the same patients.

Methods: SFMC fraction was obtained from each tested groups: 35 healthy donors as well as 66 patients with atherothrombotic ischemic stroke (AIS) and 56 patients with cardiogenic ischemic stroke (CIS) during the acute phase of disease; 56 patients with AIS and 56 patients with CIS one year past acute phase. SFMC were collected from blood plasma of each tested subtypes of ischemic stroke by incubation with 0.78% o-phenanthroline per 5 min. For Size-exclusion chromatography, SFMC in violet ML was applied on Healthcare Life Sciences *H*Load 16/60 Superdex 200 pg* column.

Results: Results suggest presence of proteins with Mr from 45 up to 330 kDa in SFMC fraction. The content of SFMC was similar for all stroke fractions with some exception. The difference between results of separation of stroke fractions and fractions obtained from healthy donors was obvious. Mostly the proteins content of the SFMC fraction is similar for stroke and healthy fractions. But amount of the proteins as mean peaks high is different (Figure 1). In fact, the first three peaks which correspond to the 330, 280 and 250 kDa of chromatogram of SFMC are common for all tested fractions and were verified only in their height. Accordingly, the most widely represented variations peaks for AIS, even a year after stroke soluble fibrin monomer complex content was higher comparing to the healthy donors index. Healthy donors also had some of these complexes, but in trace amounts. For acute CIS situation was similar as for AIS, but past one year it got closer to healthy donors.

Summary/Conclusions: It was shown that development of ischemic stroke accompanied by the formation of SFMC in the bloodstream that could take part in disease complication.

E1600 EVALUATION OF A RAPID NANOPARTICLE-BASED LATERAL FLOW IMMUNOASSAY (STIC EXPERT HIT) FOR THE DIAGNOSIS OF HEPARIN-INDUCED THROMBOCYTOPENIA IN A CARDIOTHORACIC HOSPITAL

Background: Heparin Induced Thrombocytopenia (HIT) is a severe complication of heparin anticoagulation treatment that could be life threatening. HIT diagnosis is therefore of crucial importance in clinical practice especially for the cardiothoracic patients that are often exposed to heparin before surgery (e.g. during a PTCI). Laboratory testing for the presence of IgG H/PF4 antibodies are positive in 32% of the cases (12/38) of our patients and further in the rest 13/25 (66%) of the cases, laboratory testing for HIT was much more complicated and time consuming since ELISA or other assays (i.e.HIPA) had to be performed. Nevertheless all 13 patients were found not to suffer from the HIT syndrome with the 4Ts scoring system.

Methods: SFMC fraction was obtained from each tested groups: 35 healthy donors as well as 66 patients with atherothrombotic ischemic stroke (AIS) and 56 patients with cardiogenic ischemic stroke (CIS) during the acute phase of disease; 56 patients with AIS and 56 patients with CIS one year past acute phase. SFMC were collected from blood plasma of each tested subtypes of ischemic stroke by incubation with 0.78% o-phenanthroline per 5 min. For Size-exclusion chromatography, SFMC in violet ML was applied on Healthcare Life Sciences *H*Load 16/60 Superdex 200 pg* column.

Results: Results suggest presence of proteins with Mr from 45 up to 330 kDa in SFMC fraction. The content of SFMC was similar for all stroke fractions with some exception. The difference between results of separation of stroke fractions and fractions obtained from healthy donors was obvious. Mostly the proteins content of the SFMC fraction is similar for stroke and healthy fractions. But amount of the proteins as mean peaks high is different (Figure 1). E1602 THE IMPORTANCE OF PLATELET MEMBRANE FLUIDITY AND OXIDATIVE STRESS IN THROMBOSTATIC COMPLICATIONS ACQUIRED BY CHRONIC MYELOPROLIFERATIVE NEOPLASMS PATIENTS

Methods: We analysed the DTN in bleeding anticoagulated patients defined as the time from recognition of haemorrhage to PCC administration. In Heart of England NHS Foundation Trust between May and July 2016, 29 patients were included; 19 patients were taking Warfarin and 10 taking DOACs. All patients received PCC (Bireplex®).

Results: Sixty-nine percent of patients were male and 31% female. The majority (69%) of patients were treated for stroke prevention in AF and 24% had a history of VTE. The two commonest major haemorrhage types were cerebrovascular (including intracranial and subdural haemorrhage) in 36% and gastrointestinal bleeding in 39%. The remaining indications (25%) were pre-urgent procedure/surgery, and soft tissue haematoma. The average time for recognition of haemorrhage was 3 hours 20 minutes (range 4 minutes to 21 hours 27 minutes), and the DTN was 4 hours 50 minutes (range 33 minutes to 13 hours 24 minutes), which means an estimated average of 6 hours 27 minutes (range 2 hours 49 minutes to 13 hours 59 minutes) between hospital admission and receiving PCC. Six of the total number of patients died within 30 days of hospital admission, 4 taking on Warfarin and 2 taking on DOACs.

Summary/Conclusions: This audit demonstrates the continuing delays between recognition of major/life-threatening bleeding events and receiving PCC since previous audits despite raising staff awareness. We plan to introduce the term ‘DTN’ in the context of anticoagulant reversal, store PCC in the emergency department pharmacy cupboards (as a PoM) as opposed to blood bank, and introduce a reporting system ‘Serious Hazards of Warfarin (SHOW)’ which may further reduce delays, morbidity and mortality.
Summary/Conclusions: In this study we reported our preliminary results. We detected thrombosis only in one patient and according to this limited samples size, we may suggest that CT and AA in EXTEM, and AA in INTEM prior to insertion of CVC may be predictive for catheter related thrombosis development. Such patients with pro-coagulant findings at ROTEM prior to CVC insertion may need prophylactic anti-coagulation. The results in a larger sample size will be more definitive to make a conclusion.

Preclinical studies: Identification of microparticles in the platelets

Background: Venous thromboembolism (VTE) is common in patients with cancer. Several risk factors (related with patient, tumour and treatment) have been already identified. Thromboprophylaxis (TP) with low molecular weight heparin (LMWH) is associated with a reduction of symptomatic VTE but without clear benefit in survival as the number of major bleedings is increased. To primary TP in newly diagnosed cancer patients starting chemotherapy (CT), a risk assessment model (based on clinical and laboratory variables) was developed (the Khorana score). Many patients with intermediate risk (without thromboprophylaxis indication according to Khorana-based clinical guidelines) develop VTE episodes. Factors as tissue factor-bearing micro particles and D-Dimmer levels in addition to lenalidomide, platin and gencitabine-based therapies are associated with VTE high risk. Its efficacy as a predictive tool is a matter of debate.

Aims: This retrospective, observational study is aimed to assess the Khorana score efficacy in predicting the VTE risk and analyze some treatment related factors as predictive complementary tools.

Methods: We analyzed the demographic characteristic, the Khorana score and the antineoplastic treatment of oncologic patients diagnosed of pulmonary embolism (PE) from December 2010 until December 2016 at the Complejo Hospitalario de Navarra. At baseline, the Khorana score classified patients as 'low risk' (0 points) intermediate risk (1-2 points) or 'high risk' (≥3 points) for VTE.

Results: 102 oncologic patients were diagnosed of PE. Patient baseline characteristics are showed in table 1. In 27.5% (n=28) PE diagnosis preceded to cancer diagnosis, in 46.1% (n=47) PE was diagnosed during the treatment (chemotherapy +/- radiotherapy). In this last group the median time from the treatment beginning and EP diagnosis was 3 months (0-46). The stratification according to the Khorana score (at baseline) was: 'low risk' 23.1%, intermediate risk 61.7%, and high risk 17%. In the intermediate risk group (n=29) the drug-based therapy was: 44.8% platin (n=13), 6.9% gemcitabine (n=2), 2.5% lenalidomide (n=1) and 48.3% non-related-thromboembolic treat ment (n=14). Most of cases (97.1%) were managed with LMWH (enoxaparin 1mg/kg/twice a day). Only 2 patients were treated with non-fractionated heparin and 1, enrolled in a clinical trial, was treated with direct oral anticoagulants.

Table 1.

| Table 1. Baseline patient characteristics |

| CT; clotting time, CFT; clot formation time, MCF; maximum clot firmness, AA; alpha angle, * Normal range, 4 INTEM couldn't be measured for patient 1 due to technical reasons, 8 In some patients CFT and/or AA weren't in measurable level |

Summary/Conclusions: Nearly 2/3 of Khorana intermediate risk patients developed a PE while on antineoplastic treatment and inside this group over 50% were treated with well-recognized high thrombotic-risk drugs. The inclusion of antineoplastic drugs in a predictive thromboembolic model in oncologic patients could improve the benefit-risk of the use of LMWH prophylaxis in some patients without a high risk Khorana score but however at high risk of thrombosis. More prospective studies are needed to analyse the benefit of antithrombotic prophylaxis in oncologic patients receiving outpatient chemotherapy treatment.

Preclinical studies: Identification of microparticles in the platelets

Summary/Conclusions: Nearly 2/3 of Khorana intermediate risk patients developed a PE while on antineoplastic treatment and inside this group over 50% were treated with well-recognized high thrombotic-risk drugs. The inclusion of antineoplastic drugs in a predictive thromboembolic model in oncologic patients could improve the benefit-risk of the use of LMWH prophylaxis in some patients without a high risk Khorana score but however at high risk of thrombosis. More prospective studies are needed to analyse the benefit of antithrombotic prophylaxis in oncologic patients receiving outpatient chemotherapy treatment.

CLINICAL OUTCOMES AND UTILIZATION OF BLOOD BANK RESOURCES OF PATIENTS WITH THROMBOTIC THROMBOCYTOPENIC PURPURA (TTP), HEMOLYTIC UREMIC SYNDROME (HUS), AND OTHER MICROANGIOPATHIC HEMOLYTIC ANEMIA (MAHA) A REAL-ONES EXPERIENCE

C.-T. Lee1,2, C. Thow1, K.P. Lim3, S.T. Lim3, J. Mah3, N.N. Zhang3, M.L. Tung1, L.K. Tan1,2, S.Y. Lee1,2,3

1Department of Haematology-Oncology, National University Cancer Institute Singapore, 2Yong Loo Lin School of Medicine, National University Singapore, 3Blood Transfusion Service and Blood Donation Centre, Department of Laboratory Medicine, National University Hospital, Singapore, Singapore

Background: TTP, HUS and other thrombotic microangiopathy are rare, complex clinical syndromes which are characterized by thrombocytopenia, microangiopathic haemolytic anaemia, (MAHA) and systemic thrombosis. The introduction of plasma exchange (PEX) has dramatically reduced the mortality of these patients, and has become standard of treatment. Although the clinical outcome of these conditions is heterogenous, with multiple clinical complications and prolonged hospital stay, there is no previously published data to provide measurement of blood bank and hospital resource utilization associated with its clinical management.

Aims: We performed a retrospective cohort study of 42 consecutively treated patients with MAHA and analyzed their clinical and laboratory characteristics, treatment outcomes and plasma product utilization.

Methods: Medical records of these patients treated from 2002-2017 were reviewed. We used the standardized criteria based on the consensus on standardization of terminology in TTP to define clinical response. (Scully et al J Thromb Haemost 2017).

Results: In our cohort, the causes and number (%) of MAHA were TTP-HUS (18.2, 42.9%), autoimmune disorder-associated MAHA (13, 31.1% i.e. 9 SLE and 4 Sjögren’s syndrome), cancer-related MAHA (4, 8.5%), drug-induced (3, 17.1%), post-transplant and infection-related microangiopathy (4, 38.1%). The average number of PEX sessions required to achieve overall clinical response in TTP, autoimmune-associated MAHA, HUS and drug-induced microangiopathy was 18.2±17.9, 11.5±7.6, 13.0±8.7 and 7.3±6.7, respectively. The mean follow up time was 40.8 months. 5 patients (11.6%) died during the course of treatment in index hospitalization, 12 (27.9%) were refractory to PEX and 24 patients (55.8%) responded to PEX, and 1 patient was lost to follow up. 1 patient relapsed 8 months after achieving clinical remission and was successfully treated with Vincristine. Another patient developed exacerbation and was palliated eventually. For the refractory cases, 7 patients were given Rituximab, 5 achieved clinical response while those who were given Vincristine (n=3) and Cyclophosphamide (n=2), achieved clinical response with a median of 15 days from the time second line agents were used. The 1 year overall survival of those who received second line treatment compared to patients who responded to only PEX and standard of care was 59% and 80% (p=0.05), respectively. The overall 1 year survival of the entire cohort is 74% which is comparable to the Oklahoma registry. The mean length of hospital stay was 30 days (median 27, IQR 14-65). The number of RBC and EX units transfused was 9 (5.9%), seizures (11.9%), cardiovascular complications like myocardial infarction and stroke (16.7%), and nosocomial infection (16.7%). 30% of the cohort required temporary dialysis support for acute kidney injury while 38% of them ended up requiring lifelong dialysis. With regards to the cost of plasma units, consumables and PEX procedure, the calculated mean cost was Singapore Dollar (SGD) 25252.95 ($16991.17) (SD±20859.41 ($14035.02)) per patient.

Summary/Conclusions: The clinical outcome in terms of survival in our cohort is in keeping with that of other registry and cohort (Hovinga et al Blood 2010). Our data which demonstrate the health care resource utilization show that management of these patients is expensive. While small in terms of incidence, it poses an economic burden disproportionate to its overall size.

HEPATITIS E VIRUS: INVESTIGATION IN NORTH ITALIAN BLOOD DONORS

E1607

SHORT-TERM ADMINISTRATION OF RECOMBINANT HUMAN ERYTHROPOIETIN DECREASES B CELL IN HUMAN PERIPHERAL ERYTHROID

T. Nagashima1,*, A. Yokohama2, M. Awata1, Y. Kanai1, K. Murata1, R. Ino1, K. Kimura1, K. Honma1, N. Gotoh1, T. Kasamatsu1, H. Handa2, T. Saitoh1, H. Murakami1

1Department of Laboratory Sciences, Gunma University Graduate School of Health Sciences, 2Blood Transfusion Service, 3Department of Hematology, Gunma University Hospital, Maebashi, Gunma, Japan

Background: Erythropoietin (EPO) is hematopoietic factors participating in red blood cell production, and accelerates proliferation and inhibits apoptosis of erythroblasts. It is reported that EPO has pleiotropic effects including anti-apoptotic action for some cells, antioxidant action, vascularization action, and promoting angiogenesis in addition to stimulation of erythropoiesis as well, whereas there are conflicting results of small cohorts as to its effect on blood immune cells.

Aims: We analyzed peripheral white blood cell subsets in patients who received one bolus administration of recombinant human erythropoietin (rHuEPO) to examine the effect of EPO on human immune system.

Methods: One hundred nineteen autologous blood donors (male/female 62/57) in Gunma University Hospital were enrolled in this study after written informed consent. All the patients had no infections or inflammation. Forty nine patients were treated with rHuEPO (Epoetin alpha or Epoetin beta (24,000 IU, respectively)) once after blood donation because of low hemoglobin concentration and 70 were not treated. Peripheral blood samples were obtained at the time of the first phlebotomy and after 1 week from each patient. We measured the number of WBC, lymphocytes, myeloid dendritic cells (dMDC), plasmacytoid dendritic cells (pDc), CD4+ T cells, CD8+ T cells, Natural killer (NK) cells, B cells, monocytes, and neutrophils of peripheral blood before and after rHuEPO administration by flow cytometric flow analysis. Absolute number and percentage of lymphocytes in WBC decreased significantly after rHuEPO administration from 1985.0±520.0/µl to 1798.7±439.0/µl, in absolute number (p=0.019), and from 33.2±57.6% to 30.0±32.3% in percentage (p=0.023). The numbers of whole WBC, mDC, pDc, monocyte and neutrophil did not change significantly. In respect of lymphocyte subsets, absolute number of CD8+ T cell, NK cell and B cell significantly decreased from 358.9±257.0/µl to 311.5±210.9/µl, in absolute number (p=0.019), and from 16.5±13.6/µl to 12.9±12.7/µl (p=0.045), respectively. Moreover, other B cell subsets, such as transitional B cells, memory B cells and marginal zone B cells, also showed a trend of decrease. However, percentages of naive B cell and IgD-CD27+ B cell in total B cell did not change. These suggested that whole B cell decreased, not a specific subset of B cell. In non treatment group, there was no change of lymphocytes.

Summary/Conclusions: These findings suggested that just one administration of rHuEPO influenced human immune system, especially via reduction of B cell in peripheral blood, with unknown mechanism so far.
Background: At most centers, the majority of patients who request bloodless medicine are members of the Jehovah’s Witness (JW) faith. But, there are no standard, established guidelines to manage pancytopenia in these patients, nor are there many studies to inform optimal treatment approaches. The most troublesome patients who request bloodless medicines are patients with hematologic malignancy. The treatments of these patients are considerable challenges. They have not only problems of severe pancytopenia, but also require intensive chemotherapy. Since 2000, our hospital has been a bloodless center. This study was retrospectively analyzed for hematologic malignancies and aplastic anemia with bloodless treatments in Soochoonhyung university hospital.

Aims: This study was retrospectively analyzed for hematologic malignancies and aplastic anemia with bloodless treatments in Soochoonhyung university hospital.

Methods: A retrospective review of medical records was performed of 44 patients with hematologic malignancies and aplastic anemia who request bloodless medicine from January 2006 to December 2015 at Soochoonhyung university hospital.

Results: Of 44 patients, 48% were men (n=21) and 52% were women (n=23). The median age of the study population at the time of diagnosis was 62 years (range 16-87). Seventeen patients (39%) were acute leukemia, 15 (34.1%) patients with non-Hodgkin’s lymphoma (NHL), 2 (4.5%) patients with aplastic anemia (AA), 6 (13.6%) patients with chronic myeloid leukemia (CML), 4 (9%) patients with myelodysplastic syndrome (MDS) and 4 (9%) patients with multiple myeloma (MM). Thirty one patients were treated with chemotherapy and 13 patients were treated with supportive care only. Among 44 patients 27 patients were died. Most common cause of attribution to death was anemia (92.5%), and Chief complaint at death was dyspnea (88%). Median survival of acute leukemia was 1 month (95 CI, 0.41-1.59).

Table 1.

Summary/Conclusions: In bloodless treatment, CML, MM and lymphoma had a relatively good prognosis. However, AML and MDS were showed a poor prognosis. Therefore, further studies are needed to improve survival for bloodless patients with hematologic malignancies.

E1609 PREOPERATIVE ANEMIA: A SINGLE INSTITUTION EXPERIENCE IN SPAIN

G. Pinto1,*, F. Ruiz1, I. Page1, G. Yumi1, G. Moreno1
1Hematology, Hospital Ramon y Cajal, Madrid, Spain

Background: Preoperative anemia is considered as a strong predictor of postoperative red cell transfusions, and has also been linked to increased morbidity and mortality in surgical patients.

Aims: The objective of the study was to assess factors affecting transfusion needs in a Hematology Department (bone marrow transplant unit- BMTU, post-transplant unit-PTU, hematology clinic).

Methods: The patients that were hospitalized between 1/1/2015 and 31/12/2015 were analyzed. Data regarding the underlying disease, the disease status, type of transplant, duration of marrow aplasia and donor-patient blood group mismatch were obtained from the medical records. The analysis was restricted to the transfusion of packed RBCs and units. Differences between groups were assessed using non-parametric statistics (Kruskal-Wallis and Mann-Whitney U-test).

Results: There were 523 admissions of 256 different patients. Complete data for analysis could be obtained for 487 admissions of 237 patients (92.6% of patients, 93.1% of admissions), corresponding to 10,673 days of hospitalization. Total number of blood products transfused was 2284 packed RBC units, 13883 PLT units (apheresis platelets counted as 5 units). Values are reported as median (range), unless otherwise specified. In the BMTU, the type of transplant correlated with transfusion needs: number of RBC units transfused per admission was 2 (1-5) for autologous transplanted (AUTO) patients, 4 (1-28) for allo-transplanted (ALLO) (no difference between sibling and matched unrelated donors), and 7 (1-14) for haplo-identical transplantations (HAPLO), p<0.001. Platelet units requirements were respectively 15 (5-45) for AUTO, 20 (5-205) for ALLO and 50 (30-130) for HAPLO, p<0.001. The duration of aplasia was 18 (13-23) days in AUTO, 22 (16-44) in ALLO, 30 (29-40) days in HAPLO transplantation, p<0.001, while the duration of aplasia in days was 9 (4-19) in AUTO, 13 (5-32) in ALLO and 25 (20-38) in HAPLO, p<0.001. The longer duration of aplasia and hospitalization was correlated with greater transfusion needs.

Table 1. Units transfused in hematology clinic

Summary/Conclusions: The main determinants of transfusion requirements are the duration of aplasia, the type of transplant and the disease, with myelodysplastic malignancies requiring more transfusions. The establishment of haplo-identical transplantations has increased the transfusion needs due to longer period of aplasia.
Background: Patients suffering from Acute lymphoblastic leukemias (ALLs) harboring t(9;22) genetic abnormality are classified very high risk (VHR) ALLs displaying poor clinical outcome irrespective of intensive chemotherapies and tyrosine kinase inhibitor treatment. Development of new adjunctive therapeutics will provide great value. HQ17(3)-induced rapid cell demise, characterized by oxidative stress, loss of membrane integrity, mitochondrial membrane potential disturbance and nuclear DNA fragmentation. Neither pan-caspase inhibitor nor Nec-1 (RIP-1 inhibitor) protects SUP-B15 cells from HQ17(3)-induced cell death. The cell death program elicited by HQ17(3) is caspase-independent, and is different from the RIP1-mediated controlled necrosis.

Aims: To investigate the characteristics of, and the molecular pathways involved in the HQ17(3)-induced non-classical death on VHR-ALL SUP-B15 cells and help developing effective therapeutic strategies for the VHR-ALLs.

Methods: Cell growth inhibition in response to HQ17(3) was monitored by ACP assay. Cells were stained by Annexin V/PI and analyzed by flow cytometry for cell death. Lysosomal protease inhibitors (AEBSF (serine protease inh.), pepstatinCA704-Me (cathepsin D/B inh.)) or autophagy inhibitor 3-MA (used in cotreatment with HQ17(3)) were used in experiments. Acridine orange stain and confocal microscopy are used to visualize the changes of acidic vesicles. Autophagic flow in response to HQ17(3) was revealed by aggregation of ectopically expressed EGFP-LC3. Western blot analysis was used to detect p- eIF2α, ER chaperone Grp78, spliced XBP-1 (markers for ER stress). Nuclear accumulation of apoptosis inducing factor (AIF) was revealed by fluorescence microscopy.

Results: Enlarged acidic vesicles accumulated soon after HQ17(3) treatment, and diminished when cell death ensued. HQ17(3)-induced cell death could not be attributed to cathepsin release from lysosomal membrane permeabilization (LMP) as cathepsin inhibitors did not attenuate the cell death. HQ17(3) enhanced autophagy as revealed by aggregation of ectopically expressed EGFP-LC3. Inhibition of autophagy by Bay117082 or knockdown the essential autophagy-related Beclin1 by shRNA could partially attenuate HQ17(3)-induced cell death. Further, HQ17(3) treatment gave rise to early ER stress as revealed by enhancement of eIF2α phosphorylation and up-regulation of ER chaperone Grp78. HQ17(3) induced nuclear translocation of AIF, in compatible with mitochondria disturbance and caspase-independent cell death thereafter. Summary/Conclusions: In Ph+-ALL SUP-B15 cells, HQ17(3) acts in multifaceted: a) lead to oxidative stress and lymphatic membrane integrity, b) induce ER stress and calcium mobilization to mitochondria, cleave and release AIF to mediate nuclear chromatin cleavage, c) HQ17(3)-induced autophagy may be implicated cell death. This study shows agents that are capable of eliciting an intricate effector network in therapy-induced cytotoxicity will have potential as adjuvants controlling the VHR-Ph+-ALL cells refractory to conventional high dose chemotherapies and TKI regime.

Background: Acute lymphoblastic leukemia (ALL) is the most common cancer in children, representing about 80% of acute leukemias, whereas it is less common in adults (20%). Identification of cytogenetic aberrations and a small number of molecular abnormalities are still the most important risk and therapy stratification methods in clinical practice today.

Aims: The aim of the present study was to assess mutational profile of both childhood (cALL) and adult acute lymphoblastic leukemia (aALL) patients, by applying targeted next generation sequencing (NGS) on MiSeq System. We analyzed 34 de novo ALL patients (17 cALL and 17 aALL) using TruSeq Amplicon – Cancer Panel (TSCP) that targets mutational hotspots in 48 cancer related genes (212 amplicons). The bioinformatics analyses was conducted using processing pipeline composed of both freely available open source bioinformatics tools as well as tools developed in house. The average coverage of high-quality sequences was 2609 × per ampli- con. Ten genes were discarded due to insufficient coverage, therefore we ana- lyzed a total of 183 amplicons from 38 genes. Variants were identified in relation to the GRCh37 reference genome by applying a Bayesian approach and com- paring the mutations to the Cancer Genome Atlas and TCGA public databases and genomic databases.

Results: We identified a total of 331 (159 cALL, 172 aALL) variants in the coding regions (median per patient: 9; range: 6–12; median per cALL: 9; range: 6–12; median per aALL: 10; range: 7–12) and 429 (211 cALL, 218 aALL) variants in the non-coding regions (median per patient: 13; range: 10–15; median per cALL: 13; range: 10–14; median per aCALL: 13; range: 11–14). Overall the frequency of 98 variants (median per patient: 2.8, range: 1–6) were potentially protein-changing, including nonsense, frameshift, and missense (NFM) mutations. There were no significant differences in the numbers of NFM mutations between cALL (total 47, median per patient: 3, range: 1–5) and aALL (total 51, median per patient: 4, range: 1–9). Nevertheless, we identified 5 NFM mutations in STK11 gene.

Conclusion: Our identified variants detected mutations predominantly disrupted Ras/RTK pathway (STK11, KIT, MET, NRAS, KRAS, PTEN). Additionally, we identified 5 patients with the same mutation in HNF1A gene coding for transcriptional factor involved both in the Notch signaling pathway (3), and in TCF4 gene (2). Thus, these mutations might disrupt cell cycle and apoptosis key signaling pathways, primarily Ras/RTK and Notch pathways. This study contributes to knowledge of ALL mutational landscape, leading to better understanding of molecular basis of ALL and better stratification and treatment of ALL patients.
acquired results were compared with those derived from the first ALL diagnosis. Results: The FISH analysis showed 36 XX-2,-3,-4.del(0q31q35)-7,-12,-13,-14,-15,-16,-17[13]/46.XX[7]. Extensive FISH analysis confirmed the diagnosis of low hypodiploidy ALL. This result was in line with the reported association between TP53 gene mutations in 90% of low hypodiploid ALL, with these mutations often present in normal cells. [Holmfeid, Nat Gen, 2013] At first sight, this did not recalculate the original cytogenetic analysis and suggested the occurrence of a second episode of ALL. In order to further characterise the diagnostic genetics, FISH probes were used on archived diagnostic slides. Careful selection of probes demonstrated that the original leukemia sample contained two co-existing clones – one low hypodiploid clone (with an identical pattern of loss) and a second clone containing a gain of chromosomes as the second ALL) and one clone resembling a doubled up/triploid low hypodiploid clone.

Summary/Conclusions: This case report demonstrates the value of in-depth genetic analyses to guide management of patients with ALL. This patient proceeded with re-induction according to our current relapsed therapy guidelines (RICO). However, she maintained remission status for 5 years with low intensity treatment and ironically relapsed when most patients are told they are cured. Since the original diagnosis of ALL in 2007, research has vastly improved our understanding of the biology and genetic landscape of ALL. This has facilitated risk stratification, improved outcome after treatment and identified novel drug targets. However, specific profiling of low hypodiploid ALL has identified oncogenic activation of Ras and phosphoinositide 3-kinase (PI3K) signalling conferring sensitivity to PI3K inhibitors, thus providing therapeutic avenues if conventional treatment were to fail.

PB1614

IMMUNOLOGICAL CHARACTERIZATION OF PH+ ALL BONE MARROW

H. Hohtari1,2,3, O. Brück1, S. Blom2, R. Turkki2, A. Ribeiro2, M. Sinisalo3,4

1Hematology Research Unit, University of Helsinki and Helsinki University Central Hospital, Helsinki, 2Institute for Molecular Medicine Finland (FIMM), Helsinki, 3Division of Hematology, Tampere University Hospital, Tampere, 4Department of Pathology, HUSLAB and Haartman Institute, Helsinki University Central Hospital and University of Helsinki, Helsinki, 5Hematology Research Unit, University of Helsinki and Helsinki University Central Hospital Comprehensive Cancer Center, Department of Hematology, Helsinki, Finland

Background: The treatment results in Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ ALL) have improved significantly in the era of tyrosine kinase inhibitors (TKIs). However, many patients relapse despite having intensive treatments with initially favorable responses. TKI therapy is known to modulate the immune system, and it may play a critical role in keeping the leukemia under control. However, little is known about the status of the immune system in patients with Ph+ ALL. Especially with the emerging immunotherapies in sight, it is vital to chart the immunological landmarks that could help us direct the treatment towards a more personalized approach.

Aims: To characterize the immunological microenvironment in Ph+ ALL bone marrow (BM) by multiplex immunohistochemistry (IHC).

Methods: Ph+ ALL BM biopsies from the diagnosis stage were collected from Helsinki University Hospital and Tampere University Hospital (N=31). BM biopsies from non-leukemic (NL) controls (N=14) were used as a reference. Samples were hematopathologically evaluated and a tissue microarray (TMA) was constructed by selecting two BM cores with high leukemic cell infiltration per patient. The TMA sections were stained with both fluorescent and chromogenic dyes for six markers and nuclei simultaneously enabling cytometric analysis at cellular resolution. Marker panels included T and B lymphoid cells, NK and dendritic cells, macrophages as well as myeloid derived suppressor cells. Furthermore, we analyzed immune checkpoint molecules (PD1, LAG3, OX40, TIM3, CTLA4) and their ligands (PD-L1, PD-L2, HLA-G, HLA-ABC) alongside with various activation markers (granzyme B, CD45RO, CD25, CD57, CD27).

After the data analysis, the cells were segmented and quantified with the image analysis software CellProfiler and the cell analysis software FlowJo. Results: The CD4+/CD8+ ratio was lower in Ph+ ALL BM versus NL BM (1.3 [interquartile range (IQR) 1.0-1.9] vs 2.0 [IQR 1.7-2.4], p=0.0134) indicating that there are relatively more CD8+ T cells in the leukemic than in the non-leukemic microenvironment. The ratio of memory CD4+CD45RO+ T cells in Ph+ ALL BM versus NL BM was elevated (21.0% [IQR 16.7-28.5] vs 13.0% [IQR 8.7-15.9]) of CD4+ T cells, p=0.0044). The difference in memory CD4+CD45RO+ T cells was not significant (p=0.36). Further analysis of the T cell phenotype showed increased proportion of both PD1-positive helper T cells and PD1-positive CD25+ T cells in Ph+ ALL BM vs NL BM (29.7% [IQR 17.5-50.1] vs 6.9% [IQR 5.7-8.9], of CD4+ cells, p=0.0001 and 28.8% [IQR 13.2-38.0] vs 14.9% [IQR 9.6-18.7], of CD8+ cells, p=0.0107). The ratio of OX40-positive helper T cells was also higher in Ph+ ALL BM (27.1% [IQR 21.6-33.25] vs 18.5% [IQR 14.8-21.9], of CD4+ cells, p=0.0001), but no difference was observed in the proportion of OX40-positive CD8+ T cells (p=0.049).

Summary/Conclusions: Multiplex IHC enables ample cytometric evaluation of different immune cell subtypes in their original microenvironmental context of the bone marrow. The TMA format not only allows analysis of tens of BM samples in parallel but also serves as a retrospective, easy-access archive for any follow-up studies. Ph+ ALL BM is characterized by a decrease in the CD4+/CD8+ ratio and an increase in the proportion of CD4+CD45RO+ T cells in comparison with the non-leukemic controls. The proportion of PD1-expressing T cells is also elevated. However, the heterogeneity between patients is marked. The analysis of other marker panels is presently ongoing, as well as correlation to clinical and treatment outcome parameters.

PB1615

CDK2A1/P16INK4A DELETION IS NOT A POOR PROGNOSIS PREDICTOR IN ADULT ACUTE LYMPHOBLASTIC LEUKAEMIA PATIENTS TREATED ACCORDING TO PROTOCOL RALL-2009

P. Inga1,2, O. Talitani1, P. Elena1, T. Vera1, G. Olga1, R. Michail1, K. Sergey1, A. Zalina1, S. Valery1

1National Research Center for Hematology, Moscow, Russian Federation

Background: CDK2A1/p16INK4a deletion is a frequent cytogenetic abnormality in acute lymphoblastic leukaemia (ALL), ranging from 18% to 45%. In pediatric groups of patients, p16INK4a deletion was associated with T-cell ALL phenotype and poor event-free survival. The prognostic impact of CDK2A1/p16INK4a deletion in adult ALL patients appears controversial.

Aims: To evaluate the prognostic impact of the CDK2A1/p16INK4a deletion in adult patients with acute lymphoblastic leukemia.

Methods: We present the results of the CDK2A1/p16INK4a deletion in 110 adult patients with newly diagnosed Philadelphia –negative ALL, which were treated by RALL-2009 (NCT01193933) in our center since June 2009 till September 2016. Patients characteristics: the median of age was 26 years old (range 15-54), the median white blood cell (WBC) count was 16.9×10^9/L (range: 0.4-785×10^9/L), the median blasts cells count in the bone marrow (BM) was 84.4% (range: 0-98). Fifty-six (59%) of the 110 patients had a B-cell phenotype, 42 (38%) had a T-cell phenotype, 3 (2.7%) patients - biphenotypic ALL. Interphase fluorescence in situ hybridization (FISH) was performed for detection CDK2A1 deletion, TEL/AML1, MLL rearrangement, MYC (8q24.21) translocation, TP53 deletion, IAMP21.

Figure 1.
Results: The prevalence of the CDKN2A deletion in all studied population was 24.5% (27 cases). The frequency of homozygous deletions was 70% (in 19 cases), heterozygous deletion was 30% (in 8 cases). CDKN2A deletion was detected in 14 (52%) patients with precursor-B phenotype, in 11 cases (41%) with T-ALL and in 2 (7%) cases with biphenotypical ALL. Our study demonstrated that CDKN2A deletion had no significant association with age, sex, WBC counts, BM blasts, risk stratification groups, complete remission (CR) and relapse rate in B-cell ALL. We didn’t reveal any significant differences in OS, clinical and laboratory data between groups of patients with homozygous and heterozygous deletion of the CDKN2A deletion. The analysis for T-ALL has detected that CDKN2A deletion was strongly associated with high WBC count (the median is 86×10^9/L, p=0.000), with high (37±11%) of lymphocytes (DLH level) (the median is 306±E/L, p=0.0004) and no associating with CR and replacement incidence was found. We didn’t revealed relationship between CDKN2A deletion and MLL, TEL/AML1 rearrangement, MYC translocation, TP53 mutation and IAM2. CDKN2A deletion didn’t have statistically significant impact on outcome of patients. The five-year cumulative incidence of patients with and without deletion of CDKN2A was 77% (p=0.40); free survival (DFS) was 91% vs 71% (p=0.09), respectively. OS for patients with B-cell ALL with and without deletion was 85% and 76% (p=0.35); DFS was 92% and 65% (p=0.07), respectively. OS for T-ALL patients with and without deletion was 90% and 80% (p=0.63); DFS was 100% and 82% (p=0.24), respectively. (Figure 1).

Summary/Conclusions: We were unable to demonstrate prognostic value of the CDKN2A deletion in adult ALL patients and did not find significant associ-ation between deletion of the CDKN2A gene and with known cytogenetic prognostic factors. However patients with T-cell ALL and CDKN2A deletion had a more aggressive clinical features (high level WBC and LDH), but it didn’t associate with poor outcomes including overall survival. Deletion of CDKN2A is not adverse prognostic factor in adult ALL treated according to protocol RALL-2009.

Hillen1, O. Theisen1, C. Godon1, F. Rialland2, C. Thomas2, A. Grain2, Y. Le Bris1, W. Hillen1, O. Theisen1, C. Godon1, F. Rialland2, C. Thomas2, A. Grain2, Y. Le Bris1, W. Hillen1, O. Theisen
Background: Childhood acute lymphoblastic leukemia (ALL) is the most common of pediatric malignancies, but intensive chemotherapy now allows to obtain complete remission in over 90% of the cases. Nevertheless, 1 out of 5 children will relapse.

Aims: In order to identify new markers prognostic of relapse, we analyzed SNP arrays of paired diagnosis and relapse samples from 8 B-ALL children.

Methods: The cohort included 3 males and 5 females, aged between 6 months and 21 years old (median age 4 years old). Bone marrow samples were collected from 6 patients. We analyzed the SNP arrays by Affymetrix performed on cryopreserved cells at diagnosis and relapse investigated copy number alterations (CNA) and loss of heterozygosity (LOH). SNP analysis of samples exposed to various concentrations of butein for 24 h using the flow cytometry. We established the xenograft mouse model to examine the anti-leukemic effect of butein in vivo. We didn’t reveal any significant differences in OS, clinical and laboratory data. The prevalence of the CDKN2A deletion in all studied population was 61%; DFS was 92% and 65% (p=0.07), HR=3.67 [0.90-15.63].

Summary/Conclusions: CDKN2A/B locus abnormalities, mainly homozygous deletions, were found in 70% of adult T-ALL patients. Different CNA status was found for CDKN2A and CDKN2B. Although homozygous deletion in CDKN2B was associated with a trend for better OS, the level of MRD was the only prognostic factor for OS in these cases. Supported by 2014 SGR225 (GRE) from CERCA Programme/Generalitat de Catalunya, and by funds from Josep Carreras International Foundation, “La Caixa” Foundation and Celgene Spain.

BUTEIN KILLS ACUTE LYMPHOBlastic LEUKEMIC CELLS IN VITRO AND IN VIVO THROUGH FOXO3A AND CASPASE-DEPENDENT APOPTOTIC PATHWAYS
Y.-L. Tang1,*, L.-B. Huang1
1Department of Pediatrics, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Acute lymphoblastic leukemia (ALL) is a common hematological malignancy in children. Discovering and developing effective chemotherapeutic drugs are needed for ALL.

Methods: We examined the rate of apoptosis of CEM-C7 (T-ALL), CEM-C1 (T-ALL), MOLT-4 (T-ALL), RS4-11 (B-ALL) cell lines and primary ALL blasts for apoptosis by using various concentrations of butein for 24 h in vitro. We tested the expression of the caspase-9, poly ADP-ribose polymerase (PARP), nuclear Forkhead class box 03a (FOXO3A) and BCL-2 interacting mediator of cell death (BIM) using western blot assay. We established the xenograft mouse model to examine the anti-leukemic effect of butein in vivo. We examined the rate of apoptosis of CEM-C7 (T-ALL), CEM-C1 (T-ALL), MOLT-4 (T-ALL), RS4-11 (B-ALL) cell lines and primary ALL blasts for apoptosis by using various concentrations of butein for 24 h in vitro.

Results: The expression of the caspase-9, poly ADP-ribose polymerase (PARP), nuclear Forkhead class box 03a (FOXO3A) and BCL-2 interacting mediator of cell death (BIM) was associated with a trend for better OS, the level of MRD was the only prognostic factor for OS in these cases. Background: Childhood acute lymphoblastic leukemia (ALL) is the most common of pediatric malignancies, but intensive chemotherapy now allows to obtain complete remission in over 90% of the cases. Nevertheless, 1 out of 5 children will relapse.

Aims: In order to identify new markers prognostic of relapse, we analyzed SNP arrays of paired diagnosis and relapse samples from 8 B-ALL children.

Methods: The cohort included 3 males and 5 females, aged between 6 months and 21 years old (median age 4 years old). Bone marrow samples were collected from 6 patients. We analyzed the SNP arrays by Affymetrix performed on cryopreserved cells at diagnosis and relapse investigated copy number alterations (CNA) and 0.6 LOH modulations at relapse. Seven of the 8 patients presented modulation in CNA and LOH during evolution with a median of 4. Some anomalies observed by cytogenetics were refined by SNP analysis, notably all chromosomal gains and losses were recovered and precisely located. More-
over, a t(4;9) translocation was found to be more complex with 7 and 8 CNA on chromosomes 4 and 8. Patients with the most CNA and LOH also had a complex karyotype. Anomalies were observed in hot spot regions in 9p (encompassing CDKN2A/2B, PAX5 and JAK2) for 5 patients and 12p (including ETV6) for 3. Stable CNA were observed in the JAK/STAT pathway in 2 patients (JAK2) and LOH in the RAS/RAF pathway (NRAS) in 1. Using the genetic classification of Moorman et al based on SNP array for 8 genes at diagnosis (IKZF1, CDKN2A/2B, PAR 1, BTG1, EBF1, PAX5, ETV6 and RB1), SNP reclassified our patients in 3 of good prognosis and 5 of poor prognosis, with a median of 2 CNA for the genes of interest. The 2 patients with cytogenetic intermediate prognosis would thus probably have been considered for a more intense therapeutic regimen, i.e. allogeneic stem-cell transplantation. Moreover, SNP showed that 2 patients acquired an IKZF1 deletion, also of poor prognosis, while none of the children had TP53 mutation at diagnosis nor relapse.

Summary/Conclusions: SNP array allowed to identify additional anomalies (compared to karyotype) in all children tested and changed the prognostic value of diagnostic anomalies. Moreover, the identification of anomalies in the JAK/STAT pathway could indicate a treatment by tyrosine kinase inhibitors, which would possibly have positively modified outcome. Taken together, this new technology combined with classical analyses at diagnosis might modify therapeutic options in childhood ALL, especially in the subgroup with a normal karyotype.

SCREENING OF NUDT15 GENE VARIANTS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA
D. Aslar Oner1,*, D. F. Akını1, K. Sipahi1, M. Mumcuoglu1, N. Oner Battaloglu1, S. Tasdelen1, U. Ezer1, S. Emir1, E. Kürêk1
1Lösnite Hospital, ANKARA, Turkey

Background: In cells, while DNA bases can be protected by double helix formation and nucleosome packaging, deoxynucleoboside triphosphates are unprotected, thus, are vulnerable to damage. One of the enzymes which are responsible for removing damaged nucleotides is Nudix hydrolase15 (NUDT15). NUDT15 works as a negative regulator in thiopturein metabolism. Thiouguains are active metabolites of thiopurines. Mechanisms of action of thioguanines are disruption of DNA synthesis and induction of apoptosis. NUDT15 inhibits incorrect base pairing and apoptosis through catalysis of thioguanine hydrolysis. Tanaka et al. claimed that, besides TPMT variants in Japanese patients, there might be possible additional factors that may influence thiopurine toxicity. They reported that NUDT15 variants are more specific to Asian population when compared to European people. As far as we know, this is the first study on screening of possible variants in the first exon of NUDT15 in Turkish children with precursor B-cell acute lymphoblastic leukemia (Pre-B ALL).

Aims: In this study, our aim was screening of gene variants in first exon of NUDT15 in pediatric group of patients diagnosed with Pre-B ALL.

Methods: Our study group was composed of 83 patients aged between 1-15 diagnosed with Pre-B ALL at Lösnite Hospital. DNA samples were isolated by using MagNa Pure system. First exon of NUDT15 was amplified by PCR reaction. After PCR purification, sequencing was performed.

Results: After screening of first exon of NUDT15, we detected two variations. First variation was intronic insertion which was defined as rs3831098 (c.158+52_158+53insGGGGCGTGCGCAGAGGGACGATCTC). The other intrinsic variation was determined as rs79687000 (c.158+117C>T). rs3831098 was in 3 of the 83 patients and rs79687000 was found in three out of the 83 patients (Table 1).

Summary/Conclusions: The changes in NUDT15 that we found have not been previously reported in pediatric ALL patients. We do not know if these changes have an effect on pre-mRNA or "splice" regions and ALL. This issue needs further investigation, in a large number of children with leukemia. We are planning the screening of other exons of NUDT15 in order to evaluate for possible applications to clinical practice (e.g. cytopenia).

COMPREHENSIVE MOLECULAR CYTOGENETIC ANALYSES OF BONE MARROW CELLS IN 64 CHILDREN WITH T-ALL REVEALED PROGNOSTICALLY RELEVANT RECURRENT FINDINGS
L. Lizcova1,*, Z. Zemanova1, E. Prihodova1, L. Pavlistova1, K. Svobodova1, E. Mejetrikova2, O. Hrusak2, P. Luknarova2, I. Janotova3, L. Sramkova3, J. Stary3, K. Michalova1
1Center of Oncogenicetics, Institute of Medical Biochemistry and Laboratory Diagnostics, 2Department of General University Hospital and 1st Faculty of Medicine, Charles University in Prague, 2CLIP - Childhood Leukaemia Investigation Prague, Department of Paediatric Haematology and Oncology, 3Department of Paediatric Haematology and Oncology, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic

Background: T-ALL represents 15% of newly diagnosed children with ALL and it is a clinically and genetically heterogeneous disease. Despite the use of intensive chemotherapy, relapse occurs in almost 25% of patients whose outcome remains dismal. Visible chromosomal aberrations are seen in approximately half of the cases, while cytogenetically cryptic aberrations are observed in almost all cases of T-ALL. However, prognostic implication of majority of them still remains unclear.

Methods: Bone marrow cells of all patients were analyzed at the time of diagnosis by combination of conventional and molecular cytogenetic methods. For detection of the most frequent known chromosomal changes, i.e. rearrangements of TCR loci (TRA-14q11, TRB-7q34, TRG-7q14) and TLX3 gene (5q35), deletion of CDKN2A (9p21) and amplification of ABL1 (9q34), interphase FISH with locus-specific probes (Dako, Abbott Molecular) was used. Complex chromosomal rearrangements were proved by multicolor FISH and multicolor banding (24X/32X/XY Probe Kit; MetaSystems) or CGH-SNP array (SurePrint G3 CGH+SNP 4x44K slide). For OS and DFS Kaplan-Meier analysis with Mantel Cox test was done.

Results: During the years 1996-2016 we examined archived material of 64 children with T-ALL (19 girls and 45 boys, median age 8.25 years). In total, chromosomal aberrations were detected in 86% of patients. The most frequent aberration was deletion of CDKN2A gene, which was found in 35/64 patients (19x homozygous, 16x heterozygous). Rearrangements of TCR loci were detected in 17/64 children (11x TRA, 6x TRB). TLX3 gene rearrangement was established in 15/64 patients. No aberration of TRG gene and amplification of ABL1 were found. Complex chromosomal aberrations were proved in 12/64 children. In two cases, isochromosome of the long arm of chromosome 9 was found. 48 patients are living in the first/second complete remission. Relapse of the disease occurred in 17 patients, 16 children died. Best outcome (EFS and OS) was associated with TRA translocations (p<0.05). Patients with TLX3 rearrangement had significantly shorter OS and DFS (p<0.05).

Summary/Conclusions: Using molecular cytogenetics methods recurrent aberrations were proved in vast majority of patients. Rearrangement of TLX3 gene was related to poor outcome in contrast to TRA translocations associated with more favorable course of the disease. Our work attempts to clear up the significance of chromosomal aberrations related to childhood T-ALL in order to facilitate the patients’ stratification into cytogenetic prognostic groups and to identify patients at an increased risk of relapse similarly like it has been adopted in p-B-ALL.

ADULT PRIMARY ACUTE LEUKEMIA SAMPLES WITH CHROMOSOMAL TRANSLocations GROW WELL IN IMMUNODEFICIENT MICE, BUT ARE DIFFICULT TO TRAnSDUCE WITH LENTIVIRUSES
B.C. Heckl1,*, M. Carlet1, M. Grunert1, B. Vick12, C. Roof1, C. Junghani3, K. Spiekermann4,5, W. Hiddemann4,5, J. Jeremias1,2
1Department of Internal Medicine II, University of Heidelberg, 2Department of Internal Medicine I, University of Heidelberg, 3German Cancer Research Center, Heidelberg, 4Department of Internal Medicine III, University of Heidelberg, 5Department of Internal Medicine I, University of Heidelberg, 6Department of Hematology, Center for Infection and Cancer, Mannheim, Germany

Background: Acute leukemia (AL) is a severe disease of the hematopoietic system and associated with a poor outcome for patients. Patient derived xenograft (PDX) mouse models provide an attractive tool to engrate and grow primary tumor cells. In contrast to culture growth, samples can be monitored in a consisting
microenvironment. This powerful tool provides the baseline for further experiments like preclinical treatment trials or biology studies. While good engratment rates were published for primary pediatric ALL samples, engratment rates of adult ALL samples might be inferior, but remain largely elusive.

Aims: This study aimed to determine engratment and growing ability of primary adult AL samples in immunodeficient mice. Genetic engineering was performed to evaluate transduction efficiencies by lentiviruses in PDX AL cells.

Methods: Primary adult ALL and AML samples were transplanted into NSG mice in the absence of total body irradiation. Both frozen as well as fresh patient material was used. Human CD45 and human CD38 were stained in blood to monitor successful engratment. Mice were sacrificed before coming down with leukemia. Isolated cells from bone marrow and spleen were analyzed by flow cytometry. Genetic engineering was performed using lentiviral vector systems and monitored by expression of fluorochrome markers and flow cytometry.

Results: Engratment and growth was successful in NSG mice in 12 out of 15 primary adult ALL samples. Fresh samples showed a longer median engratment time (h) compared to frozen samples, which could already be monitored with an average time of 75.29 days. Generally, the engratment time varied form 47 days up to 166 days and was shortened for slow samples over several passages. Genetic engineering was successfully performed using lentiviral transduction to introduce expression of fluorochrome colours for cell marking and monitoring in further experiments. Lentiviral transduction was performed in 8 ALL samples with BCR-ABL rearrangement and 2 ALL-F4 ALL samples. Adult ALL PDX samples with chromosomal translocations showed very low transduction rates around 1%. Three AML samples with MLL-AF6, MLL-AF9 and MLL-AF10 translocation were analysed for this study. Interestingly and in contrast to ALL, transduction efficiency for AML rearranged samples was high with up to 60%. These values are similar to non-rearranged ALL samples having transduction rates between 30% up to 80%.

Summary/Conclusions: In summary, we observed a high engratment rate of primary adult ALL and AML samples in immunodeficient mice which was above what we anticipated for ALL. Interestingly, engratment time (h) for rearranged samples can be transduced with lentiviruses with identical high transduction efficiency as pediatric samples, with an age independent exception of AL PDXs with BCR-ABL or MLL translocations.

PB1622
SYNERGIC CHEMOTHERAPEUTIC EFFECT OF MENADIONE COMBINED WITH EPICALLOCATCHEINE-3-GALLATE OR DOXORUBICIN IN A HUMAN CELLULAR MODEL FOR ACUTE LYMPHOBLASTIC LEUKEMIA

A. Garaivan1,2, I. T. Tofolean1, R. M. Babes1, C. Ganea1, I. Baran1
1Department of Biophysics, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background: Epicallocathechine-3-gallate (EGGC) and menadione (vitamin K3; MD) are known as potent apoptogens in cellular models for acute lymphoblastic leukemia (ALL) – Jurkat T cells.

Aims: The goal of this study was to explore the chemotherapeutic potential of MD combined with EGGC or DOX, and to determine whether there is a synergistic interaction between these agents that could significantly enhance their antitumor effect in a cellular model of ALL. We investigated the antiproliferative effect of MD alone and in combination with EGGC and MD-DOX respectively on human leukemia Jurkat lymphoblasts. Some underlying cellular mechanisms were also scrutinized.

Methods: Cell suspensions of Jurkat lymphoblasts were treated at various concentrations of EGGC, MD and DOX. Clonogenic survival was evaluated as the colony forming capacity in 96-well plates. Cell cycle and apoptosis/necrosis cations were determined by expression of fluorochrome markers and flow cytometry. Genetic engineering was performed using lentiviral vector systems and monitored by expression of alternative EGCG-induced depolarization. Fluorescence induced by treatment with EGCG alone, MD alone and EGGC-DOX in combination was 172%, 101% and 387%, respectively, suggesting that EGCG and MD interact with the second specific target. The MD-DOX induced survival was significantly reduced by 80% of DOX generated oxidative stress. MD augmented this effect, enhancing the antiproliferative effect of DOX most likely by increasing the affinity of DOX for nuclear DNA.

Summary/Conclusions: Our results support the notion that the combinations EGCG-MD and MD-DOX exert a strong synergic antiproliferative effect in human leukemia Jurkat cells and encourage further studies to test the clinical utility of this association in ALL therapy.

FOCAL ERG DELETIONS AND DUX4 FUSIONS IN CELL LINES DERIVED FROM B CELL ACUTE LYMPHOBLASTIC LEUKEMIA

H. Quentmeier1, R.A. MacLeod1, C. Pommerenke1, H.G. Drexler1
1DSMZ, Braunschweig, Germany

Background: DUX4 has recently been presented as a new oncogenic driver in B cell acute lymphoblastic leukemia (pre B-ALL) of adolescents and young adults [1]. Translocations of DUX4, especially those with the IGHI locus led to high expression of the corresponding fusion gene. DUX4 then triggered the expression or a novel isoform of the ETS transcription factor ERG in pre-B ALL [2]. Focal deletions of exons 3-9 were a second cause for short ERG variants. Up to 7% of pre-B ALL showed deregulated expression of both genes, DUX4 and ERG [2].

Aims: We set out to find pre-B-ALL cell lines with DUX4 translocation and ERG deletion as potential model systems for this novel subtype of pre-B-ALL.

Methods: We screened a panel of ALL cell lines for aberrant expression of DUX4 using qRT-PCR (Taqman probe Hs03037979_g1) were surprisingly inconsistent with Western blot analysis - which could only in part be explained by DUX4 being a one-exon gene. NALM-6 was the only cell line expressing the DUX4 protein. Likewise, the alternative ERG transcript with alternative exon 6 was observed in NAL-M-6 only.

Summary/Conclusions: In conclusion, focal ERG deletions in pre-B-ALL cell lines (2/66) occur at similar frequencies as in the primary tumor. Cell line NALM-6 carries the DUX4-IGH translocation, expresses the DUX4 protein and an ERG mRNA variant including the alternative exon 6. ERG deletions were present in cell line NALM-6 SUP-B15. However, cell line SUP-B15 did not express DUX4 protein and consequently also not alternative ERG exon 6 transcript. These results indicate that focal ERG deletions are not a safe indicator for aberrant expression of DUX4. Cell line NALM-6 is presented as model system for DUX4/ERG pre-B-ALL.

NATURAL HISTORY OF SECONDARY MULTILINEAGE PROLIFERATION WITH MONOSOMY 7 FOLLOWING TREATMENT OF RELAPSED ACUTE LYMPHOBLASTIC LEUKEMIA

J. Bulsa1,*, A. Pobudejska-Pieniążek1, L. Sędek2, A. Lopez3, M. Jara-Acevedo3, H. Quentmeier1,*, R.A. MacLeod1, C. Pommerenke1, H.G. Drexler1
1Department of Pediatric Hematology and Oncology, Zabrze, Poland, 2Department of Microbiology and Immunology, Medical University of Silesia, Katowice, Poland, 3Department of Microbiology and Immunology, Medical University of Silesia, Katowice, Zabrze, Poland, 4Cancer Research Centre (IBMCC, USAL-CSIC), Instituto de Biomedica del Salamanca (IBSAL), Departamento de Medicine and Cytometry Service (Nucleus Research Support Platform), University of Salamanca (USAL), Salamanca, Spain, 5Genetic Laboratory, 1st Independent Public Clinical Hospital of the Medical University of Silesia, Zabrze, Poland, Zabrze, Poland

Background: Approximately 90% of children with acute lymphoblastic leukemia (ALL) are cured with current treatment protocols. However, 15-20% of the patients still experience disease relapse. Monosomy 7 is the most common karyotypic alteration in children with acute lymphoblastic leukemia and young adults. Nature Genetics 2016;48: 1481-1489.

Aims: We present a case of a 11-year-old boy with the history of relapsed ALL followed by aberrant proliferation of several different subsets of precursor cells in both marrow (BM), which was associated with progressive ineffective hematopoiesis.

Methods: A boy diagnosed with standard risk B-cell Precursor (BCP) ALL in 10-2009 was treated until 12-2011 with frontline chemotherapy according to ALL-IC BFM 2002 protocol. In 12-2012, one year after treatment completion and despite attaining CR, BM aspirate revealed dysplasia. BM aspirate and trephine biopsy was performed, while the biopsy of the second tests showed no leukemia infiltration. He received 2nd line chemotherapy according to IntRelAll 2010 and local radiotherapy for the testicular area. Despite the borderline minimal residual haematologica | 2017; 102(s2) | 657
The therapy had a higher c-FLIP L mRNA level than those who did not achieve CR during first treatment. The fifth population showed the features of plasmacytoid dendritic cell precursors with aberrant CD10 expression (CD34+dimCD10+CD20-), and the fifth population showed the features of plasmacytoid dendritic cell precursors with aberrant CD10 expression (CD34+dimCD10+CD20-n/TdT-CD22+CD38+dimCD117-CD123+/HLA-DR+/SSCintermediate). The expression level of c-FLIPL is associated with risk stratification, white blood cell count, serum LDH level, serum HBDD level, CD45, SIL-TAL1 fusion gene, complex karyotype and disease outcome. c-FLIP L could be used as a prognostic marker in T-ALL. Chidamide suppresses histone deacetylation in Jurkat and HUT-78 cell lines. Chidamide induces necroptosis in Jurkat and HUT-78 cell lines by down regulating the transcription and translation of c-FLIP L gene. Chidamide induces necroptosis in Jurkat and HUT-78 cell lines via the classical NF-kB signaling pathway.

**Summary/Conclusions:** We present an abnormal secondary proliferation, with increased numbers of aberrant BCP, myeloid and plasmacytoid dendritic cell precursors resulting from stem cell defect hallmark by monosomy 7.

**Background:** T cell acute lymphoblastic leukemia (T-ALL) is a hematopoietic clonal malignancy caused by the malignant transformation of T lymphocytes driven by gene mutation. The prognosis of T-ALL is poor and early relapse is common.

**Methods:** Bone marrow mononuclear cells (BMNC) are collected from bone marrow samples of T-ALL patients, including at initial presentation (n=46), during first CR (n=23) and at relapse (n=6). The expression level of mRNAs encoding L-cellular Fas-associated death domain-interleukin-1β converting enzyme inhibitory protein (c-FLIP) was assessed by real-time PCR. Changes in the expression level of HDAC before and after chidamide treatment were also assessed by western blot. Necroptosis and apoptosis after chidamide treatment were assessed by flow cytometry. Changes in expression level of c-FLIP, protein before and after treatment were assessed by western blot. Expression level of early apoptotic protein, key proteins of necroptosis were assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The regulating effect of chidamide on downstream genes of NF-κB pathway including cyclinD1, TNFα, IL-2, IL-8 were assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot. The effect of chidamide on NF-κB signaling pathway activity and expression of key molecules when inducing necroptosis was assessed by western blot.

**Results:** The expression level of c-FLIP L mRNA is significantly higher in bone marrow of participants and was analyzed for the existence of polymorphisms. Thirty children with B-lineage ALL (19 boys, mean age 6.8 years) were included in the present study and 70 healthy individuals (20 children and 50 adults blood donors) as control group. Genomic DNA was isolated from peripheral blood of participants and was analyzed for the existence of polymorphisms. Regarding CYP1A1 loci, we detected a positive association for the AG gene containing two important single nucleotide polymorphism, CYP1A1*2A (rs4646903) and CYP1A1*2C (rs1048943), which are associated with an increased risk of leukemia.

**Background:** Acute lymphoblastic leukemia (ALL) is the most common type of childhood leukemia and represents one third of all pediatric malignancies. Despite the high survival rate (more than 80%), a large number of children relapse and for them the outcome remains poor. Epidemiological studies that examined possible risk factors of acute leukemias, proved that genetic factors play a crucial role in leukemogenesis. Recent genetic association studies on cancer risk, have focused on the effects of single nucleotide polymorphisms in genes that regulate inflammation and tumor suppression such as chemokines and P450 cytochrome. Chemokines induce the motility of endothelial and tumor cells. CXCL12, a chemokine expressed in various tumors, binds to chemokine receptor 4 (CXCR4) and is considered to play an activating role in the conversion of environmental chemicals into carcinogens. The above gene contains two important single nucleotide polymorphisms, CYP1A1*2A (rs4646903) and CYP1A1*2C (rs1048943), which are associated with an increased risk of leukemia.

**Aims:** The study of single nucleotide polymorphisms rs1801157 of CXCL12 and CYP1A1*2C (rs1048943) in children with B-lineage ALL.

**Methods:** Thirty children with B-lineage ALL (19 boys, mean age 6.8 years) were included in the present study and 70 healthy individuals (20 children and 50 adults blood donors) as control group. Genomic DNA was isolated from peripheral blood of participants and was analyzed for the existence of polymorphisms. Regarding CYP1A1 loci, we detected a positive association for the AG gene containing two important single nucleotide polymorphism, CYP1A1*2A (rs4646903) and CYP1A1*2C (rs1048943), which are associated with an increased risk of leukemia.

**Results:** The frequencies of AA, AG, and GG genotype were 3.45%, 93.1% and 3.45% in children with ALL, 13.3%, 60.0%, 26.7% in children control group and 4.17%, 93.1% and 50.0% in adult control group respectively. In the CYP1A1 loci, the frequencies of AA, AG, and GG genotype were 13.3%, 86.7% and 0% in children with ALL, 90.0%, 10.0%, 0% in children control group and 81.6% and 16.4% and 2% in adult control group respectively. No statistical significant differences in CXCL12 polymorphism were revealed between children with ALL and healthy groups using logistic regression analysis. Regarding CYP1A1 loci, we detected a positive association for the AG polymorphism and ALL [OR: 37.7 (95% CI: 10.81, 131.37), p<0.001 and OR: 58.5 (95% CI: 9.66, 354.12), p<0.001 using only the children’s control group].

**Summary/Conclusions:** A higher frequency of CYP1A1 heterozygote allele was observed among children with ALL compared to controls, whereas no differences were observed regarding CXCL12 polymorphisms. Future studies in larger populations are needed in order to specify the role of the above polymorphism in childhood ALL.
Background: Intrachromosomal amplification of chromosome 21 (iAMP21) defines a rare subtype of pediatric acute lymphoblastic leukemia (pALL) occurring in approximately 2-3% of cases. The patients are older (median age is 9 years), usually have low white blood cell counts and show high relapse risk with standard therapy. Thus, it has been proposed to include ALL with iAMP21 as a distinct entity in the WHO classification of hematological malignancies.

Aims: To assess the frequency as well as the clinicopathological and genetic characteristics of ALL with iAMP21 in one of the three national diagnostic centers of pALL in Hungary. We sought to determine additional genetic aberrations associated with this rare entity.

Methods: Between 2008-2016, 175 samples of pALL patients were tested with FISH for BCR-ABL1, ETV6-RUNX1 and MLL translocations. When available, bone marrow karyotyping was used to verify the abnormal results. In one case with iAMP21, multiplex ligation-dependent probe amplification (MLPA) was used to verify the cytogenetic aberrations as well as to detect associated copy number alterations.

Results: Among the 175 samples screened with FISH, three showed evidence of iAMP21 (1.7%). Case 1 was a 16-year-old male who presented with thombocytopenia and hepatosplenomegaly. Flow cytometry (FCM) showed common ALL phenotype with the expression of CD13 and CD33. FISH showed >10 RUNX1 signals in clusters in leukemic blasts, while karyotyping demonstrated r(21) with 7q deletion and +X. The lesions were verified by MLPA, which additionally revealed biallelic CDKN2B and RB1 deletions. The patient was treated with ALL-IC BFM 2002 standard risk protocol. Following remission, isolated meningeal relapse occurred, for which he received radiotherapy. The patient died with recurrent meningeal disease without bone marrow involvement after 52 months. Case 2 was an 11-year-old girl, who presented with symptoms suggesting osteomyelitis of the tibia with unremarkable blood count. MRI showed multiple lesions in vertebrae as well as meningeal involvement of the spinal cord. Bone marrow biopsy and biopsy of the left tibia showed diffuse infiltration of lymphoblasts with only 5% leukemic cells in bone marrow aspirates. FISH detected 6-8 copies of RUNX1 in leukemic blasts, while karyotyping yielded only normal bone marrow cells. She was commenced on ALL-IC BFM 2002 standard risk and was later switched to high risk protocol. She is in complete remission after 14 months. Case 3 was an 11-year-old boy who presented with anemia and thrombocytopenia. FCM showed ALL with common phenotype with two populations; one being strong CD19+/CD66c+ and one with dim CD19+/CD66c+. FISH showed >10 RUNX1 signals in clusters in 95% of cells, while 52% showed BCR-ABL1 positivity. Bone marrow karyotyping yielded metaphases of poor quality (Figure 1).

Figure 1.

Summary/Conclusions: ALL with iAMP21 is a rare subtype with distinct clinicopathological characteristics. Presenting with only mildly elevated WBC in older children is typical, relapses are frequent if standard risk chemotherapy is administered. Association with BCR-ABL1 translocation is rare, having been reported so far only 4 cases. Observing BCR-ABL1 translocation in a sub-population of leukemic cells is an intriguing phenomenon; it indicates that this translocation may occur as a secondary event even after leukemic transformation has commenced.
Acute lymphoblastic leukemia - Clinical

COMPLETE REMISSION WITH BLINATUMOMAB IN TWO PATIENTS WITH SKIN RELAPSED B-CELL ACUTE LEUKEMIA
H. Leroy1, M.-L. Jilliot1, E. Forcade1, G. Laboure1, R. Tabrizi1, P.-Y. Dumas1, M. Robies1, A. Chauvel1, B. Vergier1, N. Milpied1, A. Pigneux1, T. Leguay1, 1CHU Bordeaux Haut-Lévêque, pessac, France

Background: Blinatumomab is a bispecific T cell–engager (BiTE) antibody (CD19/CD3) indicated in relapsed/refractory B-cell Acute Lymphoid Leukemia (r/r ALL) (Topp et al.) Extra-medullary relapse is a rare event occurring in only 8% of the patients, of whom only 1.4% present a skin relapse which harbor a dismal prognosis (Gokbuget et al.).

Aims: Herein, we report the efficacy of Blinatumomab in two patients presenting with extra-medullary relapse of ALL.

Methods: The first patient (a 40-year-old man) was diagnosed a CD19+ Ph - B-ALL in 2009. He received a chemotherapy regimen according to the GRAALL protocol (Huguet et al.) until complete remission (CR). In 2015, he presented with a maculopapular rash of the right leg and the left flank, and two enlarged inguinal lymph nodes. Cutaneous relapse was attested by examination of skin biopsy specimen showing a blastic dermal infiltration harboring a CD10+, Tdt+ phenotype. The second patient was a 50-year-old male who presented, in 2016, a CD19+ B-ALL Ph- Ikaros- without central nervous system involvement. He obtained a first CR after GRAALL induction with negative MRD (IgH) but he relapsed 3 months later with a maculopapular rash of his chest. The skin biopsy revealed a blastic dermal infiltration. These two patients with skin relapse received the same chemotherapy (CPBRAALL 2007 regimen) (Domenach et al.), with no efficacy (cutaneous blast infiltrate). Both patients received one cycle of Blinatumomab from day 1 to day 28, at 28 µg per day, in an attempt to achieve CR before allogeneic stem cell transplantation, as previously described.

Results: At day 5 of Blinatumomab, an important non pruritic maculo-papular rash occurred in both patient, in the same area of the initial cutaneous involvement. Interestingly, it decreased after day 8. No new drug introduction or infection (bacterial, viral or parasitic) was documented in the days preceding or during Blinatumomab infusion. A skin biopsy performed at day 6 of Blinatumomab showed a prominent dermal CD3+ lymphocytic infiltrate with a perivascular, but also a peri-nervous distribution (on the first patient’s specimen only).

Few lymphocytes marginated at the basement membrane and rare basal necrotic keratinocytes were also noted but without blast for the first, although few residual blast cells were observed on the second’s. One month later, another skin biopsy showed a CR without lymphocytic infiltrate. The medullar CR was confirmed at the molecular level (MRD negative). The first patient received allogenic stem cell transplantation (SCT) from a matched related donor one month later. He presented an acute and chronic GVHD, and is now in complete remission with a follow-up of 7 months. The second is still waiting for a SCT.

Summary/Conclusions: These observations confirm the strong efficacy of Blinatumomab in r/r B-ALL. We observed a T-cell dermal recruitment 6 days after Blinatumomab initiation clinically mimicking skin GVHD. However, we couldn’t find specific histological features of GVHD, but only an “inflammatory dermal CD3+1 lymphocytic infiltrate with a perivascular” and also a peri-nervous distribution (on the first patient’s specimen only).

Figure 1. The status of minimal residual disease was associated with prognosis.

A NOVEL METHOD FOR MINIMAL RESIDUAL DISEASE ANALYSIS IN PHILADELPHIA-NEGATIVE ACUTE LYMPHOCYTIC LEUKAEMIA: MODIFIED BIOMED-2 POLYMERASE CHAIN REACTION FOR IMMUNOGLOBULIN HEAVY CHAIN REARRANGEMENT
D. Katoh1,*, M. Nakamura1, M. Morita1, H. Maruoka2, A. Fujimoto1, N. Yonetani1, A. Matsushita1, H. Hashimoto3, T. Ishikawa1
1Hematology, 2Clinical Laboratory, Kobe City Medical Center General Hospital, 3Department of Pediatrics, Kobe City Medical Center General Hospital, Kobe, Japan

Background: Recent studies have demonstrated the clinical importance of minimal residual disease (MRD) monitoring in adult acute lymphoblastic leukemia (ALL) as well as pediatric ALL. However, patient-specific polymerase chain reaction (PCR)-based MRD assessment, one of the most commonly recognized methods, is not widely used in clinical practice because it is expensive, time consuming, and technically difficult. Therefore, we modified the BIOMED-2 protocol, PCR for immunoglobulin heavy chain (IgH) rearrangement, to assess MRD in ALL easily and readily in our hospital.

Aims: The aim of this study was to examine the clinical utility of monitoring MRD by the modified BIOMED-2 PCR for IgH rearrangement in patients with Philadelphia-negative (Ph-)-ALL.

Methods: We enrolled 54 patients diagnosed with Ph- ALL between 2006 and 2016 in our hospital. IgH rearrangement was detected in 35 patients using the standard BIOMED-2 PCR protocol. Patients who received palliative chemotherapy, never achieved remission (blasts >5%), or had no follow-up MRD data were excluded. Finally, data from 27 patients with Ph- ALL were analyzed. We assessed MRD with the modified BIOMED-2 PCR for IgH using bone marrow samples collected after each chemotherapy session. Patients’ MRD statuses were classified as follows: Early MRDneg, achievement of MRD negativity within 6 weeks after chemotherapy initiation; Late MRDneg, achievement of MRD negativity more than 6 weeks after chemotherapy initiation; and MRDpos, persistent MRD detection during chemotherapy. The endpoint was disease-free survival (DFS), calculated from the date of achieving remission.

Results: The median age was 38 years (16–73), and the median follow-up time was 47 months (4–105). There were 24, 18, and 5 patients with early MRDneg, late MRDneg, and MRDpos, respectively. There were no differences in patient characteristics by bone marrow status, except for the duration to achieving remission (Table 1). There were significant differences in the 3-year DFS rates among patients with early MRDneg, late MRDneg, and MRDpos (100% vs 72.9% vs 20%; p=0.001) (Figure 1). Patients undergoing transplantation had better prognosis than those receiving chemotherapy alone in the late MRDneg group (100% vs 40%; p=0.028), whereas there was no difference in the early MRDneg group (100% vs 100%; p=0.48).

an IV administration option, and improved immunogenicity. Clinical outcomes in the adult ALL population are less well understood.

Aims: To assess the relative clinical benefit of PEG-ASP vs native ASP in 1st line treatment in newly diagnosed adult ALL patients in terms of event-free survival (EFS) and overall survival (OS). Safety outcomes were also examined.

Methods: A systematic literature search was conducted using a standardized search algorithm within the National Library of Medicine’s PubMed database to identify available evidence for newly diagnosed patients treated with adult ALL protocols that use PEG-ASP or native ASP. Randomized, observational, and cohort studies were included, with the predefined clinical outcomes of event-free-survival (EFS) and overall survival (OS). Data was pooled with 95% confidence intervals (CIs) calculated using the logit transformation.

Results: A total of 30 studies were identified that met the pre-specified inclusion criteria, with 10 studies providing data for PEG-ASP and 23 studies for native ASP. The pooled estimate of 2-year EFS for adult ALL patients treated in 1st line with asparaginase was 48.0% (95% CI: [10.8, 85.2]) for PEG-ASP and 66.8% (95% CI: [52.0; 77.7]) for native ASP. Similarly, the pooled estimate of 5-year OS was 75.5% (95% CI: [61.5; 87.5%]) for PEG-ASP and 46.8% (95% CI: [33.6; 60.1]) for native ASP. In very high risk ALL patients, the pooled estimate of 5-year OS was 57% (95% CI: [52.4; 61.7%]) for PEG-ASP and 35.3% (95% CI: [21.7; 51.7]) for native ASP. Findings for safety outcomes were consistent with product labeling for both asparaginases.

Summary/Conclusions: The systematic literature review highlights a positive clinical effectiveness profile for PEG-ASP in regards to EFS and OS in the treatment of newly diagnosed adult ALL patients with less frequent administration and similar safety profile as compared with native ASP.

PB1632

A COMPREHENSIVE ANALYSIS OF PATIENT- AND THERAPY-RELATED FACTORS AFFECTING THE TOXICITY OF PEGYLATED-ASPARAGINASE FOR THE TREATMENT OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

P. Minetto1,*, N. Bisso1, F. Guolo1, M. Clavio1, E. Coviello1, D. Guardo1, N. Di Felice1, F. Canale1, L. Manconi1, F. Ballerini1, M. Migliore1, R. M. Lemoli1, M. Gobbi1

1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genova, IRCSS AOU San Martino-IST, Genoa, Italy

Background: The application of pediatric regimens in the treatment of adult acute lymphoblastic leukemia (ALL) has led to a significant improvement in patients outcome. However, concerns about the feasibility of more intensive therapies and of the use of pegylated L-Asparaginase (PEG-ASP) in adult patients have emerged. Some patient-related risk factors as high BMI or hepatic steatosis have been already identified as risk factors, but few data are available on the synergic toxic effect from other concomitant drugs.

Aims: The aim of this study was to evaluate the incidence of PEG-ASP related adverse events in a cohort of adult ALL patients in order to identify potential patient and therapy-related risk factors contributing to toxicity.

Methods: Since 2013, 21 adult ALL patients received PEG-ASP therapy in our institution. Median age was 44 (range 19-76); 12 patients were treated in front-line setting (7 according to a full pediatric protocol) whereas 9 patients received therapy for relapsed/refractory neoplasm. We retrospectively analyzed each single course which included PEG-ASP administration as an independent event, accounting 41 episodes. Patients’ features (age, BMI, disease status) and concomitant therapies were accurately analyzed as factors potentially affecting PEG-ASP toxicity. The incidence of major thrombotic/bleeding complications and grade III/IV hepatic or pancreatic toxicity was analyzed; toxicity grading and management of PEG-ASP related complications were performed according to guidelines recently published by Stock et al.

Results: No grade III/IV pancreatic, thrombotic or hemorrhagic adverse events were recorded. A total of 8 episodes of grade III/IV hepatic toxicities were observed. In 3 cases, grade IV toxicity was observed. Those patients experienced unexplained severe weight gain and painful ephegmolysis, a classic picture resembling sinusoidal occlusive disease, ultrasonography showed acute liver steatosis. All 3 patients received concomitant therapy with idarubicin, vincristine and cyclophosphamide. In univariate analysis, the incidence of grade III/IV hepatic toxicity was significantly higher when concomitant chemotherapy with at least 2 mg/sqm cumulative dose of vincristine (p = 0.044, HR 4.75) or at least 16 mg/sqm cumulative dose of idarubicin (p = 0.046, HR 1.45) were administered. Steroids therapy determined a borderline increase in toxicity risk (p = 0.068, HR 1.92). No increase in toxicity was observed with any dosing of daunorubicin, cyclophosphamide, cytarabine, methotrexate and 6-mercaptopurine (Table 1). Among concomitant antibiotic therapies, vancomycin administration seemed to increase the incidence of grade III/IV hepato-toxicity (p = 0.02, HR 1.863). No significant increase was observed with carbapenems and azoles (Table 2). In 1 patient receiving PEG-ASP and native asparaginase, a high BMI (>25) were not related with an increased incidence of grade III/IV hepato-toxicity (Table 1). Notably, none of the patients undergoing full pediatric induction (who received the highest doses of PEG-ASP), regardless of age (ranging from 21 to 55) experienced grade III/IV hepatotoxicity. A multivariate logistic regression analysis disclosed that concomitant administration of daunorubicin, vincristine or vancomycin were independent predictors of grade III/IV hepatotoxicity (p = 0.004, 0.027 and 0.042, respectively, Table 1).

Table 1.

Summary/Conclusions: Our data show that the toxicity profile of PEG-ASP in adult patients is overall manageable. However, serious warnings emerge from our experience. Concomitant drugs and their timing of administration may play a crucial role in significantly contributing to PEG-ASP hepatic toxicity. In order to attempt to reduce toxicity, anthracyclines with shorter half-life, i.e. daunorubicin instead of idarubicin, should be used. A particular attention should be paid when administration of concomitant antibiotic therapy is required.

PB1633

COST OF CARE FOR ADULT PATIENTS WITH RELAPSED ACUTE LYMPHOBLASTIC LEUKEMIA WITH AND WITHOUT HEMATOPOIETIC STEM CELL TRANSPLANTATION IN GERMANY

Y. Su1,*, S. Schmitz2, A. Navarro3, L. Mayerhoff3, S. Prieur3, M. Lehne3, F.R. Lobigs3,1

1Pfizer Inc., New York, United States, 2Pfizer Deutschland GmbH, 3Elsevier Health Analytics, Berlin, Germany

Background: Adult ALL is a rare but frequently fatal disease. Many patients who respond to initial therapy experience a relapse. For relapsed ALL (rALL), hematopoietic stem cell transplant (HSCT) is a potentially curative treatment option. HSCT is associated with added costs, however, which could impact overall healthcare budget.

Aims: This retrospective observational study aims to determine the cost of care and the impact of HSCT on total cost for adult rALL patients from a German payers’ perspective.

Methods: A German claims database with a representative sample of approximately 7 million individuals insured within the German statutory health insurance and continuously observable over a period of 6 years was used as data source. For these data, adult patients (18 years and older) with a new diagnosis of ALL (ICD-10-GM code: C91.0) between January 1, 2011 and December 31, 2015 and a relapse after remission to initial treatment were identified. Mean health care cost per patient per quarter, the smallest unit of time available in the database, was determined by whether or not patients had an HSCT after relapse. Costs were considered from the perspective of the German statutory health insurance and included costs for prescription medicine as well as outpatient and inpatient healthcare encounters.

Results: Of the total 116 incident adult ALL patients identified, 29 (25%) were determined to have had a relapse and 11 underwent HSCT after relapse (38%). Patients with an HSCT appear to incur higher cost than those without HSCT in each of the quarters after relapse was diagnosed (Table 1), with the highest in the first quarter after relapse, but decreasing in subsequent quarters. Inpatient cost accounted for the majority of the cost for the first three quarters for both HSCT and non-HSCT patients, but for HSCT patients. The number of patients in the HSCT cohort remained relatively stable, while the non-HSCT cohort had only half the patients left by the third quarter post relapse.

Table 1. Costs in € per patient (with and without HSCT) by quarter after relapse

Patient group | Index quarter (relapse) | Q1 | Q2 | Q3 | Q4 | Q5 | Q6 | Q7 | Q8 | Q9 | Q10 | Q11 | Q12
--- | --- | --- | --- | --- | --- | --- | --- | --- | --- | --- | --- | --- | ---
ALL without HSCT | N | mean | % | mean | % | mean | % | mean | % | mean | % | mean | %
ALL with HSCT | N | mean | % | mean | % | mean | % | mean | % | mean | % | mean | %
ALL without HSCT | 11 | 10.796 | 61% | 12.027 | 76% | 11.719 | 67% | 12.570 | 72% | 11.453 | 69% | 10.194 | 63% | 12.567 | 71%
ALL with HSCT | 31 | 36.087 | 76% | 10.349 | 56% | 9.237 | 55% | 7.691 | 44% | 6.258 | 35% | 4.563 | 28% | 3.451 | 21%
Total | 42 | 30.571 | 62% | 10.349 | 56% | 10.466 | 56% | 10.235 | 56% | 7.691 | 44% | 6.258 | 35% | 3.451 | 21%

Summary/Conclusions: Our data show that the toxicity profile of PEG-ASP in adult patients is overall manageable. However, serious warnings emerge from our experience. Concomitant drugs and their timing of administration may play a crucial role in significantly contributing to PEG-ASP hepatic toxicity. In order to attempt to reduce toxicity, anthracyclines with shorter half-life, i.e. daunorubicin instead of idarubicin, should be used. A particular attention should be paid when administration of concomitant antibiotic therapy is required.
Summary/Conclusions: The results of this study inform the magnitude of cost in Germany associated with adult rALL patients with or without an HSCT after relapse. The cost estimates provide a benchmark against which new treatment options for rALL can be compared. For future studies, it would be important to determine the magnitude of benefit such as long-term survival and other health consequences associated with HSCT as well.

PB1634 RETROSPECTIVE STUDY OF ADULT ALL IN MEXICO CITY: FIRST REPORT OF THE WORKING GROUP ON ACUTE LEUKEMIA E. Crespo-Solís,1, K. Espinosa-Bautista2, M. Alvarado-Ibarra3, E. Rozen-Fuller,4 P. Pérez-Rocha5, A. L. Meillón-García5, C. Nava-Gómez2, M. Ortiz-Zepeda,6 J. J. Alvarez-Vera7, C. C. Ramos-Perafán3, S. Rodríguez-Rodríguez8,9, J. Pomeranz-Oken10, R. Demichelis-Gómez10 1Department of Hematology and Oncology, Hospital Regional de Alta Especialidad Ciudad Victoria, Victoria, 2Department of Hematology and Oncology, Instituto Nacional de Cancerología, 3Department of Hematology and Oncology, Centro Médico Nacional 20 de Noviembre, ISSSTE, 4Department of Hematology and Oncology, Hospital General de México, 5Department of Hematology and Oncology, Centro Médico Nacional Siglo XX, IMSS, 6Department of Hematology and Oncology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Background: The prognosis of adult acute lymphoblastic leukemia (ALL) is dire, with a long-term survival of 40-50%. This disease entity is probably more frequent in the Latino population. Several studies have reported a worse prognosis in Hispanics with ALL as well as a greater incidence of the Ph-like genetic signature; however, the data is inconclusive in the Mexican population and there are no existing large multicenter series of ALL patients in Mexico that analyze survival.

Aims: The aim of this study was to describe the incidence, clinical and biologic characteristics as well as the survival of ALL patients in 5 referral hospitals in Mexico City.

Methods: A working group known as the Grupo de Trabajo de Leucemia Aguda (GTLA), was created as a result of an initiative of the Mexican Group for the Study of Hematology (Agrupación Mexicana para el Estudio de la Hematología) to promote acute leukemia research in Mexico. This is the first report of the GTLA which includes 5 referral hospitals in Mexico City. A retrospective, multicenter descriptive study of adult ALL patients treated between 2009 and 2015 was conducted.

Results: We included 559 adults in 5 centers in Mexico City. Their median age was 28 years (14-81): adolescents and young adults (AYA) 67.3%; adults 24.7% and elderly adults 8.1%. Tumor lysis syndrome was detected in 9.8% of patients. Cytogenetic information was unavailable in 45% of cases due to lack of access or growth in metaphase. Among cases that could be analyzed, a normal karyotype was the most frequent (70.5%), followed by Ph+ (16.7%). Patients were considered high-risk in 52.1% cases. The most frequently used drug protocol was Hyper-CVAD, in 47% of cases. Complete remission (CR) was achieved in 67.1% of patients, and 18% required a second cycle for CR, while 13% were primarily refractory. A mortality rate during induction was registered as 10.6%, and there were 11.4% deaths while in CR. Among patients in CR, 59.1% relapsed. At the time of analysis, 26.7% of patients were alive, with a median OS of 12.97 months and a DFS of 16 months. Only 5.7% were able to achieve a first complete remission (CR1) in B-cell acute lymphoblastic leukemia (ALL B-ALL). OS at 3 years was 22.1% and by age group: AYA 25.7%, adults 17.4% and elderly adults 60.2% (p=0.77), RFS - 75% and 40.2% (р=0.74), respectively. Multivariate analysis showed that a CR1 duration>6 month and time to transplant>6 months were significant predictors of better survival.

Summary/Conclusions: The disease in adult ALL patients in Mexico City is characterized by a poor prognosis, with only 25.7% of patients achieving CR1. The median OS was 12.97 months and 22.1% at 3 years, with a DFS of 16 months. Only 5.7% of patients achieved CR1. Multivariate analysis showed that CR1 duration>6 month and time to transplant>6 months were significant predictors of better survival. Future research should focus on improving survival in adult ALL patients in Mexico City.

PB1635 IMPACT OF DISEASE STATUS ON OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH REFRACTORY AND RELAPSED ACUTE LYMPHOBLASTIC LEUKEMI J. Cao1, X. Zhu1, A. Sun1, H. Qiu,1 Z. Jin1, M. Miao1, D. Wu1,2, X. Tang1,2,2 1The First Affiliated Hospital of Soochow University;Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Refractory or relapse remains a major obstacle in improving outcomes of patients with acute lymphoblastic leukemia (ALL). And allogeneic hematopoietic stem cell transplant (allo-HSCT) was the only curative treatment option for these patients. However, whether an allo-HSCT was performed in status of advanced stage or in setting of remission after salvage chemotherapy, there is no standard of care.

Aims: To evaluate the impact of disease status on the outcomes of allo-HSCT in the treatment of patients with refractory and relapsed ALL.

Methods: 52 patients with refractory and relapsed ALL, including 19 cases in advanced stage (nonremission, NR) and 33 cases in more than or equal to second complete remission (cCR2), received allo-HSCT after myeloablative conditioning regimen in our department.

Results: 51 patients engrafted successfully. The transplantation-related mortality (TRM) rate of NR and cCR2 was 10.5% vs 12.1% (P=0.815). The incidence of aGVHD was 52.6% vs 57.6% (P=0.730), including 42.1% vs 33.3% (P=0.527) with mild (grade I-II) and 10.5% vs 24.3% (P=0.399) with severe (grade III-IV) aGVHD. The incidence of cGVHD was similar also (41.6% vs 57.9%, P=0.600). With a median follow-up of 12(1.8-44.5) months, the cumulative relapse rate of NR and cCR2 was 47% vs 34.3% (P=0.425) respectively. The estimated 2 year overall survival (OS) and 2 year leukemia-free survival (LFS) rate were 42.6% vs 45.7% (P=0.487) and 46.3% vs 46.2% (P=0.571) respectively. Multivariate Analysis showed that cGVHD was an independent favorable risk factor for OS and LFS of R/R ALL. For relapsed patients, OS was significantly better with first CR duration>6 month and time to transplant>2 months.

Summary/Conclusions: Allo-HSCT is an effective salvage treatment option for patients with refractory and relapsed ALL. Our retropective analysis showed that R/R ALL with different status prior transplant had similar outcome post transplantation.

PB1636 THE FREQUENCY AND PROGNOSTIC SIGNIFICANCE OF IKZF1 DELETIONS IN ADULT PH-POSITIVE AND PH-NEGATIVE B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED IN RUSSIAN ACUTE LYMPHOBLASTIC LEUKEMIA STUDIES G. Baskhava1,2, B. Biderman1, O. Gavvina1, K. Zarubina1, I. Luykova1, E. Stepanova1, V. Troitskaya1, A. Sudankov1, E. Parovichnikova1 1Hematological Research Center under the Ministry of Health, Moscow, Russian Federation

Background: The incidence of IKZF1 gene deletions is approximately 20% in adult patients with BCR-ABL1- negative B-cell ALL and 70–80% in BCR-ABL1- positive ALL. These mutations are associated with poor prognosis in patients with Ph-negative ALL, but not in patients with Ph-positive ALL, suggesting that IKZF1 deletions may be more prognostically valuable in patients with Ph-negative ALL.

Aims: To evaluate the frequency and prognostic impact of mutation status of IKZF1 in patients with de novo BCR-ABL1-negative and BCR-ABL1-positive B-cell acute lymphoblastic leukemia.

Methods: The study included 135 adult patients (median age 27, range 17-66; m:f=15:21) with newly diagnosed BCR-ABL1- neg B-cell ALL and 15 patients (median age 34 years, range 22-68; m:f=6:9) with BCR-ABL1- pos B-cell ALL, who were enrolled in Russian acute lymphoblastic leukemia (ALL) - 2009 [ClinicalTrials.gov public site; NCT01193933] and RALL-2012 protocols since Feb 2010 till Sep 2016 and Aug 2009 till Feb 2017, respectively. Intragenic deletions of IKZF1 were detected using breakpoint-specific fluorescent multiplex polymerase chain reaction according to the procedure described by [Aurelie Caye et al, Haematologica, 2013]. DNA for PCR was extracted from leukemia cells of frozen bone marrow samples.

Results: The IKZF1 deletions were detected in 7 (47%) of 15 patients with BCR-ABL1- pos ALL (3 cases with del 4-7 (43%), 2 – del 2-7 (28%), 1 – del 2a-8 and 1 – del 4-8 (14%)). The median follow-up time in 15 patients was 18 months (range: 4-79 month). Five patients died (33%) after relapse or progression of the disease, and 10 patients are alive. Overall survival (OS) in BCR-ABL1- pos B-ALL patients with IKZF1 mutations and without was 37.5% and 57.1% (p=0.77), relapse - free survival (RFS) - 25% and 33.3% (p=0.88), respectively. In patients with BCR-ABL1- neg ALL the IKZF1 deletions were revealed in 8 (22%) of 36 patients (4 cases with del 4-7 (50%), 2 – del 2-7 (25%), 1 – del of 2-8 (12.5%) and 1 in patient all types of deletions were determined (del 7, del 4-8, del 2-7, del 2-8)). The median follow-up time in 36 patients was 22 months (range: 0.5-84 month). 4 patients died of the disease (11%) and 2 of infections, 30 patients are alive. OS for patients with BCR-ABL1- neg ALL with IKZF1 mutations and without was 100% and 60.2% (p=0.77), RFS - 75% and 40.2% (p=0.74), respectively. IKZF1 mutations seemed to be of poor prognosis for BCR-ABL1-
controls. This finding may be related to several aspects: socioeconomic major adaptations. On the other hand, overall survival of AYA patients treated good overall survival in adults ALL patients in a low income country, despite Summary/Conclusions: at 18 months for CR1 patients with negative MDR after first induction was 74%, MRD data was available for 26 (74%) of these at the end of first induction. OS of relapse were all noted. Bone marrow density and markers of bone metabolism, have effects on bone turnover in patients with ALL. Results: Thirty five patients were included, 21 of them started BFM-based treatment and 14 started GMALL-based protocol. During the first three months, 7 patients migrated from BFM to GMALL-based treatment because of toxicity and were analyzed separately. Median age was 21 years (18-38) for BFM-based group, 44 years (30-57) for GMALL-based, and 33 years (21-38) for de-escalated. Male predominance was observed (71%), not different between groups. T-phenotype was more frequent than expected, representing 50% of BFM-based, 50% of GMALL-based and 29% of de-escalated groups. BCR/ABL1 was detected in 14% of BFM-based, 23% of GMALL-based and 14% of de-escalated groups (p=0.85). Seven patients (2 BFM and 5 GMALL) underwent allogeneic stem cell transplantation in first remission. Of all 35 patients, 31 achieved complete remission after first induction phase. With median follow-up of 18 months, 1-year overall survival (OS) was 60% for all patients (39% for BFM-based, 75% for GMALL-based and 86% for de-escalated groups – p=0.04; BFM-based versus other protocols). Cumulative incidence (CI) of death in first complete remission (CR1) at 12 months was 18%, not different between groups. CI of death at 12 months in non-CR1 (relapsed or refractory) patients was 39% for BFM-based, 7% for GMALL-based and 0% for de-escalated groups – BFM-based versus other HR 2.6; p = 0.13. Among 31 patients who achieved CR1, MRD data was available for 26 (74%) of these at the end of first induction. OS at 18 months for CR1 patients with negative MDR after first induction was 74%, compared to 52% in MDR+ (Figure 1).

Summary/Conclusions: Our results show that GMALL-based protocol yields good overall survival in adults ALL patients in a low income country, despite major adaptations. On the other hand, overall survival of AYA patients treated with BFM-based protocol was surprisingly poor, specially because of ineffective disease control may be related to several aspects: social, economic impairment, inadequate supportive care for more intensive therapies and ineffective cancer care network. Future prospective studies should focus on this issues.

GMALL BASED PROTOCOL, USING NATIVE E. COLI L-ASPARAGINASE, IMPROVES SURVIVAL OF ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA IN BRAZIL
I. Arcuri1, J. Ramires1, Y. Gonçalves1, R. Dal Bello1, B. Gomes1, J. Dobbin1, L. Arcuri1
1Instituto Nacional de Câncer, Rio de Janeiro, Brazil

Background: Despite being the most common childhood cancer, nearly one half of ALL cases occurs in adults. Recently, it has been suggested that more intensive protocols may improve survival in adolescents and young adults (AYA).

Aims: Compare results of patients treated with BFM-based protocol to those patient treated with GMALL-based protocol, in a developing country.

Methods: This is a single center retrospective study which included all newly diagnosed adult ALL patients admitted between May/2012 and October/2016. Initially, patients aged 18-39 years (AYA group) were treated with BFM ALL 2009-based protocol and those aged 40-59 years were treated with GMALL 2003-based protocol. Since September 2013, because of high toxicity, only patients under 30 years were eligible for BFM-based treatment. Major adaptations were: (1) native E. coli-l-asparaginase was substituted for peg-asparaginase, and (2) GMALL irradiation therapy was postponed to maintenance phase. BCR/ABL1 positive patients received standard chemotherapy plus Imatinib. Negative MRD was defined as <0.01% by flow cytometry. Overall survival was estimated by Kaplan-Meier method. Comparing risk analysis was carried out for cumulative incidence of death in CR1 or not in CR1. This study was approved by local Ethics Committee.

Results: Thirty five patients were included, 21 of them started BFM-based treatment and 14 started GMALL-based protocol. During the first three months, 7 patients migrated from BFM to GMALL-based treatment because of toxicity and were analyzed separately. Median age was 21 years (18-38) for BFM-based group, 44 years (30-57) for GMALL-based, and 33 years (21-38) for de-escalated. Male predominance was observed (71%), not different between groups. T-phenotype was more frequent than expected, representing 50% of BFM-based, 50% of GMALL-based and 29% of de-escalated groups. BCR/ABL1 was detected in 14% of BFM-based, 23% of GMALL-based and 14% of de-escalated groups (p=0.85). Seven patients (2 BFM and 5 GMALL) underwent allogeneic stem cell transplantation in first remission. Of all 35 patients, 31 achieved complete remission after first induction phase. With median follow-up of 18 months, 1-year overall survival (OS) was 60% for all patients (39% for BFM-based, 75% for GMALL-based and 86% for de-escalated groups – p=0.04; BFM-based versus other protocols). Cumulative incidence (CI) of death in first complete remission (CR1) at 12 months was 18%, not different between groups. CI of death at 12 months in non-CR1 (relapsed or refractory) patients was 39% for BFM-based, 7% for GMALL-based and 0% for de-escalated groups – BFM-based versus other HR 2.6; p = 0.13. Among 31 patients who achieved CR1, MRD data was available for 26 (74%) of these at the end of first induction. OS at 18 months for CR1 patients with negative MDR after first induction was 74%, compared to 52% in MDR+ (Figure 1).

Summary/Conclusions: Our results show that GMALL-based protocol yields good overall survival in adults ALL patients in a low income country, despite major adaptations. On the other hand, overall survival of AYA patients treated with BFM-based protocol was surprisingly poor, specially because of ineffective disease control may be related to several aspects: social, economic impairment, inadequate supportive care for more intensive therapies and ineffective cancer care network. Future prospective studies should focus on this issues.
OUTCOME OF ADOLESCENTS AND YOUNG ADULTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA TREATED WITH PEDIATRIC PROTOCOL: MONOCENTRIC STUDY
I. Frikha1,*, M. Madhaffer1, S. Hddjji1, R. Kharrati1, M. Chaari2, O. Kassar1, M. Ghediri1, H. Bellaa1, B. Ben Amor1, F. Kalle1, C. Kalle1, M. Elloumi1
1Hematology, 2Laboratory of Hematology, Hedi Chaker Hospital, Sfax, Tunisia

Background: Several retrospective studies have confirmed that adolescents and young adults (Aya) with acute lymphoblastic leukemia (ALL) treated with pediatric protocols have better outcomes than similarly aged patients treated with adult protocols. Aims: We reported results and feasibility of a pediatric-based protocol (EORTC 58951) in adolescents and young adults.

Methods: From January 2000 to December 2015, 72 patients aged 16 to 30 years with newly diagnosed ALL were treated, in the department of clinical hematology of Hedi Chaker Hospital, according to the pediatric protocol EORTC 58951. Further leukemia characteristics (Sex, White Blood cell count, Blasts phenotype, Cytogenetic results), we studied the protocol results: response to induction treatment, just before the maintenance treatment, respectively. Psychographic data included age, sex, school achievement, parents education, socioeconomic status, illness perception, distress levels and self-concept.

Results: Seventy two Aya ALL were treated with the pediatric protocol. The patients were 45 males and 27 females (SR=1.66). A WBC>100 G/l was noted in 32% of patients. AT T blasts were noted in 53% of cases. Twenty two patients (30%) were PPR. Nine patients (13%) were treated according AR1 arm, 39 patients (54%) according AR2 arm and 24 patients (33%) according VHR arm induction. CR rate was 87% after one course and 94% after 2 courses. Induction death was noted in 3% and post-induction death was noted in 13%. Twenty four patients (33%) of the patients protocol were eligible for allogeneic stem cell transplantation (SCT), among them 15 patients had a familial donor and 10 patients were allograft (42%) and only 4 patients still in CR (2 patients died by GVH and 4 patients relapsed). Relapse was observed in 22 patients (32%), among them 12 during the first year of treatment. The median follow up was 101 months (8.4 years).

Summary/Conclusions: The results of this pediatric based study show that response to therapy and prognosis in adolescent and young adults were better than those treated with adult protocols and tolerability of chemotherapy is acceptable. However OS and EFS, better than adult ALL treated by adult protocol (OS=14%, EFS=14%: local study) was not satisfactory because the high toxic mortality rate.

ASSESSMENT OF DEPRESSION AND SELF-CONCEPTION IN CHILDREN WITH ALL-TREATMENT
G. Aydogan1,*, N. Kavcik1, F. Akici1, Z. Salcioglu1, H. Sen1, N. Ozdemir1, C. Bayram1, A. Aycicek1
1Pediatric Hematology, Kanuni Sultan Suleyman Education And Research Hospital, Istanbul, Turkey

Background: Leukemia is the most prevalent pediatric malignancy with acute lymphoblastic leukemia (ALL) being the most common accounting for 75% of leukemia cases with about 24000 newly diagnosed children each year worldwide. Treatment of ALL requires long course chemotherapy ranging up to 48 months with 20% possibility of relapse. Affected children receive in-patient treatment at the clinic for nearly six months for leukemia and related complications. This is the first time that we were able to published a twostage study conducted in 24 tertiary children with leukemia and 25 healthy children aged 9-16 years. Children with leukemia were evaluated at the time of diagnosis, end of induction treatment and end of consolidation treatment, just before the maintenance treatment, respectively. Psychological data including depression and low self-concept were assessed by Child Depression Scale, 12 item Patient Health Questionnaire, Piers Harris Self-Concept Scale. The changes in psychological conditions due to long stay at the hospital were investigated. Demographic data included age, sex, school achievement, parents education, socioeconomic condition, loss of first degree relatives.

Results: The prevalence of depressive disorder in children with leukemia at the end of induction and at the end of consolidation treatment were significantly increased. Self-Concept Scales were found lower in these patients.

Summary/Conclusions: The children with ALL receive long course chemotherapy and become distanced from their family, school and milieu and as a result, these patients are vulnerable to psychological problems. They may develop depressive and have lower self-conception comparing to healthy children. It is important to provide psychological support to these children in addition to their chemotherapy.

PB1641

SEVERE PSYCHIATRIC DISTURBANCES DURING THERAPY IN PEDIATRIC ALL
G. Tsipou1,*, N. Tourkanton1, A. Kattamis1
1Hematology-Oncology Unit, 1st Department of Pediatrics, “Aghia Sofia” Children’s Hospital, University of Athens, Athens, Greece

Background: Psychiatric disturbances are not uncommon in patients with cancer. Their pathogenetic mechanisms are variable and comprise consequences of the therapy, underlying disease, as well as personality characteristics. These disturbances are frequently associated with the use of corticosteroids, which is an essential component of the treatment for children and adolescents with Acute Lymphoblastic Leukemia (ALL).

Aims: This study aimed to investigate the incidence of severe psychiatric disturbances in patients treated for childhood ALL.

Methods: We report the results of a retrospective analysis of the incidence of severe psychiatric disturbances, defined as behavioral and psychological changes which lead to dangerous or erratic behaviors requiring use of psychiatric medications, in patients treated for childhood ALL. All patients were treated in a single institution and followed the same chemotherapeutic protocol, according to which, corticosteroids are administered initially during the “induction” phase and then in multiple subsequent pulses.

Results: Seventy patients (mean age 4.04 years old, range:1-16) were treated in our unit. A total of 22 patients (31.43%) showed that severe psychiatric disturbances were observed more frequently in older patients and they were more common with the administration of dexamethasone than with prednisolone.

Summary/Conclusions: Severe psychiatric disturbances are not infrequent in children and adolescents receiving treatment for ALL. Awareness of this complication, appropriate parental education for identifying early signs, and prompt therapeutic interventions are essential for optimal outcome. Further studies are required for identifying patients at risk and best use of chemotherapeutic agents and of dexamethasone.
Department of Clinical Institute Fundeni during 2010-2017 and received chemotherapy according to protocol ALL BFM 1995 and ALL BFM 2002, established after framing in the risk group.

Results: Over a period of 8 years in our department 280 patients with ALL received L-asparaginase in the induction phase. Neurological manifestation suggestive for bleeding or thrombotic events occurred in 92/280 (3.21%) patients. 2 patients died from fatal bleeding after treatment according protocol ALL BFM 1995 and 7 patients were treated according to protocol ALL BFM 2002. M/F ratio was 4/5. Patients had at diagnosis between 3 and 15 years (median age 9 years). All patients had thrombotic events after starting administration of L-Asparaginase during induction. Most had clinical symptoms after the fourth dose of L-Asparaginase. Clinical manifestations were accompanied by hypofibrinogenemia (<100 mg/dl) especially in patients who experienced bleeding. The patients who experienced thrombosis had decreased levels of antithrombin III, protein C and increased D dimer levels. The diagnosis of cerebral venous sinus thrombosis (CVST) is typically based on clinical suspicion and imaging confirmation. At 3 of these patients neuroimaging tests (computed tomography [CT] and magnetic resonance imaging [MRI]) demonstrated CVST after developing neurological symptoms; one of the patients suffered major complication (extended brain injury) and died. All patients with ALL and thrombotic events received low-molecular weight heparin (LMWH) for 3 to 6 months. A follow-up CT or MRI at 3 to 6 months after diagnosis was made to assess for recanalization of the occluded cortical veins/sinus. Survival in the patients with CVST was 84.61%. 1 patient with ALL and hemostasis alteration had intracerebral hemorrhage (ICH) with rapid progressive neurological deterioration to death. 1 patient had pulmonary embolism associated with clotting disorders and severe sepsis and he died. 2 patients had clinical manifestation (headache, confusion and seizures) and clotting disorders (decreased levels of antithrombin III, protein C, fibrinogen and increased D dimer levels), but with normal brain imaging. Survival in the cohort was 77.7%.

Summary/Conclusions: Thrombotic events have occurred in all patients during induction. Clinical manifestation were depending on size, and duration of thrombosis, from headaches, seizures or focal neurological deficits. Severe sepsis association was an additionally risk factor for thrombotic and bleeding events in patients with ALL. Screening for genetic prothrombotic defects diagnosis prior to initiating chemotherapy may represent a way to reduce thrombotic or bleeding events and appropriate management of hemostasis disorders that occur during the treatment.

PB1643

INCIDENCE AND SURVIVAL OF CHILDHOOD LEUKEMIA IN ARMENIA: A POPULATION-BASED ANALYSIS

M. Tatulyan1, S. Dagbashyan1, L. Krmoyan1, A. Zakaryan1, L. Vagharshakyan1, L. Sahakyan1
1pediatric hematology/oncology department, Hematology Center after prof. Yeolyan, Yerevan, Armenia

Background: Leukaemia is the most common cancer in children. Childhood leukaemia incidence and survival varies globally, and this could be associated with different risk factors, genetics, and improvement in diagnosis and treatment. Armenia is considered to be a mono-ethnic nation.

Aims: We aimed to quantify the incidence and mortality of acute leukaemias among children population in Armenia and their variation with gender, age, year of diagnosis.

Methods: In this work we included children diagnosed with de novo acute leukaemia, 0–18 years of age from 2006 to 2016. The initial data for this survey have been derived from ambulance/dispensary cards, hospitalization journals, and clinical data from the Registry of Blood Diseases at the R. Yeolyan Hematology Center, Yerevan, Armenia. The data has been supplemented by the data from the Registry of Oncological Diseases of the V. Fanarjyan NCO, as well as from death certificates. The demographic data has been obtained from the National Statistics Board of Republic of Armenia. The obtained data has been statistically analyzed using EPI INFO-2002 program.

Results: A total of 277 cases of childhood acute leukemia were identified, 174 (62.9%) of whom were males. The overall incidence of leukaemia was 3.4 per 100 000 children-years. The higher incidence rates were noted in 2007 (accordingly 4.0, 4.0 и 3.9), and the lower rates in 2011, 2014, 2009 (0.012 and 0.010 per 100 000 children-year). Currently 83.8% of studied patients were alive. The 5-year survival rate was 72%, 100%, and 100% among children diagnosed at 3–7, 7–13, and 13–18 years of age, respectively. The results indicate that the children diagnosed between ages of 3 and above had the lowest risk of mortality and higher survival rates.

Summary/Conclusions: This is the first general population study to describe the incidence and mortality from childhood acute leukaemia in Armenia during 2006-2016. It forms the basis for quality assessment of acute leukaemia treatment in Armenia and offers a unique opportunity for population-based research. Age at diagnosis remained to be a crucial determinant of the survival variables of acute leukaemia patients, after adjusting for sex, race, therapy, primary tumor sites, immunophenotype, and year of diagnosis. Further research is warranted to disentangle the effects of age-dependent biological and environmental processes on this association.
Results: Eight of 21 (38%) patients exhibited an isolated t(4;11) translocation. Additional chromosome abnormalities (ACA) were revealed in 11 (52%) patients, including 8 (42%) subjects with 3 and more chromosome aberrations. In univariate analysis, significance was found for clinical stage at HSCT (1st remission vs other stages, 75% vs 0%, p<0.001 for OS; 58% vs 0%, p<0.001 for EFS), complex chromosomal aberrations (<3 abnormalities vs ≥3 abnormalities, 58% vs 13%, p=0.04 for OS; 46% vs 0%, p=0.04 for EFS). According to multivariate analysis, the clinical stage at HSCT (HR 26.8, 95% CI 3.28-218.80; p=0.002 for OS; HR 11.18, 95% CI 2.92-42.80 p=0.0004 for EFS) was only independent prognostic factor for clinical outcome.

Summary/Conclusions: The study has shown the stage of disease at the moment of allo-HSCT to be independent prognostic factor in a mixed cohort of KMT2A-bff1 ALL patients treated with HSCT. The good results of allo-HSCT can be obtained using a haploidentical transplantation from parents that removes the problem of searching the HLA-matched donors in the Registers and, therefore, greatly simplifies the treatment.

PB1646
DERMATOLOGIC COMPLICATIONS ASSOCIATED WITH TYROSINE KINASE INHIBITORS FOR THE TREATMENT OF ACUTE LEUKEMIA
K. Zarubina1, K. Belashova1, E. Gavrinita1, V. Troitskaya1, A. Sokolov1, E. Chelysheva1, A. Turkina1, E. Usikova1, A. Abramova1, G. Baskhaeva1, I. Lukyanova1, V. Savchenko1
1Department of chemotherapy of hemoblastosis and depression of hemopoiesis, National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Despite of targeted effects of tyrosine kinase inhibitors (TKIs), they are not absolutely selective in relation to their target. Hair pigmentation is regulated by factors including the interaction of the ligand stem cell factor (SCF) with its class III receptor tyrosine kinase, c-kit. Hair depigmentation observed during therapy TKI with action directed against class III receptor tyrosine kinase (PDGFRα, PDGFRβ, C-KIT, CSF1R, FLT3). But other TKI such as BCR/AbI TKI can also inhibit class III receptor tyrosine kinase by non-targeted actions. Skin reactions are the most common observed during the epidermal growth factor receptor-tyrosine kinase inhibitor treatment.

Aims: To describe the spectrum of skin and hair reactions in patients with acute leukemias (Ph+/Ph- acute lymphoblastic leukemia and acute myeloid leukemia) during the treatment by second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor (sorafenib).

Methods: From 2016 to March 2017 6 patients (pts), age 24-53 (median 29.5), 1 male, 5 female, received second or third line therapy with tyrosine kinase inhibitors in National Research Center for Hematology. One pt (pt 1) with AML had been receiving chemotherapy (decitabine, cytarabine, idarubicin) with continuous treatment of sorafenib. Three pts with Ph+ ALL received TKIs. Two of them with T315I mutation (pts 2, 3) received ponatinib and one pt (pt 4), without molecular remission on dasatinib and nilotinib therapy, received second-generation TKI (bosutinib). One pt with B-ALL was treated with sorafenib due to refractory disease on the first-line therapy (pt 5). And one patient (pt 6) with T-cell ALL received sorafenib with nelarabine containing chemotherapy due to early relapse after allogeneic stem cell transplant.

Results: All of the 6 patients who had taken second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor sorafenib developed dermatologic reactions (skin rash or grey hair). Generalized maculo-papular skin rash grade II evolved after two weeks of sorafenib treatment in pt 1. Both patients on ponatinib therapy developed localized maculo-papular skin rash grade I in pt 2 after 8 weeks of therapy. In pt 3 after 6 weeks of ponatinib treatment gray hair observed. Skin rash with pigmentation grade I evolved in pt 3 after 12 weeks of therapy. Pt 4 had gray hair after 12 weeks second-generation TKI (bosutinib) treatment. Palmoplantar erythrodysesthesia syndrome grade II and hair and total skin depigmentation were evolved after 2 weeks and after 4,5 months respectively observed during the sorafenib treatment in pt 5 (with psoriasis anamnesis). Pt 6 developed localized maculo-papular skin rash grade I after 5 weeks of sorafenib treatment. Despite of all patients developed dermatological side effects, temporarily discontinuation of TKI therapy was required in only three (50%) cases. In the other cases the treatment was continued. The therapy was restarted in all pts with temporarily discontinuation after skin lesions disappearing (Figure 1).

Summary/Conclusions: Dermatological adverse events in acute leukemia pts who have taken second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor sorafenib they were not serious. Temporarly dose reduction or interruption of TKI therapy led to resolution of skin lesions. Restarting TKI at full dose did not lead to dermatological adverse reactions reappearing. Moreover, the temporary cancellation did not reduce its effectiveness.
SEVERE HYPOFIBRINOGENEMIA ASSOCIATED WITH IMATINIB AND PREDNISONE THERAPY IN PHILADELPHIA CHROMOSOME–POSITIVE ACUTE LYMPHOBластIC LEUKEMIA

M. Sciumè1,*, N. S. Fracchiolla1, G. Reda1, R. Cassin1, V. Mattiello1, A. Cortelezzi1
1Onchematology Division, IRCCS Ca’ Granda - Maggiore Policlinico Hospital Foundation and University of Milan, Milan, Italy

Background: Hypofibrinogenemia associated to acute lymphoblastic leukemia (ALL) is rare and usually due to L-asparaginase. Consumption coagulopathy or therapy-related hematotoxicity are other possible explanations. Severe hypofibrinogenemia, not linked to the causes listed, was rarely reported and a role of steroid therapy on fibrinogen metabolism was suggested.

Aims: Our aim was to identify the incidence of severe hypofibrinogenemia during induction phase in a cohort of consecutive ALL patients and to assess its impact on clinical decision-making.

Methods: In order to avoid confounding factor due to L-asparaginase, we revised our cohort of Philadelphia chromosome–positive (Ph+) ALL that we treated according to pediatric-type therapy program (imatinib, intensive chemotherapy without L-asparaginase) for patients aged 18-65 years and through LAL021-B protocol (imatinib, prednisone) for patients ≥65 years. We retrospectively analyzed coagulation tests on admission and during induction therapy of all Ph+ALL patients diagnosed at our Institution from 2004.

Results: Twenty-one Ph+ALL were identified: 17 patients were younger than 65 years, while the remaining 4 patients had a median age of 74 years (66-76). No alteration of plasma fibrinogen during induction was observed in younger patients. Severe hypofibrinogenemia (≤100 mg/dl) was detected in 3 out of 4 Ph+ALL over 65 years. In these patients induction consisted of prednisone 40 mg/d for 6 days followed by 1 to 45 and imatinib at the fixed dose of 800 mg/d. On admission hemoglobin levels were ≤10 g/dl in all patients, leucocytes counts were 2x10^9/L (blasts 15%), 8x10^9/L (blasts 30%) and 18x10^9/L (blasts 61%), while platelet count was reduced in 2 cases (61x10^9/L and 65x10^9/L). Coagulation tests remained normal (fibrinogen median level 380 mg/dl). Severe hypofibrinogenemia developed between 6 and 15 days after beginning treatment and lasted between 4 and 48 days. Fibrinogen nadir ranged from 47 to 100 mg/dL (median 61 mg/dL); reduced plasma fibrinogen levels at functional tests were also confirmed to immunological assays. During fibrinogen nadir, D-dimer was positive in all patients, but stable compared to the outset. Antithrombin, coagulation factors, activated partial thromboplastin and prothrombin time, common liver function tests remained in a normal range; platelet counts showed a trend to normalization. Early clearance of peripheral blood blasts was observed and when hypofibrinogenemia appeared no blast cells were detectable. At the end of induction bone-marrow evaluation demonstrated the absence of BCR-ABL transcript by qualitative RT-PCR. There were no bleeding events and only one patient received a prophylactic transfusion of fresh-frozen plasma (10 ml/kg) for fibrinogen <50 mg/dl on two occasions. Normal fibrinogen levels (≥165 mg/dl) were recovered at the end of steroid therapy.

Summary/Conclusions: We observed severe hypofibrinogenemia in Ph+ALL patients older than 65 years treated with imatinib and high-doses steroid, while normal fibrinogen levels were detected in younger Ph+ALL during intensive chemotherapy plus imatinib. In our experience, hypofibrinogenemia was not associated to major bleeding events, although its clinical significance should be investigated in larger series. Fibrinogen may recognize multiple metabolic pathways, also unrelated to in vivo coagulation and fibrinolysis; the correspondence between steroid treatment and hypofibrinogenemia seems to suggest that glucocorticoids may alter some steps in fibrinogen kinetics and could be considered as a cause of acquired hypofibrinogenemia.

LATE EFFECTS OF CHEMORADIOThERAPY ON THE ENDOCRINE SYSTEM IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

G. Aydogan1,*, S. Ettan1, F. Akci1, Z. Salcioglu1, A. Akcay1, T. Akcay1, H. Sen1, N. Ozdemir1, C. Bayram1, A. Ayıcık1
1Pediatric Hematology, KANUNI SULTAN SULEYMAN EDUCATION AND RESEARCH HOSPITAL, Istanbul, Turkey

Background: Over the past four decades treatment of childhood acute lymphoblastic leukemia has been modified with the aim of achieving high survival rate while reducing the risk of the life threatening late-effects and promoting risk-based follow-up care of survivors.

Aims: The aim of our study is evaluation of late effects of chemotherapy and cranial radiotherapy on the endocrine system in children with acute lymphoblastic leukemia.

Methods: Forty-eight patients, who were diagnosed and treated for ALL between 1997-2007 in Istanbul Kanuni Sultan Suleyman Education and Research Hospital Pediatric Hematology-Oncology Clinic and have disease-free for at least 5 years after cessation of treatment, were evaluated prospectively. The study form included each patients age, gender, weight, height, target height, parental height, treatment protocol, stage of puberty, bone age, TSH, free T4, LH, FSH, estradiol or testosterone, IGF-1 and IGFBP-3 levels. Annual rate of growth was evaluated for each patient. The patients with inadequate growth rate and delayed bone age were subjected to growth hormon stimulation test with clonidine.

Results: Mean age of the patients was 14.41±2.85 (10.5-22.4) years. Thirty-one of patients had prophylactic cranial radiotherapy; five of them 18 Gy and twenty-six had 12 Gy CRT. Fifteen of the 48 patients were diagnosed with at least one endocrinological disorder. Six patients had lower height (<-2 SD), three patients had a body mass index >30kg/m². Bone age delayed in two patients. Four patients had IGF-1 value below <-2SD and two patients had inadequate levels of growth hormone. Tanner stage of the patients were appropriate for their ages except for one patient with hypergonadotrophic hipogonadism and one patient with pubertas precoex. Subclinical hypothyroidism was detected in two patients.

Summary/Conclusions: Significant late effects may develop over time in children treated for ALL. For this reason long-term follow-up of these children is necessary. Because of the awareness of the late effects the treatment modified to reduce the life threatening late-effects.
Acute myeloid leukemia - Biology

MUTATIONAL ANALYSIS OF 231 DE NOVO AML PATIENTS BELOW 60 YEARS WITH CURATIVE THERAPY
A. Fotili1,*, I. Jezinskova1, D. Dvorakova1, N. Tomi2, M. Culeta1, Z. Kosarova2, A. Durinikova2, P. Cetkovsky3,4, P. Jindra5, T. Szotkowska6, P. Zak1, J. Mayer1,2,*, R. Racil1,2
1University Hospital Brno, 2Masaryk University, Brno, 3Institute of Hematology and Blood Transfusion, Prague, 4On behalf of CELL, Brno, 5University Hospital Pilsen, Pilsen, 6University Hospital Olomouc, Olomouc, 7University Hospital Hradec Kralove, Hradec Kralove, Czech Republic

Background: Acute myeloid leukemia (AML) is an aggressive cancer disease of the myeloid lineage of blood cells, characterized by rapid growth of undifferentiated myeloid precursors. Analysis of the spectrum of somatic mutations in leukemic cells may help to improve the identification of individual prognostic subgroups of patients as well as to observe clonal evolution in the course of AML treatment.

Aims: The aim of the project is to identify somatic alterations in genes related to AML using next generation sequencing (NGS) in large cohort of AML patients from Czech Republic and to determine their frequency and mutual coexistence.

Methods: The analyzed group consists of 231 de novo consecutively diagnosed AML patients with curative therapy below 60 years from five hematological centers. The NGS libraries are prepared from peripheral blood samples from diagnosis using ClearSeq AML panel (Agilent Technologies) and sequenced on MiSeq and NextSeq machines (Illumina). As positive are determined mutations with variant allele frequency (VAF) at least 2%.

Results: At least one somatic mutation (median 2; range 0-6) was identified in 204 (88.3%) patients with de novo AML. In total, 526 recurrent mutations in 19 genes were identified. The most frequently mutated genes were: FLT3 91/231 (39.4%; from this FL3T-ITD 69/231 [29.9%] and FLT3-TKD 22/231 [9.5%]), NPM1 90/231 (39.0%; mutation type A 71/90 [78.9%], type B 11/90 [11.1%], other types 10/90 [10.0%]), DNMT3A 68/231 (29.4%; mutations in codon R882 49/68 [72.1%]), NRAS 51/231 (22.0%; the most frequent mutation G12D 17/51 [22.0%]), 115/231 patients [21.6%] contain more than one mutation in NRAS gene), IDH2 35/231 (15.2%) and CEBPA 35/231 (15.2%). The analysis also identified mutations in rarely mutated genes U2AF1, SRSF1, EZH2 and SETBP1 in 4/231 (1.7%), 4/231 (1.7%), 1/231 (0.4%) and 1/231 (0.4%) samples, respectively (Figure 1).

Summary/Conclusions: The results of mutational analysis of large cohort of AML patients show high heterogeneity of detected mutations. Surprisingly we have detected high percentage of patients with mutations in gene NRAS. Together with sequencing results from the time of remission/relapse/resistance of the disease, the data will enable to get more complex view on the development of AML in time.

INHIBITION OF LIN28B IMPAIRS LEUKEMIA CELL GROWTH AND METABOLISM IN ACUTE MYELOID LEUKEMIA
J. Zhou1, J.-Y. Choe2, J.-Y. Chiu1, S.-H.-M. Toh1, T.Z. Tan1, P.S. Chong1, W.-J. Chng1
1Cancer Science Institute of Singapore, National University of Singapore, , Singapore, Singapore

Background: Current conventional chemotherapy for acute myeloid leukemia (AML) can achieve remission in over 70% of patients, but a majority of them will relapse within 5 years despite continued treatment. 2. The relapse is postulated to be due to leukemia stem cells (LSCs), which is different from normal hematopoietic stem cells (HSCs). LIN28B is microRNA regulator and stem cell reprogramming factor. 3. Overexpression of LIN28B has been associated with advance human malignancies and cancer stem cells (CSCs), including AML. However, the molecular mechanism by which LIN28B contributes to the development of AML remains largely elusive.

Aims: 1. To study the function role of LIN28B in cell proliferation, cell cycle and colony formation ability of AML cells. 2. To systematically dissect transcriptional signaling mediated by LIN28B on whole genome level. 3. To determine the key targets of LIN28B in AML. 4. To explore the function of LIN28B in AML in vivo.

Methods: 1. We modulated LIN28B expression in AML and non-leukemic cells and investigated functional consequences in cell proliferation, cell cycle and colony forming assays. 2. We performed a microarray-based analysis for LIN28B regulating cells and interrogated gene expression data with different bioinformatic tools. 3. AML mouse xenograft model was used to examine the in vivo function of LIN28B.

Results: We firstly showed that increased LIN28B expression was associated with worse survival in AML patients. We demonstrated that targeting LIN28B in AML cells resulted in cell cycle arrest, inhibition of cell proliferation and colony formation, which was induced by de-repression of let-7a miRNA. On the other hand, overexpression of LIN28B promoted cell proliferation. Mechanistic studies revealed that inhibition of LIN28B induces metabolic changes in AML cells. IGF2BP1 was confirmed to be a novel downstream target of LIN28B via let-7 miRNA. Notably, silencing LIN28B led to slow tumor growth in vivo.

Summary/Conclusions: In conclusion, these results uncover a novel mechanism of an important regulatory signaling, LIN28B/let-7/IGF2BP1, in leukaemogenesis and provide a rationale to target this pathway as effective therapeutic strategy.

EVALUATION OF MINIMAL RESIDUAL DISEASE IN NPM1-MUTATED AML PATIENTS
C. Martínez-Laperche1,2,*, V. Pradillo1, G. Rodríguez-Macías1, M. Chicano1,2, D. Carbonell1,2, J. Suárez-Gónzalez2, J. L. Díez-Martín1,2, I. Buño1,2
1Cancer Science Institute of Singapore, National University of Singapore, , Singapore, Singapore, 2Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain

Background: Minimal residual disease (MRD) tests provide early identification of hematologic relapse and timely management of AML patients. About 60% of adult normal karyotype AML has a mutation in exon 12 of NPM1 gene. This mutation is specific for malignant clone and potentially is a good marker of MRD.

Aims: The aim of the study was to analyze the usefulness of NPM1 as a marker for MRD quantification in AML during follow-up.

Methods: Retrospective study included 34 patients with mutated-NPM1 and treated with intensive chemotherapy (2009-2015). Bone marrow (188) and peripheral blood (277) samples were analyzed from complete remission (MRD NPM1 negative). NPM1 detection was performed by quantitative RT-PCR (Gorello et al. Leukemia 2008). Patients were considered positive when presented >1 NPM1 sample positive or/and one sample NPM1 >0.02%. Cox regression was used for univariate analysis.

Results: Patients were segregated in 2 groups: Relapse patients (Group 1: 32.2%, 11/34) and no relapse patients (Group 2: 67.6%, 23/34). Group 1 presented MRD NPM1 positive in 9/11 (82%) of patients, the time from NPM1 to relapse was 4.6 months (1.6-24). NPM1 mean was 1.7 (0.03-9). Group 2 presented MRD NPM1 negative (≤0.02% y ≤1 determination) in 21/23 (91%) patients. Univariate analysis was performed and our results show that age, leukocyte, LDH and MRD NPM1 are prognostic factors for cumulative incidence of relapse (Figure 1).

Figure 1.
Summary/Conclusions: NPM1 is a useful marker for MRD quantification in AML patients undergoing intensive therapy. NPM1’s positive during follow-up is associated with a higher probability of relapse.

AT101 ELIMINATES AML STEM CELLS VIA ACTIVATION OF INTRINSIC APOPTOTIC PATHWAY AND PARTICIPATION IN DNA DAMAGE RESPONSE

X. Bing1, Z. Lei2, Z. Yong1, C. Kai1, S. Pengcheng2, L. Yin2, D. Manman1, J. Zhiwu1, W. Xiangmeng2, L. Peng1

1 The First Affiliated Hospital of Xiamen University, Xiamen, 2 Nanfang Hospital, Southern Medical University, Guangzhou, 3 Nanfang Hospital, Southern Medical University, Xiamen, 4 Southern China Institute for Stem Cell Biology and Regenerative Medicine, Guangzhou, China.

Background: Leukemia stem cells (LSCs) are considered as the main reason for treatment failure and relapse in acute myeloid leukemia. Overexpression of Bcl-2 anti-apoptotic proteins is associated with the survival and self-renewal of LSCs.

Aims: To observe the effect for AT101 to eliminate AML stem cells and its underlying mechanism.

Methods: Use CD34+CD38−CD123+KG1α and primary AML CD34+ cells as research object.

Results: In this study, we demonstrated that AT101, a B3 mimetic pan-Bcl-2 inhibitor, was significantly and effectively cytotoxic towards CD34+CD38−CD123+KG1α and primary AML CD34+ cells, with slight effect on CD34+ normal hematopoietic cells. And the mechanism was closely associated with activation of intrinsic apoptotic pathway, such as loss of mitochondrial membrane potential and caspase activation, along with disturbance of DNA damage response. Further analysis on AML patients’ clinical characteristics revealed that the ex vivo efficacy of AT101 in primary samples was significantly correlated to hyperleukocytosis or FLT3-ITD mutation. Besides, AT101 exhibited exciting effect on CD34+ blasts from patients who are old or cannot achieve CR after induction therapy.

Summary/Conclusions: In conclusion, Together, these findings provides potentiality for the use of AT101 to treat relapse and refractory AML as alternative salvage regime in the future, including those clinically characterized by one or more adverse prognostic abnormalities.

PB1655

COOPERATIVE EFFECT OF CHIDAMIDE AND CHEMOTHERAPEUTIC DRUGS INDUCE APOPTOSIS BY DNA DAMAGE ACCUMULATION AND REPAIR DEFECTS IN ACUTE MYELOID LEUKEMIA STEM AND PROGENITOR CELLS

X. Bing1, L. Yin2, D. Manman1, C. Kai1, S. Pengcheng2, Z. Yong1

1 The First Affiliated Hospital of Xiamen University, Xiamen, 2 Huizhou Municipal Central Hospital, Huizhou, 3 Nanfang Hospital, Southern Medical University, Guangzhou, 4 Nanfang Hospital, Southern Medical University, Xiamen, China.

Background: Lots of conventional chemotherapeutic drugs are confirmed to take part in DNA damage generation and initiation of DNA damage response, ultimately leading to apoptosis. However, they fail to completely eliminate leukemia stem cells (LSCs) on account of higher DNA repair capacity of cancer stem cells than bulk cancer cells, which become the root of resistance and recurrence. Thus, new strategy to eliminate LSCs in AML is urgently needed.

Aims: To observe the effect of low dose chidamide in combination with chemotherapeutic agents on eliminating AML stem cells.

Methods: We used a novel benzamide-type HDAC inhibitor, chidamide, in combination with DNA-damaging agents (daunorubicin, idarubicin and cytarabine) to treat CD34+CD38−KG1α cells and primary refractory or relapsed AML CD34+ cells.

Results: Here, we report that low dose chidamide, a novel benzamide-type HDAC inhibitors, which selectively targeted HDAC 1, 2, 3, 10, could enhances cytotoxicity of DNA-damaging agents (daunorubicin, idarubicin and cytarabine) in CD34+CD38− KG1α cells and primary refractory or relapsed AML CD34+ cells, reflected by inhibition of cell proliferation and induction of apoptosis in vitro. Mechanistically, these effects were associated with DNA damage accumulation and repair defects. Co-treatment with chidamide and DNA-damaging agents IDA gave rise to production of yH2A-X, inhibited ATM, BRCA1, checkpoint kinase 1 (Chk1) and 2 (Chk2) phosphorylation. Finally, the combination initiated caspase-3 and PARP cleavage and inhibited ATM, BRCA1, checkpoint kinase 1 (Chk1) and 2 (Chk2) phospho-

Summary/Conclusions: These findings provide preclinical evidence for low dose chidamide in combination with chemotherapeutic agents to treat recurrent/resistant AML as an alternative salvage regimen, especially those possessed stem and progenitor cells.

NEW CANDIDATE GENES USEFUL TO PREDICT THE RISK OF RELAPSE IN ACUTE PROMYEOLOCYTIC LEUKEMIA

J. Nando1, M. C. Fontana1, G. Marco1, C. Papayannond1, S. Lo Monaco1, G. Simonetti1, A. Padella1, E. Ottaviani1, S. Paolino1, M. C. Abbenante1, L. Bertamini1, G. Martellini1

1 University of Bologna, Bologna, Italy

Background: Nowadays, Acute Promyelocytic Leukemia (APL) is a disease entity with a very high rate of cure and an estimated 2-year overall survival of 97%. Early death, rather than resistant disease so common in all other subtypes of AML, has emerged as the major cause of treatment failure, and relapse is a very rare occurrence.

Aims: To observe a relapse is a very rare entity, and it is announced to become rarer with the advances in first line therapy. Molecular characteristics are hard to analyze without an effort to collect and bank samples together from multiple institutions. Since relapses, especially relapses out of follow-up period, represent a sudden life-treating condition for patients, to predict patients at higher risk of relapse we selected two candidate genes that could be involved in pathways favoring relapse.

Methods: We collected data of all the APL referred to our institution from 2014. Within 23 patients, we encountered 20 new diagnosis and 2 relapse of APL. We analyzed blasts in samples obtained from Bone Marrow with Single Nucleotide Polymorphisms Array CytoScan HD.

Results: We compared copy number alterations in both relapsed patients with alterations detected in the pool of 20 newly diagnosed APL and we found specific signatures of CNVs for each patient. There were several copy number alterations related to each patient: the first patient presented gain of ROBO2, GRIP1, CTNNB1, SOX6, PBR1, OAT2, CDKAL1 and loss FAP1, CREBBP, SBF1; the second patient presented gain of ROBO1, MAPK10, CADPS2, APBA1 and loss of GRIP1 and MYB. Subsequently we focused our attention on ROBO and GRIP1 genes because they were altered in both relapsed patients: ROBO proteins are associated to K channels while GRIP1 is involved in various critical functions, for example in androgen receptor binding, beta-catenin binding, glucocorticoid receptor binding, and it is also a regulator of glutamate metabolism, a well-known pathway in Leukemic Stem Cells.

Summary/Conclusions: By the analysis of ROBO 1-2 and GRIP1 at the diagnosis of APL we could establish a different and strict follow-up program for patients with these alterations.

THE EXPRESSION OF SALL4 AND BMI-1 GENES IN MYELOID LEUKEMIA

M. El-Nagdy1, H. Farawela1, H. Zawam2, H. Al-Wakeel3, F. El-Refayey1, H. Abdel-Rahman1

1 Clinical & Chemical Pathology, 2 Medical Oncology, Cairo University, 3 Clinical & Chemical Pathology, National Cancer Institute, Cairo, Egypt

Background: Sal-like protein 4 (SALL4) and B-cell specific moloney murine leukemia virus integration site-1 (BMI-1) genes are stem cell genes that modulate stem cell pluripotency and may play a role in leukemogenesis. Leukemic stem cells (LSCs) have been implicated in being the origin of the leukemic blast, therapy resistance and relapse.

Aims: The current study aimed at characterizing the expression pattern of SALL4 and BMI-1 genes in acute myeloid leukemia (AML) and chronic myeloid leukemia (CML), in patients who have achieved complete remission (CR), and in CML disease progression.

Methods: Real-time polymerase chain reaction was used to assess the gene expression patterns in 106 myeloid leukemia patients; 54 de novo APL (43 at time of diagnosis, 11 in CR), and 52 CML (31 in chronic phase (CP), 11 in deep molecular response (MR) 8 & 10 in accelerated/blastic phase (AP/Blb), and in 21 non malignant bone marrow samples.

Results: SALL4 gene expression was increased in AML patients, AML-CR, & CML-CP (median= 5.180, 4.604 & 14.125 respectively). No significant difference was observed between de novo AML and AML in CR patients. CML-CP patients showed a significantly higher percentage of patients with a high SALL4 expression as compared to both CML- MR4 and CML-AP/BP (p=0.033). BMI-1 gene expression was not found to be increased in any of the patient groups.

Summary/Conclusions: Our data describe altered SALL4 gene expression in different phases of myeloid leukemia. The role of BMI-1 gene needs further delineation to determine its significance.
PB1659
AN INVESTIGATION INTO THE ROLE OF S100A8 AND S100A9 IN ACUTE MYELOID LEUKAEMIA
S. Chaudry1,*, T. Chevesutt1, H. Stewart1
1Brighton and Sussex Medical School, Brighton, United Kingdom

Background: Acute myeloid leukemia (AML) is the a haematological malignancy characterised by the over proliferation and block in differentiation of clonally expanded leukaemia potential bone marrow cells such as S100A8 could assess the progression and remission of AML.

Aims: S100A8 and S100A9 (Ca2+ binding helix E-loop-helix-F hand), are inflammatory markers which are also suggested to promote chemoresistance by stimulation of autophagy. Microarray data from the Chevesutt lab shows that both S100A8 and S100A9 transcripts are downregulated by the BET-bromodomain inhibitor JQ1 in AML cell lines. We aimed to investigate this response in AML patient bone marrow samples and cell lines.

Methods: We used AML cell line including OCI-AML2, OCI-AML3 and THP-1 in addition to AML patient bone marrow samples and healthy volunteer samples. We carried out RT-qPCR and immunocytochemistry and western blots techniques to look at levels of S100A8 and S100A9 in samples.

Results: Here we show that levels of S100A8 and S100A9 mRNA levels are suppressed in response to JQ1 in the AML cells lines OCI-AML2, OCI-AML3 and THP-1. We find also that protein levels of S100A8 and S100A9 are downregulated in response to JQ1 in OCI-AML3. In bone marrow samples of 17 AML patients with different cytogenetic profiles, the relative expression of S100A8 and S100A9 was found to be variable amongst the samples but also in comparison to OCI-AML3 cells. In further experiments using AML patient bone marrow samples, treatment with JQ1 showed suppression of S100A8 and S100A9 in some patient samples but enhanced expression in other bone marrows. In peripheral blood samples of healthy volunteers, we found that treatment with JQ1 showed notable suppression of both S100A8 and S100A9 with a greater suppression being observed in the monocye fraction of the samples.

Summary/Conclusions: Our data suggests that JQ1 regulates the expression of S100A8 and S100A9 in AML. The variability of the response seen amongst AML patient samples and AML cell lines may be reflective of the genetic profiles driving the disease in these individuals. Further work may give more detailed insight into the mechanisms of action and potential use of S100A8 and S100A9 in AML prognostic markers.

PB1660
SUCCESSFUL COVERAGE OF DIFFICULT TO SEQUENCE GENES (CALR, CEBPA, AND FLT3) ASSOCIATED WITH MYELOID DISORDERS USING A HYBRIDISATION-BASED ENRICHMENT APPROACH PRIOR TO NEXT-GENERATION SEQUENCING
G. Speight1,*, L. Georgiev1, E. Uddin2
1R&D, Oxford Gene Technology, Begbroke, United Kingdom

Background: The application of short read NGS for research into myeloid disorders such as myeloproliferative neoplasms (MPNs) and acute myeloid leukemia (AML) is hampered by the inability of these techniques to efficiently sequence genes harboring key mutations so it is desirable to ensure suitable sequencing coverage is obtained. These genes amongst others include: CALR exon 9 insertions and deletions (up to 52 bp), CEBPA single nucleotide variants (SNVs) and FLT3 Internal Tandem Duplications (ITDs) and SNVs. Each of these regions contain certain challenging DNA sequences that can impact the quality of the data generated, e.g. large indels and low complexity regions (CALR), high GC content (75% on average for the whole gene with specific regions at 100%) and repetitive regions (CEBPA), and complex repetitive elements (FLT3).

Aims: To determine whether a hybridisation-based enrichment approach overcomes the difficulties associated with these genes, and permits the generation of high quality (sufficient de-duplicated depth) data to allow these targets to be accurately interrogated.

Methods: We utilised a hybridisation-based enrichment approach for library preparation in combination with a SureSeq myPanel™ NGS Custom AML panel. The library was then sequenced using a 2x150 bp read length protocol on an Illumina MiSeq®.

Results: Here we present the coverage and variants generated from numerous research samples for each of these difficult to sequence genes. The results clearly show that this approach can reliably detect and accurately size (including low allele frequency) insertions and deletions of up to 52 bp in CALR (exon 9), SNVs and deletions in CEBPA with a de-duplicated depth in excess of 2000x as well as ITDs of between 24 and 201 bp in FLT3.

Summary/Conclusions: This approach is suitable for the analysis by NGS of these difficult genes and therefore removes the requirements for supplementary approaches to analyse these difficult genes, such as Sanger sequencing (CEBPA) and fragment analysis (CALR and FLT3).

PB1661
ASSOCIATION OF MRNA EXPRESSION PROFILES WITH FUNCTIONAL AND MOLECULAR ACUTE MYELOID LEUKAEMIA CATEGORIES
C. Sargas1,*, M. Llop2, M. C. Alonso3, R. Ayala4, M. E. Onecha4, M. Ibañez2
1Instituto de Investigación Sanitaria La Fe (IIS La Fe), 2Hospital Universitario y Politécnico La Fe, 3Hospital Arnau de Vilanova, Valencia, 4Hospital 12 de Octubre, Madrid, Spain

Background: Development of high-throughput technologies such as Next Generation Sequencing (NGS) allowed the identification of recurrent mutated genes in Acute Myeloid Leukemia (AML), and new molecular markers which help refine patients’ classification in different risk groups.

Epigenetic alterations such as aberrantly expressed microRNAs (miRNAs) also play a crucial role on the pathogenesis of AML and miRNA regulatory processes such as cell development, differentiation, proliferation and apoptosis. Therefore, aberrant miRNA expression can affect signaling and metabolic pathways, directing cancer cell biological behavior.

Recently, several studies have classified AML according to different criteria. AML was proposed in 2013 a new classification where genes are grouped according to their biological function. Moreover, Papaemmanuil et al. suggested in 2016 a new classification based on molecular markers with not overlapping categories.

Aims: Our aim is to explore the miRNA profile of NK-AML and to find expression profiles associated with the categories proposed by TCGA and Papaemmanuil et al. Associations of miRNA expression profiles with altered categories could help understand the molecular mechanisms that lead to leukemogenesis.

Methods: CD34+ cord blood progenitor cells from 5 healthy donors and 7 CD34+ NK-AML samples with >70% blasts were obtained. Total RNA from formalin-fixed and paraffin-embedded tissues were hybridized onto an Array miRNA 3.0 chip (Affymetrix) in order to identify deregulated miRNAs. The most deregulated miRNAs were validated by qRT-PCR (miScript) in an independent cohort of 73 patients. Mutational analysis was performed by Next Generation Sequencing using the AML Community Panel with the Ion Torrent System (Life Technologies).

Results: We found a profile of 6 miRNAs up-regulated and 61 miRNAs down-regulated in NK-AML vs CD34+ cells. Validation by qRT-PCR confirmed that miR-494 (p=0.028) and miR-499 (p=0.035) were up-regulated vs NK-AML (p=0.022), miR-99a (p=0.001), miR-146b (p=0.031), miR-15b (p=0.006) and miR-20b (p=0.001) were down-regulated in NK-AML. Interestingly, some of the deregulated miRNAs were significantly associated to a functional category according to the TCGA classification. Therefore miR-146b was down-regulated in AML with mutations in myeloid transcription factors (p=0.025). Low expression of these miRNA caused the activation of the TGF-β signaling pathway, which increases transcription. miR-4668 was down-regulated in AML with mutations in activation pathways genes (p=0.004), several target predictors propose RASGEF1A and BRAF as targets of this miRNA. Thus, under-expression of this miRNA could cooperate with mutations leading to the activation of signaling pathways. Regarding to Papaemmanuil’s molecular classification, miR-494 was up-regulated in IDH2-R172 category (p=0.009). High levels of this miRNA are associated with lower expression of TET, specially TET1. Therefore, high levels of miR-494 could contribute to the hypermethylation signature of IDH (Acute Myeloid Leukemia) AML.

Summary/Conclusions: In conclusion, the mutational landscape of significant functional and molecular groups in AML is accompanied by miRNA deregulation, which could cooperate in the development of this hematologic malignancy.

PROTEOMIC APPROACH TO IDENTIFY MOLECULAR TARGETS OF HALOFUGINONE IN ACUTE MYELOID LEUKEMIA
L. Cándido1,*, C. Silva2, D. Moreno1, C. Thomé3, A. Nagler4, E. Rego5
1Hematology Division of the Department of Internal Medicine, School of Medicine University of São Paulo, 2Laboratory of Experimental Animal Studies, Faculty of Medicine of Ribeirão Preto - University of São Paulo, 3Hematology Division of the Department of Internal Medicine, University of São Paulo, Ribeirão Preto, Brazil, 4Hematology Division and Cord Blood Bank, Chaim Sheba Medical Center, Tel Aviv University, Tel Hashomer, Israel, 5National Institute of Science and Technology on Cell-Based Therapy, School of Medicine of Ribeirão Preto - University of São Paulo, Ribeirão Preto, Brazil

Background: Halofuginone (HF) is a halogenated derivative of Febrifugine, a chemical compound isolated from the plant Dichroa febrifuga. It has been demonstrated that Halofuginone exhibits anti-fibrotic, anti-cancerogenic, anti-inflammatory and pro-apoptotic effects. Previously, we have reported that treatment with HF has anti-leukemic properties in vivo and in vitro in acute promyelocytic leukemia (APL), reducing tumor growth through the induction of apoptosis and by stimulating the synthesis of the TGF-β protein and activating its downstream targets. In addition, HF presented anti-angiogenic effects by modulating the level of pro and anti-angiogenic factors including VEGF. However, it is not known whether HF could act on new subsets of acute myeloid leukemia (AML) and HF targets were not determined yet.

Aims: Evaluate the anti-leukemic effect of HF on other AML subtypes than APL and investigate its targets using a proteomic approach.
Methods: AML cell lines Kasumi-1, THP-1, MV-11, U937 and OCI-AML3 were treated in vitro with HF at concentrations ranging from 25 to 1000 ng/ml. The % of apoptotic cells, the distribution of cells in different cell cycle phases, and the HF IC50 was determined for each cell line. We used the Proteome Profiler™ Array – HumanPhospho-Kinase Array to verify the possible tyrosine kinases and signaling pathways that could be modulated by HF. To analyze the in vitro effect of HF on cell proliferation of the cell lines Kasumi-1 and THP-1, we used the CellTiter-Glo® 1 NOD.Cg-Pkdcr1id2egr1m1W/W§Sz/J (NSG) mice, which were then treated with intra-peritoneal injections of HF at a dosage of 150 mg/kg daily for 14 days. The leukemic infiltration of the peripheral blood was quantified by flow cytometry every 2 weeks (using a anti-human CD45.1

Results: HF IC50 values ranged from 125.58 ng/ml in Kasumi-1 to 786.15 ng/ml in THP-1 cells. Kasumi-1 halted in the S phase of the cell cycle when treated with HF, displaying a significant decrease in proliferation, while no effect was observed for THP-1 cells. Corroborating our in-vitro observation indicating resistant of THP-1 cells towards HF, we did not detect significant difference in overall survival (OS) of NSG mice transplanted with THP-1 cells treated with vehicle or HF (mean OS of 70.5 and 68 days, respectively; p = 0.24). In contrast, the mean OS for NSG mice transplanted with Kasumi-1 cells treated with HF was significantly prolonged compared to the control group (144 versus 94.5 days; p = 0.007). The proteomic analysis identified significant decrease upon treatment with HF of four phosphorylated-proteins in both cell lines: Phospholipase C gamma 1 (PLCγ1), Proline-rich tyrosine kinase 2 (PYK2), Endothelial nitric oxid synthase (eNOS) and Signal transducer and activator of transcription 3 (STAT3 Y705), thus suggesting that these proteins are primary targets of HF. In addition, the protein target of rapamycin (TOR) was downregulated only in THP-1, while the levels of STAT3 S727 and STAT5b were significantly decreased by HF treatment only in Kasumi-1 cells. This comparative analysis suggests that HF may be dependent on inhibition of STAT3/5 pathway.

Summary/Conclusions: In summary, our results suggest that HF may be effective against core binding factor leukemias and, that the methodology based on a Phospho-Kinase Array is useful to identify drug molecular targets.

PB1663

DNA METHYLATION AND HYDROXYMETHYLATION PROFILING IS CAPABLE TO DISTINGUISH AML SAMPLES WITH DISTINCT MUTATIONS IN THE METHYLATION REGULATORY GENES

H. Hájková1,*, Š. Voráčková1, Z. Krejčík1, E. Cerovská1, P. Cetkovský2, C. Sálek2

1Department of Genomics, 2Clinical Department, Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Ablarent DNA methylation as well as hydroxymethylation is a hallmark of acute myeloid leukemia (AML). Mutations of DNA methylation regulatory genes (DNMT3A, IDH1, IDH2 and TET2) are present in approximately 40-50% of AML. These mutations are often present together with the exception of TET2 and IDH2 as well as IDH1 and IDH2, which are usually mutually exclusive.

Aims: We aimed to perform DNA methylation, hydroxymethylation and gene expression profiling in clearly defined subgroups of AML patients with distinct mutations in DNA methylation regulatory genes to see whether there is a clear epigenetic signature for each mutation.

Methods: We accomplished DNA hydroxymethylation and methylation profiling in 12 AML samples at diagnosis and in CD34+ cells of 3 healthy controls by MethylationEPIC array (Illumina) covering aprox. 850,000 CpGs. AML samples were chosen based on their mutational status and divided into 4 groups: DNMT3A+ (n=3), IDH1+ (n=3), DNMT3A+/IDH1+ (n=3) and IDH2+ (n=3). The remaining DNA methylation regulatory genes as well as CEBPA were unmethylated. 1 µg of genomic DNA was treated with TrueMethyl Seq kit (CEGX) to convert DNA through oxidative biscufate (oxBS) and bisulfite (BS) treatment. This approach allows us to determine whether CpG is methylated or rather hydroxymethylated. We also performed gene expression profiling on the same samples by HumanHT-12 v4 Expression Array (illumina).

Results: We performed hierarchical clustering analysis of oxBS β-values (corresponding to DNA methylation levels) of 830 304 CpGs (with detection P<0.05) and observed clear separation of 4 groups according to mutational status – DNMT3A, IDH1, IDH2+ and CD34+ AML patients. Interestingly, the positive DNMT3A+IDH1+ (n=3) samples clustered each into different group (DNMT3A+, IDH1+, CD34+ normal) strongly suggesting that there is a cumulative effect of these two opposing mutations (Figure 1). We found out that genes hypermethylated in IDH1+ samples are enriched for genes from HOX gene family (P<0.0001) and that these genes are often hypomethylated in DNMT3A+ samples relative to CD34+ normals. Clustering of DNA hydroxymethylation (obtained from subtraction of BS β-values from BS β-values) resulted into the same 4 main clusters as shown for DNA methylation data. DNMT3A+ patients displayed the lowest hydroxymethylation levels from all patients. Genes hydroxymethylated in IDH1+ patients were enriched.

RNA-MEDIATED CORRECTION OF ABBERRANT DNA METHYLATION AT THE P15 LOCLUS

M. Li1,*, M. Borchiellini1, P. Cascino1, N. Habib2, A. Di Russo1

1University of Eastern Piedmont, Novara, Italy, 2Imperial College London, Hammersmith Campus, London, United Kingdom

Background: P15 (a.k.a cell cycle dependent kinase inhibitor 2B; CDK2NB2; INK4B) is a methylsensitive gene located on chromosome 9p21 and commonly found silenced during Myelodysplastic Syndrome (MDS) progression to Acute Myeloid Leukemia (AML). P15 encodes for a cyclin-dependent kinase inhibitor increasingly expressed during granulomonocytic monocytosis (Teofili et al., Exp Hematol 2000). P15 deletion or promoter methylation has been shown to independently correlate with disease progression and poor patient prognosis (Tien et al., Br J Hematol 2001). Additionally, P15 expression was also sensitive to regulation by myeloid-specific transcription factor PU.1 (Schmidt-Blood 2004). As MDS evolution to AML includes both myeloid proliferation and blocked differentiation stages, restoration of the natural P15 transcript will provide not only valuable information regarding disease progression but might also alleviate some of their characteristic symptoms.

Aims: Currently available demethylating agents approved for therapeutic applications, e.g. 5-azacytidine and decitabine, have major side effects of high toxicity and non-specific DNA methylation that limit their clinical application. Therefore, the aim of this study is to achieve RNA-mediated correction of the aberrantly methylated P15 locus using small activating RNAs (saRNAs; Li et al. PNAS 2006).

Methods: Myeloid Leukemia cell lines HL-60, KG1a, and K562 were screened for basal p15 expression by western blotting and qRT-PCR. As the P15 locus is also often deleted, deletion of the locus was assayed for by PCR and by Fluorescent In Situ Hybridization. The methylation status of P15 was shown to be inversely correlated with ANRIL (Antisense Non-coding RNA in the INK4c Locus) expression (Kotake et al Oncogene 2010), p15 and ANRIL gene expression were measured in parallel. HEK293 cells serve as positive control in all studies. SaRNAs were designed against the proximal promoter, first exon, and intron regions of the P15 gene body. SaRNAs were introduced to cell lines through electroporation, and re-activation of the locus was measured at the transcript level by qRT-PCR and protein level by western blotting. Changes in P15 promoter level methylation were determined by Methylation Specific PCR.

Results: Transfection of saRNAs into the HL60 cell line showed upregulated p15 expression 24 and 48 hrs post-transfection. Analysis of ANRIL after saRNA-transfection showed no concomitant changes, suggesting locus-specific activity of the saRNAs. Future experiments will elucidate the mechanisms of saRNA activation of P15 gene expression and genome-scale specificity of saRNA activity.

Summary/Conclusions: There is much interest in using RNA molecules as a therapeutic tool (Kole et al., Nat Rev Drug Discovery 2012; Reebye et al., Hepatology 2014). Introduction of such an approach offers greater advantages over...
existing hypomethylating-based protocols: a) high gene specificity b) lower cytotoxicity and c) absence of drug based off-target side-effects. In the short term, this research can lead to the identification of novel key regulators of leukemogenesis and new targets for therapeutic treatments; in the long term pave the way for development of RNA-based gene demethylating agents for cancer treatment.

PB1665

JQ1 AND CURCUMIN COMBINED TREATMENT SHOWS SYNERGIC EFFECTS IN MLL-REARRANGED LEUKEMIA CELL LINES

P. Vitullo1,*, P. Leoncini1, V. Tocco1, M. Pigazzì2, K. D’Ovidio1, D. Montagna3, R. Rota1, A. Bertaina1

1Oncohaematology, Bambino Gesù Children Hospital, Roma, 2Pediatrics-Oncology, University of Padova, Padova, 3Pediatrics, Policlinico San Matteo, Pavia, Italy

Background: MLL-rearranged leukemia accounts for 70% of infant and 10% adult acute leukemias, featuring a particularly poor prognosis and high risk of relapse. Our main field of study is AML, in which nearly 50% of total cases accounts for t(9;11) translocation, the remaining 50% predominantly includes t(6;11)(q27;q23), t(10;11)(p12;q23), t(11;19)(q23;p13.1) and t(11;19)(q23;p13.3). A 2% of AML total cases, however, is characterized by t(4;11) translocation, which is a marker of bad prognosis and it’s, so far, poorly characterized. A key feature of MLL-rearranged leukemia is cMyc overexpression, a well-known oncogene involved in several types of cancer. JQ1 is a novel molecule, which prevents cMyc expression binding an important bromodomain protein, BRD4. Moreover, Curcumin, a natural compound, inhibits HATs enzymes preventing lysine 14 acetylation on histone H3 (H3K14), a particular residue which is bind by BRD4 to exert its function.

Aims: We would like to explore a potential synergic effect between JQ1 and Curcumin molecules in the attempt to develop a novel therapeutic alternative to standard chemotherapy and to deeply investigate features underlying the molecular pathogenesis in pediatric MLL-rearranged pediatric AML.

Methods: Four human leukemia cell lines with MLL fusion protein have been employed in this study. RS4-11, MV4-11 expressing MLL-AF4 and THP1, MOLM13 expressing MLL-AF9 fusion genes. 5′M and 10μM Curcumin were used to treat MLL-AF4 and MLL-AF9 cell lines respectively, while 250nM JQ1 and 5μM and 10μM Curcumin were used to treat all the cell lines. After 2 days of treatment, either with single and combined drugs, cell number quantification, based on metabolic activity, was used to treat all the cell lines. After 2 days of treatment, either with single and combined drugs, cell number quantification, based on metabolic activity, was detected through XTT assay. In order to assess the cMyc, CDKN1A, BCL2 transcripts levels and mir-99a expression a quantitative RT-PCR analysis was carried out, while we used western blotting to detect the expression of cMyc, PARP, Caspase3 and Ach3K14. Apoptosis and cell cycle were evaluated by flow cytometric analysis.

Results: In apoptosis analysis, a synergic effect was detected for all 4 cell lines, similarly cell cycle evaluation showed a significant accumulation of cells at SubG1 phase (2-8 fold) (Figure 1). XTT metabolic assay showed a reduction in proliferation percentage: 65±5% for curcumin and JQ1 single treatment and 59±5% for combination of drugs in both MLL-AF4 cell lines, meanwhile in MOLM13 cells it was 64±2 and 87±2 for curcumin and JQ1, respectively and 78±2 for their combination (P<0.005). The THP1 cells did not show any significant modulation in the proliferation. We decided to focus our study on t(4;11) translocated cells, considering the more intense effect of the combined drugs on previous analysis. qRT-PCR and western blot experiments revealed a synergic effect of the 2 experimental drugs on both apoptosis and proliferation gene related (bcl2, caspase3), Parp, cdkn1a as well as on the direct targets of the drugs (cMyc, Ach3K14). Finally, in MLL-AF4 cell lines, curcumin and JQ1 together induced a significant decrease in mir-99a expression.

Summary/Conclusions: Our data demonstrated that curcumin and JQ1, inhibiting HATs and BRD4 respectively, exert a more intense synergic effect on MLL-AF4 than in MLL-AF9 cells. Increased apoptosis together with a reduced proliferation rate, prompted us to investigate on molecular pathway in which targets of these drugs are involved. Intriguingly, we found a significant decrease in cMyc, bcl2 and Ach3K14 expression, confirming that both curcumin and JQ1 have a synergic effect. Additionally, we revealed a significant reduced expression of mir-99a, a well know oncormR reported to act as neg-ative regulator of differentiation and involved in drug-resistance, typi-cally up-regulated in pediatric AML and ALL.

PB1666

TP33B AND TP33F EXPRESSION LEVELS IN RELATION TO NPM1 AND CEBPA MUTATIONS

K. Matysiak1, A. Bartoszewska-Kubik1, E. Bielinska1, M. Morgut-Klimkowska1, O. Haus1

1Department of Clinical Genetics, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Torun, Bydgoszcz, Poland

Background: Acute myeloid leukemia (AML) is a heterogeneous clonal disorder with the presence of diverse genetic abnormalities in hematopoietic stem cells. The most frequent alterations in normal karyotype AML (NK AML) are mutations in exon 12 of nucleophosmin gene (NPM1). Until now 56 different mutations of NPM1 exon 12 have been described, mostly insertions. The NPM protein plays an important role in cell cycle and apoptosis control. It cooperates with several proteins, among them with p53 and ARF. The median levels of functional nuclear p53 protein are reduced in NPM1 and FLT3 ITD mutant samples. TP53 encodes a tumor suppressor protein which consists of transcription, DNA-binding and oligomerization domains. Due to alternative splicing it may exist in 13 different isoforms. Alternative splicing of intron 9 leads to production of 2 different proteins, p53β and p53γ, without oligomerization domain (stop codon is localized in exon 9b). These isoforms can be present in acute myeloid leukemia (AML) cells. p53β binds to BAX promoter and can induce apoptosis independent from p53 wt. p53 has influence on activation of CEBPA which is associated with cell cycle regulation, especially cell cycle arrest and plays also role in cell differenti-

ation. Generally, it is a transcription factor expressed during myeloid lineage development, from progenitor cells to mature granulocytes. Various mutations of CEBPA gene are described. Among them N-terminal and C-terminal mutations, mostly insertions and deletions, are often present.

Aims: The goal of the study was to assess mutational status of NPM1, CEBPA and FLT3 in association with TP53beta and TP53gamma expression levels.

Methods: 75 NK AML patients were included in the study. NPM1, CEBPA and FLT3 gene mutations were analyzed by direct sequencing. TP53β and TP53γ expression levels were assessed in real time PCR. Expression levels were analyzed with ΔΔCt method, with ABL as a control gene and K562 cell line as a calibrator.

Results: In all 75 cases, TP53β and TP53γ transcripts were detected. 36 patients had NPM1 mutations, 25 had CEBPA mutations or known polymor-

phisms, and 25 had FLT3 ITD mutation. Assessed median expression level of TP53β was much higher (ΔΔCt 43,11) than TP53γ (ΔΔCt 10,85; p<0,05). Further-

more, expression level of TP53γ in CEBPA mutated group (ΔΔCt 11,4) was significantly lower than in CEBPA wt group (ΔΔCt 17,7) (p=0,03). We have not found any other important correlation between mutations of studied genes and TP53β or TP53γ expression. We also classified patients according to median expression value of TP53, to two groups: with overexpression or with low expression. Haematological and clinical features, such as white blood cells count (WBC), blasts count in bone marrow or patient age did not depend on TP53 isoform expressions. However, statistical analysis showed important difference between WBC count in NPM1mutated and NPM1wt groups.

Summary/Conclusions: Obtained results may suggest a clinical importance of simultaneous analysis of TP53 isoform expression and mutations in CEBPA gene. It may be hypothesized that a changed sequence of the latter gene might influence TP53 isoform expression and in consequence regulate the cell cycle.

EXPRESSION PROFILE OF EPIGENETIC MODULATORS IN ACUTE MYELOID LEUKEMIA OF INTERMEDIATE RISK

C. Bilbao Sieyro1,2, Y. Florida Ortega1, C. Rodriguez Medina1, S. Gamrani1
E. Molina Hoyos1, S. Sánchez Sosa1, S. De la Iglesia Ilígo1, M.T. Molero Labarta14, G. Santana Santana1, M. Perera Álvarez1, S. Jiménez Bravo de Laguna1, M. T. Gómez Casares1
1Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, 2Morfología, Universidad de Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, 3Department of Molecular and Cellular Signalling, Institute of Biomedicine & Biotechnology of Castilla-La Mancha, 4Facultad de Ciencias médicas y quirúrgicas, Universidad de Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain

Background: Whole-genome sequencing has revealed acute myeloid leukemia (AML) as a very complex and dynamic disease. Epigenetic modulation is among the functional categories of the mutational landscape in AML. According to recent reports, suppression of the epigenetic reader BRD4 with small-molecule inhibitors ( BET-i ) results in leukemic activity. Clinical trials are being developed, however, so far, identification of those patients that may benefit from this therapy is not possible as changes in mRNA BRD4 levels seem to be unrelated to outcome. It has been recently suggested that antigenic effect of BET-i could be due to c-myc suppression and also that high Bcl-2 levels may target those patients that would benefit of BET-i. We believe that establishing the expression profile of epigenetic modifiers in AML may help in the identification of patients that could benefit from BET-i.

Aims: We wanted to get a better insight regarding the expression profile of epigenetic modulator in AML of intermediate risk by studying: 1) expression levels of EZH2, ASXL1, BRD4, c-myc and Bcl-2 in a consecutive series of AML patients; 2) correlation between mRNA and protein levels; 3) Determining BRD4 binding to the c-myc promoter through chromatin immunoprecipitation ( CHIP ).

Methods: Our series consisted of 104 consecutive patients with a mean age of 55.8 years (range 15-79 years) diagnosed and treated between 2005-2016 at the Hospital Universitario de Gran Canaria Dr. Negrín with a median follow up of 12 months. Gene expression analysis was carried out through real time PCR in a LightCycler 480 Instrument II (Roche) using GUS a control gene. Results were normalized with a β-actin pool from bone marrow of 10 healthy donors which was introduced as internal control in each experiment. Western blot were performed to determine protein levels for BRD4, c-myc and Bcl2. CHIP studies for BRD4 were carried out in HL60 cell line. For statistical analysis the SPSS (v.15.0) software was used.

Results: ASXL1 levels were positively associated with EZH2 ( Spearman’s = 0.285, p=0.021) and BRD4 with- myc ( Spearman’s coefficient=0.420, p<0.001), Bcl2 ( Spearman’s= 0.471, p<0.001) EZH2 ( Spearman’s= 0.4655, p=0.008) and ASXL1 ( Spearman’s=0.949, p<0.001). Survival analysis considering 50th percentile as a cut-off value for BRD4 expression indicated that patients with higher levels of BRD4 expression had better overall survival (median OS of 27 months 95% IC 15.1-38.9) compared to those with low expression (median OS 12 months, 95% IC 0.4-23.7), although the association was not statistically significant (p=0.196) probably due to the limited series size. Protein levels of Bcl2 and c-myc correlated with those of mRNA, but not for BRD4, although other antibodies should be tested in order to confirm these results. CHIP analysis in HL60 cell lines confirmed the binding of BRD4 to c-myc promoter.

Summary/Conclusions: The positive association observed between EZH2 and ASXL1 agrees with the fact that both cooperate in the epigenetic repressive complex PRC2. The positive association of BRD4 expression level with c-myc, and high Bcl2 is in accordance to the reported binding of BRD4 to the c-myc as BET-i could be affecting enhancer regions and our CHIP analysis also support so. Further studies in a larger series are necessary to confirm the relationship between higher BRD4 levels and better overall survival. Finally, future analysis should be done to determine whether patients with higher BRD4 expression levels determine a subgroup with better response to BET-i.

FLOW CYTOMETRY IMMUNOPHENOTYPING IN CEBPA-DM DE NOVO AML. BIOLOGIC AND PROGNOSTIC RELEVANCE.

M. Fernandez1, 2, M. Pratcorona1, A. Gantbó, 3, C. Estivill1, J. Esteve2, O. Sabater3, M. M. Arranz2, B. Belotxoño, L. Zamora1, S. Vives1, R. Guardia4, S. Brunet1, 4,5, J. Sierra4, 5, J. Nómudea6, 6Pathology, Parc de Salut Mar, Barcelona, 7Hematology, ICO Badalona, L’Hospitalet de Llobregat, Barcelona, 8Hematology, ICO Hospitalet, Badalona, 9Hematology, ICO Badalona, Badalona, 10Hematology, ICO Girona, Girona, Spain

Background: CEBPAdm is a transcriptional co-factor of RUNX1 which play a major role in the fate decisions associated with physiologic myelopoiesis. Biallelic CEBPAdm mutations (c/m) define an homogeneous molecular subgroup which is associated with a favorable outcome. CEBPA mutations may be transmitted in the germ line giving rise to clusters of familial leukemias.

Aims: To analyze the immunophenotypic findings assessed by multiparametric flow cytometry in a consecutive series of de novo CEBPAadm AML.

Methods: Thirty patients with c/m CEBPA and CEBPAadm who where enrolled on the AML-03 and AML-12 protocols of the Spanish CETLAM cooperative group were included in this study The immunophenotypic analysis was performed on erythrocyte-lysed bone marrow (BM) samples obtained at diagnosis. Antigenic expression of leukemic cells was systematically analyzed by multiparametric flow cytometry using four-color staining. The antigens studied were: CD45, CD34, HLA-DR, CD10, CD20, CD19, CD2, CD33, CD7, CD117, CD66, CD13, CD64, CD36, CD56, CD14, CD123, CD61, CD42b, glycophorin, CD71, CD11b, myeloperoxidase, CD79a, TdT, lysozyme and lactoferrin. At least 10.000 events/tube were measured. Analytical gates were established according to CD45 reactivity and to FSC/SSC pattern. Positivity threshold was established at 20%. The FACS-DIVA,Paint-a-Gate and Infinicyt software programs were employed for analysis. Amplification of overlapping PCR products covering the whole CEBPA coding sequence followed by Sanger sequencing were used to investigate CEBPA mutations. FLT3-ITD, NPM1, MLL-PTD, WT1 and GATA2 mutations were also investigated by conventional PCR-based molecular methods.

Results: Antigen reaction was as follows: CD45 (39/39, 100%), CD15 (35/39, 90%), CD34 (38/39, 92%), HLA-DR (39/39, 100%), CD33/39, 100%), CD2 (2/39, 5%), CD7 (36/39, 92%),CD117(39/39, 100%), CD13/37/39, 95%), CD56 (39, 15%), CD36 (6/39, 15%), CD123/39, 100%), CD14 (1/39, 0.02%), CD71 (39/39, 97%), myeloperoxidase (38/39, 97%). In nine cases CD36 and/or CD56 expression on leukemic blasts was greater than 20% Those CD36/CD56+ cases had a shorter overall survival and leukemia free survival (see graph). Four out five tested CD36/CD56+ cases also showed GATA 2 mutations. An additional CD36/CD56+ case had a FLT3-ITD. In three out 39 cases (7%) a population showing cytoplasmic CD79a reactivity was detected (8%, 11%, 14% of the neoplastic population, respectively). Two of those cases had also a FLT3-ITD.

Figure 1.

Summary/Conclusions: CEBPAadm cases showed an homogeneous immunophenotype with positivity for CD45, CD7 CD34,CD123,CD117, HLA-DR, CD71,CD33,CD13 and CD15. CD36 and/or CD56 overexpression was detected in a subgoup of cases (9/39, 23%) with an adverse outcome. The current findings suggest that CD36 and CD56 reactivity should be investigated in larger series of CEBPAadm AML cases. Small leukemic populations with B-cell markers are not uncommon in CEBPAadm AML (3/39, 7%).

PB1669

PROTEOME CHANGES IN ACUTE MYELOID LEUKEMIA PATIENTS BEFORE AND AFTER INDUCTION TREATMENT

L.F. Restrepo Rodriguez1,*, S. Rothlisberger1
1Biomedical Engineering, Instituto Tecnológico Metropolitano, Medellín, Colombia

Background: Acute myeloid leukaemia (AML) is a malignant disorder of hematopoietic stem and progenitor cells (HSPCs), characterized by the accumulation of immature blasts in the bone marrow and peripheral blood (PB) of affected patients. Standard induction therapy, based on cytarabine and an anthracycline, leads to complete remission in approximately 50% to 75% of patients, depending on prognostic factors, such as age or the presence of certain gene or chromosomal changes. In spite of favorable primary response rates, only approximately 20% to 30% of the patients enjoy long-term disease survival.

Aims: Our aim was to compare the protein expression profile of peripheral blood mononuclear cells (PBMCs) of AML patients at time of diagnosis and after induction therapy.

Methods: PB samples were taken from seven AML patients in Medellín-Colombia before and after concluding the induction therapy. Informed consent was obtained prior to sample collection. PBMCs were isolated from the 14 blood samples using a Histopaque-1077 solution. Cells were resuspended in lysis buffer (0.5% Triton x-100, 50 mM Tris-HCL pH 8.0, 150 mM NaCl, 1 mM EDTA, protease inhibitor) and proteins precipitated with trichloroacetic acid. Pellets were separated by 2D SDS-PAGE (pI 3–10 NL), and stained with SYPRO®Ruby. The proteomes were compared using PDQuest™ Advanced 8.0.1 Software. Protein spots of interest were those with a fold change of +/- 1.5 and p <0.05.

These results suggested that the antigenic effect of BET-i could be due to c-myc suppression and high Bcl2 levels which may target those patients that would benefit of BET-i. We believe that establishing the expression profile of epigenetic modulators in AML may help in the identification of patients that could benefit from BET-i.
Results: Image analysis revealed an average of 464 protein spots in PB samples taken at time of diagnosis, and an average of 346 spots in PB taken after induction therapy, reflecting changes in protein expression due to treatment. Comparing the proteomes, we found 11 spots that differed significantly (fold change of +/- 1.5 and p < 0.05). Of these, seven proteins were up-regulated and four were down-regulated at time of diagnosis (before treatment) compared to after induction treatment. Nine of these spots correspond to low molecular weight proteins (<40 kDa) and 2 spots have a molecular weight between 40-60 kDa. Based on the molecular weight and isoelectric point information of these spots we were able to search for proteins reportedly involved in leukemia, in order to propose possible identities (see Table 1). In terms of biological processes, 4 proteins (eIF5B, HS2SP1, 14-3-3 protein zeta/delta, and GST-P) are involved in the regulation of apoptosis. The F-actin-capping protein subunit beta could also be of interest, as reorganization of F-actin reflects unique characteristics of the differentiation process in promyelocytic leukemia cells. RuVBL 1-2 is a possible regulator of histone acetylation and DNA repair. GRP78 is a protein involved in the MAPK cascade and regulation of PI3K signaling, pathways regulating diverse cellular functions altered in leukemogenesis such as proliferation, differentiation, and apoptosis. Alpha-enolase is a key glycolytic enzyme; however, it has been shown to be a multifunctional protein involved in cancer. It promotes cell proliferation by also regulating the MAPK and PI3K pathways. Transaldolase is part of the pentose-phosphate pathway. Annexin II acts in angiogenesis and has multifaceted role in human health and disease.

AMP-ACTIVATED PROTEIN KINASE ACTIVITY INTERFERENCE WITH OVEREXPRESSION OF NUCLEOPHOSMIN IN CYTARABINE-INDUCED CHEMORESISTANT AML CELLS

D. Kim1,2,*, K.N. Kim1,2, J. Kang1,2, C.S. Park1,2, H.G. Yi3

1Hypoxia-related Disease Research Center, 2Pharmacology, 3Internal Medicine, Inha University School of Medicine, Incheon, Korea, Republic Of

Background: Cytarabine is a chemotherapeutic drug used alone or in combination with other anticancer drugs to treat acute myeloid leukemia (AML). New treatment strategies are emerging to enhance the anti-cancer effect and decrease the toxicity. Nucleophosmin (NPM1 or B23) is a ribosomal protein located in nucleoli, and multifunctional enzyme in cancer cell growth and protein synthesis. AMP-activated protein kinase (AMPK) is a critical energy sensor to regulate homeostasis and plays a potential role for anti-cell proliferating activity. Aims: We investigated the effects of AMPK activation on the cell death (apoptosis) and expression of NPM1 in AML cells treated with or without cytarabine, an anti-leukemia drug, to predict the mechanisms responsible for AML cells chemoresistance.

Methods: The HL-60 (FAB M2) cells were exposed to the different drug combinations including cytarabine and AMPK activators. The molecular mechanisms of NPM1 expression in HL-60 cells and protein expression were used to elucidate the role of NPM1 expression in controlling cell viability and apoptosis were assessed using cell counting kit-8 assay and flow cytometry.

Results: We found that cell apoptosis (36.27% – 42.11%) showed little dependence on cytarabine concentrations (10, 100, and 1000 mM), while the overexpression of NPM1 overexpression increased proportionally with drug dependence, indicating the drug-induced cell resistance. In the same point, cytarabine also inhibited the phosphor-activity (Thr172) and expression level of AMPK, which has mTOR-p70S6K pathway-repressor activity. As expected, single cytarabine treatment increased the ratio of p-mTOR/mTOR and p-p70S6K/p70S6K. Co-treatment of AMPK activator (phenformin or AICAR) in cytarabine-treated HL-60 AML cells inhibited significantly the induction of NPM1 overexpression level with the decrease of phosphor-activities of mTOR and its substrate p70S6K, resulted in the accelerated cell apoptosis.

Summary/Conclusions: Our results suggest that the higher concentration of cytarabine induces NPM1 overexpression, and that AMPK activation might be used to sensitize AML cells to cytarabine with the control of NPM1 expression levels. These modulations to standard therapeutic strategies could actually enable the reduction of the chemotherapeutic dose, therefore reducing their toxicity and adverse effects.

QUERCETIN REGULATES TELOMERE-BINDING PROTEINS EXPRESSION OF POT1, TRF1, TRF2 TO INHIBIT PROLIFERATION AND INDUCE APOPTOSIS IN AML TPH-1 CELLS

S. Cui1, X. Wu2, Z. Wang1, Y. Guo2, R. Xu1,*

1Hematology Department, Affiliated Hospital of Shandong University of TCM, 2The 1st Clinical College , Shandong University of TCM, Jinan, China

Background: Leukemia cells are limitless cell sources for initiation and maintenance of leukemia. Telomere-binding proteins are key regulators for various diseases, including leukemia. Therefore, targeting telomere-binding proteins is considered as a promising therapeutic strategy for treatment of leukemia.

Aims: We aimed to explore whether quercetin, a natural flavonoids, could regulate telomere-binding proteins expression to inhibit proliferation and induce apoptosis in acute myeloid leukemia(AML) THP-1 cells.

Methods: 1. In vitro: (1) We cultured human AML THP-1 cells. (2) The cells were treated with different concentration of quercetin for 24/48 h, and the cell viability was measured by cell counting kit-8(CK-8) to determine the IC50 of quercetin. (3) The cell cycle distribution and apoptosis rate were measured by Annexin V-FITC/PI double staining flow cytometry(FCM). (4) The protein expression levels of POT1, TRF1, TRF2 were measured by western-blotting. (5) The mRNA expression levels of POT1, TRF1, TRF2 were measured by real-time fluorescent quantitative polymerase chain reaction(RT-qPCR). 2 In vivo: (1) Established AML/NOD/SCID model based on THP-1 cell line in NOD/SCID mice, and treated with optimal quercetin concentration 40mg/kg'd for 4 weeks by tail vein injection. (2) We observed the changes of mice survival status, peripheral blood and bone marrow cell morphology and organ histopathology by microscopy before and after treatment with quercetin. (3) The cell cycle distribution and apoptotic rate of spleen cells were measured by Annexin V-FITC/PI double staining FCM. The protein expression levels of POT1, TRF1, TRF2 were measured by immunohistochemistry(IHC) staining.

Results: In this study, we found that quercetin significantly suppressed THP-1 cells proliferation in dose- and time-dependent manner. Treatment with quercetin significantly increased the cell cycle arrest rate and G1 phase arrest rate. Furthermore, the protein expression levels of POT1 and TRF1 increased and the protein expression level of TRF2 decreased. The mRNA expression levels of POT1, TRF1, TRF2 were consistent with their protein expression levels, respectively.

Summary/Conclusions: Our results demonstrate that quercetin has anti-leukemia activity. It is mediated by regulating telomere-binding proteins expression of POT1, TRF1 and TRF2. Taken together, our findings support the concept that quercetin is a promising therapeutic strategy for treatment of leukemia.

PB1672

PPARG AGONISTS INHIBIT ADHESION SIGNAL TO ENDOTHELIAL CELLS IN THE DIFFERENTIATION INDUCTION OF ALL ACUTE PROMYELOCYTIC LEUKEMIA CELLS.

J. Park1,2,*, E.-M. Noh2, J.-W. Yoon2, O.-Y. Hong2, J.-S. Kim2

1Division of Hematology/Oncology, Department of Internal Medicine, Gachon University Gil Hospital, Incheon, 2Biochemistry, Institute for Medical Sciences, Chonbuk National University Medical School, Jeonju, Korea, Republic Of

Background: All-trans retinoic acid (ATRA) has successfully been used in the treatment of acute promyelocytic leukemia (APL) patients, with a remission rate of greater than 90%. Despite the high cure rates, induction mortality is a still a problem in APL. One of the most common causes of death was the differentiation syndrome (DS). The early administration of high-dose dexamethasone at the onset of the first
Background: The biological properties, genetic abnormalities of leukemic cells influence on their sensitivity to chemotherapeutic drugs. It is widely known that there can be significant differences both in genetic features as well as in drug resistance profile of individual tumors with the same phenotype.

Aims: The purpose of this study was to analyze the relationship between in vitro chemosensitivity test results using the Cell Titer-Glo assay and clinical response on chemotherapy, and to find the possibility of optimizing the treatment for individual patients according to their actual drug resistance.

Methods: For The Cell Titer-Glo assay, we obtained bone marrow aspirates or peripheral blood samples from 68 patients with newly diagnosed acute myeloid leukemia at the time of initial diagnosis. The following drugs were tested: cytarabine arabinoside, daunorubicin, idarubicin, fludarabine, etoposide, and methotrexate. We evaluated clinical response and survival outcome according to chemosensitivity of drugs and protein expression.

Results: In this study, in vitro chemosensitivity test with the Cell Titer-Glo assay showed the relationship between chemosensitivity and survival outcome significantly. The 5-year overall survival rates with dichotomized chemosensitivity of idarubicin (64.6% vs 33.3%, p=0.046), cytarabine (63.1% vs 43.3%, p=0.0291), and fludarabine (80.1% vs 37.5%, p=0.020) were higher in low centration level than in high concentration level. There was a tendency of higher relapse-free survival rate at 4-year in the patients with low level IC_{50} than in the high level IC_{50}. However, cytotoxic effect of testing drugs in vitro by the Cell Titer-Glo assay did not show a relationship with complete remission rate after induction and leukemia recurrence rate.

Summary/Conclusions: Although the Cell Titer-Glo assay did not provide the prediction of clinical response of induction treatment, it can be a useful tool in individually optimizing the chemotherapy of patients with newly diagnosed acute myeloid leukemia.

PROGNOSTIC IMPACT OF P53 EXPRESSION IN BONE MARROW BIOPSY OF PATIENTS WITH ACUTE MYELOID LEUKEMIA

H. Souza1,*, S. Saad1, I. Lordan-Metze1, B. Duarte1, G. Hayakawa1, P. Campos1, M. Delamain1, G. Duarte1, J. Vassallo1, K. Pagnano1, P. Campos1, M. Delamain1, G. Duarte1, J. Vassallo1, K. Pagnano1

1University of Campinas, Campinas, Brazil

Background: Several studies have shown that the presence of the TP53 mutation is related to an unfavorable prognosis in patients with acute myeloid leukemia (AML). However there are few reports on the evaluation of its expression by immunohistochemistry in bone marrow (BM) biopsy.

Aims: To evaluate the expression of p53 in BM biopsy of AML patients at diagnosis and its impact on survival.

Methods: This retrospective analysis included 85 patients with de novo AML diagnosed from January 2005 to December 2015 submitted to BM biopsy at diagnosis. p53 expression was detected by immunohistochemistry, and staining was evaluated using the H-score (range 0-300). The t-test and Mann-Whitney U test were used to detect differences in the distribution of continuous parametric and nonparametric variables, respectively. Overall survival (OS), disease-free survival (DFS) and event-free survival (EFS) were calculated using the Kaplan-Meier method. The log-rank test was used for comparison of survival curves. The interaction between the examined prognostic variables was tested with univariate and multivariate Cox regression analysis.

Results: Median age was 60 years (17-81). There was a predominance of patients >50 years (54.1%) and males (56.5%). The median H-score for p53 was 11.8 (0.4-161.1), with no significant correlation with age or cytogenic risk. p53 expression was significantly higher in patients with a complex karyotype (p=0.0031) and high risk by European Leukemia Net (ELN) criteria (p=0.047).

There was a positive correlation with complex karyotype and prognostic risk by ELN. Excluding early deaths (<30 days from induction), patients younger than 60 years with H-score >60 showed worse overall survival when compared with patients with H-score <60 (0% vs 14.6%, respectively) (p=0.048). There was no statistical difference in disease-free survival and event-free survival. In the Cox univariate analysis including all cases, peripheral leukocyte counts at diagnosis (p=0.014), cytogenic risk groups (p=0.07), ELN risk categories (p=0.023) and H-score (p=0.025) were significant. In a multivariate model including leukocytes, ELN risk and p53, all variables remained in the model.
Summary/Conclusions: Expression of p53 assessed by immunohistochem- istry is a fast, sensitive and inexpensive tool available for prognostic evaluation of AML. A high expression of p53 (H-score >60) was related to a lower overall survival in de novo AML.

LONG-TERM FOLLOW-UP OF SALVAGE TREATMENT FOR RELAPSED AML WITH CLADRIBINE, HIGH DOSE CYTARABINE AND IDARUBICIN

K. Mayer1, C. Hahn-Ast1, K. Schwab1, A. Glasmacher1, I. Schmidt-Wolf2, P. Brossart1, M. von Lilienfeld-Toal1
1Medical Clinic III, 2University Hospital Bonn, Bonn, Germany

Background: Despite improving response rates in induction treatment for AML during the last years the outcome for relapsed or refractory AML is still poor. Currently, no standard therapy exists for patients with relapsed AML. Furthermore, CR rates are lower than in newly diagnosed patients and range between 15% and 50%. There is evidence that clonal evolution in AML as well as an enhancing effect on other cytostatic drugs such as cytarabine (AraC) and thus may help to overcome resistance mechanisms.

Aims: Therefore, testing the combination of 2CdA, AraC and idarubicin (CAI) seems reasonable. Here we present the final analysis from our single-center phase II trial evaluating the safety and efficacy of CAI in relapsed AML patients after a follow-up of 5 years.

Methods: Patients with relapsed AML after at least 6 months of remission and COG 0-2 were included. Chemotherapy regime consisted of two courses of 2CdA 5 mg/m²/12 h, d 1-3, AraC 1000 mg/m²/12 h, d 1-3 and Idarubicin 8 mg/m²/d, d 1-3. After 8 patients, the prolonged duration of neutropenia especially in course 2 prompted us to change the protocol by 1) application of growth factors from day 15 onwards, and 2) omission of idarubicin from the 2nd course. The primary endpoint was the overall remission rate and safety of CAI.

Results: Because of slow recruitment the study was stopped after 20 patients. The median age was 63 years, 40% were female. 19/20 (95%) patients were included in the first relapse after at least 6 months of CR following 1st line therapy for AML. 1/20 (5%) patient was included with a second relapse. In 14/20 patients cytogenetic data at the time of relapse were available, according to the ELN-risk-group 2017, 9/14 (64%) intermediate and 2/14 (14%) belonged to the adverse cytogenetic group. The performance status was good in most patients (ECOG 0 in 10%, ECOG 1 in 80%), but reduced (ECOG 2) in 2 (10%) patients. After the first course, CR/CRi was achieved in 60% and PR in 10% of patients. Median duration of neutrophil recovery 19-41 days. The most frequent grade 3 or 4 non-haematologic toxicity was infection seen in 85% of courses. Nausea occurred in 30%, hepatotoxicity, mucositis and diarrhea in 11% of courses. Cardiac or renal toxicities grade 3/4 were not observed. Two patients (10%) died due to infection. Six patients received a second course of CAI/CA. Altogether, 6 patients were refractory. Nine patients (48%) proceeded to allogeneic stem cell transplantation after induction therapy with CAI. Of those, 4 patients are still alive and free of leukemia and one patient died in CR 88 months after salvage-therapy accounting for a 5-year survival rate of 55%.

Summary/Conclusions: Combination therapy with CAI in relapsed AML patients induces good response rates. Combined with allogeneic stem cell transplantation, long-term survival can be achieved. However, infection rates are a serious complication warranting intensive supportive care.

EFFICACY AND SAFETY OF DECITABINE IN ELDERLY AML PATIENTS: A REAL LIFE MULTICENTER EXPERIENCE OF THE NETWORK RETE EMATOLOGIA LOMBARDIA

E. Borlenghi1, C. Cattaneo1, M. Bernardi2, C. Basilio3, N. Frachiolla4, M. Fumagalli5, M. Rossi1, E. Sala1, M. Sciumè4, E. Todisco6, M. Petullà1, G. Rossi1
1Hematology, Spedali Civili, Brescia, 2Hematology and BMT Unit, San Raffaele Scientific Institute, Milano, 3Medicina Specialistica-Ematologia, ASST Sette Laghi, Varese, 4Hematology and BMT Unit, IRCs Ca Granda Ospedale Mag- giore Policlinico, Milano, 5Hematology, ASST Monza - San Gerardo Hospital, Monza, 6Hematology, Humanitas Cancer Center, Milano, Italy

Background: The optimal treatment decision in older patients (pts) with AML remains controversial, especially in patients pts with comorbidities, non-fit to intensive therapy or with AML adverse biologic features. Recently decitabine was approved in Italy in AML pts unfit to chemotherapy aged >65 years (y) and could be adopted in a population based setting.

Aims: To evaluate efficacy and toxicity of decitabine in a consecutive series of elderly AML pts (no M3), considered unfit to chemotherapy (CT) according to Ferrara et al (Leukemia, 2013) and treated at 6 centers of the Hematological Lombardy Network (REL).

Methods: Between Dec 2015 and Dec 2016, 46 (F/M: 22/24) newly diagnosed AML pts, aged ≥65y were treated with an average of 5 cycles of decitabine in 45 (93.5%) newly diagnosed AML pts, and 1 (2.2%) relapsed in 42 (91.3%) pts. Median age was 76 y (69-85), ECOG performance status (PS) was ≥3 in 10.8%. According to “fitness”, 41 pts (89.1%) were defined unfit to intensive CT, 1 frail and 4 fit. Unfitness causes were age ≥75y (58.3%), PS ECOG≥3 unrelated to leukemia (12.2%), and comorbidities (29.3%). AML was “de novo” in 25 pts (54%), therapy related in 3 and secondary to antecedent hematologi- cal disorders in 18 pts. WBC count at diagnosis was 4.4 ± 10×3/μL (0.46 to 63), marrow blasts were 51% (<30% in 19.5% of pts). Karyotype (K) was normal (NK) in 43%, t(8;21) in 4.5%, intermediate in 20.5%, adverse (adv) in 32% of
Results: The total number of cycles administered was 231 (median 3.5; range 1-20). In 37/46 evaluable pts (2 ongoing, 1 early and 8 aplastic deaths), overall response rate (ORR) and complete remission (CR) rate were 51% and 32%, respectively. Partial response (PR) and hematological improvement were achieved in 51.7% and in 13.6%, stable disease in 29.9% and failure in 19% of pts, respectively. Median time to best response was 3.5 months (range 1-8.5). Median response duration was 5.3 months (1-18+ ms). Relapse/disease progression was observed in 42% of responders. ORR was 21.4%, 47.3% and 77% in adv, NK and intermediate K, respectively (P<0.0289). After a median follow-up of 6.5 months, median survival was 8.4 months and projected OS at 1 and 2 y was 43%+9 (SEM) and 30%+12 (SEM). Treatment was fairly well tolerated except for a high incidence of infections (46 episodes in 231 cycles) particularly during the first three cycles (29% vs 11%) (p=0.0072). Pneumonia was the most frequent infection (46%), followed by sepsis (28%). It was more frequent during the first 3 cycles [14% vs 4%: p=0.012] when 44% of cases were of suspected fungal origin (3 probable aspergillosis and 4 possible IFI). Death occurred in 24 pts (52.2%): 12 (50%) of disease progression, 1 of early CNS hemorrhage and 11 (45.8%) of infection. In the first 3 months, infections were responsible for 46.7% of deaths. Pulmonary IFI were fatal in 57% of cases. These figures are higher than those reported by Cashen (JCO 2010) where the frequency of pneumonia was 11%.

Summary/Conclusions: These preliminary data confirm, in a population based setting, the high efficacy of decitabine and its longer time to response (more than 3 cycles) compared to CT. However infections complications were more frequent than expected and often fatal, particularly during treatment. Since pneumonia, especially IFI, was the major cause of death, the adoption of routine antimicrobial prophylaxis may be considered in order to reduce early mortality and further improve the results.

CLOFARABINE, CYTARABINE AND MITOXANTRONE FOR RELAPSED OR REFRACTARY ACUTE MYELOID LEUKAEMIA – INTERIM RESULTS OF A PROSPECTIVE PHASE 2 STUDY

H. Gill1,*, H. W. Ip2, S. F. Yip3, B. Kho4, H. Lee5, V. Ma5, J. Lau6, C. K. Lau7, S. Y. Lin1, R. Wong8, W. Li10, Y. L. Kwong8

1Medicine, The University of Hong Kong, 2Pathology, Queen Mary Hospital, 3Medicine, Tuen Mun Hospital, 4Medicine, Pamela Youde Nouthers Eastern Hospital, 5Medicine, Princess Margaret Hospital, 6Medicine, Queen Elizabeth Hospital, 7Medicine, Tseung Kwan O Hospital, 8Medicine, United Christian Hospital, 9Medical and Therapeutics, 10Clinical Oncology, Prince of Wales Hospital, Hong Kong, Hong Kong

Background: In unselected patients with acute myeloid leukaemia (AML) in first relapse or refractory to primary daunorubicin / cytarabine therapy, complete response (CR) rate is merely 20 - 30%. In patients <80-years old, CR rates of about 55% may be achieved.

Aims: We tested in a multicenter prospective phase 2 study the efficacy and safety of clofarabine, cytarabine and mitoxantrone (CLAM) in AML patients in first relapse or refractory to first-line daunorubicin / cytarabine induction therapy.

Methods: Consecutive patients aged 18 to 65 years in first relapse or refractory to first-line dose-intensified daunorubicin / cytarabine were recruited. Bone marrow pathology and karyotype at diagnosis and relapse were centrally reviewed. Next-generation sequencing of a myeloid panel of 67 genes was performed. Re-induction CLAM comprised clofarabine (40mg/m2/day, days 1-5) and mitoxantrone (12mg/m2/day, days 1-5). Bone marrow assessment was done on day 28 using standard criteria. Treatment toxicity was evaluated using the Eastern Cooperative Oncology Group Common Toxicity Criteria (ECOG-CTC). Survivals were determined using Kaplan Meier method. The primary outcome was the response on day 28. Secondary outcomes included treatment toxicity, leukaemia-free and overall survivals.

Results: In this interim analysis, 24 patients (14 men, 10 women) with a median age of 44.5 (19-66) years were treated. Karyotypic and genetic profiles were: normal karyotype (N=8) (NPM1 mutant, N=1), FLT3-ITD, N=8, (8;21)(q22;q22) (N=4) (KIT D816V mutant, N=1), inv(16)(p13.2;q22), t(16;16)(p13.2;q22) (N=1) (KIT D816V), W574R, FLT3-ITD, N=1, (11q23)(t(9;11);p(21q33) (N=1), trisomy 13 (N=1), near-triploidy (N=1), and complex karyotype (N=1). Twenty patients (83.3%) responded (CR, N=16; CR with incomplete hematopoietic recovery, N=4). Eight responding patients underwent allelogeneic haematopoietic stem cell transplantation. Grade 3/4 haematologic toxicity was observed in 17 (70.8%) and 2 (8.3%) patients respectively. Grade 1/2 rash was observed in 4 patients (20%). Cardiotoxicity or treatment-related mortality was not seen. With a median of follow-up of 4 (1-32) months, 6 patients relapsed. The 12-month overall and leukaemia-free survivals were 81.7% and 66.8% respectively.

Summary/Conclusions: CLAM resulted in a high CR rate for AML in first relapse or refractory to first-line induction therapy, which was associated with an acceptable toxicity profile.

FATAL EVOLUTION IN THE FIRST 96 HOURS OF PATIENTS DIAGNOSED WITH ACUTE LEUKAEMIA: ANALYSIS OF A SERIES OF 346 CONSECUTIVE CASES OF ACUTE LEUKAEMIA

S. Martin-Batista1,*, J. M. Rayá1, T. Martín-Santos1, B. Soria1, R. Arcas1, M. Moreno1, S. Lakhwan1, B.-J. González-González1, M.-T. Hernández-García1

1Hematology and Hemotherapy, Hospital Universitario de Canarias, La Laguna, Spain

Background: The very early death of a newly diagnosed acute leukemia (AL) patient is very frustrating, and there are very few published works (except for the case of acute promyelocytic leukemia, APL) analyzing this circumstance and the features of these patients.

Objective: To study the main characteristics of patients with acute leukemia who died within the first 96 hours after diagnosis in our centre in the last 15 years.

Methods: We studied all cases of acute leukemia diagnosed in our institution between April 2002 and January 2017, focusing on the analysis of those who died within the first 96 hours after diagnosis. In this subset of patients, we collected data concerning clinical presentation, hemogram, biochemical parameters, coagulation status, performance of a bone marrow aspirate, acute leukemia subtype, started therapy, initiation or not of induction chemotherapy, time elapsed from diagnosis to death (hours), and cause of death, among others.

Results: A total of 346 consecutive cases of acute leukemia were recorded in this period of time: 222 of acute myeloid leukemia (AML, 64%) and 124 of acute lymphoblastic leukemia (ALL, 36%). Thirty-three patients were diagnosed of acute promyelocytic leukemia (15% of all AML). Those patients who died in the first four days after the diagnosis were only seven (2%), with a median of 45 hours between diagnosis to death. The clinical and anatomical findings are shown in the Table 1. They were 5 men and 2 women with a median of 57 years (range 22-91). Two of the seven patients had an APL (6% of all diagnosed APL). All patients showed leucocytosis, but hyperleucocytosis was only recorded in 27 patients, and severe thrombocytopenia (Plt ≤ 20 x109/L) in 3/7. There was possibility of bone marrow aspiration only in 4/7 cases. Coagulopathy was detected in four of six patients, including criteria for disseminated intravascular coagulation (DIC) in three cases. The exitus took place in the Intensive Care Unit in 5 cases, while it occurred in the Hematology facility in two.

Table 1.

Summary/Conclusions: In our experience, about 2% of patients with acute leukemia die within the first 96 hours after diagnosis (including 6% of APL). Clinical and analytical features of this subset of patients are very heterogeneous, although AML clearly predominate on ALL. More extensive and multicenter studies are needed to deepen into the circumstances conditioning this early fatal course of the disease.

PRIMARY POSACONAZOLE PROPHYLAXIS IN ACUTE MYELOID LEUKAEMIA - A SINGLE CENTER REAL LIFE EXPERIENCE

T. Fıratlı Tuğlular1,*, T. Özgümüş1, T. Elibol1, F. Pepedi Tannkulu2, F. Geçgel1, A. Sezgin1, Y. İpek1, B. Ertürk Sengeł1, A. Tekin1, B. Kümürcü1, H. Bilginer1, C. Mutlu1, T. Topçat1, I. Ağaçgünüz1, Z. Odabaşı3

1Hematology, Marmara University, Istanbul, 2Hematology, Dr Ersin Arslan Research & Training Hospital, Gaziantep, 3Infectious Diseases and Clinical Microbiology, Marmara University, Istanbul, Turkey

Background: Invasive fungal infections (IFI) are a major cause of mortality and morbidity in acute myeloid leukemia (AML) patients receiving remission induction therapy, and relapsed/refractory AML patients. Posaconazole prophylaxis has shown the greatest benefit in preventing IFI in AML. We present the data of our real-life experience in AML patients under PP.

Methods: We have retrospectively reviewed the data from 82 AML patients
receiving 105 cycles of chemotherapy between June 2012 and December 2016 in Manara University Perineal Research and Training Hospital. Median patient age was 50 years (18-73); and there was no significant gender difference (38 female vs 44 male (46% vs 54%). All patients had active disease, 78 (74.3%) of them received 3+7 (idarubicine - ara-c), 25 (23.8%) of them FLAG-Ida, 1 patient received EMA and 1 patient received CLARA chemotherapy protocol. Acute promyelocytic leukemia was excluded from the analysis. All patients received posaconazole as oral suspension at the dose of 200 milligrams three times daily starting on the first day of chemotherapy. Prophylaxis was continued until marrow regeneration, or occurrence of IFI, or onset of adverse events, or discontinuation due to other reasons. All fungal infections were classified as possible, probable, or proven according to European Organization for the Research and Treatment of Cancer (EORTC) and the Mycoses Study Group (MSG) consensus criteria.

Results: Mean posaconazole prophylaxis duration was 20±13 (1-68) days. This duration was 29.7 days (16-50) in patients receiving prophylaxis until marrow recovery (21.9 (9-34) days), 8.9 days (0-28) in patients with IFI under prophylaxis and 12.7 days (1-68) in prophylaxis discontinuations due to adverse events and other reasons. Posaconazole prophylaxis was administered until marrow recovery without IFI (clinical success rate) in 42 of 105 (40%) chemotherapy cycles. In 18 cycles prophylaxis was stopped after diagnosis of IFI (7/17). Discontinuations were due to adverse events in 6 cycles (5.7%), and due to other reasons (diarrhea, intolerance of oral medication, recurrent high grade fever, death) in 39 cycles (37.1%). IFI incidence under effective posaconazole prophylaxis was 28.1% (16/64). Total clinical failure rate was 60% (63/105). IFI was diagnosed with pulmonary nodules in 12 of 18 patients (66.6%; EORTC-MSG: probable), with blastocystosis in 3 patients (16.6%; EORTC-MSG: probable), with fungal culture in 3 patients (16.6%; EORTC-MSG: proven). Data from 70 patients were available for mortality analysis. In patients receiving effective posaconazole prophylaxis, mortality incidence rate at day 100 was (6/144; 4.2%) significantly lower than patients unable to continue posaconazole prophylaxis (12/26; 46.1%) (p:0.0023). In the subset of patients receiving prophylaxis as planned; there was no statistically significant difference in IFI incidence between previously untreated AML (13/46; 28.2%) and relapsed/refractory AML (5/18; 27.7%).

Summary/Conclusions: In our real-life experience, we have demonstrated early effective benefit in patients receiving posaconazole prophylaxis. Although our IFI rate was comparable to other real-life data, our clinical failure rate was slightly higher. This is probably due to compliance issues, since in many chemotherapy cycles (37.1%) posaconazole was discontinued due to “other reasons” such as drug intolerance. Although not as effective as in the clinical trials; our data still supports the use of posaconazole prophylaxis in high risk AML patients.

PB1682

CLINICAL AND PROGNOSTIC VALUE OF FLT3 MUTATIONS IN ACUTE MYELOID LEUKAEMIA PATIENTS IN ROUTINE CLINICAL PRACTICE – SINGLE CENTRE EXPERIENCE

A. Radzhabova1, S. Voloshin1, I. Martynevich1, V. Shuvav1, M. Ivanova1, E. Motyko1, N. Cybavka1, L. Polushkina1, D. Shikhbabava1, N. Potlikhona1, S. Tyravona1, M. Zenina1, S. Kudryashova1, A. Chechetkin1

1Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Detection of FLT3 gene mutations in acute myeloid leukemia (AML) now recognized as an unfavorable factor that affects the disease course, emerging the risk of relapses and overall survival (OS) shortening. Although about 30% of AML patients harbor one of the FLT3 gene lesion, at present there are no internationally standardized assays to quantify FLT3 mutation burden and no results of randomized clinical trials intended to individualize AML treatment based on FLT3 status. Some hematologists advocate to allo-SCT as consolidation in FLT3 ITD+ patients, but this way could be hard in frail and old patients, especially with low access to transplant techniques. On the other hand, the development of target drug therapy – FLT3-kinase inhibitors gives us a new hope for improvement in the treatment results of such poor-prognosis subset of AML patients.

Aims: To assess the frequency of FLT3 gene mutations and its impact on clinical parameters of survival of the patients with acute myeloid leukemia (AML) in routine clinical practice.

Methods: We have analyzed FLT3 gene mutation frequencies, complete blood count (CBC) parameters, karyotype and survival outcomes per FLT3-mutation status in 199 patients with AML (53 male / 146 female). The median age at diagnosis was 52 years (22-88 years). To determine FLT3 gene mutations we used the method of polymerase chain reaction (PCR) with subsequent resequencing. FLT3 gene mutations were classified as internal tandem duplication (FLT3-ITD) and point mutation in the “A-loop” (FLT3-TKD). Statistical analysis was performed using the method of polymerase chain reaction (PCR) with subsequent restriction.

Results: We observed two FLT3 gene mutations rates: FLT3-ITD - 22.6% (45/199), FLT3-TKD 5.5% (11/199). FLT3-ITD and FLT3-TKD in combination 1.0% (2/199), other 70.8% (141/199) patients had no mutations (FLT3-). CBC data at the time of diagnosis were as follows (median (max-min)): - FLT3-TKD: Hb 9.7 (3.7-13.0) g/dl, WBC 40.3 (0.6-400.0) x 10^9/l, platelets 60 (2-140) x 10^9/l; - FLT3-TKD: Hb 10.2 (5.6-12.8) g/dl, WBC 62.4 (1.7-362.0) x 10^9/l, platelets 68% (23-100), platelets 55 (12-115) x 10^9/l; - FLT3-ITD+TKD: Hb 5.8, 8.4 g/dl, WBC 37.0, 157.0 x 10^9/l, platelets 65%, 86%, platelets 38, 186 x 10^9/l; - FLT3-TKD: Hb 9.0 (2.8-14.0) g/dl, WBC 12.9 (1.0-260.0) x 10^9/l, platelets 64% (20-103), platelets 63 (1-334) x 10^9/l; Significant differences across the groups were seen only in WBC and platelets. Chromosomal aberrations were revealed in 38% of FLT3-ITD, 64% of FLT3-TKD, none of FLT3-ITD+TKD and 51% of FLT3- patients. All patients received chemotherapy (7+3, 5+2, HAM). Transplantation of hematopoietic stem cells (SCT) was performed in 28 (allo/autod 17/11) (14%) patients: FLT3-ITD allo-3; FLT3-TKD allo-1, auto-1; FLT3-allo-13, auto-10. We found significant (p=0.00024) differences regarding to OS between FLT3-ITD, FLT3-TKD and FLT3- patients (Figure 1). Median survival times were: 5.1 months for FLT3-ITD, 7.1 months for FLT3-TKD and 13.0 months for FLT3- patients.

Figure 1.

Summary/Conclusions: We confirmed the role of FLT3 gene mutations as an unfavorable factor for AML patients in routine clinical practice by own experience. The investigation of qualitative assessment potential and target therapy value especially in SCT ineligible FLT3 gene mutations positive patients has of great value for AML management.

PB1683

TARGETING ENDOTHELIAL DYSFUNCTION FOR PROTECTION FROM ANTHRACYCLINE-INDUCED CARDIOTOXICITY IN PATIENTS WITH ACUTE LEUKEMIA AND CO-MORBID ISCHEMIC HEART DISEASE

T. Lymanets1, I. Strykovyn1, G. Maslova1

1Chair of Internal Medicine #1, Ukrainian Medical Stomatological Academy, Poltava, Ukraine

Background: Cardiotoxicity of chemotherapeutic drugs, in particular anthracycline antibiotics (AA), is one of the biggest problems in treatment of patients with acute leukemia (AL). Chemotherapy with AA is accompanied by systemic endothelial dysfunction, increasing the cardiovascular toxicity risk and promoting vascular complications. Patients with co-morbid ischemic heart disease (IHD) are at extremely high risk of myocardial injury and in need of anthracycline cardiotoxicity (AC) prevention.

Aims: To assess the effectiveness of L-arginine in the prevention of endothelial dysfunction as a precursor of acute AC in patients with AL and co-morbid ischemic heart disease.

Methods: A total of 66 patients with newly diagnosed acute leukemia (acute lymphoid leukemia – 7 patients, acute myeloid leukemia – 59 patients) and co-morbid ischemic heart disease were included in the study. The cohort consisted of 43 (65%) males and 23 (35%) females; median age was 57.5 years (20-72 years), ECOG I-II. The duration of IHD ranged from 3 to 15 years. Chemotherapy (CT) schemes included AA (doxorubicin). The evaluation of endothelial dysfunction was performed by determining the stable metabolites of nitric oxide – nitrate anions [NO2]- and activity of total NO-synthase in serum of patients before the CT and upon reaching a cumulative dose of AA from 100 to 200 mg/m2by doxorubicin. 166.49±27.34 mg/m2in groups I and II respectively. The study was approved by the local ethical committee and all patients gave a written consent before they were included in the study. Patients were divided into two groups: (n=36) AL patients treated with CT; II (n=30) – AL patients, whom during the CT in order for prevention of acute AC were given L-arginine hydrochloride 4.2% 100 ml IV the day before and during administration of AA, followed by oral L-arginine aspartate for a month.
Results: In the debut of AL prior to the CT in all 66 (100%) patients the increased activity of total NOS in 3.8 times compared with the norm (p<0.001) was noted, with simultaneously reduced concentration of [NO2]- in 1.5 times relatively normal values (p<0.05) (Table 1). As a result of two CT courses of remission induction in patients of group I the tendency to reduce the total NOS activity compared with its level before treatment was observed. At the same time the significant decrease of [NO2]- in 1.8 times relatively normal values (p <0.01) and a trend to lower their content in 1.2 times compared with the data before treatment (p>0.05) was noted. These changes constitute the violation of NO-dependent vasodilation mechanism and endothelial dysfunction intensification. Provided achieving low cumulative dose of AA in patients of group II on the background of AC prevention with L-arginine showed a significant decrease in 1.9 times the total NOS activity (p<0.001) with a simultaneous tendency to increase concentration of [NO2]- in 1.3 times (p>0.05) compared to that before treatment.

Table 1.

Summary/Conclusions: Thus, during the CT with the inclusion of AA without L-arginine in patients with AL and co-morbid IHD we observed the depletion of NO substrate production, accompanied by endothelial dysfunction impairment. The additional appointment of L-arginine on the background of CT can restore synthesis of NO and, respectively, the mechanism of NO-dependent vasodilation, thus reducing the risk of early anthracycline cardiotoxicity development.

CLINICAL CHARACTERISTICS AND SURVIVAL OUTCOMES IN ACUTE ERYTHROID LEUKEMIA (AML-M6): AML/MDS WORKING PARTY STUDY OF KOREAN SOCIETY OF HEMATOLOGY

1Internal Medicine, Kyung-Hee University Medical Center, 2Internal Medicine, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, 3Internal Medicine, Seoul National University College of Medicine, Seoul, 4Internal Medicine, Chonnam National University Hwasun Hospital, Hwasun, 5Internal Medicine, Korea University School of Medicine, Anam Hospital, Seoul, 6Internal Medicine, Pusan National University Hospital, Busan, 7Internal Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, 8Internal Medicine, Yonsei University College of Medicine, 9Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, 10Internal Medicine, Gachon University Gil Medical Center, Incheon, 11Internal Medicine, Inje University Busan Paik Hospital, Busan, 12Internal Medicine, Kyung Hee University School of Medicine, Seoul, Korea, Republic Of

Background: Acute erythroid leukemia is a morphologically distinct and rare entity designated as M6 in FAB classification. In Korea, patients with AML-M6 have been treated as acute myeloid leukemia with intensive chemotherapy whenever possible rather than as myelodysplastic syndrome. The 2016 revision of the WHO reclassified erythroid/myeloid subtype (a case with ≥50% BM erythroid precursors and ≥20% myeloblasts among non-erythroid cells) to MDS with excess blasts, thus reducing the risk of early anthracycline cardiotoxicity development.

Aims: The aims of this multi-center study were to characterize clinical characteristics and treatment outcomes in patients with newly diagnosed acute erythroid leukemia.

Methods: Clinical data from newly diagnosed M6-AML patients between 2002 and 2012 at 11 academic centers were retrieved from the electronic registry of AML/MDS working party of Korean Society of Hematology. Conventional cytogenetic analysis was performed on metaphase cells prepared from bone marrow aspirate by G-banding technique. Patients were classified according to the UK MRC cytogenetic risk criteria and the International Prognostic Scoring System (IPSS) risk groups for MDS based on karyotypes. Survival curves were analyzed using the Kaplan-Meier method and compared with a log-rank test. A p-value <0.05 was considered statistically significant.

Results: A total of 84 patients with AEL (M6-AML) as defined by 2008 WHO classification criteria were included in this study. The median age at diagnosis was 55 years with following distribution: age ≤ 49, 34 patients (40.5%); age 50 – 59, 17 (20.2%) patients; 60 – 69, 19 (22.6%) patients; age ≥70, 14 (16.7%) patients. There were 50 (59.5%) males and 34 (40.5%) females. Median hemoglobin, white blood cell count, and platelet count were 8 g/dL, 3.69 × 10^9/L, and 58 × 10^9/L, respectively. Peripheral blood blasts were observed in 55 (65%) patients. Cytogenetic risk analysis showed that 43 (53.8%) and complex in 13 (15.5%) patients. Trisomy 8 was observed in ten (12.5%) patients. Monosomies of chromosome 5 and 7 were observed in five (6.2%) and four (5.0%) patients, respectively. Forty (5.0%) patients had t(9:22)(q34;q11.2). Cytogenetic risk analysis showed that karyotype was normal in 43 (53.8%) patients, and poor in 17 (21.2%) patients. Seventy-two (85.7%) patients received induction chemotherapy and 55 patients (76.4%) achieved complete remission. Nineteen patients received two or three cycles of induction chemotherapy. Thirty-eight patients (45.2%) underwent autologous hematopoietic stem cell transplantation (HSCT): 8 patients, matched-sibling donor; 15 patients, matched-unrelated donor; 5 patients, alternative donor were used. Treatment-related mortality of HSCT was observed in five (17.9%) patients. Fourteen (16.7%) among the study patients relapsed. The median overall survival (OS) of total 84 study patients was 21 months. Patients with intermediate risk karyotype showed better median OS than those with poor risk karyotype (22 months vs 7 months, P=0.020). The median OS was similar in patients with good and intermediate IPSS, but significantly worse in patients with poor IPSS (21 months, 7 months, 7 months, respectively, P=0.026) (Figure 1).

PREGNANCY ACCUMULATES UNFAVORABLE MOLECULAR GENETIC AML AND SHOULD BE CONSIDERED AS A POOR PROGNOSTIC FACTOR

V. Trofimova1, E. Paroshnevskaya1, A. Sokolov1, A. Kokhno1, Z. Fidova1, A. Sidorova1, O. Gavrilina1, G. Galstian1, A. Bazhenov1, L. Kuzmina1, M. Drokov1, S. Makhinya1, O. Latishkevich2, A. Zvereva2, A. Olenev3, O. Korobitsyna4, A. Korobkin4, V. Savchenko1

1National Research Center for Hematology, 2Centre of Family Planning and Reproduction, 3City Clinical Hospital No24, Moscow, 4Chelyabinsk regional hospital, Chelyabinsk, Russian Federation

Background: Acute myeloid leukemia (AML) during pregnancy – is a rare clin-
Aims: To assess the pregnancy, as independent prognostic factor, in non APL AML-patients (pts), prospectively treated within Russian AML multicenter studies. Methods: From 1990 to 2017 yy the Russian Acute Leukemia study group has treated 33 with de novo AML, pregnant women (Me-27 (21-42) yrs), AML was diagnosed in the 1st trimester in 1 woman (3%), in the IIInd 15, (45,5%), in the IIIrd 17 (51,5%). Molecular genetic risk group was estimated in 27/33 pts: 52% (n=14) were referred to the intermediate risk group and 48% (n=13) to the poor prognosis. High risk group comprised complex karyotype (n=5), -7/7del(L) (n=4), translocations inv(16)(q22)(n=2), pt - inv(3)/7 and 1 pt - AML with myelodysplasia-related changes, normal karyotype and FLT3+.

In 1 pt at the 1st trimester medical abortion was conducted and 11 women delivered at the gestation age of 34-40 weeks before chemotherapy (CT). 21 pregnant women received CT, that was started at 23 (14-32nd) weeks of gestation. Classical chemotherapy was applied in all of pts: either with daunorubicin (45-60 mg/m2), or mitoxantrone (10 mg/m2), or idarubicin (12 mg/m2) regarding the treatment study-protocol.

Results: As our data show, AML in pregnancy is characterized by high prevalence of unfavorable cytogenetic abnormalities (46%), that is substantially different from non-pregnant woman of the same age (11,5%) (p=0,006) [Blood 2016;128;22.p5171]. 1 pt died before CT due to septic shock, 2 pts – in induction CT now. 2 pregnant women died due to severe infections in aplasia during induction (5,7%). Sc, induction results were evaluated in 30/33 pts: CR rate - 73,3% (22/30): after the 1st course CT – in 16 and after the 2nd – in 6 pts. In pts, with available cytogenetic data, CR was received in 100% (9/9) from the intermediate and in 80,0% (8/10) from the poor prognostic group. Primary resistance was registered in 6/30 pts (20%). Antenatal fetal mortality was registered in 2 cases at the 21stand 32nd weeks during induction. 29 children were born. Allogenic bone marrow transplantation (allo-BMT) was done in 10 of 28 (35,7%) AML-pts who had survived induction therapy at a median of 6 months after CR. 4 pts relapsed after allo-BMT and 1 woman remained with refractory AML after allo-BMT. Our results demonstrated rather low 10-y OS and DFS (10,48% and 10,46%) in women, whom AML was diagnosed during pregnancy. In order to evaluated the role of allo-BMT, we performed a landmark analysis (landmark=6 months of CR), that has shown better OS and DFS only in pts after allo-BMT (Pic) (Figure 1).

Figure 1.

Summary/Conclusions: Our results demonstrate: almost half of women, who were AML diagnosed during pregnancy, are referred to the poor molecular genetic prognostic group; they demonstrated very low OS and DFS whith their improvement after allo-BMT.

PB1687

PRESENCE OF MULTIPLE DRIVERS IN THE SELECTION OF HIGH AND LOW INTENSITY CHEMOTHERAPY IN AML

B. Pandya1, A. Hadfield2, B. C. Medina3, S. Wilson1, E. Berraki1, T. Bailey2, S. Flanders1, A. Rider2, L. Horvath1

1Astellas Pharma Inc., Northbrook, United States, 2Adelphi Real World, Cheshire, United Kingdom, 3Stanford University, Stanford, United States

Background: Data on the key drivers of initial treatment choice for patients diagnosed with acute myeloid leukemia (AML) in the United States is limited. The use of age as a selection driver of induction therapy is well established; however, there is limited data and a knowledge gap about additional factors driving treatment selection.

Aims: This analysis explored the key physician drivers, which led to the selection of high- and low-intensity induction therapy in AML patients.

Methods: Data from the Adelphi AML Disease Specific Programme, a real-world, cross-sectional survey conducted between February–May 2015, was analyzed. A total of 61 hematologists/oncologists provided clinical information about their management and treatment choices for AML patients via survey. Each physician was provided a pre-specified list of 16 patient characteristics. Via two separate questions, they were asked to select those considered important when choosing high and low intensity chemotherapy for their AML patients. Characteristics were analysed descriptively and ranked based on the frequency of mention from highest to lowest.

Results: The top three drivers for decision making when selecting high and low intensity treatment were: patient age, performance status and presence of comorbidities. More than 60% of physicians would prescribe high-intensity treatment to patients aged under 65, with a good performance status or with no comorbid conditions. Over half of physicians would consider those who are eligible for a stem cell transplant or have a mutation in the CEBPA gene to be eligible for high-intensity chemotherapy (Table 1). Low-intensity chemotherapy was considered by more than 60% of physicians as being the most appropriate treatment for patients aged ≥65, with a poor performance status or increased number of comorbid conditions. A total of 38% of physicians would likely consider low-intensity chemotherapy if the patient was ineligible for a stem cell transplant or had had previous cancers or exposure to radiation/chemotherapy in the past.

Table 1. Top 5 patient characteristics considered by physicians when choosing high- or low-intensity treatment in AML.

Summary/Conclusions: Irrespective of treatment intensity, patient age, performance status and the presence of comorbidities are the top three drivers of treatment selection for physicians. In addition to patient age, identification of the other key drivers for therapy selection and the physician awareness of them is critical to ensure patients receive the most appropriate therapy. This improved awareness could also lead to better communication tools for patients and improve shared decision-making.

IRAIN LONG NON CODING RNA ARE DOWN-REGULATED IN POOR PROGNOSIS AML PATIENTS

M. Eshrafi1, M. Yaghmaie1,2, H. Pashaiefa1, E. Ghesrai1, M. Montazeri1, K. Alimoghaddam1, A. Ghavamzadeh1

1Hematology, Oncology and Stem cell Transplantation Research Center, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic Of

Background

Irai, an intermediate-length non-coding RNA (lncRNA), is a key regulator of the immune system and a potential therapeutic target for hematologic malignancies. Studies have shown that Irai expression is significantly lower in acute myeloid leukemia (AML) patients compared to healthy controls, and its expression is inversely correlated with overall survival in AML patients. Moreover, Irai expression is lowest in patients with poor-prognosis AML. However, further research is needed to address the underlying mechanism of Irai down-regulation in patients with poor-prognosis AML.

Aims: The aim of this study was to investigate the expression patterns of Irai in AML patients with poor-prognosis, and to identify potential biomarkers that can be used for clinical decision-making.

Methods: The expression of Irai was determined in 67 patients with AML, including 20 patients with poor-prognosis (measured by the International Prognostic Scoring System, IPSS-R). The expression levels of Irai were compared between poor-prognosis and non-poor-prognosis AML patients using real-time quantitative PCR. Moreover, the expression of Irai was compared between AML patients and healthy controls using the same method.

Results: The expression of Irai was significantly lower in AML patients compared to healthy controls. In addition, the expression of Irai was significantly lower in patients with poor-prognosis AML compared to those with non-poor-prognosis AML. These findings suggest that Irai down-regulation is a potential biomarker for identifying poor-prognosis AML patients.

Summary/Conclusions: The results of this study support the hypothesis that Irai expression is lower in AML patients with poor-prognosis compared to those with non-poor-prognosis. This finding suggests that Irai expression can be used as a potential biomarker for identifying poor-prognosis AML patients, and may help in designing more effective therapeutic strategies for these patients.
Background: IRAIN which is produced from the insulin-like growth factor type I receptor (IGFIR) imprinted locus is a newly identified IncRNA. There are very little knowledge about the specific role of this IncRNA in tumorigenesis presses. Recent studies were revealed that IRAIN is down-regulated in leukemia cell lines and viral expression of the IRAIN IncRNA inhibits tumor cell migration, suggesting a tumor suppressor function for this transcript.

Aims: In this study, we attempted to examine the expression level of IRAIN in different cytogenetic subtypes of AML patients.

Methods: Using quantitative polymerase chain reaction (qPCR) the expression level of IRAIN were analyzed in bone marrow specimen of AML patients (n=76) and healthy individuals (n=18).

Results: The expression of IRAIN was found to be remarkably decreased in AML patients compared with healthy individuals (p= 0.02). Significant IRAIN down-regulation was observed in all FAB types except for the M3 (p = 0.11). When we analyzed the expression level of IRAIN in different cytogenetic subtypes of AML patients the statistically down-regulation of IRAIN was observed only in poor prognosis AML patients (p=0.01 2008).

Summary/Conclusions: Our results suggest that down-regulation of IRAIN in AML IncRNA might play a role in the AML development and hence may be a potential prognostic factor and serve as therapeutic target for AML treatment.

PB1689

PERFORMANCE OF THE LEUKOSTRAT® CDX FLT3 MUTATION SIGNAL RATIO ASSAY TO DETECT INTERNAL TANDUM DUPLICATION AND TYROSINE KINASE DOMAIN MUTATIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

A. Osgood1,*, E. Shaker2, V. Atkinson1, N. Khai3, C. Simon4, J. Thomas3,4,5, T. Miller3,4,6, N. L. Miller3,6

1Invisioctebes Technologies, San Diego, United States, 2Product Development, Invivoctebes Technologies, 3Laboratory for Personalized Molecular Medicine (LabPMM), San Diego, United States, 4Laboratory for Personalized Molecular Medicine (LabPMM), Kawasaki, Japan, 5Laboratory for Personalized Molecular Medicine (LabPMM), Martinsried, Germany

Background: Acute myeloid leukemia (AML) in general has a poor prognosis. Assessment of the mutation status of the FLT3 (fms related tyrosine kinase 3) receptor gene in AML is the most important prognostic indicator of disease outcome, which is often substantial, as many studies in AML have shown that the presence of FLT3 activating mutations portends a poor prognosis. The LeukoStrat® CDX FLT3 Assay targets regions of the FLT3 gene to identify internal tandem duplication (ITD) mutations and tyrosine kinase domain (TKD) mutations. Since this assay is a signal ratio (SR) assay with a validated cutoff of 0.05, demonstration of international harmonization of results is paramount. FLT3 ITD mutations are caused by duplication and insertion of a portion of the FLT3 gene that includes the region in and around the juxtamembrane region of the FLT3 gene. These mutations vary in both the location and the length of the inserted duplicated DNA sequence. ITD mutations result in constitutive autophosphorylation and activation of FLT3. FLT3 TKD mutations are caused by nucleic acid substitutions and/or deletions that result in a change in the amino acid sequence in this highly-conserved catalytic center. TKD mutations, such as D835 and I836 substitutions and deletions, result in constitutive autophosphorylation and activation of FLT3.

Aims: To assess the performance of the Invivoctebes® LeukoStrat® CDX FLT3 Mutation Assay.

Methods: Whole blood cells were removed from peripheral blood after 30 minutes of centrifugation at 2000 g to create leukocyte depleted blood (LDB). Various ratios of four ITD positive cell lines, with insert sizes from 21 bp to 279 bp, and one TKD positive cell line, with a D835 substitution mutation, were created over a wide range of signal ratios (0.02 to 1.83) and added to the LDB. Mononuclear cells were isolated from the contrived LDB samples. DNA was extracted and amplified via PCR. The amplicons were analyzed via capillary electrophoresis. The assay measured the ratio of signals from mutation against a background of wild type. A FLT3 mutation was detected (and reported as positive) if the mutant:WT type SR met or exceeded the clinical cut-off of 0.05.

Results: The resulting software package is a web app which is accessible from any Internet-enabled device e.g. iPad, Android smartphone, Blackberry, laptop; 2. should not require installation; 3. FCS data should be anonymised; 4. data transfer should be secure and encrypted; 5. software must include all basic functionality of flow cytometry software e.g. dot plot graphs, histogram graphs and gating 6. should put collaboration to the forefront e.g. analysis can be instantly linked to via a web URL.

Results: The resulting software package is a web app which is accessible from any Internet-enabled device e.g. iPad, Android smartphone, Blackberry, laptop or PC. On mobile devices such as an iPad, touch is used for drawing of gates, selection of quadrants, selections of parameters etc. On laptop’s and PCs, these are drawn via e.g.
Aims: Idarubicine 12 mg/m² days 1-3, ara-C 2 mg/m² days 1-5) in these patients. Effort to improve outcomes of patients with relapsed or refractory acute myeloid leukemia (RR-AML) (primary refractory or resistant AML as defined by not achieving complete remission after 1 cycle of intense induction therapy); 60% (n=38) of patients had a RR-AML, 37% (n=23) of them were relapsed AML and 23% (n=15) refractory AML. Based on European Prognostic Score (EPI-SCORE) for patients with RR-AML, 61% of them had a poor prognosis (10-14 points), 36% had an intermediate prognosis (7-9 points) and only 3% had a favorable prognosis (1-6 points). The next important group, 25% (n=17) were MDS patients transformed to AML. We had 9% (n=6) patients with treatment related AML and 6% with other acute leukemia (3 cases of refractory ALL and 1 case of biphenotypic leukemia). We observed a global response rate of 63%: 51% (n=33) of patients had a complete response (CR) and 12% (n=8) partial response, 17% (n=11) did not have a response and 20% of patients were not evaluated after to receive the treatment because they had a early dead. The 30-days mortality rate was 21.5% (n=14), similar to the response rate of evaluated patients. We can see in the overall survival curve (picture 1) that most patients died first months after treatment, after that patients remain alive and we achieve a plateau. The median overall survival was 82 days (standard deviation: 25 days): 10 patients were alive when we analyzed the data (Figure 1).

Summary/Conclusions: Most AML patients ultimately die from their disease. In our case serie none died by any other cause. We had a similar response rate, mortality and overall survival that other groups in our country. Despite a variety of salvage therapy options, like FLAG-IDA protocol, prognosis in patients with RR-AML is generally poor and treatment is very complex.

BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASMS - UNUSUAL PRESENTATIONS AND UNFAVOURABLE OUTCOMES
M. Guenova1,*, M. Michova1, T. Dikov1, Y. Georgieva1, B. Spassov1, K. Prisadashka2, M. Balabanova2, V. Kaleva2, G. Balatzenko2
1National Specialised Hospital for Active Treatment of Hematological Diseases, 2Alexandrovka University Hospital, Sofia, 3University Hospital St.Marina, Varna, Bulgaria

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare hematological malignancy with an aggressive clinical course. Most patients (pts) with BPDCN have skin lesions and involve bone marrow, bone marrow, and lymph nodes. Very few cases have been described with lack of skin and or bone marrow manifestations at the time of diagnosis.

Aims: To characterise the clinical presentation and clinical outcomes of a cohort of consecutive patients with a rare blastic plasmacytoid dendritic cell neoplasm in a single institution.

Methods: Patients diagnosed with BPDCN at the National Hematology Hospital between 2010 and 2016 were retrieved from the database. The diagnosis was confirmed by morphology and immunophenotyping by flow cytometry and/or immunohistochemistry, according to 2008 WHO Classification of Hematopoietic Neoplasms. The relevant clinicopathologic features were reviewed.

Results: We identified 8 adult patients at a median age of 70 years (range: 37-84 years) with a male:female ratio of 6:2 (75%:25%) and only 1 child. Mean values of blood cell counts were as follows: WBC 5 10⁹/L; hemoglobin 99 g/L; platelets 116 10⁹/L. LDH was generally elevated with a mean of 962.8 U/L. At diagnosis the skin was involved in 5/9 patients. Five patients developed a leukemic presentation with 40-95% of bone marrow infiltration. Interestingly, in 4 pts (50% of adult pts) the initial presentation affected other tissues and organs such as testis, bronchial wall, stomach and periorbital soft tissues, however, only the latter one case presented with a leukemic picture. Biopsies revealed diffuse, monomorphic infiltrate of medium-sized blast cells with irregular nuclei, fine chromatin with ≥1 nucleoli, scant and agranular cytoplasm, without angioinvasion or coagulation necrosis. Immunophenotype generally demonstrated CD45+, CD4+, CD56+, CD123+. No standard therapies were applied. Patients received CHOP or HyperCVAD or AML-induction therapy. However, response rates in adult patients were low and the mean OS was 2.6 months (ranging from early deaths before any treatment could be initiated to 10 months).

Summary/Conclusions: BPDCN is a rare aggressive disease that typically affects elderly patients. The most commonly affected non-hematopoietic organ is the skin, however any other organ or tissues can also be involved. Response to therapy if any is relatively short and long-term prognosis is poor despite of the site of presentation. Larger scale studies are warranted to understand the pathophysiology of the disease and to find optimal management.

PREDICTIVE RELEVANCE OF CLINICAL CHARACTERISTICS IN PEDIATRIC PATIENTS WITH RELAPSED ACUTE MYELOID LEUKEMIA TREATED AT SINGLE INSTITUTION– REPORT OF AN OUTCOME ANALYSIS
S. Al-Sweedian1,2, K. Siddiqui1, R. Jafri1, I. Ghemlas1, A. Al-Ahmari1, A. Al-Seraihy1

Aims: To evaluate our response rates and the survival with FLAG-IDA protocol. We compared our results with other groups in our country.

Methods: Aims: To evaluate our response rates and the survival with FLAG-IDA protocol. We compared our results with other groups in our country.

Results: 65 patients received treatment with FLAG-IDA protocol between 2007-2016, 36 of them female, with and average age of 54.3 years (DS±23.3). We treated with this protocol mostly patients with relapsed or refractory acute myeloid leukemia (RR-AML) (primary refractory or resistant AML as defined by not achieving complete remission after 1 cycle of intense induction therapy); 60% (n=38) of patients had a RR-AML, 37% (n=23) of them were relapsed AML and 23% (n=15) refractory AML. Based on European Prognostic Score (EPI-SCORE) for patients with RR-AML, 61% of them had a poor prognosis (10-14 points), 36% had an intermediate prognosis (7-9 points) and only 3% had a favorable prognosis (1-6 points). The next important group, 25% (n=17) were MDS patients transformed to AML. We had 9% (n=6) patients with treatment related AML and 6% with other acute leukemia (3 cases of refractory ALL and 1 case of biphenotypic leukemia). We observed a global response rate of 63%: 51% (n=33) of patients had a complete response (CR) and 12% (n=8) partial response, 17% (n=11) did not have a response and 20% of patients were not evaluated after to receive the treatment because they had a early dead. The 30-days mortality rate was 21.5% (n=14), similar to the response rate of evaluated patients. We can see in the overall survival curve (picture 1) that most patients died first months after treatment, after that patients remain alive and we achieve a plateau.

Summary/Conclusions: Most AML patients ultimately die from their disease. In our case serie none died by any other cause. We had a similar response rate, mortality and overall survival that other groups in our country. Despite a variety of salvage therapy options, like FLAG-IDA protocol, prognosis in patients with RR-AML is generally poor and treatment is very complex.
**Background:** Western hospitals have achieved First Complete Remission (CR-1) and Overall Survival (OS) rates of 90% and 60% for children with Acute Myeloid Leukemia (AML). Intensified regimen of standard chemotherapy along with precise risk classification and improvements in supportive care are mainly attributed to this achievement.

**Aims:** We analyzed clinical data of our pediatric AML patients treated at KFSH&RC from 2005 to 2015 in order to assess the outcome of our treatment efforts including Hematopoietic Stem Cell Transplantation (HSCT).

**Methods:** A total of 155 pediatric patients with AML were registered at our institution from 2005 to 2015. 55.5% (86) of patients were boys with a F:M ratio 1.1.2 and median age at diagnosis 5.5 years (Min: 1.3months, Max: 13.8 years). 12 patients were excluded from further analysis for not being able to complete induction therapy. Donor’s syndrome (7.7% (11 of 143) had concomitant malignancies. 85.7% (120) of CNS-1, 27.4% (20 of 73) had MLL Gene rearrangements, 21.2% (14 of 66) were positive for TEL/AML1/ RUNX1/RUNX1T1 and 22% (13 of 59) had PMYLR/AML High Risk (P-value: 0.003) were found to be significantly associated with Relapse. Age at diagnosis, or Time to CR-1 were not found to have any association with relapse. 51.9% (27 of 52) who relapsed, went for HSCT. With a median follow-up of 63.3 months, five year overall survival for our cohort of patients was (0.687±0.046); significantly poor (P-value: 0.001) in relapsed (n=52, 0.176±0.051) compared to non-relapsed (n=82, 0.86±0.041); resulting in a five year event free survival of 0.47±0.044. Among relapsed group (n=52), five year overall survival was significantly better (0.160±0.073) for those who received HSCT (27) than those who did not (n=25, 0.114±0.073). P-value: 0.029. Five year overall survival was also significantly better for Non-Relapse group (n=31, 0.828±0.070) compared to relapsed patients (n=27, 0.160±0.073. P-Value: 0.000). HSCT was administered (n=58)

**Summary/Conclusions:** The results of our treatment efforts are in conformity with the western literature. Precise risk classification can be a vital predictor in planning for first line and salvage therapies including HSCT for pediatric patients with AML.

**IS HIF-2 ALPHA A POOR PROGNOSIS FACTOR IN HUMAN ACUTE MYELOID LEUKEMIA? A SINGLE CENTER ANALYSIS - PRELIMINARY RESULTS**

**J. Dybko1,*, D. Urbania-Kujda1, D. Szymczak1, O. Haus1,2, B. Jaźwiecz1, M. Kulickowski1,1 and Bone Marrow Transplantation, Wrocław Medical University, Wrocław, 2Department of Clinical and Molecular Medicine & Sant’Andrea AOU, Sapienza University of Rome, Italy**

**Background:** Hypoxia-inducible transcription factors (HIF) are well known regulators of cellular response to hypoxia. HIFs control functional, metabolic and vascular adaptation to hypoxia on transcriptional level. HIF-1 alpha has been described in mouse model as increasing myeloid preleukemic cell proliferation and accelerating disease progression linked with overexpression of HIF-1α has been published. Moreover another HIF subunit - HIF-2 alpha - has been described in mouse model as increasing of HIF-2 alpha positive blasts in blood after chemotherapy to be proportional to death probability (p=0.0036) (Figure 2).

**Results:** In all samples leukemic blasts were counted and determined by flow cytometry and the subpopulation of HIF-2 alpha positive blasts was estimated as well. We found bone marrow donor were the control group in this study and the CD34+HIF-2α+ subpopulation was assayed in their bone marrow samples during the routine harvest procedure. The study was approved by the local Ethics Committee.

**Aims:** After the first line chemotherapy patients achieved complete remission (CR group) and 11 did not (NR group). We did not find significant differences between the groups regarding patients age, the mean percentage of blasts in bone marrow and blood before the treatment, the percentage of HIF-2 alpha positive blasts in BM and blood before and 48 hours after the treatment start (data not shown). But the analysis of the percentage of HIF-2 alpha positive blasts in blood before and 48 hours separately in CR and NR groups revealed quite different dynamics. In CR group the mean percentage of HIF-2 alpha positive blasts was 14.65 (±33.32) and 8.48 (±11.63) before and after chemotherapy respectively (p=NS); in NR group the values were 11.74 (±22.6) and 24.01 (±33.68) respectively (p=0.007) (Figure 1). The Cox analysis revealed HIF-2 alpha positive blasts in blood after chemotherapy to be proportional to death probability (p=0.0036) (Figure 2).

**Figure and 2.**

**Summary/Conclusions:** We are aware our results are preliminary. But if they are confirmed it will be very interesting to determine the role of HIF-2 alpha inhibitors in improving the prognosis and survival in human AML.

**PB1696**

**RARE BCR/ABL FUSION PROTEINS AND THEIR CLINICAL SIGNIFICANCE INTO PH+ ACUTE MYELOID LEUKEMIAS**

**A. Campagna1, L. Cicconi2, G. Galassi1, S. Pelliccia1, A. Leporace1, F. Lo Coco2, A. Tafuri1, 1Department of Clinical and Molecular Medicine & Sant’Andrea AOU, Sapienza University of Rome, 2Department of Biomedicine and Prevention, University of Tor Vergata, Rome, Italy**

**Background:** The Philadelphia (Ph) t(9;22)(q34;q11) results in an oncogenic BCR/ABL gene fusion, representing the hallmark of chronic myeloid leukemia (CML), although it has been also described in acute lymphoblastic (ALL) and myeloid (AML) leukemia. Three main different transcripts have been described (p210, p190 and p230), but rare atypical BCR breakpoints outside the cluster regions have been also reported and their clinical significance is under investigation. Atypical transcript p190 e6a2 is a rare fusion protein associated with aggressive phenotype and dismal prognosis. The breakpoint in BCR intron 6 is responsible for increased kinase activity and greater transforming potential because of the partial loss of the Guanine Exchange Factor (GEF)/dbl-like domain, completely absent in p190 proteins. This truncation could increase the BCR/ABL oncogenic activity.

**Aims:** In this report we describe 2 rare cases of Ph+ AML patients with the atypical p190 e6a2 isoform.

**Methods:** Routine morphologic, immunophenotypic, genetic and molecular analyses were carried out in all samples at diagnosis. cDNA extracted from bone marrow was synthesized from 1 μg of total RNA. Most common AML genetic alterations were investigated and a quantitative RT-PCR (qRT-PCR) for p190 transcripts was performed. qRT-PCR assay for FLT3-ITD and p190 e6a2 transcript were designed in a common fluorescence multiplex assay.

**Results:** Case 1, a 78-years old male was admitted at our hospital with clinical and laboratory features allowing to make the diagnosis of AML. No evidence of a preceding CML (spleenomegaly or basophilia) was found. The karyotype on G-banded metaphases was 46,XY, t(9;22)(q34;q11). While the molecular analysis was negative for both BCR-ABL1 and AML1/ETO translocation based on cytogenetic analysis. The molecular biology analysis revealed the simultaneous presence of the common p190 e1a2 and the rare e6a2 isoforms (Figure 1A). Because of persisted pan cytopenia and presence of blasts, according to the molecular data, he was then switched to TKIs treatment. Nevertheless, after 2 months, the patient was still not in remission and started treatment based on decitabine. The molecular biology analysis revealed the simultaneous presence of the common p190 e1a2 and the rare e6a2 isoforms (Figure 1A). Because of persisted pan cytopenia and presence of blasts, according to the molecular data, he was then switched to TKIs treatment. Nevertheless, after 2 months, the patient was still not in remission and started treatment based on decitabine. Case 2, a 61-years old male was admitted with a diagnosis of AML 46XY, FLT3-ITD post MDS. Immediately, after cytoreduction, chemotherapy was started, obtaining the complete remission. Because of infectious complications, the

**haematologica | 2017; 102(s2) | 683**

**Madrid, Spain, June 22 – 25, 2017**
consolidation chemotherapy was postponed, relapsing without reach of the already planned allogenic transplantation. At the base karyotype was 46XY, t(9;22)(q34;q11) and the molecular biology showed the presence of p190 e1a2 and e6a2 isoforms and FLT3-ITD mutations with a low mutant allelic burden (Figure 1B). Salvage chemotherapy was then performed, allowing at this time to obtain disease remission and further allogeneic transplantation. Nevertheless, the patient died 5 months later for transplant complications. qRT-PCR assays performed in diagnosis sample showed the main clone FLT3-ITD accompanied by subclones with p190 e1a2 and e6a2 isoforms. These data indicate a clonal selection process and the expansion of a resistant clone with p190 e6a2.

Figure 1.

Summary/Conclusions: The atypical p190 e6a2 transcript seems to be associated in AML with aggressive disease. TKI therapy alone does not seem to control the disease. Prompt observations on these patients carrying rare BCR/ABL transcripts may allow help to establish optimal treatment approaches on these aggressive BCR/ABL phenotypes.

HYPOMETILATING AGENTS AS SALVAGE THERAPY IN RELAPSED OR REFRACTORY AML: A 2-CENTERS RETROSPECTIVE STUDY

F. Lessi1, A. Branca1, M. Laurino1, D. Lazzarotto2, C. Fil2, A. Candoni2, G. Semenzato1

1Department of Medicine, University of Padua, Hematology and Clinical Immunology Unit, Padova, 2Division of Hematology and Bone Marrow Transplantation, Azienda Sanitaria-Università Integrazione, University of Udine, Udine, Italy

Background: 5-azacytidine and decitabine have been widely studied as first line chemotherapy in acute myeloid leukemia (AML) patients not eligible for allogenic stem cell transplantation, but data on their use as salvage chemotherapy are limited.

Aims: To define efficacy and feasibility of hypomethylating agents (HMA) as salvage chemotherapy in patients without previous allogenic stem cell transplantation.

Methods: We retrospectively reviewed clinical records of 15 patients treated with HMA as salvage therapy in our institutions since their introduction in clinical practice for AML patients.

Results: Median age was 66 years. Six patients were men and 9 women. One patient was AML with t(8;21), 7 were AML MRC, 1 was therapy-related AML, 6 were AML NOS. Two patients were favorable risk sec ELN 2010, 11 were intermediate I and II and 2 were adverse risk. 67% of patients received HMA as second line therapy for their disease, 27% as third line and 6% were beyond the third line. Seven patients were treated with decitabine and 8 with azacitidine. Five patients reached CR or CRi after HMA. All patients underwent intensive chemotherapy (i.e. FLA-like or 3+7 like) as first line induction, and we excluded patients who had a HMA as first line chemotherapy and another one as second line. Median number of hospitalization days during HMA therapy was 16; median number of HMA cycles was 2 (range 1-31). 28% of patients underwent allogenic stem cell transplantation after HMA therapy. Median OS was 197 days from the starting of HMA and median EFS was 70 days. Median OS in patients with refractory disease was 91 days and median OS in relapsed patients was 331 days (p=0.0049). Median EFS in patients with refractory disease was 74 days and median EFS in patients with relapsed disease was 186 days (p=0.039). We did not find significant differences between transfusion needs before and after salvage therapy but this could be due to the small size of our sample.

Summary/Conclusions: HMA showed efficacy and a considerable OS in our patients. In our cohort refractory patients were almost all refractory to HMA too, and their OS was dismal. So HMA could be a good clinical option in a selected population of relapsed patients, especially in those not suitable for allogenic bone marrow transplantation, in whom the prognosis is generally extremely poor. Further studies are needed to determine which are the cytogenetic subsets of patients who could benefit from such a salvage chemotherapy.

PB1698

OMITTING CYTARABINE FROM CHEMOTHERAPY FOR ACUTE PROMYELOCYTIC LEUKEMIA REDUCES TOXICITY AND NOT EFFICACY

C. Lalayanni1, G. Karavaliakis1, E. Gavrilaki1, A. Lazaridou1, M. Iskas1, A. Syrigou1, M. Papathanasiou1, G. Papaioannou1, A. Athanasiadou1, A. Papalexandri1, C. Vadikoliou1, N. Stavroyianni1, R. Saloumi1, A. Anagnostopoulou1

1Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: The introduction of retinoic acid (ATRA) has changed the treatment paradigm in Acute Promyelocytic Leukemia (APL). Combination of ATRA plus anthracyclines (ATO+ID) has shown high efficacy in Spanish and Italian studies. However, early mortality resulting from coagulation disorders remains high. Furthermore, ARAc administration during consolidation is questioned and often limited to high-risk patients.

Aims: We aim to compare the efficacy, tolerance and toxicity between 2 consecutive treatment protocols that differed in ARAc administration during consolidation.

Methods: We studied clinical characteristics, prognostic factors, response to treatment, tolerance and outcomes in APL patients treated in our Department during the last decade. All patients received induction with AIDA (Idarubicin, ATRA until day 15, Dexamethasone, Asparaginase) and 2 and year maintenance therapy. Protocol 1 included 2 cycles of consolidation with anthracyclines/AraC. Protocol 2 was implemented the last 5 years and included 3 cycles of anthracyclines and AraC only in high-risk patients (PETHEMA LPA2005).

Results: APL was diagnosed in 35 patients, of whom 2 patients older than 80 years did not receive treatment and were not included in the analysis. The rest 18 male: 15 female patients aged 37 (10-75) years old presented at diagnosis with: thrombocytopenia (22), leukopenia (6), impaired performance status/PS >2 (10), lactate dehydrogenase >400 IU (17), increased d-dimers (33), low fibrinogen (11), fibrinogen <1 mg/dl (5). Five patients died during induction from severe differentiation syndrome (2), bleeding (2) and infection (1). In the multivariate analysis, these patients had significantly impaired PS (3, p=0.005), older age (median of 59 years, p=0.014) and lower fibrinogen (median of 0.9 mg/dl, p=0.05). Among 28 patients eligible for the comparison, all patients achieved complete remission (CR=100%). Protocoll 1 (ARAc) was applied to 16 patients and 2 to 12 patients. Complete molecular remission was achieved after a median of 2 chemotherapies (1-3). Efficacy could not be compared between protocols because there was only 1 relapse in Protocol 2, refractory to chemotherapy, ATRA, arsenic trioxide and allogeneic transplantation. However, there were significant differences in tolerance and toxicity. Patients in Protocol 1 had significantly higher transfusion needs compared to Protocol 2 (p<0.001): 9(2-15) versus 1(0-17) red blood cell and 11(3-32) versus 2(0-10) platelet transfusion. Duration of grade 4 leukopenia was significantly higher in Protocol 1 [16(5-19) versus 9(0-18) days, p=0.002]. The same was true for neutropenia (p=0.04) and resulted to higher infection rates in Protocol 1 (58% versus 17%, p=0.03), including 2 aspergillosis and 1 fatal sepsis. 10-year overall survival probability was 73.1%, with no difference between Protocols.

Summary/Conclusions: Our study confirms that early mortality is a significant issue in APL, in particular for older patients. ARAc can be safely omitted from treatment of low- and intermediate-risk patients, resulting in significantly reduced toxicity.

PB1699

DISEASE CHARACTERISTICS AND TREATMENT PATTERNS OF AML PATIENTS <60 YEARS OLD VERSUS ≥60 YEARS OLD

1Stanford University, Stanford, 2Astellas Pharma Inc., Northbrook, United States, 3Adelphi Real World, Cheshire, United Kingdom

Background: There is limited real-world data in patients with acute myeloid leukemia (AML) that looks at presenting disease characteristics and subsequent treatment decisions made for patients <60 and ≥60 years of age in the United States (US).

Aims: This analysis examined the characteristics of patients <60 years of age and ≥60 years of age at the point of AML diagnosis and further investigated subsequent treatments.

Methods: Data from the Adelphi AML Disease Specific Programme, a real-world, cross-sectional survey conducted between February–May 2015, were analyzed. A total of 61 hematologist/oncologists provided data on their 457 AML patients treated at various stages of AML. Disease characteristics upon
Acute Promyelocytic Leukemia (APL) is one of the favourable variants of acute myelocytic leukaemias due to the usage of ATRA in the treatment simultaneously with chemotherapy. But relapses occur in 13–33% cases after achievement the remission and there are cases of early death from the bleeding. High leucocytosis, the presence of lymphoid immunophenotypic markers and gene mutations are important prognostic factors.

Methods: The materials for research were the samples of whole venous blood and bone marrow of 40 patients with APL treated in the period of 2009-2016 in Hematology department for adults, Gomel. The diagnosis was proved by the presence t(15;17) or PML/RARA. Induction therapy was carried out according to the protocol <t7>15</t> using ATRA. Immunophenotypic analysis was carried out by standard immunofluorescence methods. The method of polymerase chain reaction (PCR) with specific primer and following electrophoretic detection was used for recognition of gene mutations.

Results: Out of 40 examined patients (mean age 48.5), 80% (32) achieved remission and 15.5% (6) subsequently relapsed after the first course of chemotherapy. Clinical, laboratory, molecular genetic and immunophenotypic data which could affect remission results and general survival rate were analyzed within all the patients. As a result, mutations were detected in 55% of cases. FLT3-ITD mutations were detected in 32.5%(13), NPM1 mutations in 12.5%(5), combination of FLT3-ITD and NPM1 in 7.5%(3), TP53 and CEBPA mutations were detected in 5%(2) and 12.5%(5) of cases respectively. After achievement of remission after the first course of chemotherapy NPM1 mutation remained at 6.2%(2). Mutations were identified more frequently within the patients with the absence of response to the therapy or with the developed relapse. FLT3-ITD and NPM1 mutations had the combination with high leucocytosis, presence of CD56 and CD2 immunophenotypic markers, who didn’t achieve remission or had the recurrence when the treatment was dropped. The presence of leucocytosis was detected in 25% of cases, in 90% (9/10) of cases leucocytosis was combined with FLT3-ITD mutations and 80% of these patients subsequently had the recurrence. Within the patients with the combination of FLT3-ITD and NPM1 mutations who brought into remission after the first course of chemotherapy these mutations were not detected later on. There were the patients who had leucocytosis rate less than 20x10^9/l and didn’t have CD56 and CD2(11.5%) at the time of verification. The presence of TP53 mutation was combined with high leucocytosis of the patient and with the absence of effect on the conducted therapy. When analyzing the immunophenotypic markers CD56 and CD2, they were detected in 75% of the patients, but in the absence of gene mutations and leucocytosis, such patients had a favorable prognosis (67.7%(93/138, p<0.046)).

Summary/Conclusions: Our results prove that the presence of only one of the signs is not a factor of high risk. Only combination of clinical, laboratory, molecular-genetic and immunophenotypic markers can include the patients into a high risk group and influence general survival rate.
which makes our case unique. Thrombotic risk factors in APL include high leukocyte count, presence of coagulation disorder, ATRA+chemotherapy+antifibrinolytic therapy and ATRA syndrome. None of these were seen in the presented case. The effects of known predisposing risk factors to thrombosis meaning DM, HL and smoking cannot be ruled out. But development of acute thrombosis concomitant with APL diagnosis points out to the relationship between these two entities.

Summary/Conclusions: Current literature knowledge is based on case reports and 9 patients with APL who presented with acute lower limb ischemia were reported yet. As far as we know our case is the first APL case presenting with aortoiliac occlusive disease (Leriche syndrome).

PB1702

A CASE OF THERAPY-RELATED ACUTE LEUKEMIA WITH MIXED PHENOTYPE WITH BCR-ABL1 AFTER TREATMENT OF DIFFUSE LARGE B-CELL LYMPHOMA

D. Yang1,*, J. Lee2, S. R. Cho3, Y. S. Kim4, J. R. Cho5, M. H. Kim
1Laboratory Medicine, Kosin University Gospel Hospital, Busan, 2Yeongam-gun Public Health Center, Yeongam, 3Laboratory Medicine, Ajou University School of Medicine, Suwon, 4Internal Medicine, Kosin University Gospel Hospital, Busan, 5Laboratory Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: Although therapy-related acute leukemia (tAL) is a well-recognized clinical syndrome and is increasing owing to the prolonged survival of patients treated with chemoradiotherapy, tAL with mixed phenotype is extremely rare.

Aims: Here, we report a rare case of tAL with mixed phenotype with BCR-ABL1 after achieving complete remission (CR) of Diffuse Large B-Cell Lymphoma (DLBCL).

Methods: A 57-year-old woman was diagnosed as DLBCL. The patient received six cycles of R-CHOP regimen with G-CSF injected after each cycle and achieved CR. The patient was readmitted to the hospital after a follow-up examination revealed the presence of immature cells in the blood.

Results: Her complete blood count findings were as follows: hematocrit, 35.1%; hemoglobin, 116 g/L; platelet count, 129×10^9/L; and white blood cell count, 2.41×10^9/L, with 4% blasts, 26% segmented neutrophils, 3% band neutrophils, 39% lymphocytes, and 26% monocytes. Bone marrow aspirations revealed 40.7% lymphoblasts with medium cell size, ovalantoround shape vesicular nuclei, fine chromatin patterns, and basophilic cytoplasm. On cytochemical staining, these blast cells were positive for PAS and NSE staining, but were weakly positive for MPO staining. Flow cytometric analysis showed that the blasts were positive for both T-lymphoid and myeloid markers (cytoplasmic CD 3, 87%; CD 5, 90%; CD 7, 96%; cytoplasmic myeloperoxidase, 20%; CD 13, 91%; CD 33, 87%) and negative for CD2, CD10, CD14, CD15, CD19, CD20, CD61, CD117, and TDT. Immunophenotyping fully filled the diagnostic criteria of T/myeloid biphenotypic leukemia based on the scoring system of the EGIL and WHO classifications. Multiplex reverse transcription PCR using Hexaplex kits revealed the presence of minor BCR-ABL1 (e1a2) fusion transcripts. Chromosome analysis of bone marrow cells failed because of insufficient mitotic cells. Immunoglobulin heavy chain gene rearrangement and TCR gene rearrangement were not detected on bone marrow aspirations.

Summary/Conclusions: Mixed phenotype acute leukemia is an uncommon subtype that comprises 0.5%-1% of leukemia. The T/myeloid phenotype is rarer and represents 35% of all MPAL cases. The risk of secondary malignancies after lymphoma treatment is relatively increased for leukemia. AML, ALL, MDS, CML and chronic myelomonocytic leukemia are reported secondary hematologic malignancies. Until now, only one case of tAL with mixed phenotype after lymphoma has been reported worldwide. To the best of our knowledge, this is the second case of tAL with mixed phenotype after DLBCL. This case is also unique because the BCR-ABL1 has not been described in the literature for patients with tAL with mixed phenotype, after hematologic malignancy. According to the 2008 WHO classification, TAL can be attributed to radiation, alkylating agents, or topoisomerase II inhibitors. Our patient did not receive radiation therapy but previously received cyclophosphamide and doxorubicin. Therefore, this is the first case of tAL with mixed phenotype and BCR-ABL1 after alkylating agent and topoisomerase II inhibitor therapy for DLBCL.

PB1703

CROSS-SECTIONAL ANALYSIS OF CONCORDANCE RATES BETWEEN KARYOTYPING AND RT-PCR IN ACUTE MYELOID LEUKEMIA: REAL WORLD CHALLENGES

D. Katoch1,*, Y. Uday1, T. Verma1, R. Kapoor1, S. Das1, V. Nair1
1Hematology, Army Hospital (Research & Referral), Delhi, India

Background: Translocation and chromosomal anomalies have prognostic implications in acute myeloid leukemia (AML). Cytogenetic analysis assumes great importance in their diagnosis and treatment stratification which are assessed by karyotyping and/or reverse transcriptase polymerase chain reaction (RT-PCR). Given the decreasing use of karyotyping on sample quality, more and more centers are now relying on RT-PCR to detect specific translocations. Varying rates of concordance between Karyotyping and RT-PCR have been reported and no consensus has prevailed. Given the resource constraint, it is economically non-viable to perform both for prognosis in real world scenarios. Therefore, the cost of the extra tests also adds to the burden of healthcare economy.

Aims: In 132 patients of AML, we aimed at determining the incidence of cytogenetic abnormalities and molecular anomalies detected by Karyotyping and RT-PCR respectively. Concordance rates between conventional cytogenetic tests and RT-PCR were also calculated.

Methods: We conducted a retrospective analysis on the medical records of 132 patients of AML at a tertiary health care facility in India, treated during 2010-2017. Results from commercially available molecular assays for detection of specific translocations by RT-PCR and of adequate samples of karyotype and RT-PCR were compared.

Results: In AML patients, out of those tested 50.6% had chromosomal aberrations detected by karyotyping while 30% had a positive detection with RT-PCR. The concordance rate in AML was found to be 56.3%. In a large number (31 in AML) karyotyping provided additional information in the form of detection of deletions, additions and hyper-diploidy (Table 1).

Table 1.

Summary/Conclusions: RT-PCR cannot substitute conventional cytogenetic analysis due to the absence of a broad based application for detection of aberrations other than translocations. However, given its efficiency and reliability it can have a complimentary role in prognosis assessment.
Results: Four pts were treated with 3+7 chemotherapy. Complete remission (CR) was achieved in 3 pts, and treatment was continued according to the HIDAC and IDAC protocol. The duration of remission was 3, 8 and 11 months respectively, followed with relapse and lethal outcome. One of the pts died within first 0.5 months after BPDCN was diagnosed. Three pts, treated with Hyper-CVAD, are alive and in CR with duration of 1, 3 and 10 months respectively. The continuation of the treatment within the programme of allogeneic stem cell transplantation is planned in 2 pts.

Summary/Conclusions: BPDCN diagnostics is difficult due to the heterogeneity of immunological characteristics of disease. Aggressive course of disease with median survival of 12-18 months, in the view of the unique treatment recommendations indicates necessity of further clinical investigations on larger patients groups.

Aggressive Non-Hodgkin lymphoma - Clinical

ECONOMIC IMPACT AND HEALTHCARE UTILIZATION IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA IN ROUTINE CLINICAL CARE IN THE UNITED STATES – A CLAIMS DATABASE STUDY

A. Galaznik1,*, J. Bell1, L. Hamilton2, A. Ogbonnaya2, K. Hennenfent2, M. Eaddy2, Y. Shou1

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda LLC, Palm Harbor, United States

Background: DLBCL is the most common histologic subtype of non-Hodgkin lymphoma (NHL), accounting for about 33% of all NHL cases. However, the healthcare burden associated with DLBCL has not been extensively studied in a US population.

Aims: We evaluated the costs of care and healthcare utilization (HCU) of DLBCL patients treated during routine care in the US.

Methods: The Optum claims database was used to identify adult patients (≥18 years old) with newly diagnosed DLBCL between 01/01/08 and 10/31/15. DLBCL diagnosis was based on ≥1 inpatient claim or ≥2 outpatient claims with DLBCL diagnosis codes, with the index date being the first DLBCL claim. Patients were followed from index date until end of continuous enrollment, death, or end of study period (12/31/15) for the assessment of HCU and costs. DLBCL-related and non-DLBCL-related HCU and costs incurred during follow-up were evaluated. DLBCL-related HCU and costs were medical claims with a primary diagnosis of DLBCL or DLBCL-related treatment (chemotherapy, radiation, stem cell transplant [SCT], supportive care) and pharmacy claims for DLBCL treatment. Proportions of patients with HCU were reported. Costs were calculated as per-patient-per-month (PPPM) costs and reported as mean and standard deviation (SD). Patients with a capitated payment plan were excluded from the cost analysis.

Results: 1,267 treated DLBCL patients were identified. Over the follow-up period, 66.0% of patients had ≥1 inpatient admission, with more patients having a non-DLBCL-related than DLBCL-related admission (Table 1). 60.0% of patients had ≥1 emergency room visit over the follow-up period; visits were predominately for non-DLBCL-related admissions. Nearly all patients had ≥1 physician office visit (92.4%) and other outpatient visits (99.6%). The mean PPPM costs incurred during the follow-up period was $11,890 (SD: $11,515) (Table 1), and costs were higher in Year 1 ($14,402, SD: $10,951) than in Year 2 ($4,190, SD: $8,076). About 55% of costs overall were related to DLBCL medical services ($6,532 PPPM, SD: $6,457). DLBCL-related medical PPPM costs decreased substantially from Year 1 ($8,327, SD: $5,925) to Year 2 ($1,443, SD: $4,349). This decrease was driven by the decreases in chemotherapy and supportive care medical services from Year 1 to Year 2. Non-DLBCL-related medical costs accounted for about 42% of the overall PPPM costs ($4,955, SD: $7,210); and a decrease was observed from Year 1 ($5,840, SD: $7,488) to Year 2 ($2,447, SD: $5,456). Inpatient admission was the main component of non-DLBCL-related costs, and associated costs decreased from Year 1 to 2.

Table 1.
Summary/Conclusions: The economic burden associated with the treated DBLCL population is high, with the majority of costs incurred during the first year of diagnosis. Between the first and second year of diagnosis, costs decrease mainly because of the decrease in the DLBCL-related treatment costs. In addition, HCU for DLBCL-related services decreased in Year 1 vs Year 2.

PB1706

PHARMACOKINETICS OF RITUXIMAB IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

S. Rožman1, I. Grabnar2, S. Novakovic3,4, A. Mrhar2, B. Jezersek Novakovic2,4
1Pharmacy Department, Institute Of Oncology Ljubljana, 2Department of Bio-pharmaceutics and Pharmacokinetics, Faculty of Pharmacy, University of Ljubljana, 3Department of Molecular Diagnostics, 4Department of Medical Oncology, Institute Of Oncology Ljubljana, Ljubljana, Slovenia

Background: Rituximab dosing is based on evidence from clinical practice rather than from consideration of pharmacokinetics and factors influencing individual exposure. Clinical use of rituximab can be improved through a more individualized treatment.

Aims: The objective of this investigation was to typify rituximab pharmacokinetics in 29 newly diagnosed patients with the diffuse large B-cell lymphoma who received rituximab in combination with cyclophosphamide, doxorubicin, vincristine and methylprednisolone every three weeks. The association of rituximab pharmacokinetics with clinical outcome was also investigated.

Methods: Rituximab serum levels were defined by enzyme-linked immunosorbent assay and assessed by a population pharmacokinetic analysis applying the non-linear mixed effects modelling.

Results: A 2-compartment model comprising linear non-specific clearance of 0.206/lh (0.070 – 0.279) /day and inter- and intra-patient variability of 0.278 (95% CI: 0.181 – 0.390) /day, corresponding to target-mediated drug disposition of rituximab was recognized to best describe the data. The nonspecific clearance was found to be lower in older patients and those with lower body weight. Additionally, the central compartment volume was higher in males. An unambiguous association of clinical response with rituximab pharmacokinetics has been detected. The rate constant of specific clearance decay was 0.143 day-1 (95% CI: 0.0478 – 0.418) in patients with no disease progression, while in patients with disease progression it was 0.82% lower (95% CI: 0.33.4 – 95.0).

Summary/Conclusions: These results imply that time-changes in clearance could serve as a predictive marker of response to rituximab. Our findings prove the rationale for studies evaluating higher doses of rituximab in selected patients.

PB1708

LOW ALBUMIN LEVEL CORRELATES WITH POORER SURVIVAL OF PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA: SERBIAN LYMPHOMA GROUP EXPERIENCE

J. Jelíc1,2, D. Antić2, M. Todorovic Balint2, B. Andjelic2, O. Markovic3, I. Mihalic1, V. Nikolic3, M. Predica3, V. Djurasinovic4, A. Sretenovic1, V. Vukovic1, M. Smiljanic1, B. Mihajlevic2
1Clinic of Hematology, Clinical Center of Serbia, 2Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, 3Clinical Hospital Center “Bezanijska Kosa”, University of Belgrade, Belgrade, 4Clinic of Oncology, University Clinical Center Niš, 5Clinic of Hematology, Clinical Center Niš, Serbia

Background: Current prognostic scores are not sufficient to define high risk patients with diffuse large B cell lymphoma (DLBCL). Besides parameters included in the International Prognostic Index (IPI), other clinical and laboratory parameters can be used to develop potentially prognostic markers. However, contradictory data have been reported.

Aims: The aim of this study was to evaluate prognostic significance of clinical and laboratory parameters on the overall survival (OS) of patients with DLBCL.

Methods: A total of 393 patients (188 females/205 males) with the median age 68 years (range 18-92) were included. All patients were initially treated with rituximab plus CHOP (Cyclophosphamide, Doxorubicin, Vincristine, Prednisone) or CHOP-like protocols.

Results: Ann Arbor stage I, II, III and IV had 56 patients (14.2%), 142 (36.1%), 71 (18.1%) and 124 (31.6%), respectively. Bulky disease had 99 patients (25.2%), B symptoms 263 patients (66.9%), and poor performance status according to the European Cooperative Oncology Group (ECOG) was 82 (20.9%). Bone marrow involvement was present in 68 patients (17.3%). Low IPI risk was present in 194 patients (49.4%), low intermediate in 86 (21.9%), high intermediate in 77 (19.6%), and high in 36 (9.2%). Median absolute lymphocyte count (ALC) at diagnosis was 1.35x10^9/l (range 0.07-50.7x10^9/l), absolute monocyte count (AMC) was 0.64x10^9/l (range 0.06-5.8x10^9/l), and albumin level (p=0.001, 95% CI 0.905-0.953). Optimal cut off point for albumin level was 34g/l, and was determined by Receiver operating characteristic (ROC) curve (AUC 0.699, 95% CI, 0.629-0.770; p<0.001). The prognostic value of IPI was highly statistically significant for OS (p<0.0001, 95% CI, 1.545-2.236). However, other analyzed parameters did not influence OS. Multivariate analysis among significant parameters (presence of B symptoms, IPI, and albumin) has pointed to IPI (HR 1.81, p<0.0001, 95% CI, 1.489-2.222), and albumin level (HR 1.77, 95% CI, 1.164-2.69, p<0.008) as the most important parameters that influenced survival.

Summary/Conclusions: Although ALC is widely used as a prognostic index in DLBCL, it cannot fully recognize high-risk patients. Pretreatment albumin level may represent a useful tool in order to discriminate high-risk patients and is likely to add significant information to the IPI.

PB1709

TREATMENT PATTERNS AND TREATMENT RESPONSE IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA IN ROUTINE CLINICAL CARE IN THE UNITED STATES – A CLAIMS DATABASE STUDY

A. Galaznik1, J. Bell1, L. Hamilton2, A. Ogbonnaya3, K. Hennenfent2, M. Eaddy2, Y. Shou2
1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda LLC, Palm Harbor, United States

Background: DBLCL is the most common histologic subtype of non-Hodgkin lymphoma. Treatment guidelines recommend rituximab in combination with chemotherapy as first-line therapy (1LT). For patients who are refractory or relapse, high-dose chemotherapy with stem cell transplant, combination chemotherapy, or single-agent rituximab are recommended in subsequent lines.

Aims: To compare real-world treatment patterns of patients with newly diagnosed DBLCL to NCCN guideline recommendations.
Methods: The Optum claims database was used to identify adult patients (≥18 years old) with newly diagnosed DLBCL between 01/01/08 and 10/31/11. DLBCL diagnosis was based on ≥1 inpatient claim or ≥2 outpatient claims with DLBCL diagnosis codes, with the index date being the first DLBCL claim. Patients were followed from index date until end of continuous enrollment, death, or end of study period (12/31/11). Treatment patterns and response to treatment were recorded as per the protocol. Possible remission was defined as no additional chemotherapy and no supportive care use or receipt of supportive care <30 days after end of line of therapy (LOT) for <30 days. Lack of remission was defined as receipt of supportive care <30 days after end of LOT for >30 days. Progression was defined as initiation of another LOT or evidence of supportive care >30 days after end of a LOT.

Results: Of the 2,216 patients selected into the study, 1,267 (57.2%) initiated 1LT and median (interquartile range [IQR]) time to therapy was 0.7 (0.4–1.1) months. The majority of patients received combination (87.7%) vs single-agent (12.3%) chemotherapy. R-CHOP (60.5%) was the most frequently used combination chemotherapy, while rituximab monotherapy comprised 22.4% (2.2%) of single-agent use in 1LT. Median (IQR) duration of 1LT was 4.2 (2.3–4.5) months. At the end of 1LT, 64.0% (n=811) had evidence of remission, 15.0% (n=190) progressed, and 12.2% (n=155) had no evidence of remission. Second-line therapy (2LT) was initiated by 198 patients who progressed after 1LT; 29.6% received a single agent, and 70.4% received combination chemotherapy. In 2LT, rituximab (12.6%) remained the top single agent used, while bendamustine+rituximab (15.7%) and R-CHOP (8.2%) were the most common combinations; 82% of patients received stem cell transplant. Median (IQR) duration of 2LT was 2.1 (1.2–3.8) months. Of the 2LT patients, 44.0% (n=70) had evidence of remission, 26.4% (n=42) progressed, and 31.1% (n=56) had no evidence of remission. 34 patients who progressed after 2LT received third-line therapy (3LT); 29.4% received a single agent, while 70.6% received combination chemotherapy. In 3LT, rituximab (5.9%), etoposide (5.9%), and carboplatin (5.9%) were the most common single agents, while bendamustine+rituximab (20.8%) and etoposide+carboplatin+rituximab (17.6%) were the most common combinations; 88% of patients received stem cell transplant. Median (IQR) duration of 3LT was 3.5 (0.9–5.2) months. Following 3LT, 32.4% (n=11) had evidence of remission, 29.4% (n=10) progressed, and 5.9% (n=2) had no evidence of remission.

Summary/Conclusions: DLBCL treatment in routine clinical care aligns with guidelines, with most patients receiving rituximab in combination with chemotherapy. A small proportion of patients received single-agent chemotherapy in 1LT. As expected, remission rates decreased with subsequent lines of therapy. Some patients were untreated; therefore, subsequent studies should explore reasons for lack of treatment.

TP53 GENE MUTATIONS IS A PREDICTOR OF HIGH GRADE B-CELL LYMPHOMA PROGRESSION

A. Misyurina1,*, V. Misyurin1, S. Kravchenko1, A. Misyurina2, E. Baryakh2, A. Magomedova1, E. Nesterova1, E. Pushkova4, J. Finashutina2, A. Misyurina1,*, V. Misyurin2, S. Kravchenko1, A. Kovrigina1, A. Misyurin2, A. V. Kvashnin1, A. T. Fedoseenko2

1National Research Center for Hematology, 2Federal State Institution “Russian Cancer Research Center. NN Blokhin” Russian Ministry of Health, 3State budget health care institution “City Clinical Hospital №52 Moscow Health Depart- ment.”, 4LLC “GeneTechnologiy”, Moscow, Russian Federation

Background: High grade B-cell lymphoma (HGBL) is subdivided on poor prognosis double-hit (DH) and not otherwise specified (NOS) variant, which appears sometimes with primary refractory behavior. Mutations in TP53 gene (MUT-TP53) lead to blockage of apoptosis in cells and appearance of additional oncogenic events contributing to tumor progression. Correlation between presence of MUT-TP53 and anti-tumor response in patients with HGBL is unclear.

Aims: To evaluate an effect of MUT-TP53 on survival parameters of patients with high grade B-cell lymphoma.

Methods: Since 2005 to 2017 years in FGBU National Research Center for Hematology of Ministry of Health Russian Federation diagnosis of high grade B-cell lymphoma were established in 47 patients: 13 – double hit, 34 – not otherwise specified. Among them, 53% was hematology malignancy (T cell lymphoma; 41%, B cell lymphoma; 29%, MPN; 18%, MDS; 12%). Solid tumor was carrier or smoldering. Among them, occurrence of primary malignant neoplasm was 32%, they were all patients who progressed after 2LT received third-line therapy (3LT); 29.4% received a single agent, while 70.6% received combination chemotherapy. In 3LT, rituximab (5.9%), etoposide (5.9%), and carboplatin (5.9%) were the most common single agents, while bendamustine+rituximab (20.8%) and etoposide+carboplatin+rituximab (17.6%) were the most common combinations; 88% of patients received stem cell transplant. Median (IQR) duration of 3LT was 3.5 (0.9–5.2) months. Following 3LT, 32.4% (n=11) had evidence of remission, 29.4% (n=10) progressed, and 5.9% (n=2) had no evidence of remission.

Summary/Conclusions: DLBCL treatment in routine clinical care aligns with guidelines, with most patients receiving rituximab in combination with chemotherapy. A small proportion of patients received single-agent chemotherapy in 1LT. As expected, remission rates decreased with subsequent lines of therapy. Some patients were untreated; therefore, subsequent studies should explore reasons for lack of treatment.

HTLV-1 INFECTION INCREASED THE RISK OF OTHER MALIGNANCY

A. Nakanaya1,*, S. Fujita1, A. Satake1, T. Nakanishi1, Y. Azuma1, Y. Tsubokura1, M. Hotta1, H. Yoshimura1, K. Ishii1, T. Ito1, S. Nomura1

1First Department of Internal Medicine, Division of Hematology and Oncology, KANSAI MEDICAL UNIVERSITY, Osaka, Japan

Background: The correlation between HTLV-1 infection and malignant neoplasm other than ATL remains unknown. Some previous studies have indicated that the frequency of primary malignant neoplasms in patients with HTLV-1 seropositive is higher than HTLV-1 seronegative.

Aims: To clarify the correlations between HTLV-1 infection and malignant neoplasms other than ATL.

Methods: We retrospectively analyzed 203 patients with HTLV-1 seropositive who were diagnosed between 2006 and 2015 at Kansai Medical University Hospital.

Results: Among 203 patients (median age 62 years: range 19 to 86 years), 43% was carrier and 57% was diagnosed with ATL. According to clinical subtype, 5% was chronic, 38% was smoldering, 28% was acute, 29% was lymphoma type. Median overall survival was 30 months in carrier, 10 months in acute, 8 months in lymphoma, and smoldering was not available. In all HTLV-1 seropositive patients, the occurrence of primary malignant neoplasm was 32%, they were all carrier or smoldering. Among them, 53% was hematology malignancy T cell lymphoma; 41%, B cell lymphoma; 29%, MPN; 18%, MDS, 12%. Solid tumor was 47% (lung cancer; 33%, prostate cancer 13%, colon cancer; 13%, renal cell cancer; 13%). Four patients with HTLV-1 carrier who developed primary malignant neoplasm received standard chemotherapy for the neoplasm, and after the chemotherapy they developed 3 acute type and 1 smoldering type ATL.

Summary/Conclusions: In our cohort, the occurrence of primary malignant neoplasm with HTLV-1 seropositive patients was significantly high. Chronic HTLV-1 infection might associate with reduction of cytotoxic T cells and an increased risk of developing other malignancy. Furthermore, cytotoxic chemotherapy for primary malignant neoplasm might reduce cytotoxic T cells for HTLV-1 and exacerbate ATL conditions.

1BAYLISser, Madrid, Spain, June 22 – 25, 2017

haematologica | 2017; 102(s2) | 689
survival (PFS), secondary end-points were 2-year overall survival (OS), overall
EPOCH regimens (third group). Primary end-point was 2-year progression-free
risk groups.
Methods: All patients treated with TBC/ASCT for PCNSL or SCNSL from
August 2010 to November 2016 in our centers were researched by using
CHIMIO® software. TBC combined Thiotepa (250mg/m²/d from d-9 to d-7),
Busulfan (3.2mg/kg/d from d-6 to d-5) and 1.6mg/kg/d on d-4) and Cyclophos-
phamide (60mg/kg/d on d-3 and -2) followed by ASCT transplantation at
d0. Clinical data were extracted from the medical records. We measured OS
and PFS from the date of ASC and transplant related mortality (TRM) (defined by
death occurred 3 months after ASC).
Results: 24 patients, without any major co-morbidity, were included. Median
age at ASC was 58 years (23-66). 22 of 24 were DLBCL and 2 follicular lym-
phoma and there were 15 PCNSL and 9 SCNSL. All but one, received 1 or 2
lines of chemotherapy (with high doses Methotrexate in first or second line)
before ASC. 15 were in complete response (CR) and 9 in partial response
(PR) before TBC/ASCT. Median duration of hospitalisation was 33 days (15-
78 d) and of aplasia was 14 days (7-37 d). Median follow-up was 10 months
(0-73). At the end of follow up 5 patients have died. Among the 3 patients older
than 60 years in PR before ACSCT, no one survived. At 1 year,
PB1715
PROGNOSTIC MODEL WITH NEUTROPHIL-LYMPHOCYTE RATIO AND PERFORMANCE STATUS IN DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH R-CHOP
S.-I. Go1, G.-W. Lee1*
1Internal Medicine, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of
Background: Growing evidences suggest the close relationship between
inflammation, host immune, and tumor cells. The neutrophil to lymphocyte
ratio (NLR) has been known to predict the prognosis in patients with diffuse
large B-cell lymphoma (DLBCL).
Aims: This study was planned to confirm the prognostic and predictive value
of NLR and to make a model to predict the prognosis more precisely in patients
with DLBCL.
Methods: Data of 192 DLBCL patients treated with R-CHOP from 2004 to
2016 were retrospectively assessed. Patients with NLR ≥4 and <4 were deter-
mined as the high and low NLR groups, respectively. Treatment response and
survival were compared according to the NLR status and using the model
including NLR and other variable interacting with NLR.
Results: High NLR group was associated with old age, poor performance
status (PS), elevated lactate dehydrogenase, and more advanced prognostic
indices than low NLR group. High NLR group had a low complete response
(CR) rate compared to low NLR group (57.5% vs 81.4%, p=0.004). However,
the other NLR as prognostic factor was non significant in multivariate analysis,
which showed strong interaction between NLR and PS. The model composed of
NLR and PS could stratify the patients into low-, intermediate-, and high-risk
groups for overall survival (OS). On multivariate analysis, compared to low
risk group, the hazard ratios of intermediate and high risk groups on OS were 1.871 (p=0.019) and 2.733 (p=0.004).
Summary/Conclusions: High NLR is associated with poor treatment response
and unfavorable clinical features in DLBCL. The prognostic model using NLR
and PS can predict more precisely the prognosis of this population and needs
to be validated in the independent cohort.

lymphoma patients (11/34; 32.3%). The complete remission rate for lymphoma patients with and without autoimmune diseases were 72.0% and 83.3%, respectively (mean±standard deviation: p=0.334). These two groups of patients had similar OS time as well (46.4 ±31.5 months vs 52.9±28.0; mean±standard deviation; p=0.337). Univariate analysis did not show autoimmune diseases were associated with inferior OS in lymphoma patients (crude hazard ratio: 1.32; 95% confidence interval: 0.75–2.29; p=0.627).

Summary/Conclusions: The results of this case-control study showed the autoimmune disease was not a poor prognostic factor for lymphoma patients.

THE DIAGNOSTIC AND PROGNOSTIC IMPLICATIONS OF CIRCULATING MiRNA-21 IN A SAMPLE OF HEPATITIS C/NONE HEPATITIS DIFFUSE LARGE B-CELL LYMPHOMA EGYPTIAN PATIENTS

M. Moussa1,*, N. Elhalawani2, A. Nazir1, N. Mashali1, M. H. Nafea1, A. Sorour3

1Hematology, 2Pathology, 3Clinical Pathology, Alexandria Main University Hospital, Faculty of Medicine, Alexandria University, Egypt. Alexandria, Egypt

Background: MicroRNAs (miRNAs) are small RNA molecules which control the expression of many target messenger RNAs involved in cell differentiation, proliferation and apoptosis. Circulating microRNAs are potential biomarkers of diagnostic and prognostic impact in various inflammatory and malignant diseases. Unlink all other malignancies, studies of the prognostic implication of miRNA-21 expression in diffuse large B-cell lymphoma (DLBCL) patients have been a matter of debate. To our knowledge, there are no existing data up to date on the expression of miRNA-21 in hepatitis C virus (HCV) associated DLBCL.

Aims: Linking inflammation with malignancy, we studied the expression of miRNA-21 in sera of hepatitis-C-virus and none hepatitis DLBCL patients, aiming to identify its differential expression and prognosis in DLBCL with its subtypes; germinal center B-cell (GCB) and activated B-cell-like (ABC) and to evaluate its relation with HCV.

Methods: MiRNA-21 expression was measured using Taq-Man quantitative RT-PCR in sera of 30 newly diagnosed DLBCL patients (HCV positive (n=10), HCV negative (n=20)) and 20 controls (HCV positive (n=10), HCV negative (n=10)). The diagnosis of DLBCL and its sub-classification in GCB and ABC subtypes were done by applying the criteria of the WHO classification of tumors of the hematopoietic and lymphoid tissues 2008 and revised in 2016. All the patients were confirmed by Immunohistochemistry using antibodies to CD10, BCL-6, MUM-1 and BCL-2. HCV was diagnosed by detection of anti-HCV antibodies in sera of patients and controls by Enzyme-Linked Immunosorbent Assay (ELISA) technique and HCV genetic detection and quantification by polymerase chain reaction (PCR). All the patients received CHOP chemotherapy and were followed up for an average of 24 months.

Results: MiRNA-21 expression was significantly higher in DLBCL patients than in controls (p<0.00). Significant positive correlations between miRNA-21 and LDH, IPI and disease stage were detected (p<0.05). Significantly higher miRNA-21 levels were detected in ABC subtype compared to GCB subtype (p=0.00). Significantly higher miRNA-21 expression levels were detected in BCL6 negative, CD10 negative, MUM1 positive DLBCL cases compared to its levels in BCL6 positive, CD10 positive and MUM1 negative cases, (p=0.018, 0.002 and 0.001 respectively). Higher miRNA-21 was associated with worse response (p=0.016), 2-year progression-free survival (p=0.017) and 2-year progression-free survival with statistical significance (p=0.003). Significantly higher miRNA-21 levels were detected in HCV positive DLBCL patients compared to HCV-negative patients (p=0.00). Higher miRNA-21 levels were detected in HCV positive ABC subtype than GCB subtype (p=0.05). Significantly higher levels were also detected in HCV positive controls compared to HCV-negative controls.

Summary/Conclusions: Our study showed that miRNA-21 was overexpressed in DLBCL patients, displaying higher levels in ABC than in GCB subtypes. MiRNA-21 was associated with poor response to treatment and survival in DLBCL. According to our results, miRNA-21 is a potential marker of necro-inflammation independent of its role in tumorigenesis, showing higher expression in HCV positive DLBCL patients compared to none hepatitis patients.

A NEW SCORING SYSTEM FOR PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA – A RETROSPECTIVE MULTI-CENTER ANALYSIS IN TAIWAN

Y.-C. Su1,2,*, S.-W. Lai3, C.-C. Lin1, W.-L. Hwang1

1Division of Hematology/Oncology, Department of internal medicine, Taichung Veterans General Hospital, Taichung, Taiwan, Republic of China

Background: Previous epidemiological studies have shown that autoimmune diseases increase the risk of lymphoma development. Immune dysregulation could be the possible underlying pathogenesis. Whether autoimmune diseases deteriorate outcome of lymphoma patients, however, remains unclear.

Aims: The objective of this study is to compare the clinical outcome among lymphoma patients with and without autoimmune diseases.

Methods: From January 2008 to November 2016, we retrospectively reviewed medical records of 913 newly diagnosed lymphoma patients. From these 913 lymphoma patients, 34 (3.71%) patients were diagnosed to have autoimmune diseases before their lymphoma identification. Among these 34 patients, six patients were excluded due to the loss of total 28 lymphoma patients with pre-existing autoimmune diseases. These patients were finally analyzed. For the further comparison, 56 patients lymphoma patients without pre-existing autoimmune diseases who were adjust-

Results: Rheumatoid arthritis was the most common autoimmune disease in lymphoma patients (11/34; 32.3%). The complete remission rate for lymphoma patients with and without autoimmune diseases were 72.0% and 83.3%, respectively (p=0.178). The PFS for patients with and without autoimmune diseases were 44.3±32.1 months and 50.9±28.6 months, respectively (mean±standard deviation: p=0.334). These two groups of patients had similar OS time as well (46.4 ±31.5 months vs 52.9±28.0; mean±standard deviation; p=0.337). Univariate analysis did not show autoimmune diseases were associated with inferior OS in lymphoma patients (crude hazard ratio: 1.32; 95% confidence interval: 0.75–2.29; p=0.627).

Summary/Conclusions: The results of this case-control study showed the autoimmune disease was not a poor prognostic factor for lymphoma patients.
Background: Primary central nervous system lymphoma (PCNSL) is a rare type of non-Hodgkin’s lymphoma. Two independent prognostic scoring systems have been developed at the Memorial Sloan-Kettering Cancer Center (MSKCC) and the International Extranodal Lymphoma Study Group (IELSG). The former considers age and Karnofsky’s performance status (PS) as prognostic parameters (JCO. 2006;24:5711). The latter includes age, Eastern Cooperative Oncology Group (ECOG) PS, the presence of deep lesions, serum lactate dehydrogenase (LDH) and total protein levels in the cerebrospinal fluid (CSF) /JCO 2003;21:266). Neither of the two systems has been verified in the Asian population, leading to concerns regarding applicability in this region.

Aims: This study was conducted to test the prognostic power of the 2 systems in PCNSL patients in Taiwan. In addition, we analyzed the parameters of the IELSG system to figure out the most powerful prognostic factors and then established a new scoring system.

Methods: The medical records of patients with tissue-processed PCNSL were retrieved from 15 academic hospitals in Taiwan through January 2002 to December 2011. They were stratified into different groups according to the MSKCC or the IELSG system and the overall survivals (OS) were evaluated. All parameters in the IELSG system were checked by multi-variable analysis to establish a new scoring system.

Results: When the IELSG scoring system was applied, the 2-year OS in low, intermediate and high-risk groups were 78.3%, 43.9% and 37.5% respectively with a crossover in the latter 2 groups (Figure 1A). When the patients were stratified by the MSKCC scoring system, the 2-year OS of class I, II and III were 65%, 68% and 20% (Figure 1B), respectively. We conducted single-variable analysis of the 5 parameters included in the IELSG scoring system and only age and ECOG PS were statistically significant. In the multi-variable analysis, these 2 factors were almost equally weighted. Based on these findings, we re-stratified the patients into 3 groups. Group 1 comprised patients with both age <60 and ECOG PS ≤2 and Group 2 with both age ≥60 and ECOG PS ≥2. The patients not fulfilling criteria of either Group 1 or Group 3 were categorized as Group 2. According to this new scoring system, the median OS of Groups 1, 2 and 3 were 1,573, 548 and 304 days (Figure 1C), respectively, and their OS curves could be nicely distinguished.

Background: The incidence of lymphomas is increasing with age. Many aggressive lymphomas are now considered to be curable. All fit patients, even elders, are candidates for optimal treatment with a curative intent. Diffuse Large B Cell Lymphoma (DLBCL) is the most common non-Hodgkin Lymphoma, with 60% of curative rates after standard R-CHOP regimen. Patients that relapse can be rescued with salvage treatment in 20-30%. The elders are not considered for full standard treatment in many centers. Geriatric scales are starting to be used to stratify patients and offer them individualized treatments. The use of GSCF for neutropenia prophylaxis is not a standard of care in this population.

Aims: The objectives of this study were: 1) Validate CIRS score in a DLBCL cohort; 2) Analyze the impact of CIRS score in OS; 3) Analyze the impact of GSCF prophylaxis in neutropenia prophylaxis.

Methods: Between November 2008 and November 2015, 41 DLBCL patients with ≥60 years at diagnosis from a single institution and homogeneously treated with R-CHOP were analyzed. Patients were evaluated for comorbidities with Cumulative Illness Rating Scale (CIRS). CIRS score was used to detect the most unfit population and evaluate the average of admissions stay and the impact on OS. The CIRS scale was adjusted by removing the hematological question since all our patients were diagnosed with a hematologic malignancy. The cut-off point for CIRS score was selected using a ROC analysis. Neutropenic fever (NF) events were recorded and the use of GSCF in prophylaxis were analyzed, as well as the admission days for adverse events.

Results: In our series, 20 patients (48%) were males. Median age at diagnosis was 73 years old (range 60-90) with a median follow-up of 32 mo. (range 0-96), the median PFS was 51 months and the OS was 61 mo. The patients were stratified by the R-IPI and the NCCN-IPI. The ROC analysis showed a scoring of 5.5 in CIRS to identify two different risk groups, with an AUC of 70.5%, a sensitivity of 87% and a specificity of 48% (ρ=0.02). In the low risk group, with CIRS <6 (n=17), 7 (41%) patients were admitted with a mean of stay of 6.2 days (range 1-16) vs the high-risk group with CIRS >6 (n=24). Of this group, 11 (40%) patients were admitted with a mean of stay of 10.6 days (range 1-62). p=0.035. The CIRS scale was also used to discriminate two OS groups; the low risk showed a median OS not reached vs 29 mo. the high-risk group, with a Hazard ratio of 2.68 (C95%; 1.031-5.882, p= 0.042). NF was the most common ER visit, n=18 (36%). Of the 18 patients with NF, 10 (55%) were prescribed with GCSF prophylaxis mid cycles. Of all patients with GCSF (n=43) only 10 (24%) NF were reported. 11/17 patients (65%) who didn’t use GCSF prophylaxis had an NF episode. The Odds ratio (OR) for the patients under prophylaxis was 0.232 (C1 95%; 0.085-0.634, p=0.004) (Figure 1).

Figure 1.

Summary/Conclusions: The OS and the PFS in our sample is similar as described in larger studies. The days of admissions adjusted to the CIRS score give us a tool to help physicians to discriminate patients who will have prolonged admissions when treated with the standard of care. The CIRS scale also help separate two distinct OS curves, giving physicians a new tool to help discriminate worse prognostic patients, making them good candidates for adapted therapies. The use of GSCF prophylactic can protect the elderly patients from NF, and should be used in all patients in this category.

PRIMARY ADRENAL LYMPHOMA: A SINGLE-CENTER EXPERIENCE
L. Yuan1, L. Sun2, W. Du3, Y. Zhao1.1
1Department of Hematology, 2Department of Pathology, 3Department of Oncology, Chinese PLA General Hospital, Beijing, China

Background: Primary adrenal lymphoma (PAL) is rare, with slightly more than 250 cases currently described in the English-language literature. In current classifications, there is not yet a consensual definition of PAL. The aim of this study was to report a large single-center clinical case series of primary adrenal lymphoma (PAL) in terms of clinical presentation, pathological and imaging features, and treatment outcome.

Methods: We performed a retrospective analysis of 21 patients diagnosed with PAL who presented to our center between January 2005 and January 2014.

Results: Median age at presentation was 48 years (range: 27–73) with a male-to-female ratio of 5:2. Bilateral and right-sided adrenal involvement were seen in 12/21 and 7/21 patients, respectively. Adrenal insufficiency (AI) was seen in
6/10 evaluated patients. Computed tomography scans showed slight to moderate contrast enhancement of adrenal masses in 4/5 patients (80%), and magnetic resonance imaging identified a normal T1 and longer T2 phase. Diffuse large B cell lymphoma (DLBCL) was the most common immunophenotype (82.6%). Two patients died due to rapid disease progression before treatment. Three patients were treated with chemotherapeutic agents: biologics and therapy. Five-year overall survival and progression-free survival were 54.2% and 51.0%, respectively.

Summary/Conclusions: These findings suggest that PAL should always be considered in differential diagnosis of adenral mass with AI. Moreover, DLBCL was observed as the most common histological subtype of PAL. Despite the contrasting previous reports, long-term prognosis of PAL is not necessarily inferior to that of non-Hodgkin lymphoma in general.

PB1723
HEMATOLOGICAL MALIGNANCIES IN SOLID ORGAN TRANSPLANT RECIPIENTS: RETROSPECTIVE SINGLE-CENTER ANALYSIS IN JAPAN

Background: Solid organ transplant recipients have elevated onset risks of hematological malignancies (HMs) due to long-term administration of immunosuppressives. Two previous studies, however, few studies about the incidence and impact on survival of HMs following solid organ transplantation have been conducted in Asian countries.

Aims: The aim of this study was to identify the incidence, characteristics, risk factors and prognosis of HMs in solid organ transplant recipients at our institution.

Methods: Clinical data of patients undergoing kidney, liver and heart transplantation following solid organ transplantation without disease (D) were retrospectively analyzed. Kaplan-Meier analysis was performed for the cumulative incidence rates (CI) of HMs, graft survival and patient survival. Patient’s characteristics were compared between groups by the student t-test or Kaire-square test.

Results: A total of 16 cases of HMs were identified, 9 post-transplant lymphoproliferative disorder (PTLD) (EBV positive PTLD = 5), 2 chronic myeloid leukemia, 3 acute myeloid syndrome (MDS), 1 myeloproliferative neoplasm (MPN)) and 1 recurrent non-Hodgkin lymphoma. The CI of PTLD were 1.1%, 1.5% at 10 years in kidney transplant recipients (n=352), 0.92%, 2.6% at 5 years in liver transplant recipients (n=287) and 29% at 1 year heart transplant recipients (n=5), respectively (P<0.0001). AML/MDS and MPN had higher incidence of HMs, and CI were 2.3% at 5 and 10 years (P<0.01). There was no difference in background factors other than transplanted organ type between recipients with HMs and without HMs. Patients with EBV-positive PTLD were younger (P<0.05) and had less extranodal diseases (P<0.05) compared with EBV-negative PTLD (n=4). All patients with monomorphic PTLD (n=4) were treated with chemotherapy combined with rituximab and had been in remission. In patients with other PTLD, reduction or withdrawal of immunosuppressant or rituximab alone resulted in stable disease or remission. All AML/MDS but 2 acute promyelocytic leukemia in pediatric patients were chemo-refractory and died. 10-year OS were 92% and 100% in kidney and heart transplant recipients. In liver transplant recipients, 10-year OS were 74%, 100% and 50% in patients without disease, with PTLD and with myeloid neoplasms, respectively. Survival in adult liver transplant recipients with myeloid neoplasms was inferior to that without disease (P<0.05), 10-year graft survival rates were 72% and 77% in adult liver transplant recipients without PTLD and with PTLD, respectively.

Summary/Conclusions: The incidence of PTLD in solid organ transplant recipients in Japan is comparable to that in Western countries, whereas the incidence of myeloid neoplasms is higher in liver transplant recipients. PTLD does not have a negative impact on the prognosis of solid organ transplant recipients under appropriate management, while myeloid neoplasms in liver transplant recipients predict a poorer outcome.

PB1724
MYC REARRANGEMENT HAS A STRONG PROGNOSTIC IMPACT IN THE FEMALE PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

Background: In Japan is comparable to that in Western countries, whereas the incidence of myeloid neoplasms is higher in liver transplant recipients. PTLD does not have a negative impact on the prognosis of solid organ transplant recipients under appropriate management, while myeloid neoplasms in liver transplant recipients predict a poorer outcome.

Aims: The aim of this study was to determine the incidence and impact on survival of HMs following solid organ transplantation are needed.

Methods: In order to identify prognostic factors, we analyzed gender segregation from the medical records of patients with DLBCL, including newly diagnosed and relapsed patients diagnosed at Juntendo University Hospital between 2009 and 2010. We retrospectively evaluated the data of 161 consecutive DLBCL patients.

Results: In various clinical trials of rituximab with standard dosing, female receiving rituximab had better outcomes than male. However, gender-segregated outcomes of patients with MYC rearrangement have not been reported. In addition, the gender segregation of known prognostic factors, such as high international prognostic index (IPI) score, elevated lactate dehydrogenase (LDH) level, poor Eastern Cooperative Oncology Group performance status (PS), advanced stage, and extranodal sites, not as yet been fully elucidated.

Aims: The aim of this study was to determine the gender segregation of clinical and genetic prognostic factors, including MYC (fluorescence-in-situ hybridization: FISH) in patients with DLBCL by analyzing data from consecutive DLBCL patients.

Methods: In order to identify prognostic factors, we analyzed gender segregation from the medical records of patients with DLBCL, including newly diagnosed and relapsed patients. The median age was 70 years (range: 27–92 years). In order to identify prognostic factors, we analyzed gender segregation from the medico-logic records of patients with DLBCL, including newly diagnosed and relapsed patients. The median age was 70 years (range: 27–92 years). In order to identify prognostic factors, we analyzed gender segregation from the medical records of patients with DLBCL, including newly diagnosed and relapsed patients. The median age was 70 years (range: 27–92 years). The median age was 70 years (range: 27–92 years). In order to identify prognostic factors, we analyzed gender segregation from the medical records of patients with DLBCL, including newly diagnosed and relapsed patients. The median age was 70 years (range: 27–92 years). In order to identify prognostic factors, we analyzed gender segregation from the medical records of patients with DLBCL, including newly diagnosed and relapsed patients. The median age was 70 years (range: 27–92 years). In order to identify prognostic factors, we analyzed gender segregation from the medical records of patients with DLBCL, including newly diagnosed and relapsed patients. The median age was 70 years (range: 27–92 years). In order to identify prognostic factors, we analyzed gender segregation from the medical records of patients with DLBCL, including newly diagnosed and relapsed patients. The median age was 70 years (range: 27–92 years). In order to identify prognostic factors, we analyzed gender segregation from the medical records of patients with DLBCL, including newly diagnosed and relapsed patients. The median age was 70 years (range: 27–92 years). In order to identify prog
patients developed an intestinal perforation. Six of the perforations (60%) were concentric and transmural (n=31, 74%) (as opposed to non-transmural). Of the entire cohort was 64 years (54.5-77 IQR). Early stage (1, 2) according to the Lugano system was reported in 35% of cases. Small intestine involvement was most frequent (61%), followed by large intestine and ilio-cecum (23 and 16%, respectively). Forty-three (88%) patients underwent CT scan at diagnosis. The incidence of DHL/THL was 5.5%. The median age was 70 years (range 53-93). The patients included in DHL/THL group had a higher prevalence of MYC and BCL2 rearrangements which are detected by fluorescence in situ hybridization (FISH) or standard cytogenetic. This rearrangement defines a subgroup of DLBCL so-called double hit or triple hit lymphomas (DHL/THL) which are included in the 2016 WHO classification revision of lymphoid neoplasms in a new category "High-grade B-cell lymphoma with rearrangements of MYC and BCL2 and/or BCL6". DHL/THL have an aggressive clinical course and poor response to standard chemotherapy and a median overall survival of 0.2-1.5 years. The best therapeutic option in these patients is not yet well established.

Aims: To evaluate retrospectively the incidence, clinical-biological characteristics, type of treatment, overall survival (OS) and progression-free survival (PFS) of patients diagnosed with DHL/THL and to compare them with patients with DLBCL without double/triple-hit genotype (DLBCL-noDH/TH) in a single institution.

Methods: From January 2000 to April 2016, we analyzed 18 patients with DHL/THL and 312 patients with DLBCL-noDH/TH. DHL/THL cases were identified using FISH for MYC, BCL2 and BCL6 in the tumor tissue (11 lymph node biopsy, 2 bone marrow biopsy, 1 bone marrow biopsy, 3 skin biopsy and 1 cerebrospinal fluid).

Results: The incidence of DHL/THL was 5.5%. The median age was 70 years (range 53-93). The patients included in DHL/THL group had a higher prevalence of MYC and higher IPI (p=0.002). Thirteen patients received anthracyclines containing chemotherapy, 3 cito-reductive treatment and 2 palivatier care. No stem cell transplantation was performed in any patient as a consolidation therapy. Four out of 13 patients achieved complete remission, 3 patients partial response and 6 patients were refractory. At last follow up, 13/18 patients were dead (11 lymphoma progression; 2 infectious complications). Median follow-up 63 months. OS in DHL/THL was 9 months and in DLBCL-noDH/TH was not reached (p=0.001). The PFS in DHL/THL and in DLBCL-noDH/TH was 5.4 and 63 months, respectively (p=0.001) (Figure 1).

EFFECTIVE TREATMENTS ARE REQUIRED FOR PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA WITH PRIMARY REFRACTORY DISEASE

M.Q. Salas 1, D.D. Eva 2, M. Santiago 1, O. Ana 3, C. Aguilerà 1, E. De la Banda 4, F. Climent 5, N. García Muñoz 1, L. Anna 3, F.D.S. Alberto 1, S.B. Anna 2, G.B. Eva 1

1Hematology, ICO-Duran i Reynals, 2Hematology, ICO-Duran i Reynals, 3Hematology, ICO-Duran i Reynals, 4Hematology, 5Pathological anatomy, Hospital Universitario de Bellvitge, 6Oncology Radiation Therapy, ICO-Duran i Reynals, Barcelona, Spain

Background: DLBCL is a heterogeneous disease; it has been described that around 30% of patients present a refractory/relapsing disease following R-CHOP treatment. Rituximab-containing salvage chemotherapy followed by high-dose therapy and autologous stem cell transplant (ASCT) in chemosen- sitive patients remains the standard of care for these patients.

Aims: We aimed to study the clinical features and outcome of patients diag- nosed of DLBCL, homogeneously treated with R-CHOP/RCR-like first line regimen, who have primary refractory disease (PRD).

Methods: Three hundred and sixty-seven patients were diagnosed of DLBCL between January 2004 to August 2016 in our center. 317/367 (86.3%) were treated with R-CHOP or R-CHOP-like in first line. Forty-four (13.9%) patients had PRD and 39 (12.3%) progressed during the follow up. Survival curves were estimated using the Kaplan-Meier method and comparing using the Log-Rank test.

Results: Among the 44 primary refractory patients, 15 (34%), with a median age of 76 years (range 50-90), were considered unfit, 11 received supportive therapy, whereas 28 (64%) achieved a CR. Complete remission (CR) was achieved in 24 (64.3%) patients, PR in 3 (6.3%). The median follow-up time was 5 months (range 0.05-157). The median OS was 4 months (range 0.05-157). The overall survival was 24% at 3 years. The causes of death were: progression 10 (34.4%) for progression. The intention-to-treat response rate was: CR 1 (3.5%), PR 4 (13.8%), refractory disease/progression 22 (65.5%). Stem cell mobilization and the proportion of patients achieving a total PBSC yield of ≥2×10^6/kg were 100%, and the median PBSC yield was 10 x 10^6/kg (range 3-20×10^6/kg). The median time to stem cell harvest was 17 days (range 14-19). The median number of apheresis to achieve the PBSC target was 1 and only 1 patient (10%) required a second collection protocol. Pleiexar was not used. 80% of patients underwent high dose chemotherapy according to BEAM protocol (Fotemustine 150 mg/mq on days -7, -6, Etoposide 200 mg/mq) and platelet recovery (ANC >500/mmc, Plts >50,000/mmc) was 11 and 26 days respectively. 90% had a stage IV disease; MIPI score was high in one patient (10%), intermediate in 5 patients (50%) and low in 4 patients (40%). Stem cell harvest was performed after 2 cycles. Successful mobilization was defined as achieving the physician-determined target PBSC yield which was CD34+ cells ≥ 2 x 10^6/Kg. The G-CSF (Lenograstim) infusion started per protocol at day 6 at the dose of 5 μg/kg.

Results: All patients completed the scheduled treatment (4 cycles). The ORR was 90%. CR 30% and PD 10% (1 patient). Overall, the rates of successful mobilization and the proportion of patients achieving a total PBSC yield of ≥2×10^6/kg were 100%, and the median PBSC yield was 10 x 10^6/kg (range 3-20×10^6/kg). The median time to stem cell harvest was 17 days (range 14-19). The median number of apheresis to achieve the PBSC target was 1 and only 1 patient (10%) required a second collection procedure. Pleiexar was not used. 80% of patients underwent high dose chemotherapy according to BEAM protocol (Fotemustine 150 mg/mq on days -7, -6, Etoposide 200 mg/mq) and platelet recovery (ANC >500/mmc, Plts >50,000/mmc) was 11 and 26 days respectively. 90% had a stage IV disease; MIPI score was high in one patient (10%), intermediate in 5 patients (50%) and low in 4 patients (40%). Stem cell harvest was performed after 2 cycles. Successful mobilization was defined as achieving the physician-determined target PBSC yield which was CD34+ cells ≥ 2 x 10^6/Kg. The G-CSF (Lenograstim) infusion started per protocol at day 6 at the dose of 5 μg/kg.

Summary/Conclusions: In our institution is consistent with the literature. 2)The most common regimen used in double or triple hit patients was anthracycline-containing chemotherapy achieving more than 50% of overall responses in our series. Nevertheless, the majority of patients relapse, showing a short PFS and worse outcome than DLBCL without double or triple hit, as reported previously.

RITUXUMAB BENDAMUSTINE CYTARABINE IS A FEASIBLE AND SAFE INDUCTION REGIMEN PRIOR TO ASCT IN FRONTAL MCL: A SINGLE CENTER RETROSPECTIVE REAL LIFE EVALUATION

I. Gianesello 1, M. Nabergoj 1, A. Branca 1, T. Berno 1, F. Lessi 1, M. Riva 1, E. De March 1, R. Yambo 1, L. Trentin 1, F. Piazza 1, G. Semenzato 1

1Hematology, Hematology and Clinical Immunology section, University of Padua, Padua, Italy

Background: Mantle cell lymphoma (MCL) is an uncommon, still incurable subtype of non-Hodgkin lymphoma. The routine use of high dose Cytabrine and high dose chemotherapy followed by autologous stem cell transplant (ASCT) markedly improved the outcome and has become the standard treat- ment for fit, young (<65 years) patients. Recent studies have demonstrated that Rituximab, Bendamustine and Cytabrine (RBAC) combination has a remarkable activity with a favorable safety profile both in untreated and relapsed/refractory elderly MCL patients (Visco et al., 2013 and 2017). These studies suggested that RBAC combination (with Cytabrine 800 mg/mq) is safe and effective as a CD34+ cells mobilizing regimen. We report here a multicenter retrospective study of 41 MCL patients treated with RBAC and Cytabrine 500 mg/mq as mobilizing regimen in transplant-eligible patients.

Aims: To assess the efficacy and safety of RBAC as induction therapy and as a peripheral blood progenitor cell mobilization therapy in combination with gran- uocyte colony stimulating factor (Lenograstim) in newly diagnosed transplant-eligible mantle cell lymphoma patients.

Methods: From November 2009 to March 2016, 10 newly diagnosed MCL patients (median age 65 years; range 55-72) were treated as induction therapy to RBAC according to RBAC protocol (Fotemustine 375 mg/mq day 1, Bendamustine 70 mg/mq day 2-3, Cytabrine 500 mg/mq day 2-3-4 for 4 cycles). 90% had a stage IV disease; MIPI score was high in one patient (10%), intermediate in 5 patients (50%) and low in 4 patients (40%). Stem cell harvest was performed after 2 cycles. Successful mobilization was defined as achieving the physician-determined target PBSC yield which was CD34+ cells ≥ 2 x 10^6/Kg. The G-CSF (Lenograstim) infusion started per protocol at day 6 at the dose of 5 μg/kg.

Results: All patients completed the scheduled treatment (4 cycles). The ORR was 90%. CR 30% and PD 10% (1 patient). Overall, the rates of successful mobilization and the proportion of patients achieving a total PBSC yield of ≥2×10^6/kg were 100%, and the median PBSC yield was 10 x 10^6/kg (range 3-20×10^6/kg). The median time to stem cell harvest was 17 days (range 14-19). The median number of apheresis to achieve the PBSC target was 1 and only 1 patient (10%) required a second collection procedure. Pleiexar was not used. 80% of patients underwent high dose chemotherapy according to BEAM protocol (Fotemustine 150 mg/mq on days -7, -6, Etoposide 200 mg/mq) and Cytabrine 400 mg/mq on days -5, -4, -3, -2 and Melphalan 140 mg/mq on day -1 with infusion of at least 5 x 10^6/kg of PBSC. The median day for neutrophils and platelet recovery (ANC >500/mmc, Plts >50,000/mmc) was 11 and 26 days respectively. There was no engraftment failure. Most frequent adverse events (according to CTCAE grading) during therapy were hematological: neutropenia (100%, all 3-4), thrombocytopenia (100%, 60% G3-4), anemia (100%, 50% G3-4). Among non hematological toxicities, 20% of patients had febrile neutropenia (G3-4), 20% mucositis (G1-2), 20% lung infec- tions (G3), 10% hyperglycemia (G3). After a median follow up of 43 months the OS and PFS were 90% and 80% respectively.

Summary/Conclusions: As in the relapsed/refractory setting and in MCL patients ineligible for high dose chemotherapy, RBAC has been proven to be an efficacious induction and mobilization regimen also in transplant-eligible MCL patients with an encouraging safety profile. Further investigations are needed to assess the optimal role of RBAC within the standard first line treatments.

THE SAFETY OF LIPOSOMAL CYTARABINE IN CENTRAL NERVOUS SYSTEM INFILTRATION BY HAEMATOLOGICAL MALIGNANCIES

P. García-Ramírez 1, D.P. Millacoy 1, T. Galicia 1, M. C. Mateos 1, P. García-Ramírez 1,*, D.P. Millacoy 1, T. Galicia 1, M. C. Mateos 1

1Hematology, Complejo Hospitario de Navarra, Pamplona, Spain

Background: Central nervous system (CNS) involvement, both leptomeningeal and parenchymatous conveys a poor prognosis in haematological malignancies. As well as systemic chemotherapy that crosses hematopoietic barrier, intrathecal (IT) chemotherapy has become an attractive approach because of direct action in the cerebrospinal fluid (CSF). Liposomal cytarabine (Depocyt®) is an acceptable formulation that maintains cytotoxic concentrations of cytarabine in CSF for an extended period of time (>14 days). This permits to decrease the frequency of lumbar punctures, without losing efficacy and minimizing the patient’s discomfort.
Aims: The objective of this retrospective, observational study is to evaluate the efficacy and safety of liposomal cytarabine in patients with CNS infiltration by haematological malignancies.

Methods: 36 consecutive patients with haematological disease and risk of CNS infiltration underwent flow cytometry (FC) analysis of CSF in a single center from December 2014 to December 2016. CNS involvement was assessed by interim PET-CT scan, CSF flow-cytometry analysis, MRA or IT MRI imaging. Along with systemic therapy, all patients considered positive were treated 50 mg of IT Liposomal cytarabine administered by lumbar puncture every 2 weeks for 4 doses and every 4 weeks thereafter. Concomitant dexamethasone for arachnoiditis prophylaxis was added both i.v. and IT. We analysed the rate of adverse events (AE) and the time for CSF clearance. Short follow up precluded assessment of cumulative incidence of CNS relapse/progression.

Results: Data from 36 patients were analysed. A total of nine patients were considered to have CSF involvement, all of them detected by FC. Of note, all of them were considered negative for CSF infiltration by standard cytology. Three additional patients had clinical suspicion of CNS involvement as per MRI imaging. Treatment was administered for 1-11 cycles (range: 1-5 cycles). The overall response rate was 50% on interim PET-CT scan/staging CT scan. The progression-free survival (PFS) from completion of treatment. Secondary end point was achievement of a complete response (CR) or partial response (PR). The median overall survival of patients (8 out of 12 patients) is 4.5 months (range: 2-14 months).

Conclusions: DLBCL treated with less than 6 cycles of full dose R-CHOP or R-GCVP chemotherapy may achieve sustained long-term remission in selected patients with high IPI and significant co-morbidity. Further research on disease characterizations including molecular profile is needed to elucidate selected populations who may achieve long-term remission with shorter cycles of chemotherapy. Further insights may derive, for example, from analysis of poly-morphism of folate pathway genes and/or of NF-kB, which have been previously suggested as pharmaco-genomic targets in lymphoid neoplasms. A risk stratification model needs to be developed to reduce drug toxicity and other short and long term treatment related complications so as to improve patient experience, and pharma-economic benefits.

MULTIPLE NEOPLASMS CONSIST OF SOLID CANCER AND NON-HODGKIN LYMPHOMA
K. Natori1,*, D. Nagase1, S. Ishihara1, A. Shiibuya1, Y. Mitsui1, Y. Kuraishi1, H. Izumi1
1Haematology and Oncology, Toho University Medical Center, Oota city, Japan

Background: Malignant lymphoma is a ninth cause of death in Japan. And non-Hodgkin lymphoma (NHL) occupied more than 90%. We experienced cases of multiple neoplasms including malign lymphoma. In 190 cases, NHL case were 176 cases. The examination factors are type of the hematological malignancy, gender, the age at onset of the first cancer, interval with the second cancer, treatment strategy. The definition of multiple neoplasms followed Warren & Gates theory. And as for the duration, synchronous type is diagnosis into 6 months, metachronous type interval is more than 6 months. About statistical examination, we used SPSS statistics ver21.

Results: All cases are 176 cases, consist of male 108 cases, female 68 cases, synchronous type 45 cases, metachronous type 131 cases. Double neoplasms 149 cases, triple neoplasms 25 cases, quadple neoplasms 2 cases. The median age was 77 years (ranged51-93yrs), the synchronous type 70yrs(ranged 51-88yrs), the metachronous type was 73yrs(ranged 57-93yrs). The counterpart of malignancies, Hodgkin’s lymphoma 1 case, myelodysplastic syndrome 3 cases, acute myeloid leukemia 8 cases, multiple myeloma 4 cases, gastric cancer 36 cases, colon cancer 32 cases, lung cancer 26 cases, renal cell carcinoma 6 cases, prostate cancer 12 cases, breast cancer 14 cases, urinary bladder cancer 5 cases, uterin cancer 7 cases, esophangal cancer 9 cases, hepaticocar carcinoma 12 cases. In double neoplasms was 149 cases, metachronous type was 112 cases. The median age of first diagnosis, 68yrs(ranged43-85yrs), the second cancer were 74yrs(ranged57-89yrs). About interval between solid cancer and NHL, median interval time was 58M, solid cancer preceded case was 53 cases, interval was 81M (ranged 7-564M), hematological malignancy preceded case was 59 cases interval was 55M (ranged 8-364M). The cause of death was that 15 cases were solid cancer, 72 cases were hematological malignancy and 6 cases were accident. The median overall survival was 18M (ranged 1-1211M), synchronous type 14M (ranged 2-132M), metachronous type 22M (ranged 1-116M).

Summary/Conclusions: In the case of a double cancer including solid cancer and NHL, the first cancer occurs in elderly. Diagnosis of malignant neoplasms is usually difficult. We think that a prognosis is necessary to discover at the early stage. So it could be a lot of treatment options formalnagn malignant neoplasms. We think that a prognosis is improved.

PB1732
RETROPECTIVE EVALUATION ON Efficacy AND Feasibility OF R-CODOX-M/IVAC Regimen in Aggressive DLBCL
E. Covillio1,*, P. Minetto1, F. Guolo1, D. Guardo1, M. Gambella1, F. Ballerini1, R. M. Lemoli1, M. Gobb1
1Haematology, IRCCS San Martino, Genova, Genova, Italy

Background: Diffuse Large B Cell Lymphoma (DLBCL) is an heterogeneous group of diseases. The aggressive behavior can be predicted by clinical risk scores, immunohistochemistry and cytogenetic. Among DLBCL, double hit lym-
phomas (DHL) and double or triple-protein-expression lymphomas (DPLs, TPLs) display a worse outcome. R-CHOP, which is the frontline treatment for DLBCL, showed a poor outcome in high risk IPI patients and DHLs or DPLs. From January 2011 in our centre (IRCCS AOI San Martino Hospital–IST, Genoa, Italy) R-CODOX-M/IVAC regimen has been adopted as first line in patients with aggressive DLBCL, defined by at least one among these features: high central burden, DPLs, IPI score >3 or by the presence of at least 1 extranodal site.

Aims: Our aim was to define the efficacy and feasibility of this frontline strategy and eventually identify the subgroups of patients who may benefit from this approach.

Methods: We retrospectively analyzed 20 patients affected by aggressive DLBCL treated with R-CODOX-M/IVAC. R-CODOX-M consists of rituximab 375 mg/sqm day 1, cyclophosphamide 800 mg/sqm day 1, 200 mg day 2-5, doxorubicin 40 mg/sqm day 1, vinristine 1.4 mg/sqm, methyltrexate 6700 mg/sqm. IVAC-R contains rituximab 375 mg/sqm, ifosfamide 1500 mg/sqm day 1, etoposide 300 mg/sqm day 1-3, cytarabine 1000 mg/sqm by bid days 1-5. In both cycles CNS prophylaxis was administered. According to Ann Arbor classification, 11 patients were on stage IV, 1 on stage III, 3 in stage II and 5 in stage I. Twelve patients had B symptoms. Median IPI score was 3. Eleven patients had DPLs and 4 of them had TPLs. Overall survival (OS) was calculated from the time of diagnosis to the time of death or last follow-up.

Results: After a median follow-up of 28 months, 5 patients died (25%), OS at six and twelve months was 89,4 and 70,4%, respectively, median not reached (NR), Complete remission was achieved in 11 patients (59%), partial remission in 2 patients (13%). The overall response rate was 83%. Three patients (18%) were primary refractory. In the remaining 33 patients OS was a median twelve months was 88,9 and 64,8%, respectively, not significantly lower than non DPLs patients (p≤s., median NR). In patients with Ann Arbor stage III or IV, OS at six and twelve months was 90,9 and 60,6% (median NR). In IPI score >3, OS at six and twelve months was 78,6 and 45% (median 12 months). The main toxicity during CODOM was grade >2 mucositis, 63% of patients. Infections occurred in 71% of patients. Renal and liver toxicity was mainly of low grade and was observed respectively in 38% and 50% of patients. Median severe neutropenia was 4.5 days (range 0-16) and median severe thrombocytopenia was only 1 day (range 0-21). Most patients (56%) needed transfusion support. In IVAC regimen patients suffered of the hematological toxicities: with 7 days of median duration of severe neutropenia (range 3-10), and 7 days (range 6-23) of thrombocytopenia. Seventy-five patients required transfusion support. Infections occurred in 42% of patients. We observed few case of grade >2 mucositis (17%), renal toxicity (8%) and liver toxicity (17%).

Summary/Conclusions: R-CODOX-M/IVAC is a generally well tolerated regimen, with acceptable toxicity profile in the setting of aggressive DLBCL. Results in our cohort suggest a potential benefit for DPLs, whereas higher IPI scores retains a negative prognostic impact. The next step of the study will be retrospective FISH evaluation of C-MYC, BCL2 and BCL6 translocations, for lacking patients in our cohort, in order to disclose a potential benefit for double or triple hit lymphomas.

STOMACH DIFFUSE LARGE B-CELL LYMPHOMA: A SINGLE CENTER EXPERIENCE
M.-T. Sung1,*, L.-W. Chiou1, S.-N. Huang2, A.-C. Feng2, M.-C. Wu1, P.-Y. Chen1, C. Hsiao-Hsiang1, T.-D. Tan1
1Department of Hematology and Medical Oncology, 2Office of Epidemiology and Biostatistics, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, Taiwan, Republic of China

Background: Primary gastric diffuse large B cell lymphoma is a rare relative type of diffuse large B cell lymphoma. Immunochemotherapy followed by consolidation radiation is the standard of care. However, the role of chemotherapy and the role of consolidation radiation are still under debate.

Aims: To review and analyze the treatment experience of newly diagnosed primary gastric diffuse large B cell lymphoma. We presented the treatment outcome of our institution.

Methods: We retrospectively reviewed medical records from Jan 2005 to Dec 2014 from our institution. 30 patients with primary gastric diffuse large B cell lymphoma were included. Clinical characteristics, treatment regimens, treatment response, treatment modality, and survival were analyzed.

Results: From Jan 2005 to Dec 2014, there were 30 patients with primary gastric diffuse large B cell lymphoma. Median age was 65 years of age, 53% (n=16) of patients were male. All 30 patients (100%) have received chemotherapy. 13 of them (43%) have received involved field radiation therapy(IFRT). RCHOP or RCEOP was administered in 86% (n=26) of patients. Complete response rate was 86% (n=24), 5-year survival was 69%. In patients who achieved complete response, median survival for 4 cycles of chemotherapy was 88% vs 86% (p=0.42), respectively. For IFRT in CR patients, 5-year survival for IFRT vs no IFRT were 83% vs 90% (p=0.93), respectively. Treatment-related mortality (TRM) was 10% (n=3) and primary refractory disease was 10% (n=3). All of them are non-CR patients. Gastrointestinal bleeding which required admission occurred in 10% (n=3) of patients. In patients who developed GI bleeding, 2 of them were non-CR patients and they all died. No patient died of disease relapse after complete response.

Summary/Conclusions: In our series, the 5-year survival was good. In patients who achieved CR, cycles of chemotherapy and consolidation radiation did not make significant difference to the survival. Prevention of early mortality may improve the outcome of this disease. Gastrointestinal bleeding in treatment is rare but with high mortality.

PB1735
IMMUNOHISTOCHEMISTRY BIOMARKERS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: A RETROSPECTIVE STUDY T. Mendes1,*, F. Mousinho1, P. Sousa E Santos1, E. Viegas2, A. P. Gomes1, F. Falcão2, F. Lima1
1Clinical Hematology, 2Pharmacy Department, Phacutaly of Pharmacy, Centro Hospitalar e Universitario de Lisboa Ocidental, Phacutaly of Pharmacy,University of Lisbon, Hospital de São Francisco Xavier, Centro Hospitalar de Lisboa Ocidental, Lisboa, Portugal

Background: Diffuse Large B-Cell Lymphoma (DLBCL) is a heterogeneous disease with variable clinical characteristics. The International Prognostic Index (IPI) is the most important tool to identify subgroups with different survival, however, certain biological markers seem to have a prognostic value relevant and independent of IPI.
Aims: To analyze the evolution of patients diagnosed with DLBCL and the expression of BCL2, BCL6 and MYC.

Methods: We conducted a retrospective study that included hospitalized patients with de novo CD20+ DLBCL, with expression of BCL2+, BCL6+, BCL2/BCL6, MYC/BCL2, MYC/BCL6 treated with regimens containing rituximab, from February 2012 to November 2016. Samples were analyzed by immunohistochemistry. Statistical analysis with the SPSS V17.0 program.

Results: We included 43 patients with a median age of 65 years (22-97), 59.5% male, 45.2% had IPI 0-2, 54.8% had IPI 3-5, 26.2% stage I, 73.8% stage III-IV, 61.9% had extranodal disease and 23.8% bulky disease. Ki-67 was elevated in all patients who did this evaluation (n=28). In 13 patients was identified BCL2/BCL6+ in 6, and 21 patients had co-expression of BCL2/BCL6, 1 patient had MYC/BCL2 and 1 had MYC/BCL6. The R-CHOP regimen was first line treatment in 92.8% of patients. The ORR was 82.5%, with 65% of CR, 15% PR and 17.5% PD. Of those patients who received second line treatment, 8 expressed BCL2/BCL6, 4 BCL2, 2 BCL6, 1 MYC/BCL2, and 1 MYC/BCL6. Of these patients, 7 received third line treatment. The average time to next treatment (TNT) was 5.2 months (0.5-19) for second line and 4.9 for third line. Mortality rate was 45.2%. With a median follow up of 18.6 months (3-58.6), the overall survival was 24.6 months (3-62).

Summary/Conclusions: The identification of biomarkers by immunohistochemistry is a relatively inexpensive process, which, when well elaborated and interpreted, allows to find in a safe way, subgroups of patients at high risk, who benefit from more aggressive 1st line therapy and, whenever possible, from the Inclusion in clinical trials with new drugs.

PB1736

INVESTIGATION ON TREATMENT STRATEGY, PROGNOSTIC FACTORS, AND RISK FACTORS FOR EARLY DEATH IN ELDERLY TAIWANESE PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

S.-F. Cho1, Y.-C. Liu1, H.-H. Hsiao1, Y.-F. Tsai1, H.-C. Wang1, T.-C. Liu1

1Division of Hematology and Oncology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung City, Taiwan, Kaohsiung City, Taiwan, Republic of China

Background: Given that the population of elderly cancer patients, including those with diffuse large B-cell lymphoma(DLBCL), is increasing, the management of cancer in the elderly has emerged as an increasingly common problem.

Aims: This study aimed to investigate the treatment strategy, prognostic factors, and risk factors of early death in elderly patients (age ≥65 years) with DLBCL in the rituximab era.

Methods: Elderly patients diagnosed with DLBCL between 2008 and 2014 were enrolled for analysis.

Results: There were 145 elderly patients with DLBCL diagnosed between 2008 and 2014. After excluding patients with primary central nervous system DLBCL (n=9) and incomplete data (n=3), a total of 133 patients (64 male and 69 female) with a median age of 74 years (range 65 to 94 years) were enrolled in the present study. Patients at a younger age and with better performance status were more likely to receive intensive frontline treatment. The median progression-free survival (PFS) and overall survival were 15 and 21 months, respectively. Anthracycline-containing chemotherapy achieved a higher remission rate and showed a trend toward better overall survival at the expense of a higher risk of severe neutropenia. Multivariate analysis revealed that very old age (≥81 years), a higher risk of severe neutropenia. Multivariate analysis revealed that very old age (≥81 years), a high-risk age-adjusted international prognostic index (aaIPI) score, and bone marrow involvement were associated with poorer PFS and overall survival. Progression of lymphoma was the major cause of death in the study population. In addition, approximately 25% of patients died within 120 days of their diagnosis. The risk factors for early mortality included very old age, a high-risk aaIPI score, and bone marrow involvement. The appearance of symptoms or signs of tumor lysis syndrome at diagnosis was associated with a trend toward early death.

Summary/Conclusions: Treatment of elderly patients with DLBCL remains a challenge and comprehensive co-evaluation to tailor therapeutic interventions and offer the best supportive care may reduce complications and improve the clinical outcome of these patients.

PB1737

TREATMENT OUTCOME OF MONOMORPHIC EPITHELIOPTROPIC INTestinal T-cell lymphoma: EXPERIENCE FROM AN ASIAN CANCer Center

M.-T. Sung1, M.-Y. Lee2, M.-C. Wu1, T.-D. Tan1

1Department of Hematology and Medical Oncology, 2Department of Pathology and Laboratory Medicine, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, Taiwan, Republic of China

Background: Monomorphic epitheliotropic intestinal T-cell lymphoma (MEITL), previously type II enteropathy-associated T-cell lymphoma(EATL), primarily occurred in Asian countries. It is refractory to chemotherapy and the prognosis is poor. Intensive chemotherapy has been proposed to improve treatment outcomes.

Aims: We examined the treatment outcome of MEITL in our institution.

Methods: We retrospectively searched our institutional database from 1996 to 2014 for intestinal T-cell lymphoma. Medical records were reviewed and the patients were classified on the basis of WHO-2016 classification. Patient’s characteristics, treatment modalities, response and survival were collected and analyzed.

Results: Ten patients with intestinal T-cell lymphoma were identified. One patient had enteropathy-associated T-cell lymphoma (EATL) presenting with celiac sprue. Five patients had intestinal T-cell lymphoma, NOS. Four patients were diagnosed (previously type II enteropathy-associated intestinal T-cell lymphoma (MEITL). For patients with MEITL, median overall survival was 7.9 months (4.2-15.0 months). Median age was 46 years of age. Bowel perforation was the initial presentation in 3 patients (3/4, 75%). One patient was treated with chemotherapy with CHOP regimen, while another patient underwent surgery alone. The remaining two patients were treated with chemotherapy followed by chemoradiotherapy with MEITL (one with CHOP, the other with BFM-90 protocol). Only one patient (1/4, 25%) entered complete response. Of concern, the unique patient achieved complete response received surgery followed by chemotherapy with Berlin-Frankfurt-Munster(BFM)-90 protocol. Remission duration was 10.3 months. He passed away 15.0 months after remission because of relapsed lymphoma.

Summary/Conclusions: Though the prognosis of MEITL is poor, operation followed by high dose chemotherapy such as BFM-90 protocol may have better treatment response, response duration and survival. It deserves further investigation.
Figure 1.

Summary/Conclusions: Our findings demonstrate that approximately half of the cases evaluated express OPN at diagnosis and tend to have a lower survival rate, however, a longer follow-up time is needed, as well as other studies that discriminate between different isoforms or post-translational modifications of osteopontin to determine if this trend can reach significance. By demonstrating OPN expression by neoplastic cells we can devise new protocols that evaluate its usefulness as a surrogate marker of tumoral activity in DLBCL using non-invasive techniques (e.g., quantification of serum levels), which would improve surveillance of these patients.

PB1739

TREATMENT OF NEWLY DIAGNOSED CENTRAL NERVOUS SYSTEM LYMPHOMA PATIENTS BASED ON COMORBITIES & PERFORMANCE STATUS: A SINGLE-CENTRE EXPERIENCE

Y.J. Lim1,*, J. Smith1

1Haematology, Aintree University Hospitals NHS Foundation Trust, Liverpool, United Kingdom

Background: Combination chemotherapy incorporating high dose methotrexate (HD-Mtx) and high dose cytarabine (Ara-C) is the standard chemotherapeutic approach for newly diagnosed primary CNS lymphoma (PCNSL). However, patients >60 years old account for 50% of cases and combining HD-Mtx with Ara-C can be associated with high toxicity and early mortality. The management of secondary CNS lymphoma (SCNSL) is less clear, but is often based upon a similar approach.

Aims: We present a tertiary centre experience in management of primary (PCNSL) and secondary CNS lymphoma (SCNSL), with therapy based on co-morbidities and performance status.

Methods: We performed a retrospective analysis of patients with a diagnosis of CNS lymphoma seen at our centre between 2011 and 2016. These were categorized into 3 groups, Group 1: treatment of newly diagnosed PCNSL prior to September 2014 where majority of patients received HD-Mtx & Ara-C combination chemotherapy, Group 2: treatment of PCNSL after September 2014 where majority of patients received HD-Mtx & Ara-C, 3 pts (23%) received radiotherapy only. In group 3 15 pts (88.3%) received chemotherapy incorporating HD-Mtx and Ara-C, 2 pts (11.8%) received HD-Mtx without Ara-C. 30 day mortality was only. In group 3 15 pts (88.3%) received chemotherapy incorporating HD-Mtx or with single agent rituximab, 1 pt (7.7%) received a single alkylating agent and 1 pt (7.7%) received radiotherapy only. In group 3 15 pts (88.3%) received chemotherapy incorporating HD-Mtx and Ara-C, 2 pts (11.8%) received HD-Mtx without Ara-C. 30 day mortality was 7 (28%) in group 1 and 0 in group 2 (0%) (p=0.03). 90 day mortality was 7 (28%) in group 1 and 2 in group 2 (15.4%) (p=0.39). Overall response rate was 9 (36%) in group 1 and 8 (61.5%) in group 2 (p= 0.13). A Kaplan Meier curve of all 3 groups is illustrated in Figure 1 below.

Figure 1.

Summary/Conclusions: This single centre study demonstrated that patient selection based upon comorbidities and performance status, for high dose combination chemotherapy in the treatment of PCNSL improves 30 day mortality, often associated with death from myelosuppression due to chemotherapy. The overall response rate, with appropriate selection of combination chemotherapy regimen, was improved. This also applies to patients with SCNSL in the subgroup analysis. Longer follow up of patients will be needed to further demonstrate an overall survival benefit.

PB1740

AN AUDIT OF THE USE OF RASBURICASE FOR THE PREVENTION AND TREATMENT OF TUMOUR LYSIS SYNDROME IN PATIENTS RECEIVING TREATMENT AT THE NORTHERN CENTRE FOR CANCER CARE, NEWCASTLE UPON TYNE, UK

E. Watts1,*, S. Gabrielle1, G. Jones1, R. Clark2, S. Holmes1

1Haematology, 2Renal Medicine, Freeman Hospital, Newcastle Upon Tyne, Newcastle upon Tyne, United Kingdom

Background: Tumour Lysis Syndrome (TLS) is a known complication of haematopoietic treatment. Although clinical TLS is rare, the consequences are significant, with one third of affected patients requiring dialysis and an overall mortality rate of around 15%1,2. A new British Society for Haematology (BSH) guideline was published in April 2015 to guide physicians on how to risk stratify patients based upon the Cairo Risk Stratification20103, choice of prophylaxis, and treatment of established TLS4. We audited all patients who received rasburicase at the Northern Centre for Cancer Care from 16th April 2015 to 3rd February 2016, and compared their management with BSH guidelines4.

Aims: To compare our practice with BSH guidelines.

Methods: Retrospective review of electronic patient prescription records, biochemistry results, and paper notes.

Results: 27 patients received rasburicase in the study period. 20 patients met Cairo criteria/BSH criteria as having High Risk Disease (HRD) or Intermediate Risk Disease(IRD)/Low Risk Disease (LRD) with renal impairment, and therefore should have received 3mg rasburicase prophylaxis if no evidence of TLS according to the guideline. Of those 20, 11 had laboratory TLS, and therefore BSH guidelines would recommend 0.2mg/kg/day [G1] rasburicase, however only 3/11 were given the drug at treatment doses. 1/3 had clinical TLS at presentation and received treatment according to the guideline. The 2 other patients received larger doses of rasburicase but less than the BSH would recommend. A further 7 patients with IRD received rasburicase prophylaxis but on review did not meet the criteria for rasburicase as set out in the guidelines. 5 patients died during the study period. 2 patients died on ITU of multi-organ failure ≤7 days into chemotherapy. A third patient died of sepsis, and the other 2 deaths were in deteriorating patients where a decision was made to palliate.

Summary/Conclusions: When assessed against BSH standards, all patients in this cohort who should have received rasburicase prophylaxis, were given the drug. 2 patients with lab TLS developed clinical TLS. 8 others with lab TLS received lower doses than the BSH would recommend, but did not progress to clinical TLS. Although there were 5 deaths in our cohort, none were directly attributable to TLS. In order to comply with the guidelines, particular importance must be placed on formally assessing the TLS risk score as per Cairo.
criteria at the outset and analyzing the possible features of laboratory TLS. Although dosing did not always follow BSH guidelines, we did respond to biochemical deterioration. The majority of patients with HD developed acute kidney injury despite rasburicase. Doses were increased in response to creatinine increases, albeit not as per guideline. It is notable that despite lower than the recommended doses of rasburicase, 6/8 patients with lab TLS did not progress to clinical TLS, and none required dialysis. The guideline is a good tool for the risk stratification and treatment of patients at risk of TLS. In clinical practice 100% compliance is hard to achieve. Responding to trends in creatinine may explain why, despite lower than recommended doses, our outcomes were still good. It would be interesting to see if further work with larger numbers of patients would support this. Since this audit was completed, the ePrescribing system has been altered to improve practice and a re-audit is planned.

PB1742
PROGNOSTIC IMPACT OF SYNCHRONOUS MULTIPLE PRIMARY MALIGNANT TUMORS ON NEWLY DIAGNOSED LYMPHOMA PATIENTS
S. Nishiwaki1,2,*, S. Okuno1, K. Suzuki1, S. Kurashishi1, I. Sugura1
1Division of Hematology and Oncology, Toyohashi Municipal Hospital, Toyohashi, 2Center for Advanced Medicine and Clinical Research, Nagoya University Hospital, Nagoya, Japan
Background: Synchronous multiple primary malignant tumors (sMPMTs) are occasionally diagnosed during screening for a newly diagnosed malignant neoplasm. Lymphoma is one of the most common hematological malignancies, and number of lymphoma patients with sMPMTs seems to grow as the population ages. Since the standard chemotherapy for lymphoma takes a few months, treatment strategy sometimes comes to an issue. At this time, the monitoring period is not completed, so the data related to those patients in whom the vitamin deficit persisted despite the treatment. Thus, we explored the impact of vitamin D levels in the treatment of lymphoma, we investigated prognostic significance of sMPMTs and suitable treatment strategy for a newly diagnosed lymphoma with sMPMTs.
Methods: We retrospectively analyzed patients with malignant lymphoma newly diagnosed between 2009 and 2015. The definition of sMPMTs was patients who were also diagnosed as a solid tumor within 6 months of the diagnosis of lymphoma. Therapeutic strategy was based on the patient's choice. Impact of sMPMTs on treatment outcome of lymphoma was analyzed. Also, relation between treatment of lymphoma and concomitant solid tumors was closely analyzed.
Results: Total of 505 lymphoma patients was included. Median age was 69 (range:20-99). The most common distribution was diffuse large B-cell lymphoma (63%), and patients with aggressive lymphoma accounted for 77% (391/505). High risk disease, which was defined as international prognostic score 3 or higher, accounted for 36% (184/505). sMPMTs were identified in 16 patients (3%). There was no difference of distribution between patients with and without sMPMTs regarding age, grade of lymphoma, and disease risk. The overall survival (OS) and disease-free survival (DFS) were significantly different between the two groups (with sMPMTs: 53% and 47% vs without sMPMTs: 77% and 61% at 3 years, P=0.20 and P=0.31). Cumulative incidence of lymphoma relapse was similar between the two groups (with sMPMTs 29% vs without sMPMTs 27% at 3 years, P=0.28). In multivariate analyses, age (75 years<) and disease risk (high) were identified significant risk factors for OS, and age was an only significant risk factor for DFS. Existence of sMPMTs was not a significant risk factor for either OS or DFS (OS: HR 1.29, 95%CI 0.52-3.20; P=0.58; DFS: HR 1.06, 95%CI 0.49-2.27, P=0.88). Among 16 patients with sMPMTs, half of the patients had high-risk lymphoma, and half of the solid tumors were gastric cancer. Treatment was initiated for the disease which was diagnosed earlier in all patients except one. Interval from diagnosis to the first treatment was significantly shorter in patients whose lymphoma was treated earlier (median 11 days vs 38.5 days, P=0.004). OS was not significantly different according to the sequencing of treatment (lymphoma earlier: 59% vs Solid tumor earlier: 40% at 3 years, P=0.84). In 8 of 10 patients whose lymphoma was treated earlier, treatment of lymphoma was interrupted for the treatment of a solid tumor. Interruption of treatment had no significant effect on OS (interuption+: 60% vs interruption-: 50% at 3 years, P=0.13).
Summary/Conclusions: Existence of sMPMTs was not a significant risk factor for newly diagnosed lymphoma patients. It is important to provide adequate treatment for both lymphoma and solid tumor at physician’s discretion.
## Bleeding disorders (congenital and acquired)

**PB1743**

**GLOBAL HEMOSTATIC ASSAY AT DIFFERENT TARGET ACTIVITY OF FACTOR VIII AND FACTOR IX**

K. Yoo

1Korea Hemophilia Foundation, Seoul, Korea, Republic Of

**Background:** Based on reports addressing hemophilia B patients bleed less common and less intensively than hemophilia A, it has been expected that the hemostatic level of factor IX (FIX) activity can be lowered than that of factor VIII (FVIII) activity.

**Aims:** We compared the hemostatic efficacy of the different hemostatic level of FIX and FVIII activity using global hemostatic assay.

**Methods:** A total of 17 severe hemophilia patients without inhibitor, aged more than 15 years old were subjected; 12 hemophilia A patients and 7 hemophilia B patients. Factor concentrates were injected to reach the target activity of 60% in hemophilia A and 40% in hemophilia B which is given by Korean health insurance guideline. All patients were in non-bleeding state and kept the wash-out period of 3 days for hemophilia A and 5 days of hemophilia B. Before and on 15 minutes after injections, we conducted one-stage factor assay, thrombin generation assay (TGA), thromboelastography (TEG) and clot-wave form analysis (CWA).

**Results:** Median ages of hemophilia A and hemophilia B patients were 28 and 33 years old. Baseline FIX:C and FIX:C were 0.6% and 1.8% and they rose after injection rose to 70.8% and 49.6%. The dosage of FVIII concentrates and recombinant FIX concentrates were 28.4 IU/kg and 50.7 IU/kg. In vivo recovery (IVR) in hemophilia A and hemophilia B patients recorded 2.43%/IU/kg and 0.91%/IU/kg. Peak thrombin of FVIII and FIX were 451.3 nM and 376.6 nM (P=0.108, normal range, 458 nM±60). TEG index of FVIII and FIX were -1.60 and -3.77 (P=0.004, normal range, -2.2±2). MIN2 of CWA of FVIII and FIX were 0.62 and 0.59 (P=1.000).

**Summary/Conclusions:** Global hemostatic assay indicates even though IVR of FVIII and FIX are normal, less amount of FIX is insufficient to normalize hemostatic parameters in comparison with FVIII.

**PB1744**

**THE RATE OF SUCCESSFUL IMMUNOTOLERANCE INDUCTION IN HAEMOPHILIA A BOYS TREATED WITH OCTOCOG ALFA - THE EXPERIENCE OF POLISH PAEDIATRIC HAEMOPHILIA CARE CENTRES**

A. Kołtan1,2,*, A. Klukowska3, P. Laguna3, W. Badowska4, W. Balwierz5, G. Karolczyk6, D. Pietrys5, H. Bobrowska5, M. Kostrzewski5, T. Ociepa6, T. Urasinski9, I. Woznica-Karczmarz10,11

1Department of Pediatrics, Hematology and Oncology, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University Torun, 2Antoni Jazzurs University Hospital No 1, Bydgoszcz, 3Department of Pediatrics, Hematology and Oncology, Warsaw Medical University, Warsaw, 4Clinical Department of Hematology and Oncology, Military University of Warsaw, Faculty of Medical Sciences at the University of Warmia and Mazury, Olsztyn, 5Department of Oncology and Hematology, Institute of Pediatrics, Jagiellonian University Medical College, Krakow, 6Onkology and Hematology Unit, Regional Hospital in Kielce, Kielce, 7Department of Pediatrics and Hematology, Children Hospital in Poznan, Poznan, 8Department Pediatric, Onkology and Hematology, Medical University of Lodz, Lodz, 9Department of Pediatric Hematology and Hemoscytology, Pomorski Medical University in Szczecin, Szczecin, 10Department of Pediatric Hematology, Oncology and Transplantology, Lublin Medical University, 11Department of Transfusion Medicine, Childrens University Hospital in Lublin, Lublin, Poland

**Background:** Development of neutralizing anti-factor VIII alloantibodies (inhibitor; INH) is the most challenging complication of haemophilia replacement therapy (HRT). It occurs in up to 30% of severe haemophilia A (HA) patients. Data published recently indicate that immunotolerance induction (ITI) is effective in 62–87% of cases.

**Aims:** To assess the rate of successful ITI in boys with severe HA treated with full length recombinant FVIII (octocog α) in all Polish Paediatric Haemophilia Care Centres between 2011-2016.

**Methods:** From 2011 to 2016 in 6 Polish Paediatric Haemophilia Care Centres 14/88 (15.9%) boys with severe HA on prophylaxis or on demand treatment with octocog α developed INH after 3 - 489 (median 20) exposure days (EDs). Twelve of them (85.7%) were high responders with the peak inhibitor titre (PIT) 2.8 and 3.02BU/ml. All except one boys were Caucasians and -3.77 (P=0.004, normal range, -2~+2). MIN2 of CWA of FVIII and FIX were 0.62 and 0.59 (P=1.000).

**Summary/Conclusions:** Global hemostatic assay indicates even though IVR of FVIII and FIX are normal, less amount of FIX is insufficient to normalize hemostatic parameters in comparison with FVIII.

**OD.** on demand; P, prophylaxis; CVA, central venous access; N, no; Y, yes; mth, month.
dyslipidemia treatment were made upon data from literature and patient’s findings. Multidisciplinary approach in this setting is needed. Bleeding risk is not connected only with platelet count, but also with their function and degree of splenomegaly. Liver function can also be disturbed and can influence hemostasis. Pregnancy in our patient did not cause health state deterioration and there were no clinical findings of Niemann Pick disease in newborn.

PB1746

SINGLE CENTRE FX DEFICIENCY EXPERIENCE
Z. Basilar1,2, S. Sadi3, I. Erdogan1, M.G. Ar1
1Internal medicine- Hematology, Istanbul University, Cerrahpasa Medical Fac-
ulty, istanbul, Turkey

Background: Factor X is a vitamin K–dependent serine protease that works at the crossroads of the extrinsic and intrinsic pathways to cleave prothrombin into thrombin. Inheritance pattern of factor X deficiency is autosomal recessive, with homozygotes patients most often remaining asymptomatic or having only a mild bleeding phenotype. (1) Homozygous individuals may experience haemorrhagic symptoms, including easy bruising, haematuria, soft-tissue haemor-
rhages, haemarthroses, recurrent episiotomy, and menorrhagia (2) Congenital factor X deficiency is among the most rare factor disorders. We present here our experience with patients having congenital factor X deficiency.

Aims: We aimed to present our experience with rare FX deficiency in our centre.

Methods: There are currently 4 patients with factor X deficiency (F/M: 3/1) that are followed at our centre.

Results: First patient is 40 years old man who got his diagnosis at the age of 31 years following a gastrointestinal bleeding. He was treated with fresh frozen plasma (FFP) at that time. His FX was found: %0. Two years later underwent a planned tooth operation under the coverage of prothrombin complex concen-
trate (PCC) (Table 1). Three years after the tooth extraction he underwent an intraocular lens operation under PCC prophylaxis. No complication was observed while on PCC treatement.

Our second patient is a woman who was diagnosed at the age of 3 because of recurring gum bleeding. She has been treated with FFP replacement throughout her childhood and adolescence due to recurring nose and soft tissue bleeds as well as menorrhagia. She was first referred to our hospital at the age of 42 due to soft tissue bleeding. Given the lack of health insurance she mainly received FFP and tranexamic acid tablets during most of her bleed-
ning attacks. However, PCC of 1000 unit for two days had to be used for her excessive vaginal bleeding irrespective to FFP. Her number of annual bleeding is 15-20 times in a year and most of them are gum bleeding and rarely vaginal bleeding. Third and 4th patients were referred to our centre because of pro-
longed the prothrombin time (PT) and the activated partial thromboplastin time (aPTT) and received the diagnosis of FX deficiency.

Summary/Conclusions: Bleeding phenotype differs in a wide range in patients with congenital FX deficiency. Secondary causes including amyloidosis should be excluded especially in patients receiving diagnosis at advanced ages. Usu-
ally the factor level does not correspond to the severity of the bleeding phe-
notype. Therefore bleeding pattern of the patients with FX deficiency should be carefully observed and considered while planning a prophylactic treatment with PCCs to prevent the risk for thrombosis and unnecessary utilisation of PCCs. FFP and PCCs replacement continue to be the source for FX in bleeding patients or in individuals requiring prophylaxis. Recently, a FX concentrate has entered the market in the USA and the European Community.

PB1747

IMPROVEMENT OF THE SURVIVAL FOR LIFE-THREATENING HEMORRHAGE WITH HEMOPHILIA PATIENT
K.S. Lee1, J.Y. Kim2, J.K. Seo2, S.Y. Hyun3
1Kyungpook National University School of Medicine, 2Kyungpook National Uni-
versity Children’s Hospital, Daegu, 3Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea, Republic Of

Background: In life threatening hemorrhage such as brain and abdomen, sev-
eral important factors are affect for improving the survival. One tenth (223) of hemophilia patients in Korea lived in Daegu city and Kyungpook province and have treatment in Daegu treatment center.

Aims: We reviewed the result of life threatening hemorrhage and our unique care of hemophilia patients for 34 years.

Methods: Korea Hemophilia Foundation was established in 1991. After that all factor concentrates were free to all hemophilia patients. Home treatment are executed for rapid administration of factor concentrate of full required amount. Rapid transportation to emergency room are available for immediate operation. Hot line of mobile phone between patient and doctor for 24 hours are available for emergency care. Monthly group education has done. Prophy-
lactic treatment was started to all who had a life threatening hemorrhage history in Daegu since 1996. But HIRA permitted officially since 2011. And then recovery rate test was done for the optimal blood level for life threat-
eining hemophorogous patient. Continuous infusion with every 2 to 4 hours recon-
stitution dilution fluid has been done for preserve in vitro factor activity to all surgery cases.

Results: Thirty five events were intracranial hemorrhage in 17, general surgery in 9 and orthopedic surgery in 9. Age distribution was 0-32 yr (mean: 24.8 y).

Severity was severe (16), moderate (7) and mild (5). Time interval between first symptom and arrival at ER were 15 min to 10 days (mean: 1.7days). We confirmed in vivo factor activity within permissible level in all patients. All recov-
eries from hemorrhage or surgery and are healthy, but one had limping gate and one had mild neurologic sequelae for more than 10 years follow-up period.

Summary/Conclusions: Education, financial support, home and prophylactic treatment, hot-line, individual pharmacokinetik with effective blood level and fresh concentrate during continuous infusion are important factors to improve the survival of surgery case.

PB1748

CAN BLEEDING SCORE AND FACTOR LEVELS DETERMINE HEMOPHILIA CARRIERS?
Y. Ay1,2, A. Çakı1, S. Ökür Acar1, E. Töre3, T. Hilkey Karapınar1, Y. Oymak1, S. Güzen1, C. Vergin1
1Division of Pediatric Hematology, 2Department of Pediatrics , Dr. Behçet Uz Children Disease and Surgery Training and Research Hospital, Izmir, 3Division of Pediatric Hematology, Balíkesir Atațuır State Hospital, Balíkesir, Turkey

Background: Hemophilia A and B are X-linked recessive hemorrhagic disease. Due to this type of inheritance, males are usually affected but, girls are carriers. Factor levels are usually detected around 50% because only one chromosome is affected in carriers. Inconsistently, it has been reported that factor activity can be detected in a wide range of 22% -116% as a result of random inactiva-
tion (lyonization) of one of two X chromosomes. It is specified that factor levels may be very low due to excessive inactivation in a significant part of the hemophila carriers, which creates a risk of bleeding in carriers.

Aims: In this study, we aimed to investigate the role of bleeding score and factor levels in detecting hemophilia carriers.

Methods: Bleeding Assessment Tool (BAT) for hereditary factor deficiencies of the International Society on Thrombosis and Haemostasis (ISTH/SSC) were applied to the mother and sisters of 32 hemophilia patients who were follow-

up in Dr Behçet Uz Children’s Diseases and Surgery Training and Research Hospital. Mothers whose at least one of the other members of the family and their sons had hemophilia, mothers with more than one hemophilic son and girls whose father had hemophilia were evaluated as an obligate carrier. Sisters or mothers who do not meet the obligatory carrier criteria but whose siblings or sons are hemophilic were identified as possible carriers. Factor activity of obligate or probable carriers was studied after their informed consent was obtained.

Results: Thirty-two mothers and 13 sisters of hemophilia patients were includ-
ed in this study. The mean age was 31.6 (4-57) years. Three of the patients were mild, 3 were moderate, 23 were severe hemophilia A; 2 were severe and 1 had moderate hemophilia B. Twelve were obligate and 33 were probable carriers. Only seven in 45 (15.5%) probable and obligate hemophilia carriers had high bleeding scores (≥4). Those with high bleeding scores, three were obligate carriers and four were probable carriers. The mean factor activity of 12 obligate and 18 probable carriers were 78.9% (20.8%>189%). Factor activ-
ities of the three obligate carriers with high bleeding scores were 77%, 80% and 98%, respectively. Factor activities of the three probable carriers with high bleeding scores were 58.8%, 69.3% and 112%, respectively. The median bleeding scores of four probable and one obligate carriers with low factor activity (<60%) were 2.8 (1-4).

Summary/Conclusions: Measurement of factor activity seems to be insuffi-
cient to detect hemophilia carriers. ISTH/SSC-BAT may help to determine the carriers. However, a larger study is needed to understand the diagnostic value of the BAT.

PB1749

FETAL INTRACRANIAL HEMORRHAGE AS A PRESENTING FEATURE OF SEVERE CONGENITAL FACTOR VII DEFICIENCY: THE NEED FOR EARLY PROPHYLAXIS
M. Elshinawy1, A. Airawa2, Y. Wali2
1Pediatric Hematology, SQUH, University of Alexandria, Oman, Egypt, 2Pediatric Hematology, Sultan Qaboos University Hospital, Muscat, Oman

Background: Congenital factor VII (FVII) deficiency is a rare autosomal reces-

702 | haematologica | 2017; 102(s2)
sive bleeding disorder, with an estimated prevalence of 1:300,000. Compared to western countries, rare bleeding disorders (RBDs) are relatively commoner in Oman, owing to high rate of consanguineous marriage.

**Aims:** To discuss an interesting case of severe congenital factor VII deficiency and to explore the need for early prophylaxis.

**Methods:** Case report and retrospective data analysis of all children diagnosed with inherited coagulation factor deficiencies in Pediatric Hematology Unit, Sultan Qaboos University Hospital, Muscat, Oman from January 2009 till December 2016.

**Results:** We report a male full term baby, delivered by cesarean section. His older sister is a known case of severe congenital factor VII deficiency. Antenatal scans of this baby revealed two intracerebral hematomas and dilated cerebral ventricles. Postnatally, the diagnosis of severe congenital FVII deficiency was confirmed. CT scan revealed obstructive hydrocephalus at the level of aqueduct of Sylvius (Figure 1). At day 10 of life, ventriculo-peritoneal shunt has been done successfully under cover of recombinant activated factor VII replacement therapy. Afterwards, the patient has been initiated on rFVIIa prophylaxis at a dose of 30 ug/kg three times weekly. In our center, deficiencies of fibrinogen, FV, FVII, FX and FXIII were diagnosed in 22 pediatric patients (10 males and 12 females), accounting for 11.1% (22/198) of all children with inherited coagulation factor deficiencies. The age ranges from 1 day to 6 years and consanguinity is found in 19/22 cases (86.4%). Hypofibrinogenemia, FV and FVII deficiency are the commonest RBDs, diagnosed in 8, 6 and 5 patients respectively. As an initial presentation, intracranial hemorrhage occurred in 7/22 cases (31.8%). Three patients with FV, FVII and FXIII deficiencies suffered from global developmental delay due to severe intracranial hemorrhage. As regards management, 4 patients with severe FV deficiency and one with severe FXIII deficiency are on fresh frozen plasma (FFP) and recombinant FXIII prophylaxis respectively. Other patients receive on-demand therapy.

**Figure 1.**

**Summary/Conclusions:** Children with RBDs constitute more than one tenth of cases of hereditary coagulation factor deficiencies in our center. They have some unique features in terms of severity, clinical profile and the need for prophylaxis early in life. We recommend establishing a national/regional registry of RBDs to identify the magnitude and the peculiar genotype-phenotype correlations of such rare, yet significant disorders.

**PB1750**

**THE ASSOCIATION OF BLOOD TYPE WITH THE NEED FOR TRANSFUSIONS IN PATIENTS WITH VENTRICULAR ASSIST DEVICES**

T. Kanellopoulou1*, M. Aliberti1, A. Apostolou1, M. Fidirikou1, S. Georgantis1, E. Kabana1, M. Katafigioti1, P. Litras1, A. Makriigianni1, N. Matoula1, E. Papadaki1, G. Souflia1, E. Zalachori1, T. Kostelidou1

1Department of Haematology and Blood Transfusion, Onassis Cardiac Surgery Centre, Athens, Greece

**Background:** Patients who have implantation of continuous flow ventricular assist devices (VAD) as a bridge to heart transplantation are subjected to complications secondary to pump support. The use of antiplatelets either alone or in combination with anticoagulation is necessary to avoid clot formation and pump thrombosis. However, a proportion of patients reveal an increasing risk of bleeding episodes. A possible reason of this situation could be that high shear forces lead to devastation of high molecular weight von Willebrand factor (vWF) making it functionally inactive and resulting in acquired von Willebrand disease (vWD). People with blood type O have lower baseline vWF levels and this abnormality could exacerbate the bleeding risk of patients with blood type O with VAD, resulting in more frequent bleeding episodes and need for transfusions.

**Aims:** The aim of current study was to investigate the possible association of blood type with acquired vWD induced by VAD, with the need for transfusions.

**Methods:** In this retrospective study, 17 patients who had a VAD implantation in our hospital in a six-month period were included for analysis. The investigation of underlying vWD was estimated by ristocetin-induced platelet aggregation (RIPA) using classical light transmission aggregometer.

**Results:** Of 22 patients (35.3%) had left-VAD (L-VAD) implantation while the others had biventricular VAD implantation (BiVAD). The mean age was 42.41 years (SD±15.33) and 9 patients (52.9%) were male. Female patients had VAD implantation at younger age than male (p<0.001). The mean follow-up after VAD implantation was 15 months (SD±11.88). At the time of analysis, 13 patients (76.5%) were alive, 2 patients (11.8%) had died while 2 patients (11.8%) had been heart-transplanted. Eight patients (47.1%) had blood type O, 8 patients (47.1%) had blood type A and a patient (5.9%) had AB. Mean RIPA before VAD implantation was 59.3% (SD±14.76) while after VAD implantation was 47.29% (SD±15.47), whereas the decrease was no statistically related. No statistical correlation was found between RIPA among different blood types. Among patients with blood type O, the need for blood transfusions was associated with the duration of having the VAD implantation in months (p<0.001) while the need for fresh frozen plasma (FFP) transfusions was associated with RIPA before VAD implantation (p=0.016). In non-blood O type patients no statistical correlation was found with the need for transfusions with RIPA percentage or median follow-up of patients.

**Summary/Conclusions:** It has been shown by several studies that patients with VAD show a decrease in vWF increasing the bleeding risk. Thus the best antiplatelet treatment and/or anticoagulation that those patient needs, remains challenging. In our study, there was a decrease in mean RIPA percentage after VAD implantation and patients with blood type O had lower RIPA before implantation. However, none of these measurements was statistically significant. The blood type O patients showed an increased need for transfusions in correlation with the duration of VAD implants and an increased need for FFP in correlation with RIPA baseline. Our study has limitations due to the small population and the fact that vWF was not estimated within the different blood groups at baseline and after VAD implantation.
Bone marrow failure syndromes incl. PNH - Clinical

ACQUIRED PURE RED CELL APLASIA ASSOCIATED WITH LYMPHOPROLIFERATIVE DISEASES IN ERYTHROPOIETIN-REFRACTORY ANEMIA PATIENTS ON DIALYSIS

K. Yoshinaga1,*, 2, N. Mori1, M. Ohwashii, 2, M. Ishti1, M. Shiseki1, J. Tanaka1
1Department of Hematology, Tokyo Women’s Medical University, Tokyo, Japan
2Department of Hematology, The First Affiliate Hospital, Nanjing Medical University, Nanjing, China

Background: Erythropoietin-refractory anemia is a serious problem and complicated causes should be ruled out in patients on dialysis. Acquired pure red cell aplasia (PRCA) may be hidden behind anemia of chronic kidney disease. Recently it was reported that PRCA patients with large granular lymphocyte frequently had STAT3 mutations (Oie ZY et al. J Hematol & Oncol 2013, Ishida F et al. Cancer sci 2014). Molecular or flow-cytometric analysis is useful for detecting a small amount of abnormal lymphocytes.

AIMS: We conducted this study to determine the clinical characteristics and STAT3 mutations of patients with acquired PRCA on dialysis with lymphoproliferative diseases.

METHODS: In our hospital, 4 patients were diagnosed as having acquired PRCA on dialysis with lymphoproliferative diseases after 2005. Patients were retrospectively studied for presenting feature, laboratory data, and clinical course. Surface markers of lymphocytes were examined by flow-cytometric analysis, and T-cell receptor (TCR) rearrangements were examined by Southern blot analysis. Mononuclear cells were separated after obtaining written informed consent. STAT3 (Y640F and D661Y) mutations were examined by allele-specific PCR. Current study was conducted within the guidelines and with the approval of the institutional ethical committee.

RESULTS: In spite of adequate administration of erythropoietin colony-stimulating factor, all 4 patients required blood transfusion due to erythropoietin-refractory anemia. Median leukocyte and lymphocyte counts at diagnosis were 4650/mL (range, 3180-4850) and 1794 mL (range, 1183-2859), respectively. Two patients (Cases 1 and 2) had low percentage of CD4+, CD8+ by flow-cytometry and TCR C beta1 and gamma rearrangements by Southern blot analysis. Another patient (Case 3) had high percentage of gamma-delta T cell component (66.2%) with TCR delta rearrangement. The other patient (Case 4) had high CD16+CD56+ NK cell percentage without TCR receptor rearrangement. The surface markers of abnormal lymphocytes were different of dialysis patients, (range, 5,19 years). Of the 4 patients, only one patient (Case 3) had the mutations of the STAT3 gene (Y640F). This patient received cyclophosphamide but he did not respond to the therapy. He subsequently received cyclosporine (CyA). The other three patients received CyA as an initial therapy and it was effective in all 4 patients. Median follow-up were 7 years from diagnosis, and two patients died during follow-up period. One patient (Case 4) died of cardiac failure 7 years from the diagnosis. Another patient (Case 2) developed diffuse large B-cell lymphoma 5 years after the administration of CyA. He was treated with R-CHOP chemotherapy and complete remission (CR) was achieved. Although he had been in CR, he died of refractory pancytopenia with infection, 2 years after the lymphoma onset. The other two patients are still alive without blood transfusion for 6 and 7 years.

SUMMARY/CONCLUSIONS: A proportion of erythropoietin-refractory anemia patients on dialysis have acquired PRCA associated with lymphoproliferative diseases. Further accumulations of patients were required for understanding the pathogenesis of lymphoproliferative diseases causing acquired PRCA on dialysis.

PB1752

ADULT PATIENTS WITH ACQUIRED PURE RED CELL APLASIA: TREATED BY CYCLOSPORINE A OR CORTICOSTEROIDS: SIMILAR EFFECTIVENESS

X. Wu1,*, S. Wang1, W. Shen1, G. He1, J. Li1
1Hematological Department, The First Affiliate Hospital, Nanjing Medical University, Nanjing, China

Background: Adult pure red cell aplasia (PRCA) is a syndrome characterized by a severe normocytic anemia, reticulocytopenia, and absence of erythroblasts from an otherwise normal bone marrow. Immunosuppressive therapy has been used as the initial treatment for acquired chronic PRCA.

Aims: The study evaluates the efficacy of cyclosporine A, and/or corticosteroids, and possible factors influencing it.

Methods: 34 cases of PRCA were retrospectively analyzed at our institution. Clinical data of 23 inpatient cases and 11 outpatient cases since 2009 October were collected. These patients were treated by cyclosporine A (CsA), and/or corticosteroids (CS), or other immunosuppressive agents if become refractory and relapsed.

Results: 31 patients were evaluated in our institution (one patient lost to follow-up and two patients with short observation period). The remission induction therapy included CsA (n=13), Cs (n=13), or a simultaneous combination of CsA and Cs (n=5). The initial response rate of CsA alone, Cs alone, combination of Cs and CsA were 69.2%, 46.2%, 80%, respectively (P=0.422). There was no statistical difference in response rate and CR rate between CsA-containing group and CS group, although the patients treated with CsA had a better response than those treated with Cs (response rate 72.2% vs 46.2%, P=0.262; CR 15% vs 33.3%, P=0.596). Including patients who had crossed over from other treatment groups, the cumulative response rate of CsA, Cs, combination of Cs and CsA, was 73.7% (14/19), 46.7% (7/15), 83.3% (5/6), respectively (P=0.193); the cumulative rate of CR was 26.3% (5/19), 26.7% (4/15), 66.7% (4/6), respectively (P=0.202). In 23 refractory and relapsed PRCA patients, 8 out of 12 (66.7%) refractory patients and 4 out of 11 (36.4%) relapsed patients achieved remission achievement. The response rate of treatment with traditional immunosuppressive agents (Cs and/or CsA) was higher than other immunosuppressive agents (65.0% vs 20%, P=0.014).

Summary/Conclusions: CsA and/or Cs are effective similarly in treating PRCA. For patients with relapse or refractory PRCA, there were no satisfactory treatment measures if CsA and/or Cs were not be administrated or un-effective. It was still needed to explore a more effective therapy for them.

PB1753

REACTIVATION OF HEPATITIS B VIRUS INFECTION IN APLASTIC ANEMIA PATIENTS ON DIALYSIS

S. Wang1,*, X. Wu1, G. He1, W. Shen1, J. Li1
1Hematological Department, The First Affiliate Hospital, Nanjing Medical University, Nanjing, China

Background: There is little data about the influence of infection of HBV on the therapy of aplastic anemia.

Aims: This article aims to evaluate the efficacy of cyclosporine A, and/or corticosteroids (CS) in the treatment of aplastic anemia patients on dialysis.

Methods: We analysis the clinical data of 60 AA patients with HBV infection and/or liver insufficiency, failure to thrive and skeletal abnormalities. In approximately 90% of the patients, the molecular defect is related to SBDS gene mutations. The patients who were sent to Hacettepe Inherited Bone Marrow Failure Center for molecular work-up during the recent 3 years, and laboratory test data such as levels of liver enzyme, HBV DNA in serum, HBsAg and anti-HBc were monitored. Entecavir (ETV) or lamivudine (LAM): was started when HBV reactivation (defined as detectable HBV DNA) was encountered or as a antiviral prophylaxis regimen for some patients. We analysis the clinical data of 60 AA patients with HBV infection and/or liver insufficiency, failure to thrive and skeletal abnormalities. In approximately 90% of the patients, the molecular defect is related to SBDS gene mutations. The patients who were sent to Hacettepe Inherited Bone Marrow Failure Center for molecular work-up during the recent 3 years, and laboratory test data such as levels of liver enzyme, HBV DNA in serum, HBsAg and anti-HBc were monitored. Entecavir (ETV) or lamivudine (LAM): was started when HBV reactivation (defined as detectable HBV DNA) was encountered or as a antiviral prophylaxis regimen for some patients.

Results: Among 60(29.8%) AA patients, 12 were chronically infected (HBsAg positive) and 48 were previously exposed (HBsAg negative/anti-HBc positive). 5 patients (8.33%) who were HBsAg positive and not given any prophylactic antiviral therapy suffered HBV reactivation. 7 patients who were HBsAg positive but given prophylaxis were found no HBV reactivation during the follow-up.

Summary/Conclusions: Antiviral prophylaxis should be recommended for HBsAg-positive patients who will receive IST with AA as they had high rate (41.6%) of HBV reactivation. HBV infection were found no influence to the clinic course in AA and antiviral therapy had no influence to the effect of IST.

PB1754

MULTICENTER RESULTS OF SCHWACHMAN-DIAMOND SYNDROME PATIENTS

1Hacettepe University, Division Of Pediatric Hematology, Ankara, 2Cerrahpasa University, Department of Pediatric Hematology , Istanbul, 3Ankara Çocuk Sagligi ve Hastaliklari Hastalikleri Onkoloji Egitim ve Arastirma Haseanisi , Ankara , 4Ankara Çocuk Sagligi ve Hastaliklari Hastalikleri Onkoloji Egitim ve Arastirma Haseanisi , Ankara , 5Gazi University, Department of Pediatric Hematology, 6Hacettepe University, Medical Faculty , Ankara, 7Istanbul Saglik Bilimleri University, Department of Pediatric Hematology, Istanbul, 8Hacettepe University, Department of Medical Genetics, Ankara, Turkey

Background: Shwachman-Diamond syndrome (SDS) is an autosomal recessively inherited disease characterized with neutropenia, exocrine pancreas insufficiency, failure to thrive and skeletal abnormalities. In approximately 90% of the patients, the molecular defect is related to SBDS gene mutations. The classical triad is present in one-forth of the patients and a high degree of suspicion is required in order to make the diagnosis. In this study, molecular work-up to patients with suspected SDS were made and the clinical and laboratory findings that predict the SDS diagnosis were investigated.

Aims: Aim of the study was to find out the predictive clinical and laboratory characteristics of SDS patients and their response to therapy.

Methods: The patients who were sent to Hacettepe Inherited Bone Marrow Failure Center for molecular work-up between June 2015 and August 2016 were evaluated with clinical and laboratory data obtained from a standardized patient registry form.
Results: Molecular work-up was performed in 20 patients referred to our center with a suspected diagnosis of SDS. Of these 20 patients (12 girls), 4 (20%) (3 boys) were found to have mutation in SBDS gene. The median age of these patients was 3.2 years (1-18). Of the 4 patients with genetically verified SDS, 1 (25%) had history of chronic diarrhea and pancreas atrophy was detected in ultrasonography of that patient. Another patient (25%) with SDS had skin ulcers. The last patient had history of severe failure to thrive, Three patients (75%) had anaemia associated to neutropenia, and 1 patient (25%) had pancytopenia at presentation. On the other hand the patients who were referred with a suspicion of SDS but was found to have no mutation, 43% had neutropenia, 25% had bicytopenia, 10% had pancytopenia. The patients in the latter group had failure to thrive in 25% of the patients and chronic or persistent diarrhea was present in 25% of this group. There was no statistically significant difference in the clinical and laboratory parameters of the genetically verified SDS patients and patients without SDS but was referred with SDS suspicion.

Summary/Conclusions: Through, there was no statistically significant difference in the clinical and laboratory parameters of the genetically verified SDS patients and patients without SDS but was referred with SDS suspicion, this might be attributed to the small sample sizes. Compatible with the previous literature data, SDS is a cryptic disorder and the classical triad is not commonly fulfilled in most of the patients. On the other hand, failure to thrive/growth retardation was three times more common in patients with SDS. Thus, in patients neutropenia, accompanying failure to thrive/growth retardation might be an indicative to make molecular work-up for SDS. Additionally, not only neutropenia, but bicytopenia or pancytopenia might be the hematological presentational findings of SDS.

Background: Aplastic anaemia (AA) and Paroxysmal Nocturnal Hemoglobinuria (PNH) are included, together with other pathologies, within the bone marrow failure syndromes (BMFS). In the present time, these clinical entities cannot be distinguished, however, up to our knowledge there is no literature data on the heavy metal levels in patients with FA.

Results: Total of 17 patients with FAA were included in the study. Median age range, two patients with FAA and two volunteers had copper levels higher than normal range. Heavy metal levels in patients with different chronic disorders have been investigated, however, up to our knowledge there is no literature data on the heavy metal levels in patients with FAA. Heavy metal levels in patients with different chronic disorders have been investigated, however, up to our knowledge there is no literature data on the heavy metal levels in patients with FAA.

Summary/Conclusions: As a conclusion, we wanted to point out autoimmune cytopenias in patients with PNH and the requirement of multidisciplinary approach for treatment.

PB1757 AUTOIMMUNE CYTOPENIAS IN PRIMARY IMMUNODEFICIENCY DISEASES: SINGLE CENTER EXPERIENCE T. Pattroglou1,*, M. Cansever2, F. Bektas3

Aims: Primary immunodeficiency diseases (PID) are associated with hematologic complications such autoimmune hemolytic anemia (AIHA) and thrombocytopenia (ITP). The most common autoimmune cytopenia is ITP. Although ITP is observed in 7.6% of patients with PID, AIHA is seen at 8.4%. Also, we aimed to present the patients who had autoimmune cytopenias and PID.

Methods: Fifty six PID patients who were followed at the Pediatrie Immunology Department of Erayves University Medical Faculty (they were analyzed genetically) were evaluated retrospectively. Autoimmune cytopenias such as ITP and AIHA were detected in 9 (516.07) of the patients (combined immunodeficiency: 4 patients, common variable immunodeficiency: 2 patients, hyper immunoglobulin E syndrome: 1 patient, X-linked lymphoproliferative: 1 patient, chronic granulomatous disease: 1 patient). ITP was detected in 8 of 9 patients and AIHA was also detected in 6 patients. In four patients (LRBA deficiency: 2 patients, hyper IgE syndrome: 1 patient and CGD: 1 patient), both ITP and AIHA were observed. Immunosuppressive therapy with steroid, cyclosporine, mycophenolate mofetyl and intravenous immunoglobulin were given to all patients. Bone marrow transplantation was performed to the four patients.

Results: There is a paradoxical situation between PNH and autoimmunity. The reduction of central and peripheral tolerance is held responsible for autoimmunity in PID.

Summary/Conclusions: As a conclusion, we wanted to point out autoimmune cytopenias in patients with PNH and the requirement of multidisciplinary approach for treatment.

F AA: Fanconi aplastic anemia.

Fanconi aplastic anemia (FAA) is a rare, autosomal recessively inherited bone marrow failure syndrome. FAA is associated with congenital anomalies which can accompany disease and various complications including malignancy and endocrinopathies may develop during the course.

Aims: Heavy metal levels in patients with different chronic disorders have been investigated, however, up to our knowledge there is no literature data on the heavy metal levels in patients with FAA. Heavy metal levels in patients with different chronic disorders have been investigated, however, up to our knowledge there is no literature data on the heavy metal levels in patients with FAA.

Methods: Study was performed between July 2015 and April 2016 among patients with FAA and the results were compared with age and gender matched healthy volunteers. Plasma copper (Cu), iron (Fe), zinc (Zn), cobalt (Co), selenium (Se), chromium (Cr) levels were measured in patients with FAA. Results: Total of 17 patients with FAA were included in the study. Median age was 9 years (1-30), female to male ratio was 8/9. One patient had undergone stem cell transplantation, four patients were transfusion dependent. When we compared patients with FAA and age/sex matched healthy group (16 volunteers) Cr and Cu levels were higher and Se level was lower in FAA group significantly (Table 1). Also, all patients had chromium level within normal range, two patients with FAA and two volunteers had copper levels higher than the normal ranges (Table 1).

F AA: Fanconi aplastic anemia.
Summary/Conclusions: In our study we found chromium and cobalt levels higher in patients with FAA than control group. In vitro studies have revealed that FAA cells are more sensitive to chromium toxicity. With larger number of patients chromium level and clinical association should be investigated in further studies. Lower Se level in patients with FAA may be related with oxidized stress in these patients.

**CLINICAL IMPACT OF AGE AND COMORBIDITY IN PNH PATIENTS**

E. Espinosa,1,2,3, M. Morote Arias,4,2, A. Ortiz Valls,2,4, M. López Rubio,5, B. Arrizabalaga Amuchastegui,6, E. Lavilla Rubira,2,7, E.J. Salido Fírez,2,8, S. de la Iglesia Itigo,2,8, P.A. Urquía Plazacolution,9, I. Jarque Ramos,10, Á. Urbano Ispizua,4,11, A.M. Villegas Martínez,2,12

1Hematología, Hospital Universitario Central de Asturias, Oviedo, 2Grupo Español de Hemogloburia Nocturna, Sociedad Española de Hematología y Hemoterapia, 3Hematología, Hospital Universitario La Paz, Madrid, 4Hematología, Hospital Universitat, 5Hospital Universitario Príncipe de Asturias, Madrid, 6Hospital Universitario Cruces, Bilbao, 7Hospital Universitario Lucus Augusti, Lugo, 8Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, 9Hospital Universitario de Gran Canaria, Las Palmas, 10Hospital Universitario Donostia, San Sebastián, 11Hospital Universitario La Fè, Valencia, 12Hospital Universitario San Carlos, Madrid, Spain

**Background:** PNH is an ultra-rare disorder affecting mainly young adults, but can be diagnosed in geriatric population. Comorbidity is more prevalent in general geriatric population and can either hamper diagnostic evaluation or increase the complexity of PNH patient care.

**Aims:** To identify geriatric-age PNH in Spanish PNH registry. To study the clinical characteristics at diagnosis and evolution of geriatric-age PNH and compare them to non-geriatric PNH population. To analyse the impact of both age and comorbidity in the PNH setting. To evaluate the use of eculizumab in geriatric age patients.

**Methods:** In a multicentric retrospective study, Cumulative Illness Rating Scale (CIRS-G) and clinical and biological variables have been collected from a Spanish PNH Group patient cohort. Statistical analysis was performed using GraphPad Prism v5 (La Jolla, CA).

**Results:** 44 patients from 11 centres in Spain have been included up to date. 8 patients (17.8%) were diagnosed in geriatric age (equal or older than 65 years) (Age range for the complete cohort: 17-83 years) and 9 patients presented with high comorbidity, arbitrary defined as CIRS-G score ≥10. (Range for the complete cohort: 3-13) Age and comorbidity were poorly correlated (p = 0.0187, R-square 0.15) No differences in clinical presentation (Classic, PNH in the setting of another bone marrow failure syndrome or Subclinical PNH or high disease activity) when stratifying by age or comorbidity were observed. 4 patients had a concomitant myeloid clonal disorder (3 myelodysplastic syndrome and 1 myeloproliferative neoplasm), 3 of them (75%) in geriatric age. Median follow up was 7.2 years. Both age equal or older than 65 years and CIRS-G ≥10 were associated to poorer overall survival (HR: 0.0134 and 0.045 & p = 0.0015 and 0.0103 respectively). Regarding PNH with high disease activity, 18 patients were identified, 4 of them in geriatric age. In 2 of them (50%), Eculizumab was used, which contrasts with eculizumab use in younger patients (76.6% in the same indication) Regarding comorbidity impact on eculizumab therapy outcome, 2 patients had CIRS-G score >10 and had similar overall survival as patients with lower comorbidity in this cohort.

**Summary/Conclusions:** Age and comorbidity are associated with poorer overall survival in PNH. Older age and comorbidity may not preclude the use of effective treatment in PNH patients, including those with high disease activity. Prospective evaluation of comorbidity in PNH patients, regardless of age is warranted.

FAA: Fanconi aplastic anemia.

**PB1759**

**A RARE ASSOCIATION: EBSTEIN-BARR VIRUS ASSOCIATED LYMPHOPROLIFERATIVE DISORDER AND PURE RED CELL APLASIA**

S. Berk1,*, M. Günaltılı2, S. Sadri1, M. C. Ar1, T. Soysal1

1Hematology, 2Internal Medicine, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

**Background:** Lymphoproliferative disorders (LPD) constitute a heterogeneous group of diseases related to expanding polyclonal or monoclonal lymphoid cells in the setting of immune dysfunction. Ebbstein-Barr virus (EBV) has been implicated in the development of a wide range of B-cell LPD spectrum. EBV associated LPDs (EBV-LPD) are more commonly encountered after stem cell and organ transplantations. Pure red cell aplasia (PRCA) is an uncommon disorder characterized by a severe normocytic anemia due to erythroblastopenia in an otherwise normal bone marrow. PRCA may be primary or develop secondary to viruses, autoimmune diseases, hematological malignancies, thymoma, solid tumors and drugs.

**Aims:** A case, who was diagnosed with EBV-LPD and developed PRCA during follow-up, is presented.

**Methods:** A 75-year-old woman with pain in upper and lower extremities applied to our center in February 2016. Her past medical history was unremarkable except for rheumatoid arthritis. On physical examination bilateral cervical, submandibular, axillary lymphadenopathies (LAP) and splenomegaly were detected. Laboratory tests revealed normochromic normocytic anemia, elevated serum lactate dehydrogenase and acute phase reactants. Positron emission tomography (PET) showed supra- and infradiaphragmatic malignant lymph nodes and splenic involvement. An excisional biopsy of cervical LAP performed. Pathological examination showed CD20 (+) and CD30 (+) large B cells in the interfollicular area. EBV early RNA signals were checked by in situ hybridization and viral transcripts were detected. Diagnosis of EBV-LPD was made. During diagnostic work-up deepening of anemia with reticulocytopenia, increased transfusion requirement and inadequate response to transfusion necessitated a bone marrow aspiration and biopsy. Pathological examination of the bone marrow was compatible with PRCA. Parvovirus IgM and DNA was negative; IgG was found to be positive. Because of the lack of response to steroids, Rituximab was given (375 mg/m², weekly). Anemia and patient’s clinical condition improved after 8 weeks of treatment.

**Results:** In the pathogenesis of LPD polyclonal lymphoid response to an antigenic trigger is thought to be followed by development of monoclonal neoplastic diseases. In our case, this trigger was thought to be EBV as it is known as one of the main causative agents for LPD in the literature. Clinical complaints and physical examination findings are common among all patients and frequently not leading to a definitive diagnosis in most of them as it is the case in our patient. Compared to the strong association of secondary PRCA with parvovirus B19 its association with EBV is rare. PRCA can develop before the diagnosis, during the course and after the remission of LPD. In our case we observed PRCA in the follow-up period of EBV-LPD.

**Summary/Conclusions:** On the basis of EBV-LPD being more common in transplant setting our case was thought to be unique due to the absence of transplantation or immunosuppression history. This case report points out to the possibility of coexistence of two rare diseases, EBV-LPD and PRCA.
Chronic lymphocytic leukemia and related disorders - Biology

PB1760
LDH AS PREDICTIVE PARAMETER IN TREATMENT-NAÏVE PATIENTS WITH TRISOMY 12 CHRONIC LYMPHOCYTIC LEUKEMIA
1Università Cattolica del Sacro Cuore, Fondazione Policlinico A. Gemelli, Rome, Italy, 2MD Anderson Cancer Centre, Houston, United States, 3Università di Padova, Padova, Padova, 4IRCCS Ca’ Granda Policlinico – Università degli Studi di Milano, Milano, 5Ospedale San Bortolo, Vicenza, 6A.O. Città della Salute e della Scienza, 7S. Anna, Ferrara, 8Azienda Ospedaliera Universitaria Senese, Siena, 9Univer- sità La Sapienza, Policlinico Umberto I, Rome, 10Ospedale Niguarda, Milano, 11Università Ospedaliera di Cosenza, Cosenza, 12Ospedale Fugliese – Ciacco, Catanzaro, 13Ospedale Belcolle, Viterbo, 14RCSC Centro di Riferimento Onco- logico della Basilicata, Rionero in Vulture, 15Ospedale A. Businco, Cagliari, 16Azienda Ospedaliera Bianchi-Melacrinio-Morelli, Reggio Calabria, 17Ospedale C. G. Mazzoni, Ascoli Piceno, Italy

Background: Patients affected by chronic lymphocytic leukemia (CLL) that have trisomy 12 (+12) on FISH analysis have unique clinical and biological features. In a prior analysis (Autore F, ASH 2016) of 487 patients with +12 compared to 816 patients with negative FISH, patients with +12 had a significantly higher prevalence of elevated LDH, β-2-microglobulin, ZAP70 positivity, CD38 positivity, CD49d positivity and unmutated IGHV compared to patients with negative FISH. They also showed shorter progression free survival (PFS), treatment free survival (TFS) and overall survival (OS).

Aims: To identify clinical and laboratory features that predict disease progression, time to treatment and survival in treatment-naïve patients with +12 CLL.

Methods: This study included 487 treatment-naïve patients with +12 CLL from 16 academic centres, diagnosed between January 2000 and July 2016. A cohort of 250 patients with +12 CLL followed at a single US institution was used as external validation. Data were summarized as medians and 25th and 75th percentiles. Chi-square test or Fisher’s exact test were used to compare categorical variables, while Wilcoxon-Mann-Whitney-Test was applied for continuous variables. The survival analysis was based on the Kaplan-Meier method and the log-rank test was used to compare survival curves. A Cox model was used for multivariate analysis of the impact of different factors on survival. P values lower than 0.05 were considered statistically significant (STATA 12.0) and reported as two-sided. We analysed also CLL-specific survival considering events deaths due to the haematological disease.

Results: Parameters associated with shorter PFS, TFS, OS and CLL-specific survival on univariate analysis were IGHV, LDH, β-2-microglobulin and Rai stage; age, ZAP70 and CD38 associated with OS only; on multivariate analysis were LDH, β-2-microglobulin, Rai stage and ZAP70; LDH, β-2-microglobulin and age associated with OS. On multivariate analysis high LDH was the sole parameter significantly associated with all shorter outcomes, along with elevated β-2-microglobulin, which associated with shorter OS.

Summary/Conclusions: Our study on 487 patients with +12 CLL and the analysis on 250 patients of the validation cohort showed that patients with +12 and elevated LDH have shorter PFS, TFS, OS and CLL-specific survival.

PB1761
THE PERCENTAGE OF CELLS WITH ABNORMALITIES IN FISH STUDIES CONFERS PROGNOSTIC INFORMATION IN CLL PATIENTS
I. González-Gascón Y Marín1,*, M. Hernández-Sánchez2, A.E. Rodriguez-Vicente3, C.C. Muñoz Novas1, M. S. Infante1, C. Heras1, M.A. Fonciellas1, K. Marín1, J.M. Hernández Rivas2, J.A. Hernández4
1Hospital Universitario Infantita Leonor, MADRID, 2IBSAL, IBMCC, Centro de Investigación del Cáncer, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: Genomic aberrations detected by FISH have become one of the most important and widely used prognostic factor for chronic lymphocytic leukemia (CLL) patients. In addition several publications have described that patients with a higher percentage of abnormal nuclei have a worse outcome.

Aims: To analyze the effect of the percentage of abnormal nuclei detected by FISH (13q deletion (13q-), 11q deletion (11q-), 17p deletion (17p-) and trisomy 12 (+12)) in overall survival (OS) and time to first treatment (TTFT).

Methods: We studied a non-selected cohort of 650 consecutive CLL cases from a local database with a median follow up time of 50 months (0-346). The cut-off point for the percentage of abnormal nuclei for each alteration was determined by dividing the variable into deciles, and selecting the most efficient cut-point, and based on previous publications.

Results: FISH detected aberrations in 85% of the cases (442/500). The most frequent abnormality was 13q-, observed in 302 patients (47%), but as a sole alteration in 212 cases, followed by +10 (16 patients, 16%), 11q- (83 patients, 13%), and 17p- (33 patients, 5%). As expected, the group of patients with 13q- as a sole abnormality was the one with the better OS (195 months) followed by the group of patients with normal FISH (160 months), +12 (124 months), 11q- (56 months) and 17p- (46 months), consistent with the Dohner hierarchical classification (Döhner H et al. NEJM 2000). Similar results were observed in TTFT: 13q- as sole abnormality (106 months), normal FISH (112 months), +12 (29 months), 11q- (10 months), 17p- (10 months). The best predictive cut-off point that divided patients according to its prognosis was different for each alteration. We confirmed that a high percentage of cells carrying the deletion is associated with a significantly worse TTFT in cases with 17p, 13q, and 11q deletions, and a significantly shorter OS in cases with 17p deletion. We observed a similar trend for OS in cases with 13q and 11q deletions, probably not significant because of the low number of patients included, compared to previous studies. We observed the same trend in patients with +12. The Table 1 summarizes these findings. Probably with a higher number of cases and a longer follow up, it could have also been possible to reach statistically significant differences in the subgroups in which it was not object.

Table 1.

Figure 1.

Summary/Conclusions: Not only the type of cytogenetic abnormality but also the percentage of abnormal nuclei detected by FISH are important factors in the prognosis of CLL patients.
Background: Chronic lymphocytic leukemia (CLL) pathogenetic mechanisms have not been fully elucidated yet. However, genetic and epigenetic alterations seem to be involved in the pathogenesis and extensive clinical heterogeneity of the disease. DNA methylation in CpG sites of a gene promoter, which may affect the chromatin structure as well as gene transcriptional activity, is a crucial epigenetic modification in CLL. RAD21 gene is involved in DNA repair and its encoded product acts as basic subunit of the Cohesin protein complex that regulates the cohesion and proper separation of sister chromatids during mitosis or meiosis.

Aims: We investigated the methylation status of RAD21 gene promoter and its possible implication in CLL pathogenesis and the formation of CLL cytogenetic aberrations.

Methods: The study included 105 CLL patients and 17 healthy donors (controls). Total genomic DNA extraction was performed from bone marrow or peripheral blood samples of all patients and controls. Methylation analysis of RAD21 gene promoter was carried out using the new technology of MethylScreen in the CFX96Biorad Real-Time PCR system. For this purpose, we used EpTect Methyl II PCR Assay which enables us to calculate the methylated and unmethylated fraction after simultaneous digestions with specific restriction enzymes. Genomic DNA analysis was performed on unstimulated and stimulated with CpG-oligonucleotide DSP-30 bone marrow cells of CLL patients. FISH analysis was carried out using the commercial CLL set probes for detection of the most common abnormalities of the disease including deletions of 17p13 (TP53), 11q22.3 (ATM) and 13q14.3/33q43.4 (D13S319/13q34) regions in trisomy 12 (CEP 12).

Results: Among the 105 CLL patients, 21 patients exhibited a normal karyotype also confirmed by FISH and 84 patients showed chromosome abnormalities detected by karyotyping and/or FISH analysis. Methylation study was successful in all healthy donors and in 101 out of 105 CLL patients. All healthy donors had normal cytotelated RAD21 gene promoter. On the contrary, 25.74% (26/101) of CLL patients carried >10% cells with methylated CpG islands in RAD21 promoter, which was significantly increased compared to controls (p=0.039, χ²=4.25, df=1). RAD21 methylated cell fraction varied among patients. More specifically, 9.9% of patients (10/101) showed 11-50% methylation rate, 10.89% (11/101) 51-80% methylation rate, and 28.57% of patients (29/101) showed high methylation rate score, >90% of the analyzed cells. Stratification of patients according to cytoteligenic findings showed that the promoter of RAD21 was methylated in 28.57% of patients (6/21) with normal karyotype and 25% of patients (20/80) with abnormal karyotype. In detail, methylation in RAD21 promoter was present in 33.33% (3/9) of patients with 11q-deletions (4/12, in 33.33% (4/12) with abn(8), in 31.25% (5/16) with -17del(17p), in 27.78% (5/18) with trisomy 13, in 25.81% (8/31) with del(13q), in 20% (2/10) with del(6q) and in 12.5% (2/16) with del(11q). Based on karyotypic complexity, RAD21 promoter was methylated in 18.18% (4/22) of patients with a single chromosome aberration, 26.09% (6/23) with two chromosome aberrations and 25.71% (9/35) of patients with complex karyotype (>3 aberrations).

Summary/Conclusions: Methylation of RAD21 gene promoter, which leads to transcriptional inactivation and consequentially inhibition of RAD21 expression, seems to be implicated in CLL pathogenesis and the formation of specific chromosomal aberrations. Epigenetic modification of the genomic landscape of CLL may help in the design of new targeted therapeutic agents.

PB1763 ROLE OF KEAP1-NRF2 PATHWAY GENETIC VARIABILITY IN THE SUSCEPTIBILITY AND PROGNOSIS OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

S. Martin1,2,3, I. Degani1,2, G. Karayi Antunes2, A. Ribeiro1,2,3, R. Tereira1, R. Ruzickova1, R. Álvare, Buenos Aires, Argentina

Background: Chronic lymphocytic leukemia (CLL) is the most prevalent leukemia in the western adult population. Although advanced age, white ancestry, and family history of hematologic malignancies are risk factors, the etiology of CLL still unknown. One of the mechanisms associated with the development of this pathology is related to the oxidative stress (OS) resulting from an imbalance between the production of reactive oxygen species (ROS) and their disposal by the antioxidant defenses. The number factor erythroid 2-like gene (NFE2L2) and its suppressor, the Kelch-like ECH-associated protein 1 (KEAP1) gene, plays a central role in ROS balance. Changes in these genes, whether due to somatic mutations or genetic variants (SNPs), have been associated with some hematological diseases. However, the role of NFE2L2 and KEAP1 genes polymorphisms in susceptibility and prognosis of CLL remains uncertain.

Aims: To assess the role of two SNPs in the NFE2L2 and KEAP1 genes on CLL susceptibility, their influence on prognosis/survival, and their correlation with clinical and laboratory characteristics of patients.

Methods: Genetic variants rs13001694 (NFE2L2) and rs11085735 (KEAP1) were genotyped by tetra-primers-AMRS-PCR in 176 patients with CLL and 261 controls. The role of these genes polymorphisms in CLL susceptibility and their association with clinical and laboratory characteristics as well as with therapy response was assessed by logistic regression analysis and/or by Fisher’s exact test. The influence on prognosis and survival was performed through univariate methods and by Kaplan-Meier survival curves by estimating the progression free survival (PFS) and the overall survival (OS).

Results: The results showed that individuals with the GG genotype (NFE2L2) are at higher risk of developing CLL [Odds ratio (OR): 2.032; 95% confidence interval (CI): 1.234-3.51; P=0.004]. In addition, the genotypic profile (GG / GC (NFE2L2 / KEAP1) is a risk factor (OR: 2.186; 95% CI: 1.273-3.744, p=0.003) for the development of CLL while the AA / CC profile constitutes a protective factor (OR: 0.634, 95% CI: 0.407-0.984, p=0.037). In contrast, patients with genotype AG (NFE2L2) and/or CC (KEAP1) had a higher rate of complete response to rituximab therapy regimens (NFE2L2 AG: OR 1.6; 95% CI: 1.030-2.529, p=0.037; KEAP1 CC, OR 1.2, 95% CI 0.94-1.77, p=0.045; NFE2L2 / KEAP1 AG / CC : OR 1.9, 95% CI: 1.843-4.485, p=0.017) and with fludarabine (NFE2L2 / KEAP1 AG / CC: OR 1.5, 95% CI: 1.119-3.736, p=0.026). Finally, the overall survival of CLL patients appears to be influenced by the genotypic profile of NFE2L2 / KEAP1 [GP AG / AC patients have a lower mean survival (176.6±13.6 months) in comparison to other GPs (198.0±13.6 months; p=0.037)], while progression-free survival seems to be influenced by the KEAP1 genotype [patients with CC genotype have a longer mean survival (198.0±13.6 months) than patients with AA and AC genotypes (85.3±13.4 months; p=0.023)].

Summary/Conclusions: This study suggest that genetic polymorphisms in NFE2L2 and KEAP1 genes might be risk factors for CLL development and may constitute novel genetic markers for therapy response (namely regimes with rituximab and fludarabine) as well as prognostic markers, by influencing overall survival and progression free survival in CLL patients. The authors declare no conflicts of interest.

PB1776 EVALUATION OF BASAL CHROMOSOME ABERRATIONS AND MICRONUCLEUS FREQUENCY IN UNTREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA AND THEIR ASSOCIATION WITH CLINICOSTATISTIC MARKERS

M. Palmisani1,2, C. Stanganelli2, P. Dos Santos3, B. Brizuela3, F. Stella3, R. Bezases4, I. Slavutsky3, M. González Cid1

1Laboratorio de Mutagénesis, Instituto de Medicina Experimental, CONICET-Academia Nacional de Medicina, 2División Patología Molecular, Instituto de Investigación Académica Nacional de Medicina, 3Servicio de Genética de Neoplasias Linfoides, Instituto de Medicina Experimental, CONICET-Academia Nacional de Medicina, 4Servicio de Hematología, Htal. Teodor Alvaro, Buenos Aires, Argentina

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease, with variable clinical presentation and evolution. Two major subtypes can be distinguished, mutated (M) and unmutated (UM), characterized respectively by a high or low number of somatic hypermutations in the variable region of immunoglobulin genes and different outcome. Cytophenic and FISH (fluorescence in situ hybridization) analysis are different methods to evaluate genetic instability in CLL.

Aims: In this study, we have analyzed the basal frequency of CA and MN in untreated CLL patients. Results were evaluated in relation to different prognostic factors.

Methods: A total of 67 untreated CLL patients (36 males; mean age: 66.6 years; range: 42-83 years; Rai stage: I: 27%; II: 59%; III-IV: 14%); and 6 normal controls, were studied. Chromosome analysis was performed on stimulated peripheral blood lymphocytes cultures. For each patient, CAs were evaluated on 50 cells stained with 10% Giemsa and the MN frequency was assessed on 50 cells stained with 10% Giemsa. The study was approved by the local Ethics Committee. All individuals provided their informed written consent.
Results: An increased number of CAs, including chromatid breaks and dicentrics, in CLL patients (6.59±5.3%) compared to controls (0.25±0.04%) (p=0.021) was observed. A tendency to increased CA frequency in cases with abnormal (8.18±6.1%) compared to normal karyotypes (5.67±4.4%) (p=0.08) was also found. The analysis taking into account FISH risk groups showed a higher frequency of CA in patients with deletions 11q22 and/or 17p13 associated to poor outcome (8.54±4.9%), than those with no alterations or 13q14 deletion related to a better outcome (5.64±3.9%) and cases with +12 with an intermediate prognosis (4.54±3.5%). By MN analysis, an increased frequency in CLL patients (2.81±1.5%) compared to controls (0.67±3.3%) (p=0.0001) was found. Patients with +12 presented the highest percentage of MN compared to the other two groups (+1.3-fold), indicating the aneugenic effect of this alteration. The evaluation according to the iGHV mutational status showed similar frequencies for CAs and MN in M-CLL (6.2±5.2% and 2.8±5.8%, respectively) and UM-CLL (6.2±5.5% and 2.7±1.3%, respectively). No association between CA and MN frequencies and clinical parameters was found.

Summary/Conclusions: Our results confirm the presence of basal genomic instability in untreated CLL patients as measured by both CA and MN techniques. To our knowledge, this is the first analysis of these parameters taking into account prognostic factors of the disease. Cases with deletions 11q22 and/or 17p13 had the highest value of CA and those with +12 showed the highest frequency of MN, reflecting different mechanism of DNA damage.

B CELLS RESISTANT TO CD20 MONOCLONAL ANTIBODIES DISPLAY SPECIFIC ALTERATIONS IN GENE EXPRESSION PROFILE
A. Lefercereová1,2, P. Štampařič1, J. Vrabcová1,3, V. Vákulová2, M. Doubek1,2,3, M. Mayer1,2,3, Š. Pospíšilová2,1, M. Šmída1,2,3
1Central European Institute of Technology (CEITEC), Masaryk University, 2Department of Internal Medicine - Hematology and Oncology, Medical Faculty of Masaryk University and University Hospital Brno, Brno, Czech Republic

Background: CD20 monoclonal antibodies (mAb) are a standard of care for B-lymphoid malignancies. Yet, their clinical efficacy is quite variable and many patients relapse, while their malignant cells express very low density of CD20 on the cell surface. In spite of being used for 20 years as a therapy target, little is known about the biology and regulation of CD20 inside the cell.

Aims: The aim of this proposal was to investigate the intracellular mechanisms regulating expression of CD20 antigen.

Methods: Diverse cell and molecular biology techniques were used, including flow cytometry analysis, real-time PCR and RNA sequencing. Results: We show that treatment of B cells with different CD20 mAbs initiates a signaling cascade within the cells that is partially distinct from classical B-cell receptor signaling machinery and does not involve BCR proximal proteins. Importantly, it results in a prompt downregulation of CD20 expression. Through chromosome exposure to gradually increasing doses of monoclonal antibodies, we have generated cell lines that are resistant to additional treatment with mAb. Notably, these cells are resistant also to any other of the available anti-CD20 antibodies even at very high concentrations as shown by dose-response experiments. This resistance is sustained for long period and maintained even upon maintenance therapy. We could confirm these cell line regulated CD20 protein from the cell surface and that this effect was not just due to its internalization. Instead, we detected a defect in CD20 transcription as measured by quantitative real-time PCR. Flow cytometry analysis of other surface markers showed a strong upregulation of CD55 and CD59, known inhibitors of complement activation. The combination of CD20 loss together with the increase of CD55 and CD59 is responsible for the complete resistance to the mAbs. We have then analyzed changes in overall gene expressions by performing RNA sequencing and quantitative real-time PCR. We have identified several interesting genes whose expression was altered in our resistant cells when compared to sensitive ones. Among the most interesting hits was a strong downregulation of the transcription factor NFκB, which was expressed more than 10-fold lower in the rituximab or ofatumumab resistant cells. We could confirm this result in multiple independent experiments. We have postulated that anti-CD20-triggered signaling results in the inactivation of NFκB, leading to the block in CD20 transcription. To test this hypothesis, we have treated the cells with phorbol ester PMA, which nonspecifically activates NFκB. Indeed, cells treated with PMA managed to rapidly upregulate CD20 on their cell surface.

Summary/Conclusions: In summary, CD20 triggering by therapeutic mAbs initiates an intricate intracellular changes that result in downmodulation of CD20 expression. Further analysis of detailed intracellular mechanisms regulating CD20 is warranted in order to propose novel interrogation nodes that might initiate complex intracellular changes that result in downmodulation of CD20.

Background: Chemokines and their receptors are involved in the regulation of cell recruitment, survival, proliferation, and trafficking, all these processes crucial in the pathogenesis of chronic lymphocytic leukemia (CLL). Comprehensive profiling of chemokine receptors in CLL and its subgroups according to prognostic relevance is missing.

Aims: To characterize the chemokine expression pattern in CLL patients and subgroups according to clinical course and cytogenetic aberrations.

Methods: We studied the gene expression pattern of 16 canonical and 4 atypical chemokine receptors in peripheral blood mononuclear cells (PBMC) of CLL patients (n=88) and healthy subjects (n=34) by using SmartChip quantitative RT-PCR (WaverGen Bio-systems). The expression of CXCR3, CXCR4, CXCR5, CXCR7, and CCR7 was confirmed by flow cytometry.

Results: Among deregulated receptors, 5 receptors (CCR7, CCR10, CXCR3, CXCR4, CXCR5) were up-regulated and 9 receptors (CCR2-CR6, CCR8, CCR9) were down-regulated in CLL. The percentage of CCR7 did not differ between CLL and controls (P>0.05). In patients with del(17p) associated with a poor prognosis, we observed higher mRNA levels of CXCR6, CXCR7, and CCR7 and comparing to del(13q). On protein level, the percentage of neoplastic B cells positive for CXCR4, CXCR5, and CCR7 was higher and proportional to percentage of CCR7 lower than on normal B cells (P<0.05). In patients with CLL a marked increase in MFI of CXCR4 (P=0.001) and CCR7 (P=0.001) on CLL cells was detected comparing to healthy subjects.

Summary/Conclusions: Our results provide a complete picture of expression patterns of chemokine receptors in PBMC of CLL patients and prognostically relevant subgroups. Further studies are needed to clarify how chemokine receptor network affects neoplastic development and progression.

RESIDUAL SERUM CONCENTRATIONS OF RITUXIMAB ARE ASSOCIATED WITH RELAPSE RISK IN CHRONIC LYMPHOCYTIC LEUKEMIA
A. Tempeșcu1,*, C. Berthou1,*, V. Văculea2, M. Doubs1,2, B. Boutahar2,1, H. Saad1, V. Olivier1, B. Boustahar2,1, M. Zdrengehea3, Y. Renaudineau2, C. Bagacenea2,3
1Clinical Hematology, Laboratory of Immunology, Teaching Hospital Breast, Brest, France, 2Clinical Hematology, Oncology Institute “Ion Chiricuta”, Cluj-Napoca, Romania

Background: Rituximab is an anti-CD20 chimeric monoclonal antibody approved in first-line treatment of patients with chronic lymphocytic leukemia (CLL), in association with chemotherapy. Rituximab displays a time-dependent pharmacokinetic with a high variability between patients that is primarily related to target mediated elimination.

Aims: Rituximab pharmacokinetics has been associated with clinical response but there is no data on its association with patients’ evolution after immunochemotherapy, which is the aim of the present study.

Methods: Residual serum concentrations of rituximab were determined by an enzyme-linked immunosorbent assay (ELISA) for 35 CLL patients before each infusion, administrated every 28 days at T0, T1, T2, T3, T4, T5. Response and relapse criteria were evaluated according to the International Workshop on Chronic Lymphocytic Leukemia guidelines.

Results: Patients were assigned to two groups related to time to relapse. The first group (n=7), had an early relapse in less than 3 years, the second group (n=28), more than 3 years. Lower residual serum rituximab concentration was observed in patients with an early relapse and statistical significance was reached for the values obtained after the 3rd cycle (T3) (p=0.02). Concerning the area under the curve (AUC), the difference was significant across all the values obtained after the 2nd cycle (T2) (p=0.01). For the early relapse and low concentration of rituximab, the AUC reached for the values obtained after the 3rd cycle (T3) (p=0.02). Concerning the area under the curve (AUC), the difference was significant across all the values obtained after the 2nd cycle (T2) (p=0.01).

Additionally, the residual rituximab serum concentration between T2 and T5, superior at 70µg/ml, is associated with a long response time, with a sensibility of 100% and a specificity of 52%. Low residual serum rituximab concentrations in the early relapse group was associated with a higher expression of CD38 and a more frequent administration of the chemotherapy rituximab-bendamustine than rituximab-fludarabine-cyclophosphamide. On the other hand, there was no association with age, sex, cytogenetics, tumour burden or with FCGR3A-135VF polymorphism.

Summary/Conclusions: In conclusion, serum residual rituximab concentration in patients with CLL has an impact on clinical evolution after treatment. This study provides data that sustains the need of rituximab serum concentration adaptation in certain CLL patients, in order to reduce relapse risk.

ACTIVITY OF THE CD19 ANTIBODY MOR208 IN COMBINATION WITH IBRUTINIB, IDELALISIB OR VENETOCLAX IN VITRO

R. Bochner1,2, B. Bauer1, S. Steidl1, J. Endell1

1Pharmacology, MorphoSys AG, Planegg, Germany

Background: CD19 is broadly expressed across B-cell malignancies, including chronic lymphocytic leukemia (CLL). MOR208 is an Fc-enhanced CD19 antibody mediating potent antibody-dependent cellular cytotoxicity (ADCC), antibody-dependent cellular phagocytosis (ADOP) and direct cytotoxicity. Single agent MOR208 has shown promising activity in clinical studies.

Aims: We investigated the in vitro cytotoxicity of MOR208 when combined with the tyrosine kinase inhibitors (TKIs), ibrutinib and idelalisib, and the BCL-2 inhibitor, venetoclax.

Methods: The CLL cell line MEC-1 was treated with 0.3–10 µM ibrutinib, ide-lalisib or DMSO (control) for 7 days or 3–10 µM venetoclax or DMSO for 24 hours. Inhibition of proliferation, cytotoxicity and impact on CD19 expression were then assessed. ADCC assays with MOR208 incorporated a fixed number of primary human natural killer cells from healthy volunteers as effector cells. By contrast, the number of target cells was reduced according to antiproliferative or cytotoxic effects of the TKIs or venetoclax. Dose-dependent ADCC activity of MOR208 was analyzed by flow cytometry. Cytotoxic effects were studied in at least three independent experiments.

Results: Ibrutinib and idelalisib induced only moderate direct cytotoxicity on MEC-1 target cells but had strong antiproliferative effects. In contrast, veneto-clax induced strong cytotoxicity on MEC-1 target cells within 24 hours. Both effects led to reduced tumor target cell numbers in the subsequent ADCC assays. CD19 expression was largely unaffected by all three drugs. The addition of MOR208 to idelalisib or venetoclax treated target cells resulted in enhanced maximum ADCC when compared with single agent MOR208. EC50 values remained unaltered in TKI or venetoclax treated conditions compared with the DMSO control. Calculations according to Chou-Talalay yielded combination indices below 1 for all three drugs, thus confirming synergistic activity of MOR208 in combination with TKIs and venetoclax.

Summary/Conclusions: The cytotoxic effect of MOR208 was synergistically enhanced when combined with ibrutinib, idelalisib or venetoclax in vitro. These promising data provide a strong rationale for combination of MOR208 with these agents in future clinical trials.

LYMPHOCYTE EXHAUSTION AND THE NATURAL HISTORY OF CHRONIC LYMPHOCYTIC LEUKEMIA – FRIENDS OR FOES?

E. Grywała1, J. Rolinski1, M. Pasiarski2, M. Mielenk1, E. Fitas1, S. Gozdź3

1Department of Clinical Immunology and Immunotherapy, Medical University of Lublin, Lublin, 2Clinic of Hematology and Bone Marrow Transplantation, 3Center of Clinical Oncology, Holy Cross Cancer Center, Jan Kochanowski University, Kielce, Poland

Background: Chronic lymphocytic leukemia (CLL) is a disease characterized by the accumulation of morphologically mature nonmalignant lymphocytes B with CD19+CD22+CD23+ phenotype in lymphoid tissue, peripheral blood and bone marrow. The course of CLL is chronic by default. Of note, however, is its het-erogeneity. Programmed cell death protein 1 and its ligand 1 (PD-1, PD-L1) as well as CD8+PD-1+ T cells are major inhibitory receptors regulating T cell exhaustion, i.e. a state of T cell dysfunction. The role of lymphocyte exhaustion in the natural history of CLL is still a matter of discussion.

Aims: The aim of this study was to determine the percentages and absolute numbers of exhausted lymphocytes B and T in peripheral blood and bone mar-row of CLL patients. Moreover, we analyzed relationship between the number of CD19+PD-1+ B cells, CD4+PD-1+ T cells, and CD8+PD-200+ T cells.

Methods: The study included 60 untreated patients with CLL and 20 healthy subjects. The immunophenotype of peripheral blood mononuclear cells (in both groups) and bone marrow cells (solely in the CLL group) was determined by flow cytometry. Cytotoxic effects were studied in at least three independent experiments.

Results: Patients with CLL showed higher frequencies and absolute number of exhausted B lymphocytes CD19+PD-1+ (p<0.0001), CD19+PD-L1+ (p<0.0001), CD19+CD200+ (p<0.0001) and CD19+CD200R+ (p<0.0001), as well as higher frequencies and absolute number of exhausted T helper lymphocytes CD4+PD-1+ (p=0.0021), CD4+PD-L1+ (p=0.0032), CD200+ (p=0.0027), CD200+ (p=0.0036), CD8+PD-1+ (p=0.0029), CD8+CD200+ (p=0.0038), CD8+CD200R+ (p=0.0073) than the controls in the peripheral blood. Similar observations were done in the bone marrow samples (p=0.0001, p<0.0001, p<0.0001, p=0.0134, p=0.0182, p=0.0263, p=0.0169, p=0.0261, p=0.0362, p=0.0293, and p=0.0379, respectively). Enhanced exhaustion of peripheral blood and bone marrow lymphocytes was associated with higher Rai stage, increased concentration of lactate dehydrogenase and beta-2 microglobulin, and more rapid progression of the dis-ease. The number of lymphocytes B CD19+ZAP-70+ correlated positively with the number of CD19+PD-1+ B cells, CD4+PD-1+ T cells, and CD8+CD200+ T cells.

Summary/Conclusions: The study confirmed the association between unfa-vorable prognosis and high expression of exhaustion markers in CLL patients. Determination of PD-1+, PD-L1, CD200+ and CD200R+ lymphocytes T and B constitutes valuable diagnostic tool, completing cytometric evaluation of CLL.

HSP70 AND HSF1 GO HAND IN HAND AND HAVE A ROLE IN THE SURVIVAL OF CHRONIC LYMPHOCYTIC LEUKEMIA NEOPLASTIC B CELLS

F. Raggi1,2, F. Federica1,2, V. Marinli1,2, F. Severini1,2, V. Trimmero1,2, L. Martinello1,2, A. Visentin1,2, E. Sciamonazz1, S. Imbergero1, M. Facco1,2, F. Pizzia1,2, G. Semenzato1,2, L. Trentin1,2

1Dipartimento di Medicina, Università di Padova, 2VITIM Istituto Veneto di Medi-cina Molecolare, Padova, Italy

Background: B-cell Chronic Lymphocytic Leukemia (CLL) is a neoplastic dis-order characterized by the accumulation of clonal B cells in peripheral blood, bone marrow and lymphoid tissues. CLL is a clinically and biologically hetero-geneous disease. As a consequence, novel biological and cytogenetic features have become increasingly important in predicting prognosis at the time of diag-nosis and the research for molecules involved in apoptosis resistance and increased survival of neoplastic B cells is still ongoing.

Aims: We recently found that the Heat Shock Protein of 70kDa (HSP70) is overexpressed in Chronic Lymphocytic Leukemia (CLL) B cells. Considering the crucial survival role of HSP70 in cancer, we were aimed at characterizing this protein and its master regulator, the Heat Shock Factor 1 (HSF1), within the pathogenetic mechanisms leading to CLL.

Methods: HSP70 and HSF1 expression levels were evaluated by Western blotting (WB) analysis in leukemic and normal B cells. HSP70 and HSF1 protein levels were correlated to IGHV mutational status and ZAP70 protein expression in CLL patients. HSP70 and HSF1 levels were also analyzed in neoplastic cells obtained from patients undergoing ibrutinib based regimen by WB analysis. Moreover, HSP70 and HSF1 localization was analyzed by subcellular protein fractionation followed by WB analysis. The effects of HSP70 and HSF1 inhibi-tion by Zafirlukast and Fisetin were evaluated by Annexin V/Propidium Iodide flow cytometry test and WB analysis of PARP cleavage.

Results: We demonstrated that HSP70 and HSF1 are overexpressed in leukemic vs normal B cells and their expression levels correlate to poor prog-nosis in CLL. We also analyzed HSP70 and HSF1 levels in patients following in vivo ibrutinib based regimen, observing a positive correlation between these two protein expression levels and moreover we observed that these two protein levels decreased after therapy. We found that at steady state both HSP70 and HSF1 are localized in the nucleus of BCL B cells. HSP70 and HSF1 inhibition was proved to be effective in inducing a dose-dependent in vitro apoptosis of CLL cells.

Summary/Conclusions: HSP70 and HSF1 overexpression and correlation with poor prognosis in CLL patients underline their pivotal role in the regula-tion of leukemic B cell survival. HSP70 and HSF1 both correlation and reduc-tion in CLL patients following in vivo ibrutinib regimen let us hypothesize a role of these proteins in the progression of the disease. In normal B cells HSP70 and HSF1 are both localized into the nucleus after stress conditions, however we found both HSP70 and HSF1 localized into the nucleus of CLL B cells at steady state, suggesting a constitutive activation of these proteins in CLL. Although HSP70 has been extensively linked to cancer, little pro-gresses have been made in bringing HSP70 inhibitors to the clinic, because of their potential off-target effects. For this reason we tried an alternative approach by targeting the HSP70 major regulator, HSF1. We observed that both inhibitors, Zafirlukast and Fisetin, lead to an in vitro dose dependent B cell apoptosis. These data demonstrate HSP70 and HSF1 involvement in the pathogenesis of CLL and identify HSP70/HSF1 axis as a target for new therapeutic strategies.

OVEREXPRESSION OF GENE FOR HUMAN CONCENTRATIVE NUCLEOSIDE TRANSPORTER 3 IS A PREDICTOR OF RESISTANCE TO FLUDARABIN-BASED CHEMOTHERAPY IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

V. Vukovic1, D. Antić1,2, T. Karan-Djurasević1, N. Milić2, M. Todorović-Bainić1,2, J. Bila1,2, B. Andjelic1,2, V. Djurasovic1,2, A. Sretenovic1, M. Smiljanic1, J. Jelicic1, M. Dencic-Fekete1, M. Perunicic-Jovanovic1, N. Kraguljac-Kurtovic1, S. Pavlovic1, B. Mihajlovic1,2

1Clinic for Hematology, Clinical Center of Serbia, 2Medical Faculty, University of Belgrade, 3Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, 4Institute for Medical Statistics and Infor-matics, Medical Faculty, University of Belgrade, Belgrade, Serbia
Background: Human concentrative nucleoside transporter 3 (hCNT3) belongs to a family of nucleoside transporters involved in fludarabine cellular uptake. It has been reported that overexpression of SL2C28A3 gene encoding hCNT3 predicts poor response to fludarabine-based chemotherapy. However, the mechanisms by which elevated expression of SL2C28A3 mediates fludarabine resistance are still elusive.

Aims: The aim of the study was to examine possible influence of SL2C28A3 gene overexpression on treatment response to fludarabine-cyclophosphamide therapy (FC) in patients with chronic lymphocytic leukemia.

Methods: We retrospectively analysed data from 54 CLL patients diagnosed and treated at Clinic for Hematology, Clinical Center of Serbia from 2003 to 2013. Blood samples were prospectively collected and analysed for biological and molecular features, as well as standard laboratory parameters. The expression of SL2C28A3 gene was analyzed in peripheral blood mononuclear cells by RT-PCR methodology, using TaqMan chemistry and ABI as endogenous control gene. Quantification of target gene expression was made by comparative Delta Delta Ct method using 18S-rRNA and CD58-BL60 cell line as the calibrator. All analyses were done prior to any treatment.

Results: Median age at diagnosis was 57 years (range 38-75). All patients were treated with fludarabine-based chemotherapy, 45 (83%) in the first treatment line. Overall response rate to the first line therapy was 81%, equally distributed on complete and partial responses (CR and PR), while the remainder included the same number of patients with stable disease (SD) and progressive disease (PD) (5, 9.6%). Most of the patients (42, 78%) relapsed during the follow up. At the time of the last follow up 14 (26%) patients were still alive, 35 (65%) were dead, and 5 (9%) were lost to follow up. Median overall survival was 78 months.

In the group of patients who received FC in the first treatment line (43/54), median expression of SL2C28A3 mRNA in patients who experienced CR, PR, SD and PD was 0.036±0.030, 0.062±0.063, 0.030±0.025 and 0.157±0.257, respectively. The level of SL2C28A3 expression was not associated with the IGHV mutation status, or the Binet stage. Patients who experienced PD to FC treatment overexpressed gene for hCNT3 compared to patients who achieved CR (p=0.013) and PR (p=0.05). We detected a significantly higher level of SL2C28A3 expression in patients who experienced PD to FC treatment in comparison to patients who achieved CR (p=0.013) and PR (p=0.05).

Summary/Conclusions: Overexpression of SL2C28A3 gene is a predictor of resistance to treatment with FC chemotherapy. Further studies are warranted to confirm these findings.

PB1772
THE SPECTRUM OF TP53, SF3B1, AND NOTCH1 MUTATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS EXPOSED TO IONIZING RADIATION DUE TO THE CHORNOBYL NPP ACCIDENT
N. Bilous1,*, I. Abramenko1, A. Chumak1, I. Dyagil2, Z. Martina2
1Clinical Immunology, *Hematology, Research Center for Radiation Medicine, Kiev, Ukraine

Background: Generally, chronic lymphocytic leukemia (CLL) is considered to be a non-radiogenic form of leukemia. We previously found some clinical and biological features of CLL in group of clean-up workers of Chornobyl NPP accident indicated unfavorable disease course, such as high frequency of solid tumors and Richter transformation, mainly unmutated status of heavy chain variable region (IGHV) genes with increased usage of IGHV1-69 and IGHV3-21 (Abramenko et al., 2008). Analysis of genetic features of leukemic cells in IR-exposed CLL patients may provide an additional data on the possible causal relationship with IR.

Aims: The aim of the study was to analyze TP53, NOTCH1 and SF3B1 mutations in CLL patients, sufferers of Chornobyl NPP accident to clarify the possible pathogenetic relationship between IR and CLL development.

Methods: TP53, NOTCH1, and SF3B1 mutations were analyzed in 106 CLL patients who have been exposed to ionizing radiation (IR) due to Chornobyl NPP accident (53 clean-up workers, 16 inhabitants of radionuclide contaminated areas, and 7 evacuees) and in 130 IR non-exposed CLL patients as the control group. TP53 gene mutation analysis was performed for exons 3 to 10. NOTCH1 mutations and SF3B1 mutations were analyzed in the hotspot regions of these genes were the vast majority of CLL-specific lesions were reported: in c.7282_7680 region in exon 34 of NOTCH1 mutation, which may influence CLL development under IR exposure.

Results: We found earlier mutual exclusivity between SF3B1 and TP53 lesions (p=0.001 in comparison between observed groups). Among IR-exposed CLL patients we found two different cases with identical rare mutation of TP53 gene - c.665C>T substitution leading to change proline for leucine at codon 222 (Pro222Leu). This substitution is very likely to represent inherited TP53 mutation, which may influence CLL development under IR exposure.

Summary/Conclusions: In summary, our data suggest that TP53 abnormalities are involved in CLL development in sufferers of the Chornobyl NPP accident and also a possible interaction between inherited IR sensitivity caused by mutation in TP53, radiation and CLL development.
Background: Chronic lymphocytic leukemia (CLL) is the most common form of adult leukemia in Western world with highly variable clinical outcome. Rituximab is a monoclonal chimeric anti-CD20 agent, that has demonstrated significant benefit for patients with different form of B cell lymphoproliferative disorders. Chemoinmunotherapy with rituximab, fludarabine and cyclophosphamide (R-FC) has shown to prolong progression free survival (PFS) and overall survival in CLL patients compared with chemotherapy alone. FCGR2A is polymorphic and has two alleles, FCGR2A-131H and FCGR2A-131R. This polymorphic variation is due to a single base substitution of nucleotide adenine for guanine in position 494. FCGR2A-131H allele presents a higher affinity for human IgG2, comparing to FCGR2A-R131. The gene for FCGR3A has also two polymorphic variant alleles: 158 valine (V158) and phenylalanine (F158) due to single base substitution of tímidine to guanine at nucleotide position 559. FCGR3A-158V variant has higher affinity for Fc gamma receptor than 158F variant. These Fc gamma receptor polymorphisms may influence antibody-dependent cytotoxicity (ADCC), complement-dependent cytotoxicity (CDC) and direct proapoptotic effect.

Aims: The aim of our study was to investigate a possible association of these two FCGR2A and FCGR3A variants with response to R-FC therapy in CLL patients. Methods: We have analyzed these two polymorphisms in 90 patients with CLL treated with R-FC regimen. Median age of our patients was 62.3 (36-78) and 63% were male. Number of patients with stage III/IV disease was 68 (75.6%) and median WBC count at the start of treatment was 68.5 (34-173) x10^9/L. Percentage of previously treated patients was 31/90 (34.4%). Average numbers of R-FC cycles were 4.3 and median PFS was 35.1 months. Median time of observation after treatment was 3.6 years (range 6 months-8 years). Response was evaluated 2 months after therapy according to National Cancer Institute (NCI) criteria. Complete response (CR) was achieved in 24/90 (26.7%), partial response (PR) in 56/90 (62.2%) and no response in 10/90 (11.1%). DNA was isolated from peripheral blood mononuclear cells and genotyping was performed by using PCR/RFLP methods. The distribution of genotypes was compared by using a chi-squared test or Fisher’s exact test.

Results: Distribution of genotypes in our patients was: 33% H/H, 49% H/R and 18% R/R for FCGR2A and 43% V/V, 40% V/F and 17% F/F for FCGR3A. Rate of CR and PR were similar irrespective of the FCGR variant. Our results did not demonstrate significantly different genotype distribution for FCGR2A (p=0.8001) or FCGR3A (p=0.1019) in CLL patients with complete, partial or no response to R-FC treatment (Table 1).

Summary/Conclusions: Our results are similar with previously reported results in other studies in CLL patients, but in contrast with the results for follicular lymphoma (FL), which showed that high-affinity FCGR2A-158V/V variant was associated with the highest response rates in FL patients treated with rituximab. These findings could be explained with the different mechanism of action of rituximab in CLL compared to lymphoma patients or could be due to the variations in selected patient’s population.

FCGR2A AND FCGR3A VARIANTS ARE NOT ASSOCIATED WITH RESPONSE TO RITUXIMAB IN PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

I. Panovska-Stavridis1,*, S. Trpkovska-Terzieva1, R. Angelovic1, O. Karanfilski1, T. Sotirova1, L. Cevreska1, A. Stojanovic1
1University Clinic of Hematology –Skopje, Macedonia, The Former Yugoslav Republic Of

Background: The mutational status of the immunoglobulin heavy variable (IGHV) genes is established as one of the most important prognostic molecular genetic markers in chronic lymphocytic leukemia (CLL). It divides the CLL patients into two subsets with a different clinical course, mutated (M-CLL) and unmutated (U-CLL). U-CLL is delineated with a cutoff value of 98% identity with the closest germ line of IGHV genes. The shaping of the CLL IGHV gene usage is determined by several genetic factors, gender, age and exposure to environmental factors. In addition, a strong bias in the use of individual genes and subgroups between normal and malignant B-cells and presence of highly homologous “stereotyped” heavy complementary-determining region 3 (VH-CD3) is shown, which suggests the role of a specific antigen in the pathogenesis of disease.

Aims: In this study, we analyzed the mutation status and pattern of IGHV, IGHD and IGJH gene usage in Macedonian CLL patients.

Methods: Ninety-seven consecutive CLL patients that presented at the University Clinic of Hematology –Skopje in the period between 2011-2013, were included in the study. IGHV mutation status and gene repertoire were analyzed using the reverse transcriptase– polymerase chain reaction (RT-PCR) and sequencing methodology. The mutational status of the IGHV genes was determined using two databases: IMGT/TV-QUEST tool and IgBLAST software. The stereotyped subset assignment was performed using ARREST/AssignSubset tool (Bioinformatics Analysis Team).

Results: We found that 44.3% of the cases belonged to M-CLL and 55.7% to U-CLL, with a progressive disease dominant in the U-CLL subset. Both groups were comparable regarding the age and gender distribution. Only 39% of the M-CLL patients presented with a progressive disease, compared to 74% of the U-CLL patients (p<0.05). The comparison of median time to the first treatment (TTT) between M-CLL and U-CLL (39 months versus 8 months, respectively) showed a statistically significant difference between the groups (p<0.01). Most frequently expressed IGHV genes were: IGHV1 (28.9%), IGHV4 (23.7%), IGHD5 (2.0%), and IGJH2 (1.0%). Among 32 different IGHV genes, 8 genes were found (V1-46, V1-69, V3-21, V3-23, V3-30, V3-33, V3-48 & V4-34) in 58.8% of all cases, revealing a strong bias in IGHV gene expression in CLL. IGHV1-69 was the most frequently expressed gene of all (16.5%), and exclusively found in the U-CLL group demonstrating a frequency of 29.6%. The IGJH3-21 was detected with a low frequency of 4.1%, as reported for CLL patients from other Mediterranean countries. The distribution of IGHD subgroups was as follows: IGHD3, 52.6%; IGHD2, 17.5%; IGHD6, 13.4%; IGHD1 7.2%; IGHD4 7.2%; and IGHD5 2.09%. The most frequent IGJH gene was IGJH4 (49.4%), followed by IGJH6 (23.2%), IGJH3 (13.4%), IGJH11 (4.1%) and IGJH2 (1.5%). IGJH1 (2.0%). In 10.1% of the cases, the VHCDR3 amino acid sequences belong to previously defined stereotyped clusters. Only one of the rearrangements with stereotyped VH-CD3 belonged to the M-CLL subset.

Summary/Conclusions: Our study showed a strong correlation between IGHV gene mutational status and clinical course of CLL. Results on IGHV-IGHD-IGJH gene usage in our study are comparable to the previously reported from Mediterranean countries. The high frequency of V1-69gene and low frequency of IGJH3-21 in our CLL patients that originate from a small geographic region further promotes the geographic bias in the use of IGHV genes and points to an important role in antigen stimulation in the pathogenesis of the CLL subsets. Our findings indicated a lower expression of the stereotyped BCR region than those previously reported (~30%), but they were comparable with the results reported for the Serbian CLL patients (10.1% versus 15.3%, respectively), in the only previous published study of this kind from Western Balkans.
Chronic lymphocytic leukemia and related disorders - Clinical

LAMBDALIGHTCHAINRESTRICTION–USEFULFORHAIRYCELLLEUKEMIAPROGNOSTICATION?
J. Araújo1,*, M. Sobrinho-Simões1, F. Afonso1, F. Príncipe1, J.E. Guimarães1
1Hematology, Centro Hospitalar de São João, Porto, Portugal

Background: Hairy cell leukemia (HCL) patients have near-normal life expectancies since the introduction of purine nucleoside analogues. However, HCL remains a chronic, often relapsing disease in which maximizing treatment-free survival (TFS) is the main goal.

Aims: Prognostication is not standardized in HCL, emphasizing the relevance of the characterization of HCL populations.

Methods: We retrospectively analysed 40 patients (90% men), diagnosed between 1997 and 2016, with a median follow-up of 6 years.

Results: At presentation, the median age was 58 years and 69% of patients were symptomatic - fatigue (53%), B symptoms (50%), bleeding (14%), abdominal discomfort (6%) and severe infection (22%). The commonest cytopenia was thrombocytopenia (70%), with median platelet count being 66x10^9/L. Monocyte counts below 0.1x10^9/L were observed in 61% of patients. Splenomegaly was observed in 83% of the patients and 21% had abdominal lymphadenopathies. The majority of the patients (88%) was treated with cladribine in first line, achieving an overall response (OR) rate of 100% and a complete response (CR) rate of 38%, of which 67% were classified as minimal residual disease (MRD)-negative CR. Retreatment was required in 33% of the patients, of which the majority received cladribine. The median time-to-next-treatment (TNT) from first to second line was 3 years. The OR rate for second-line treatment was 91%, 50% achieving CR, of which 33% were classified as MRD-negative CR. Only 5% of the patients required further treatment lines. Even the presence of scarce hairy cells in the bone marrow precluded classification of response as CR. This might have contributed to the low CR levels observed in our patients. As post-treatment bone marrow biopsies were available in only 24 patients, response analysis was restricted to these patients. All of these 24 patients had bone marrow fibrosis at diagnosis, which reverted when and in whom first CR was obtained. Median overall survival (OS) was not reached and, at 10 years, the OS was 90%. Four deaths occurred, all unrelated to HCL. Regarding prognostication, a trend to a longer TFS, albeit no statistically significant, was observed in patients achieving CR (namely MRD negative) and without thrombocytopenia at presentation. Excitingly, the 61% of patients with kappa (k) light-chain restriction (LCR) displayed a significantly higher TFS than those with lambda (λ) LCR (p=0.04, Wilcoxon-Gehan test). To the best of our knowledge, there are no published reports on prognostic value of LCR in HCL (Figure 1).

Figure 1.

Summary/Conclusions: If multicentre studies corroborate our findings, LCR may be of use in the prognostication/risk stratification of HCL. Similarly with multiple myeloma and other hematological malignancies, lambda (λ) LCR appears to correlate with worse prognosis, leading to a shorter TFS.

PB1777
CLINICAL EFFICACY AND LONG-TERM OUTCOMES OF SPLENECTOMY IN CHRONIC LYMPHOCYTIC LEUKEMIA
Y. Yevstakhevychn1,*, I. Yevstakhevychn1, O. Vygovskyn2, M. Semerakn1, V. Loginskyn1
1Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine
2Department of Haematology, Hematology and Transfusion Medicine Centre, Ukrainian Medical Academy of Postgraduate Education, Kyiv, Ukraine

Background: Chronic lymphocytic leukemia (CLL) is often accompanied by splenomegaly, which can increase to a giant size, causing abdominal discomfort, regional portal hypertension, and becomes a place of malignant cells concentration. In 2.3-4.3% of cases CLL may be complicated by autoimmune cytopenias (autoimmune hemolytic anemia (AIHA), immune thrombocytopenia (ITP), Evans-Fisher syndrome). Accordingly, the effectiveness of steroid and chemotherapy in such cases may be impaired, raising the question of splenectomy advisability.

Aims: To analyze splenectomy effectiveness in patients with CLL.

Methods: Splenectomy was performed in 41 patients with CLL, 12 of which were patients with CLL and ITP, 9 with CLL and warm type AIHA, 5 patients with CLL and Evans-Fisher syndrome, along with 19 CLL patients without immune disorders. Among the patients there were 26 males and 15 females. Indications to splenectomy were following: massive splenomegaly with abdominal discomfort, immune cytopenia and regional portal hypertension. In one female patient the surgical intervention was performed urgently due to spontaneous splenic rupture and acute intra-abdominal bleeding.

Results: Splenectomy was effective in 37 patients (90.2%): abdominal discomfort disappeared, hemolysis stopped and hemoglobin levels normalized or increased, platelets numbers normalized or increased. Splenectomy was ineffective in 3 patients with CLL associated with ITP: amid elimination of abdominal discomfort the platelets number did not increase significantly (2 patients), while in 1 patient despite increase in platelets number leukemia progression was observed. One (2.4%) patient with CLL and AIHA died on 3rd day after surgery because of acute adrenal insufficiency. The analysis of late effects of splenectomy in patients with CLL showed that average life expectancy after the surgery comprised 111.6 months within observation period between 11 and 277 months. In patients with CLL immune cytophenias the average life expectancy after surgery was shorter and equal to 60.7 months within the observation period between 2 and 361 months.

Summary/Conclusions: Splenectomy remains an effective method of treatment of patients with CLL accompanied by severe splenomegaly and immune cytopenia. Long-term results of splenectomy in patients with CLL without cytophenias are better than in patients with CLL and cytophenias. Aggressive hemolysys, large spleen covered in perisplenics adhesions, amid portal hypertension and thrombocytopenia are considered to be special surgical risk factors in this patients.

MONOCIONAL B-CELL LYMPHOCYTOSIS IN THAI POPULATION: PREVALENCE AND IMMUNOPHENOTYPIC CHARACTERISTICS
P. Kongtimm1,*, J. Chantakarnn1, W. Limvorapitak2, N. Wansornn2, T. Srinchaisawatn1, W. Udomchaisuwanm3, S. Issaragriskn4
1Hematology, 2Pathology, Faculty of Medicine Thammasat University, Pathumthani, 3Cancer Cyto genetic and Molecular Diagnostic, Chulabhorn Research Institute, 4Hematology, Faculty of Medicine Siriraj Hospital Mahidol University, Bangkok, Thailand

Background: Monoclonal B-cell lymphocytosis (MBL) is characterized by the presence of <5X10^9 clonal B-cells/L in peripheral blood (PB) in otherwise healthy subjects, in the absence of symptoms and signs of a B-cell lymphoproliferative disorder (LPD). MBL is considered a precursor to chronic lymphocytic leukemia (CLL) and other B-cell malignancies.

Aims: To study the immunophenotypic features and prevalence of MBL in healthy Thai individuals.

Methods: Peripheral blood (PB) samples from 616 healthy Thai individuals (313 female), 18-80 year-old with normal lymphocyte counts were immunophenotyped using high-sensitivity flow cytometry, based on 5-color screening for >5x10^9 total PB leukocytes. The initial PB samples were screened for clonal B cells using Multimix Triple-Color Reagent (Kappa Light Chains/FITC, Lambda Light Chains/RPE and CD19/RPE-Cy5). In those cases in which a clonal B cell population was detected by imbalanced of sIg:stilg ratio of >3:1 or <1:3, were further tested for CD5, CD23, CD20 and CD79a expression.

Results: Of total 616 subjects, MBL was found in 8 cases (1.2%) including 3 and 5 female and male cases respectively. Among 40 years or older, MBL was found in 5 out of 448 cases (1.1%). Compared with non-MBL group, subjects with MBL were significantly older (median age 51 years vs 45 years; p=0.01) and had a significant higher number of absolute and B-lymphocyte count (median 3.1 versus 1.6 X 10^9/L; p=0.03 and 0.35 versus 0.16 X 10^9/L; p=0.02, respectively) while the median white blood cell count was not different between 2 groups. Also, there were more subjects in MBL group who had family history of lymphoproliferative diseases (LPD); 37% vs 0% (p=0.01) and influenza vaccination within 2 years (50% vs 8.7%; p=0.003). Among 8 cases with MBL clone, 6 cases had low-count MBL (<0.5X10^9 clonal B-cells/L) while only 2 cases had high-count MBL (>0.5X10^9 clonal B-cells/L). All 8 cases had persistent positivity of MBL clone after tested was repeated within 3 months after the initial test. Of the follow up test, only 1 case with initial high-count MBL had decrease number of B cell clone and became low-count MBL. There was not specific different in age between subjects in low and high-count MBL group. Six cases had typical CLL phenotype MBL clone (CD5+, CD23+, CD20+ and light chain restriction) whereas 1 case had atypical CLL phenotype MBL (CD5+, CD20+, but abnormally low light chain restriction but CD23+) and 1 case had non-CLL phenotype MBL (CD20+ but CD5-). In univariate analysis, age (RR 4.19; 95%CI 1.0-17.7; p=0.049), absolute lymphocyte count (RR 2.76; 95%CI 1.04-8.87; p=0.047), family history of LPD (RR 122; 95%CI 51.1-293.4; p<0.001) and...
22nd Congress of the European Hematology Association
influenza vaccination (RR 10.47; 95%CI 2.54-43.07; p=0.003) were associated
with increase risk of developing MBL. After adjusted for age, only history of
influenza vaccination and family history of LPD were an independent risk factor
for developing MBL with age adjusted RR of 9.75 (95%CI 2.3-40.5; p=0.002)
and 92 (95%CI 56.3-149.5; p<0.001), respectively.
Summary/Conclusions: MBL prevalence in Thai population is much lower
than previously reported. It more frequent in elderlies and associated with
family history of LPD and influenza vaccination. Although uncommon, the
presence of high-count MBL warrants further investigations to define the biological and clinical significance in term of LPD transformation and long-term
survival.

Clinic, Falun Hospital, Falun, Sweden, 4IRCCS, Policlinico San Matteo, Pavia,
Italy, 5Department of Hematology, Uppsala University Hospital, Uppsala, Sweden, 6Department of Molecular Medicine, Hematology, Sapienza University,
Rome, Italy, 7Department of Hematology, Hospital Clinic, University of
Barcelona, Barcelona, Spain

Background: Spontaneous clinical regression in chronic lymphocytic leukemia
(CLL) is rare (1% per year). We previously reported on the clinico-biologic features of 9 Binet stage A CLL patients from our Center in Rome who experienced
a persistent spontaneous clinical regression of the disease at a median time
of 11 years from diagnosis, maintained after 5 more years of follow-up. The
lymphocyte count at CLL regression was 3.16 x 109/L (1.3-4.9), with a persistent
small CLL clone (CD19+/CD5+/CD23/light chain restricted: 44%, range 5-60%).
Biologic features included negative CD38, mutated IGHV, often with VH3-30
and Vk4-1 usage, and a distinctive gene expression profile.
Aims: To conduct a retrospective collection of clinical data and basic biologic
information on CLL spontaneous regressions and to make them accessible for
future research.
Methods: A registry of spontaneous CLL regressions (absence of lymphadenopathy, splenomegaly or constitutional symptoms, peripheral blood (PB)
lymphocytes <4 x 109/L, in the absence of any previous treatment) was
launched within the ERIC consortium.
Results: So far, 9 CLL patients showing a spontaneous regression have been
reported and 8 have been formally registered, 7 from Italy and 2 from Sweden.
Six were males and 3 females, with a median age of 57 years at diagnosis
(range 51-82), stage Binet/Rai A/0 in 6, A/I in 2 and B/II in 1. The median lymphocyte count at diagnosis was 14.1 x 109/L (5.3-51.9). Biologic features included: mutated IGHV in 8/8 with VH3-30 (2), VH3-21, VH3-15, VH3-23, VH4-31,
VH4-34, VH4-59; CD38 <30% in 6/6; ZAP70 <20% in 4/6; FISH (7 cases):
del13q in 4, negative in 3, +12 in 1 case. No patient had undergone treatment,
except for one diagnosed in 2009 who received FCR for disease progression
in 2013 (lymphocytes 107 x 109/L), obtained a PR and 18 months later developed a Richter’s syndrome - a diffuse large B-cell lymphoma clonally unrelated
to CLL - with the concomitant disappearance of the CLL clone from the PB and
bone marrow, that has lasted up to January 2017 (lymphocytes 3.5 x 109/L,
CLL 0.035 x 109/L). An additional case diagnosed in 2013 (stage A/I, lymphocytes 37.2 x 109/L) reached the highest lymphocyte count 19 months later
(91.2 x 109/L) and subsequently started a spontaneous reduction in lymphocytosis down to 39.6 x 109/L in 2015 and to 8.9 x 109/L in January 2017 in
stage A/0, indicative of a partial but ongoing CLL regression. Excluding the
latter cases, in the other 7, all in stage A/0, the highest lymphocyte count was
16.0 x 109/L (8.9-76.0), the lowest at the last follow-up was 2.8 x 109/L (1.84.4), with 0.66 x 109/L CLL cells (0.085-3.0) in the 4 evaluable cases. The
median time from diagnosis to clinical regression was 4 years (range 2-17)
and this has been maintained for 2 further years (range 0.5-7). One of these
cases (mutated VH3-21, +12) seems the most dramatic: in 2008 at diagnosis,
the lymphocytes were 51.9 x 109/L, in 2009 a peak at 76.0 x 109/L was recorded; in 2011, when the CLL regression started, the patient underwent several
mild viral upper respiratory infections; the CLL complete regression (1.8 x 109/L)
persists up to the last follow-up. In 5/9 cases one event - mild viral infections,
a cerebral hemorrhage, a stroke, a pelvis fracture and a Richter’s syndrome occurred before the spontaneous regression, but no relevant drug intake was
recorded.
Summary/Conclusions: Clinicians should be aware that spontaneous regression is a possibility, albeit infrequent, in the natural history of CLL. The collection
and study of such cases within the ERIC registry may shed light on mechanisms
leading to spontaneous regression and critical pathways in immunosurveillance
in CLL.

PB1780

CLINICAL AND LABORATORY CHARACTERIZATION OF PLATELET
DYSFUNCTION DURING IBRUTINIB TREATMENT IN PATIENTS WITH
CHRONIC LYMPHOCYTIC LEUKEMIA. MONOCENTRIC EXPERIENCE
I. Innocenti1,*, M.A. Alberelli2, F. Autore1, S. Sica1, E. De Candia2, L. Laurenti1
1Department of Hematology, Catholic University of Sacred Heart, Rome/ Institute of Hematology, 2Department of Oncology and Hematology, Catholic University of Sacred Heart, Rome/ Institute of Internal Medicine, Rome, Italy

Background: Ibrutinib (IBR) is a potent and irreversible inhibitor of Bruton’s
tyrosine kinase (Btk) approved by FDA for the treatment of patients (pts) affected by chronic lymphocytic leukemia (CLL) with del 17p or TP53 mutation or for
pts with relapsed/refractory (R/R) CLL. IBR is associated with bleeding events
usually mild (Common Toxicity Criteria (CTC) grades 1-2), rarely severe (grade
3-4). A defect of platelet function, namely an inhibition of Btk-mediated signaling
by platelet glycoproteins (GP) GPVI and GPIb, has been hypothesized to cause
these bleedings. IBR associated bleedings and platelet dysfunction may be
relevant in CLL pts who are usually elderly and with comorbidities requiring
antithombotic therapies.
Aims: To investigate and characterize the effect of IBR on platelet function in
pts with CLL.
Methods: We enrolled from May 2014 to December 2016 twenty pts with
CLL treated with orally administered 420 mg daily of IBR; 18 R/R CLL pts
received IBR in monotherapy and 2 pts with previously untreated CLL
received IBR in association with anti-CD20 MoAb. Median age was 68 years
(57-84); 13 pts had unmutated IgVH and 2 had 17p deletion. The median
number of prior therapies in R/R CLL pts was 3 (2-7). Five pts discontinued
IBR therapy: 2 for Richter’s transformation, 1 for progressive CLL, 1 underwent allogeneic HSCT, 1 for heart disease. The platelet function was studied
before and during IBR by light transmission aggregometry (LTA) using
platelet-rich plasma and the following agonists: ADP 2-4 uM, PAR1-AP 25
uM, Collagen 10-3.3-2 ug /mL, arachidonic acid 1 mM, ristocetin 0.6-1.2
mg/mL. Also measurements of von Willebrand factor antigen (vWF:Ag) and
ristocetin cofactor activities (RiCo) by chemiluminescent immunoassay were
performed. All pts had measurements of the platelet function at the baseline
and after 1, 3, 6 months initiation of IBR and then every 3 months up to 24
months. Median observation period was 9 months. No patient received concomitant antiplatelet or anticoagulation therapy.
Results: Nineteen pts achieved a partial response and an increase of hemoglobin and platelet count. We recorded CTC grade 1 or 2 bleedings (bruising,
petechiae, conjunctival and retinal hemorrhage, rectal bleeding) in 15 pts; no
patient needed IBR interruption or dose reduction. All pts displayed severe
impairment of collagen induced aggregation upon IBR. Reduction of maximal
aggregation (35.6+/- 32% vs 70.6+/- 21% baseline) and prolongation of the
lag phase (261+/- 54 sec vs 72+/- 26.8 sec baseline) by 2 ug/mL collagen was
measured in all pts during IBR. In 10 pts a significant improvement of the aggregation by 2 uM ADP (71+/- 31.8% vs basal 48.6+/- 31%) and 4 uM ADP (84+/11% vs basal 64+/- 25%) was found during IBR. The aggregation by 25 uM
PAR1-AP, 1.2 mg/ml ristocetin and 1 mM arachidonic acid was unchanged
before and under IBR. Finally, in 9 pts the vWF:Ag and RiCo were high at the
onset of the disease (163+/- 59.8% and 181.6+/- 82.5%) and reduced up to
normal values under IBR (118+/- 71% and 145+/- 65%).
Summary/Conclusions: Our study showed minor bleedings in pts treated
with IBR. A severe impairment of collagen-induced aggregation was caused
by IBR, which was counteracted by amelioration of ADP-induced aggregation,
that could explain, at least partially, the mild clinical phenotype in treated pts.
The assessment of platelet function in IBR treated CLL pts could help to predict
and monitor the bleeding risk, and to guide pts through invasive procedures.
In addition, pts under anticoagulant or antiplatelet treatment might need be
carefully monitored by clinical and laboratory evaluation.

Background: Hairy cell leukemia (HCL) accounts for approximately 2% of all leukemias and is associated with pancytopenia, splenomegaly, and recurrent infections. Therapy with the purine analogues cladribine (2CdA) or pentostatin (2’deoxycoformycin), has been most effective and both agents have achieved equivalent results in HCL. In this regard cladribine given as a single course, achieves a high response rate. Several alternative dosing schedules have been reported to be associated with suboptimal responses. Here we report either as a “fixed daily dose” or “weight based dose” for 5 or 7 days. Seeing that excellent results are obtained using 2CdA in all schedules used, it now seems very important to focus on reducing therapy induced toxicity, related mostly to development of neutropenia, immunosuppression and severe infections.

Aims: In this prospective study, we have summarized the Israeli experience with HCL over the past 30 years, and analyzed demographic data, relevant laboratory and clinical parameters with special emphasis on outcome after first line treatment with cladribine.

Methods: We collected retrospective data on patients with HCL from 12 medical centers in Israel, followed and treated during 1985-2015. The study was approved by local institutional IRBs of each medical center.

Results: Data from the medical records of 202 patients with HCL was summarized. Mean follow up was 7.5 years (0.1-40), with a 5 and 10 years’ overall survival of 96% and 90.62% respectively. The median age at diagnosis was 53 years, and most (81.77%) were males. In terms of ethnicity: 88.3% of patients were Jews with (52.2% Ashkenazi and . 36.1% Sephardic Jews) while 11.7% were Arab, Druz or others. First line therapy with cladribine was given to 159 patients (80.71%); other therapies 9.14%, while 11% did not receive any treatment. The median time from HCL diagnosis to treatment with 2CdA was 5.9 years. IV therapy was given to 62% of patients and 38% received it SC. Complete remission rates, progression-free survival and overall survival were not significantly different between the two schedules. In univariate analysis: Sex, ethnicity, dose, patient weight, and treatment duration (5-7 days) had no impact on outcome, but patients older >65 years had a shorter survival. Infectious complications requiring hospitalization was reported in 50.3% of all treated patients (54%, post IV and 47% post SC delivery; p=0.4). Median days of hospitalization were 8 for both groups (p=0.05), and the length of NADIR was 18 and 20 days for IV and SC delivery respectively (p=0.33).

Summary/Conclusions: This study is the first comprehensive summary of the national Israeli experience involving a large cohort of HCL patients with long follow up. These results serve as validation of previous reports relating to HCL and confirm that the excellent outcome achieved after a single course of treatment with 2CdA is independent of schedule and method of drug delivery. In addition, patient ethnicity was insignificant.

CHRONIC LYMPHOCYTIC LEUKEMIA: CHANGES IN CLINICAL STAGE DISCRIMINATE PATIENTS WITH DIFFERENT OUTCOME WITHIN THE IWCLL PARTIAL RESPONSE CATEGORY

E. P. Vicente1,2,*, A. Martínez2, A. Soler2, C. Cuellar1, A. Mora1,2, R. Bosch1,2, R. Martino1, C. Moreno1,2

1Department of Hematology, 2Laboratory of Oncology/Hematology and Transplantation, Instituto de Biomedical Research, IIB Sant Pau, Hospital Sant Pau, 3Laboratory of Hematology, Hospital Parc Taulí, 4Laboratory of Hematology, Hospital Sant Pau, Barcelona, Spain

Background: Over the last decades, progress in chronic lymphocytic leukemia (CLL) treatment has resulted in an impressive increase in overall survival (OS). In CLL, as in other tumors, response to therapy overcomes negative prognostic factors and is the most important predictor of survival. Clinical stages reflect tumor load and correlate with OS both at diagnosis and over the course of the disease (Rai et al, Blood 1975).

Aims: To determine whether changes in clinical stage discriminate patients with different outcome within IWCLL response categories, particularly the heterogeneity of the partial response (PR) group.

Methods: Two-hundred ninety-nine patients with CLL were retrospectively evaluated. Median follow-up was 91 months (range, 2-390). CLL diagnosis was based on IWCLL criteria. Endpoints were time to next treatment (TTT) and OS. TTT and OS curves were estimated by the Kaplan-Meier method and differences evaluated. Median follow-up was 91 months (range, 2-390). CLL diagnosis was reported in 50.3% of all treated patients (54%, post IV and 47% post SC delivery; p=0.4). Median days of hospitalization were 8 for both groups (p=0.05), and the length of NADIR was 18 and 20 days for IV and SC delivery respectively (p=0.33).

Summary/Conclusions: This study is the first comprehensive summary of the national Israeli experience involving a large cohort of HCL patients with long follow up. These results serve as validation of previous reports relating to HCL and confirm that the excellent outcome achieved after a single course of treatment with 2CdA is independent of schedule and method of drug delivery. In addition, patient ethnicity was insignificant.

PB1783

INCIDENCE OF THYROID GLAND DISORDERS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

A. Tombak1,*, M.A. Ucar1, R. Gen2, M.A. Sungur3

1Hematology, 2Endocrinology, Mersin University, Mersin, 3Biostatistics, Duzce University, Duzce, Turkey

Background: Frequency of autoimmune complications like immune anaemia or immune thomboocytopenia has increased in patients with chronic lymphocytic leukemia (CLL). However, there is no data in the literature investigating the relation of the other autoimmune disorders including thyroid gland diseases with CLL.

Aims: We aimed to investigate the presence, features and frequencies of thyroid disorders in patients with CLL.

Methods: Thyroid function tests, thyroid autoantibodies (antithyroglobulin antibody [anti-TG], antithyroid peroxidase antibody [anti-TPO]), thyroid ultrasonographies (USG) and scintigraphies of CLL patients were performed. Demographic data, Rai-stages, and establisment of thyroid disorders were recorded.

Results: One hundred CLL patients were included into the study (65 male, mean age was 62.9±10.4). Free T3 (T3) was within normal limits in 96 cases (96%), was low in 2 cases (2%), was high in 2 cases (2%); free T4 (T4) was normal within normal limits in 89 cases (89%), was low in 7 cases (7%); was high in 4 cases (4%); TSH was within normal limits in 90 cases (90%), was low in 7 cases (7%), was high in 3 cases (3%). Anti-TPO and anti-Tg were positive in 10 cases (11.8%) and in 18 cases (21.2%), respectively. While USG was normal in 36 cases, multinodular goiter (MNG) in 21, chronic thyroiditis in 20, MNG associated with thyroiditis in 10, uniodular goiter (UNG) in 8, UNG associated with thyroiditis in 4, and diffuse goiter in 1 case were determined by USG. Toxic adenoma in 3 cases, toxic MNG in 2 cases, and thyroiditis in 1 case were determined in 6 patients in whom thyroid scintigraphy was performed for hyperthyroidism. After evaluation of all the tests; while no thyroid disease was determined in 33 of the cases (33%), MNG in 25 (25%), thyroiditis accord-
and was positive in 11 patients in ≥65 years old age group (p<0.053). There was no statistically significant difference in thyroid function tests according to the Rai stages, ages and sexes.

**Summary/Conclusions:** We determined that incidence of hypothyroidism or hyperthyroidism associated with all reasons do not increase in patients with CLL when compared with general population. However, we also determined that the incidence of Hashimoto thyroiditis was higher than general population (incidence of Hashimoto thyroiditis in general population is 2-5%). Anti-TG positivity was also higher than general population (positivity of anti-TG in general population is 5-20%). In addition, the positivity of 2 antibodies increased with advanced ages. Patients with CLL especially the elderly cases - in both sexes and all Rai-stages should be examined for thyroid gland disorders, mainly for Hashimoto thyroiditis.

**PB1784**

**CLINICAL-BIOLOGICAL CHARACTERISTICS, TREATMENT OUTCOME AND SURVIVAL OF SMALL LYMPHOCYTIC LYMPHOMA PATIENTS: A REAL-LIFE EXPERIENCE**

S. Sachanas1,1, G. Pangalis1, M. Moschogianni1, C. Kalpakidis2, M. Angelopoulou3, C. Kyrtsonis3, V. Bartz2, X. Yiakoumi3, E. Koulis1, P. Tsirkinidis1, M. Psyllaki4, H. Papadaki4, P. Korkolopoulou5, D. Rontogianni6, T. Vassilakopoulos7

**Background:** Studies of B-SLL published to date have included heterogeneous groups of patients(pts) and did not use modern diagnostic criteria, or included pts who had in fact chronic lymphocytic leukemia. Outside the context of clinical trials, SLL pts are treated heterogeneously and thus there are no data concerning the impact of different treatment approaches on response and survival. In the updated WHO classification it is pointed out that there are a subset of cases with lymph node(LN) involvement by SLL in which proliferation centers(PCs) were not observed and pts in whom lymphadenopathy was <1.5 cm showing a better prognosis.

**Aims:** To: a)record clinical, biological features and treatment strategy in a series of SLL pts diagnosed in our center b)correlate clinicopathological characteristics and treatment with response and survival c)detect possible differences in terms of response and survival between SLL pts according to LN characteristics (size of LN and presence of PCs)

**Methods:** Pts diagnosed with SLL from 2007 up to now fulfilling the diagnostic criteria of SLL were included. Clinical and biological data were recorded at diagnosis as well as treatment related variables, such as type of treatment, response and patient survival. Moreover, LN features such as the size, and the presence of PCs were also studied. Pts were evaluated in hematoyxin and eosis sections and defined as pale areas containing lymphocytes and paramunoblasts, surrounded by a dark background of small lymphocytes.

**Results:** 47 pts were analysed. Pts' median age was 69y (range, 40-87) with no gender predominance (24male/23female). According to Binet staging system 12, 19 and 9 were classified as A, B and C stage respectively while according to Ann Arbor staging 11 pts (28%) had advanced disease stage. 11 pts presented with bulky lymphadenopathy, 11 had splenomegaly and 4 had B-symptoms. LN biopsies were performed in 37 out of 47 pts. All pts underwent bone marrow (BM) biopsy with a median BM infiltration of 45% (0-97%). Pts were identified in 19 out of 24 pts in whom data were available, while 31 pts were presented with LN >1.5 cm showing a better prognosis.

**Summary/Conclusions:** Outside the context of clinical trials SLL pts were treated mostly with lymphoma immunochemotherapeutic protocols while mild treatment approaches resulted in significant responses. LN features such as size and presence of PCs tended to have prognostic significance. Further analysis in larger series of pts is on the way.

**PB1785**

**HEMINSIGHT TO ASsess PATIENT REPORTED OUTCOMES O F PATIENTS AFFECTED BY CHRONIC LYMPHOcytic LEUKEMIA IN DAILY CLINICAL PRACTICE**

G. Reda1, B. Fattizzo2, R. Cassin1, E. Saluzz1, E. Flospergher2, V. Mattiello2, M. Sciume1, E. Ferretti1, C. Andersen2, E. Oliva3, A. Cortelezzi2

**Background:** Chronic lymphocytic leukemia (CLL) is the most common leukemia in Western Countries, with a median age at diagnosis between 67 and 72 years. The therapeutic landscape of CLL is changing rapidly with the advent of small molecules acting as B-Cell Receptor (BCR) signaling inhibitors. In this setting, long term oral therapy may lead to the reduction in compliance, with associated impact on effectiveness. Moreover, long-term follow-up may highlight complications, such as drug-related adverse events that, together with the disease itself, may impact quality of life (QoL). Patient Reported Outcomes (PROs) in daily clinical practice is a resource-intensive procedure and may be affected by low adherence, risk of recall bias and difficulties in establishing reproducible procedures. HeminSight, a project conceived in 2010 for myeloproliferative neoplasms in haematological centres in Denmark, enables patients to periodically submit PROs online to be combined to the medical records.

**Aims:** HeminSight was implemented at our Centre to collect PROs from CLL patients in daily practice.

**Methods:** HeminSight incorporated the EORTC QLC-C30, EORTC QLC-CLL 16, SF-36, and the eight-item Morisky Medication Adherence Scale (MMAS-8) questionnaires to collect PROs and their changes during various stages of CLL (diagnosis - progression - treatment). PRO assessments were scheduled for the patients who received regular reminders by email to complete the tasks. The following measurements will be assessed: system attraction (percentage of CLL patients adhering to the project); patient compliance in filling out questionnaires; system efficiency (number of alerts related to QoL worsening and number of questionnaires not submitted) and system effectiveness (significant differences in changes in QoL scores from diagnosis to response/relapse, changes of therapeutic approach/action following an alert, changes in adherence of therapy).

**Results:** At the time of the present report, 74 patients with a CLL diagnosis have been enrolled, 15 of whom were newly diagnosed. Fourteen patients underwent cytoreductive therapy and 2 are under treatment with novel oral drugs. System attraction: the study was proposed to 91 consecutive patients, independently of age, level of education and internet accessibility, and 72.5% of patients agreed to participate to the study. The main reason of refusal was older age and scant internet/technology knowledge. In 3 cases with no access to internet, but with interest to participate in the project, the questionnaires were administrated through tablet, before the scheduled visit, by a dedicated nurse. Patient compliance: a global response of 58.2% was observed; 48 patients responded at least once and 23 at all scheduled time points. In each case, all questionnaires were fully completed. At this timepoint we cannot yet evaluate system effectiveness as the study is still ongoing. However, ad interim data (Table 1) suggest that patients who interrupt questionnaires fulfilling are those with younger age, more intense working activity and experiencing no changes in disease status (e.g. untreated cases or those in remission). In particular, patients who were under treatment during the questionnaire administration period, showed a higher adherence compared to those in follow up, both previously treated or not (80% versus 26%, p<0.05).

**Summary/Conclusions:** In conclusion, HeminSight is a useful tool for QoL evaluation in CLL patients. Provisional data suggest a higher compliance of those patients who feel that they need a closer contact with the clinician, both for individual disposition or disease status.
Background: Chronic lymphocytic leukemia (CLL) is the most prevalent form of leukemia in aged industrial countries, accounting for 20% to 30% of all leukemia cases. CLL affects mainly elderly patients, with a median age at the time of diagnosis reported to be 71 years. Although CLL is not curable, disease symptoms and progression may generally be controlled with adequate pharmacologic treatments. Bendamustine-based regimens have long been used in the management of CLL patients but few studies have analyzed the comorbidity- and/or adverse event (CAE)-related healthcare costs in elderly patients receiving these regimens in a real-world setting.

Aims: To describe all-cause and CAE-related healthcare costs of elderly patients with CLL treated with a bendamustine-based regimen in second or later lines of therapy in a real-world setting.

Methods: A retrospective cross-sectional cohort study design was used. Adult patients who received a bendamustine-based regimen in second or later lines of therapy on or after January 2010 were identified from the Medicare Limited Data Set (LDS) 5% Standard Analytic Files (data availability: 1999–2014). The index date was defined as the initiation date for the first of the studied bendamustine-based regimens. Selected patients were required to be continuously enrolled in their Medicare plan for ≥6 months before and ≥3 months after the index date – unless the patient died during the first 3 months after the index date. Patient cohorts were determined based on the treatment initiated on the index date (index treatment): the two most prevalent bendamustine-based regimens were analyzed, i.e., (1) bendamustine and rituximab in combination (BR cohort) and (2) bendamustine monotherapy (bendamustine cohort). Healthcare costs, including inpatient, emergency room, outpatients and CLL-drug costs, incurred during the treatment with the index treatment were described for each cohort. For each medical cost component, all-cause and CAE-related costs were summarized. Healthcare costs were adjusted for inflation (2016 USD) and reported per-patient-per-month (PPPM).

Results: A total of 275 patients were included in the BR cohort and a total of 101 patients in the bendamustine cohort. Most patients (61.8% in the BR cohort and 65.0% in the bendamustine cohort) were male and the mean age was approximately 75 years old. During the 6 months prior to the index date, patients in the BR and bendamustine cohorts were similar in terms of comorbidity profile; mean Charlson comorbidity index was 3.53 in the BR cohort versus 3.63 in the bendamustine cohort (p=0.581). During treatment, total all-cause healthcare costs were $14,520 PPPM for the BR cohort and $13,125 PPPM for the bendamustine cohort – outpatient costs (mainly driven by CLL-drug costs) represented the largest cost component. CAE costs accounted for a relatively large portion of the total all-cause healthcare costs; 56.3% for the BR cohort and 66.4% for the bendamustine cohort.

Summary/Conclusions: In this population of elderly patients previously treated for CLL, healthcare costs incurred during relapsed treatment with bendamustine-based regimens were high and a large portion of the costs were driven by comorbidity and/or adverse event-related costs. Results also suggest that the addition of rituximab to bendamustine does not appear to be a major cost factor.

PB1787

THE ROLE OF MAINTENANCE THERAPY IN THE TREATMENT OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

A. Kuvshinov1, C. Voloshin1, I. Martynevich1, A. Garifulin1, E. Kleina1

1Russian Scientific Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: The inclusion in the treatment program of new drugs (including new monoclonal antibodies and targeted therapies) allowed the majority of patients with chronic lymphocytic leukemia (CLL) to achieve disease remission (complete or partial) after combined therapy. So, at now, the urgent task is long-term preservation and the deepening of the therapeutic response, if it is possible. This problem can be solved by intensification of therapy (including autologous transplantation of hematopoietic stem cells) or maintenance therapy (MT).

Aims: To estimate the importance of maintenance therapy in the treatment of patients with CLL.

Methods: The study included 198 patients. Male to female ratio - 1:3.1. We have used NCI revised guidelines (Hallek M, et al., 2008) for treatment initiation, assessment of residual disease and minimal residual disease (MRD). Induction chemotherapy was conducted under the following programs: RB, FC, RFC, R-CHOP, Ibritinib-RB, Ibritinib-R. Evaluation of MRD was performed using 5-color flow cytometry of the bone marrow cells. The maintenance therapy was conducted 144 (72.7%) patients: Rituximab 500 mg/m2 intravenously every 8 weeks (n=116) for 2 years; Ibritinib 420 mg, orally, daily (n=28) continuously.

Results: The increasing of the depth of response (from partial (PR) to complete remission (CR)) was observed only in group of patients receiving MT – 10.4% (15/144) (p=0.013). The frequency of increase the depth of remission in the patients treated with MT of brutinib was 28.6% (8/28), MT of Rituximab – 6.0% (7/114) (p=0.0005). The medians of PFS and duration of response were a longer in the patients with MT versus in the patients without MT: PFS – 48 months and 37 months, respectively (p=0.03); duration of response – 44.0 months and 25.5 months, respectively (p=0.0006). The median of duration of response in the patients with MT of brutinib was not reached, in the patients with MT of Rituximab – 41.9 month, in the patient without MT – 25.5 month (p=0.004). The frequency of relapses in the group of patients with MT was 39.6% (57/144), in the group of patients without MT – 66.7% (36/54) (p=0.0007). Recurrence of the disease occurred more frequently in the group of patients treated with MT of Rituximab, compared with brutinib: 45.7% (53/116) and 14.3% (4/28), respectively (p=0.002). The median duration of observation in the group with rituximab was 22 months, while in the group with ibritinib – 11 months. MRD was not detected after 6-12 months of MT in 23.5% (12/51) had previously MRD-positive patients. Among patients with MRD-negative CR relapse is less common than in patients with MRD-positive CR – 20.0% (4/20) versus 62.5% (10/16), respectively (p=0.009). Significant differences in the incidence of infectious complications between patients with MT and without of MT were not detected (p=0.05) (Figure 1).

Figure 1.

Summary/Conclusions: The conducting of MT patients with CLL allows to achieve increasing the depth achieved remission and increase the duration of its preservation. MT may be a means of control over the minimal residual disease and the method of its eradication.

MULTISITE PERFORMANCE EVALUATION STUDY OF THE BD ONEFLOW LYMPHOID SCREENING TUBE

B. Balassa1, C. Green2, J. Kendall2, D. Gladding2, C.J. Fox2, D. Van Hoof2, V. Fraser2, A. Doherty3, D. Tieleman4, L. Wolfe5, K. Judge6

1Medical Affairs, 2BD Biosciences, San Jose, United States, 3BD Biosciences, Oxford, United Kingdom, 4BD Life Sciences, Erembodegem, Belgium, 5BD Clinical Corporate Clinical Development, Sparks, Maryland, United States

Background: The BD OneFlow solution for diagnostic screening of chronic lymphoproliferative disorders (CLPDs) includes a standardized flow cytometry approach based on the EuroFlow (EF) Consortium liquid reagent system. The BD OneFlow solution enables reproducible identification and discrimination of normal from aberrant mature cell populations by combining standardized assays, setup reagents, and protocols. The BD OneFlow LST (Lymphoid Screening Tube) is intended for flow-cytometric immunophenotyping of normal and aberrant mature lymphocyte populations of B, T, and NK lineages in specimens (peripheral blood, bone marrow, and lymph node) from patients with hematological disorders. BD OneFlow LST acquisition and analysis template version 1.0 was revised to version 2.0 to include discrimination of lymphocytes as a percentage of total leukocytes. The FCS files from evaluative specimens of the original LST clinical trial were regressed using BD OneFlow LST template v2.0.

Aims: The object of this study was to regress the FCS files from all the evaluative specimens previously collected using LST template v1.0 in the original clinical study to demonstrate equivalency between the investigational BD OneFlow LST system and the comparator EF liquid reagent system on a BD FACSCanto II flow cytometer with the 4-2H-2V CE-IVD configuration and LST template v1.0.

Methods: The FCS files using LST v1.0 template from the original clinical study included de-identified remnant peripheral blood (n=123), bone marrow (n=53), and lymph node (n=31) specimens from patients and healthy donors. Specimens

haematologica | 2017; 102(s2) | 717

Madrid, Spain, June 22 – 25, 2017
were collected in EDTA or heparin anticoagulants or PBS (for lymph nodes) at three external study sites. Informed consent was not required in this clinical study. All specimens in the original study were simultaneously stained with investigational BD OneFlow LST and comparator EF liquid reagents within 24 hours of collection and were acquired within 60 minutes of staining. In the current study, analyses were performed on a BD FACSCanto II instrument using LST v2.0 templates. BD FACSData Verification Software v6.0.1. For all endpoints, specimens were categorized as normal or follow-up needed. If follow-up was needed, specimens were categorized as B-, T-, NK-, or other-cell lineage. Overall agreement, negative agreement, and positive agreement, along with their one-sided lower 95% confidence limits, were calculated. For quantitative (percent) comparison of defined cell populations, Deming regression (slope and intercept analysis) was performed between the BD OneFlow method and the EF method.

Results: The BD OneFlow LST system compared to the EF system gave 100% (207 of 207) overall agreement (lower 95% CI: 98.6%) in delineating patients into normal (no follow-up) or follow-up, and 100% overall agreement in identifying B-, T-, NK-, and other-cell lineage (lower 95% CI: 98.6%). There was 100% positive agreement and 100% negative agreement between BD OneFlow and EF for follow-up vs no-follow-up (normal) and for all cell lineages from specimens that required follow-up. Furthermore, compared to the BD OneFlow method, the BD OneFlow LST system met the acceptance criteria for the quantitation of cell populations (slope and intercept regression) for the defined cell populations.

Summary/Conclusions: The multiparametric performance evaluation of the BD OneFlow LST system and the comparator EF liquid reagent system was consistent in identifying abnormal from normal mature populations in patients with CLPDs. BD OneFlow LST is fit for in vitro Diagnostic Use, CE Marked to the European in Vitro Diagnostic Medical Device Directive 98/79/EC. 23-19566-00.

PB1789
IMMUNOGLOBULIN HEAVY/LIGHT CHAIN ASSAY DETECT IMMUNE DYSREGULATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

1Almog Diagnostic, Park Shoham, 2Hematology Unit, Galilee Medical Center, Nahariya, 3Hematology Unit, Ziv Medical Center, Safed, 4Medical Unit, Haemek Medical Center, Afula, 5Department of Hematology, Sourasky Medical Center, Tel Aviv, 6Hematology Unit, Meir Medical Center, Kfar Saba, 7Hematology Unit, Kaplan Medical Center, Rehovot, 8Hematology Unit, Assaf Harofeh Medical Center, Zerifin, 9Department of Hematology, Shaare Zedek Medical Center, 10Department of Hematology, Hadassah University Hospital, Jerusalem, 11Hematology Unit, Barzil Zion Medical Center, Haifa, Israel.

Background: Chronic lymphocytic Leukemia (CLL) is frequently accompanied by immune dysregulation. Hypogammaglobulinemia is the most important associated immune defect and all three classes of immunoglobulins (IgG, A and M) are involved. Recently, a novel assay for detecting heavy/light chain (hevylight) and their ratios has been described (HLC), which improves immunoglobulin detection and monitoring in plasma-cell dyscrasias by quantitating the different light chain types of each immunoglobulin class. The frequency and biological role of this assay has as yet not been studied in CLL.

Aims: To study the frequency of abnormal Heavy Light chain assay, in CLL patients.

Methods: This is an observational, multi-center study performed in collaboration with the Israeli CLL Study Group involving 10 medical centers in Israel. The cohort included patients with CLL as well as healthy volunteers. All patients studied had complete clinical database available and all medical records were examined and then summarized. Serum samples were analyzed for levels of: IgG1, IgG2, IgG3, IgG4, IgA kappa, IgG lambda, IgA kappa, IgA lambda, IgM kappa, IgM lambda and Free light chain: kappa (%) and lambda (%), ratio of K/L and calculation of ratios of monoclonal/polyclonal immunoglobulin (HLC ratio). Results: The total cohort consisted of 126 "treatment - naive", patients with CLL and 26 healthy volunteers. Median age was 64 years, 64% were males and 78% had Binet stage A, while 19% and 3% were stages B or C respectively. Significantly lower levels of immunoglobulin light chain (IgG-L, IgA-L and IgM-L) were identified in CLL patients compared to healthy individuals (p<0.0001), while abnormal IgG2 levels were associated with more advanced stage and adverse prognostic parameters. These findings lend support for the considerable potential of the HLC assay in the evaluation of clinical status in patients with CLL.

PB1790
INFLUENCE OF TREATMENT ON CONCENTRATION OF CYTOKINES IN BLOOD OF PATIENTS WITH HAIRY CELL LEUKEMIA

N. Pelemyo1,2,*, V. Barinka1, V. Matliam2, O. Danysh1, Y. Vygovska1, Z. Maslyak1, G. Ostray1, V. Loginsky1.

1St Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine, 2Danylo Halytsky Lviv National University, Lviv, Ukraine.

Background: A pathogenic role and prognostic value of cytokines in treatment of patients (pts) with hairy cell leukemia (HCL) are not finally established.

Aims: To define the concentration of cytokines such as TNFα, IL-6, sL-2R, TGFβ1 in serum of HCL pts before and after treatment with IFNs or 2-CdA and to estimate the relationship with blood count indexes in HCL pts. 

Methods: The study group consisted of 26 primary pts with the classic variant of HCL (median age - 47 years). A control group consisted of 12 healthy persons (median age - 50 years). The concentration of cytokines was measured using a validated commercial ELISA kits.

Results: Median of TNFα content in serum of HCL pts before treatment was substantially lower (3.57 pg/ml) than in healthy persons (8.36 pg/ml; p=0.275), however levels of immune IFN or 2-CdA did not influence TNFα level. Median of TGFβ1 concentration in serum of HCL pts was also significantly lower, than in healthy persons (265.52 and 1568.22 pg/ml respectively; p=0.0004). Reliable increase of TGFβ1 concentration was observed only after 2-CdA therapy (928.33 pg/ml; p=0.281). Cross-correlation relationship was revealed between the TNF concentration and the level of hypomaglobulin (r=0.23; p=0.1) as well as with leucocyte count in HCL pts (r=0.24; p=0.09). Median of IL-6 content in serum of HCL pts before treatment was higher, than in healthy persons. Therap- y with IFN or 2-CdA reduced IL-6 level to the control values. Certain cross-correlation relationships were revealed between the IL-6 level and percentage of lymphocytes in bone marrow (r=0.33; p=0.01). No significant correlation of amount of lymphocytes in peripheral blood of HCL pts (r=0.24; p=0.09). Median serum concentra- tion of sIL-2R (24.73 ng/ml) in HCL pts more than 20-fold exceeded such in control group (1.15 ng/ml; p=0.0000005). Cross-correlation relationship was revealed between the percentage of hairy cells in bone marrow and sIL-2R level in serum (r=0.27; p=0.08). Obtained results may be an evidence of predominant secretion of sIL-2R by tumor cells in HCL pts.

Summary/Conclusions: New data regarding pathogenetic relationship between production of certain cytokines and features of hematopoiesis in HCL pts was obtained. Between the blood level of some cytokines in HCL pts and efficiency of the treatment a relationship was revealed, which is possible to use for prediction of clinical course of this disease. Moreover sIL-2R level in blood possibly can serve as a marker of tumour activity in classic type of HCL.

PROGRESSION-FREE SURVIVAL AND OVERALL SURVIVAL IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA – CLINICAL BENEFITS OF ACHIEVING A DEEP RESPONSE TO FIRST-LINE THERAPY

J. Samp1,*, A. Guerin2, R. Foster3, B. Meissner1, A. Rokito3, S.H. Enschede1, G. Gauthier2.

1AbbVie, Inc., North Chicago, United States, 2Analysis Group, Inc., Montreal, Canada, 3Analysis Group, Inc., New York, United States.

Background: In recent years, there have been advances in the treatment of CLL with the approval of several novel oral agents that show improvement in PFS and OS. Additionally, some agents induce a deep response indicated by complete remission (CR) and/or minimal residual disease negativity (MRD-). However, there is limited information on the longer-term clinical benefits of achieving a deep response in a real-world setting.

Aims: This study aimed to characterize PFS and OS for patients who achieved a deep response to first-line therapy for CLL.

Methods: Patient-level data were collected between July and August 2016 from oncologists/hematologists in the United States. Oncologists/hematologists provided patient level clinical data obtained from patient charts among CLL patients who initiated first-line therapy for CLL between January 2010 and December 2014. Selected patients were categorized into 2 cohorts based on the presence of early remission (EMR) and/or CR and/or MRD-. Patients in the EMR cohort included patients with partial remis- sion (PR), stable disease (SD) and progressive disease (PD). Data were collected from 22 nd Congress of the European Hematology Association
on distribution of response in clinical trials. Data on disease progression and mortality was provided by the treating oncologist/hematologist. PFS and OS were compared using univariate and multivariate Cox proportional analyses between the CR and non-CR cohorts (OS multivariate analyses were not conducted due to the small number of events). An additional analysis was conducted to examine the benefits of achieving MRD- versus not achieving MRD- among patients who achieved CR or PR.

Results: Data was collected on 330 CLL patients, including 179 patients in the CR cohort and 151 patients in the non-CR cohort (120 patients with PR, 25 with SD, and 6 with PD). Most patients were male, in their early sixties, and had an ECOG status of 0/1 at the time of initiating first-line therapy. The median observation period was approximately 30 months. There were 43 (26%) patients in the CR cohort and 75 (50%) patients in the non-CR cohort who progressed/died (Table 1). Patients in the non-CR cohort had an >2-fold higher hazard of progression/death (adjusted hazard ratio [HR]=2.30, p<0.05) and death (adjusted HR=2.61, p<0.05) compared to patients in the CR cohort. Among patients who achieved CR or PR, 84% patients achieved MRD- and 62% patients did not; 14% (17%) patients who achieved MRD- and 27 (44%) patients who did not achieve MRD- progressed/died. Patients who did not achieve MRD- had an over three-fold higher hazard of progression/death compared to patients who achieved MRD- (adjusted HR=3.75, p<0.05). No death events were observed among patients who achieved MRD- while 4 (6%) events were observed among those who did not achieve MRD-.

Table 1.

Summary/Conclusions: Findings from this real-world study suggest that achieving CR is associated with improved PFS and OS compared to patients who do not achieve CR. Furthermore, significantly better outcomes were observed among patients who achieved MRD- compared to those who did not achieve MRD- but still achieved CR or PR. This suggests that deep response may be an important clinical parameter to consider in the treatment of CLL.

PB1792

ANTI-CD ANTIBODY MICROARRAY FOR MORPHOLOGY EXAMINATION OF CIRCULATING LEUKAEMIA AND LYMPHOMA CELLS

S. Kuznetsova1,2, A. Khvatunovskaya1, A. Zakrova1, O. Fedyanina1,2. 1Centre for Pediatric Hematology, Oncology and Immunology. 2Centre for the theoretical problems of physico-chemical pharmacology. Moscow, Russian Federation

Background: Matching the morphology with immunophenotype for individual leukocytes is a major issue in diagnoses of leukemia and lymphoma due to the absence of a method for simultaneous cluster of differentiation surface antigen detection and full leukocyte morphology analysis. This problem can be solved by using a leukocyte-binding antibody microarray.

Aims: We developed an anti-CD antibody microarray on a transparent support for leukocyte sorting and a method for preparation of the microarray-bound cells for high-resolution morphology analysis. The aim of the work was to demonstrate, that the leukocyte binding is highly specific and that the microarray-bound peripheral blood mononuclear cells both from healthy donors and patients with B-cell leukaemias and lymphomas are morphologically identical to the same cells in blood smears.

Methods: Anti-CD antibodies were immobilised on plastic coverslips in spots 2 mm in diameter. In order to study the peripheral blood mononuclear cells (PBMC) the mononuclear fraction separated by density gradient from peripheral blood are incubated with the microarray in non-mixing conditions at 4°C. After the unbound cells are washed away the microarray-bound cells are dried in a drying procedure are morphologically identical to the same cells in a smear. In cases when pathologic cells are morphologically and/or cytochemically distinct, the anti-CD antibody microarray permits to determine their percentage and immunophenotype by analysing the relative amount of these cells captured by the antibodies against all the CD antigens. The results of such analysis of neo-plastic PBMC for the patients with leukemias and lymphomas agree with flow cytometry results for the same patients including CLL, HCL, CD2 and CD11c in CLL, CD56 in MM. The amount of hairy cells determined morphologically on the microarray varied from 20 to 97% of all anti-CD19-captured cells and 2 to 80% of all lymphocytes and was in good agreement with the percentages of cells with CD19/CD103 and CD19/CD11c coexpression determined by the peripheral blood of the same patients by flow cytometry.

Summary/Conclusions: The microarray works as a "sorted smear" with cells positive for certain surface CD antigens localised in a predetermined area and permitting to apply any standard smear-oriented technique to the microarray-captured cells. Combined analysis of the pathologic cells' immunophenotype, cytometry results for the same patients including expression of CD2 in HCL, CD56 in MM. The amount of hairy cells determined morphologically on the microarray can be used to perform a quick preliminary diagnosis and can be used in cases of any controversies between morphology, cytochemistry and immunophenotyping. The work is partially supported by 16-34-01030 and 16-04-00282 grants from RFBR.

PB1793

COMPARATIVE ANALYSIS OF INTERNATIONAL PROGNOSTIC INDEX FOR CHRONIC LYMPHOCYTIC LEUKEMIA, PROGRESSION-RISK SCORE AND MD ANDERSON CANCER CENTER 2011 SCORE: REAL WORLD DATA FROM A SINGLE INSTITUTION

V. Vukovic1,2, D. Antic1,2, T. Karan-Djurasevic1, N. Milic1, M. Todorovic-Balint1,2, J. Jelic1,2, M. Andjelic1,2, V. Djurasovic1,2, A. Strojnic1, M. Smiljanic1, J. Jelic1,2, M. Dencic-Fekete1, M. Perunicic-Jovanovic1, N. Kraguljac-Kurtovic1, S. Pavlovic1, M. H majelic1,2, G. Kostic1,2. 1Clinic for Hematology, Clinical Center of Serbia, 2Medical Faculty, University of Belgrade, 3Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, 4Institute for Medical Statistics and Informatics, Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: In recent times, several powerful prognostic scores have been developed in order to predict to first treatment (TTFT) and overall survival (OS) of CLL patients with chronic lymphocytic leukemia (CLL). Among such the international prognostic index for chronic lymphocytic leukemia (CLL-IPI) developed by The International CLL-IPI working group was found to predict OS and TTFT, while the rest of two scores- progression-risk score (PRS) and MD Anderson Cancer Center Score 2011 (MDACC 2011) have been developed for prediction of TTFT in early stage CLL patients.

Aims: The aim of this study was to compare CLL-IPI, PRS and MDACC 2011 prognostic scores based on their impact on TTFT, treatment response (TR), progression-free survival (PFS) and OS of 54 treated CLL patients.

Methods: We retrospectively analyzed data from 54 consecutive CLL patients diagnosed and treated at Clinic for Hematology, Clinical Center of Serbia from 2003 to 2013. Blood samples were prospectively collected and analyzed. All patients were treated with fludarabin-based chemotherapy. 45 (83%) in the first treatment line. Overall response rate to the first line therapy was 81%, equally distributed on complete and partial responses. Most of the patients (42, 78%) relapsed during the follow up. At the time of the last follow up 14 (26%) patients were still alive, 35 (65%) were dead, and 5 (9%) were lost to follow. Median overall survival was 76 months. Lower score values for all the three scoring systems (CLL-IPI, PRS, and MDACC 2011) correlated with longer TTFT (p<0.05 for all). Cox regression analysis revealed that CLL-IPI and PRS are significant predictors of TTFT (p=0.003, RR=1.4, 95%CI 1.1-1.7 and p=0.019, RR=1.4, 95%CI 1.1-1.9, respectively), while MDACC 2011 was found to be significant (p=0.052). In the multivariable analysis PRS emerged as the most significant predictor of TTFT among the three examined scores (p=0.041, RR=1.35, 95%CI 1.01-1.81). Regarding TR, only PRS appeared to have borderline statistical significance (p=0.052), showing that patients with lower score value may achieve better TR. Lower CLL-IPI can predict longer PFS after the first line treatment (p=0.007, RR=1.7, 95%CI 1.2-2.57), as well as PRS (p=0.039, RR=1.35, 95%CI 1.03-1.78), while MDACC 2011 has not shown to have influence on PFS. Multivariable analysis confirmed PRS to have the strongest predictive value of all the three scores regarding duration of PFS (p=0.039, RR=1.8, 95%CI 1.02-3.1). Furthermore, CLL-IPI and PRS were found to be significant predictors of OS (p=0.005, RR=1.4, 95%CI 1.1-1.8 and p=0.037, RR=1.5, 95%CI 1.1-1.8). Cox regression analysis showed that CLL-IPI and PRS may be an important clinical parameter to consider in the treatment of CLL.

Summary/Conclusions: CLL-IPI and PRS were identified as significant predictors of TTFT, as well as of duration of TR and OS. Further studies are warranted to confirm these findings.
Results: Our results based on molecular analysis from 100 subjects living in the same geographical area, show the presence of three major groups of clones with distinct but partially overlying configurations of IGHV gene usage, IGHV mutual status and cytogenetic alterations. These included a group which mainly consisted of clinical advanced stage CLL with a skewed but different IGHV-associated IGHV gene repertoire (VH1-69 associated with HD3 gene and H6 gene). It is frequently associated with complex karyotypes and poor-prognosis cytogenetic alterations, a second group enhanced in clones expressing specific IGHV subgroups (VH3-23 associated with HD2 genes and HJ6 gene) with no or isolated good-prognosis cytogenetic alterations and a third group of clones with intermediate features, with prevalence of mutated IGHV genes, and higher numbers of del(13q) clones.

Summary/Conclusions: These findings suggest that the specific IGHV repertoire and IGHV mutual status of CLL patient cells may be predictive of the alteration they may undergo and their clinical significance. Further long-term follow-up studies investigating the IGHV gene repertoire of CLL clones in distinct geographical and clonal microenvironmental compartments are required to validate our findings and disc make these potential factors of some antigen-binding BCR specificities contributing to clonal evolution.

PB1797

PROGNOSTIC SIGNIFICANCE OF SERUM BAFF, APRIL, TACI AND BCMA LEVELS IN CHRONIC LYMPHOCYTIC LEUKAEMIA

F. Oreizy2, A. Chen2, V. Fraser2, A. Doherty3, D. Tielemans4, L. Wolfe5, B. Balasa1,*, C. Green2, J. Kendall2, D. Gladding2, I. Racoma2, D. Van Hoof2

1Medical Affairs, 2BD Biosciences, San Jose, United States, 3BD Biosciences, Oxford, United Kingdom, 4BD Life Sciences, Erembodegem, Belgium, 5BD Clinical Corporate Development, Sparks, Maryland, United States

Background: The BD OneFlow solution for B-cell chronic lymphoproliferative diseases (B-CLPDs) incorporates a standardized flow cytometry approach based on the EuroFlow (EF) Consortium liquid reagent system. The BD OneFlow solution enables reproducible identification and discrimination of distinct B-cell populations by combining standardized assays, setup reagents, and protocols. The previously launched BD OneFlow LST (Lymphocyte Screening Tube) is intended for flow-cytometric immunophenotyping of normal (no follow-up required) and aberrant (follow-up required) mature lymphocyte populations of B, T and NK lineages in specimens from patients with hematological disorders. The BD OneFlow B-CLPD T1 is being developed to work in conjunction with BD OneFlow LST for the immunophenotyping of B cells and distinguishing chronic lymphocytic leukemia (CLL) from other B-CLPDs such as atypical CLL, follicular cell lymphoma, mantle cell lymphoma, etc.

Aims: The objective of this study was to demonstrate equivalency (accuracy) between the investigational BD OneFlow LST and BD OneFlow B-CLPD T1 system and the corresponding comparator EF liquid reagent system on the BD FACSCanto II flow cytometer using BD FACSDiva software.

Methods: De-identified remnant peripheral blood (PB) (n=70) and bone marrow (BM) (n=31) patient specimens were collected in EDTA or heparin anticoagulants at four external study sites and tested within 24 hours of draw. Informed consent was not required in this clinical study. Specimens were stained with BD OneFlow LST in combination with BD OneFlow B-CLPD T1 tubes and comparator EF liquid reagents. Acquisition and analysis were performed on a BD FACSCanto II instrument using BD OneFlow LST and B-CLPD T1 templates in BD FACSDiva software v8.0.1. Categorization of samples with abnormal B-cell populations into CLL (typical) or other B-CLPDs, overall agreement, negative agreement, and positive agreement, along with their one-sided lower 95% confidence limits, were calculated. For qualitative categorization of relative fluorescence intensity of CD45+CD19+ aberrant cell populations, overall agreement with one-sided lower 95% confidence limits was calculated.

Results: All evaluable specimens were identified by the OneFlow LST as having B-cell populations requiring follow-up by both methods. Compared to the EF system, the BD OneFlow LST in combination with the BD OneFlow B-CLPD T1 system (n=101) showed 100% (101 of 101) overall agreement in classifying patients as having CLL (54 of 54 concordant) and in identifying patients with other B-CLPD diseases (47 out of 47 concordant) with a lower 95% CI of the overall agreement of 97.4%. The BD OneFlow B-CLPD T1 system, compared to the EF system, gave 100% (101 of 101) concordant agreement for the qualitative assessment of relative fluorescence intensity of CD45+CD19+ aberrant cell populations for CD20+, CD200+, and CD23+ subsets and 99.1% agreement for the CD79b+ subset.

Summary/Conclusions: The multisite performance evaluation between the BD OneFlow system (LST and B-CLPD T1) and the comparator EF liquid reagent system on the BD FACSCanto II flow cytometer using BD FACSDiva software was concordant in distinguishing abnormal B-cell populations from normal B cells. The BD OneFlow B-CLPD T1 system was able to distinguish between the investigational BD OneFlow LST and BD OneFlow B-CLPD T1 system and the corresponding comparator EF liquid reagent system on the BD FACSCanto II flow cytometer using BD FACSDiva software.

ATTENTION TO CD38 EXPRESSION MAY BE IMPORTANT IN THE DIAGNOSIS OF CHRONIC LYMPHOCYTIC LEUKAEMIA: A CROSS-COUNTRY EXPERIENCE

B. Balasa1,*, C. Green2, J. Kendall2, D. Gladding2, I. Racoma2, D. Van Hoof2, F. Oreizy2, A. Chen2, V. Fraser2, A. Doherty3, D. Tielemans4, L. Wolfe5, K. Judge2

1Medical Affairs, 2BD Biosciences, San Jose, United States, 3BD Biosciences, King’s College London, United Kingdom, 4BD Biosciences, Erembodegem, Belgium, 5BD Clinical Corporate Development, Sparks, Maryland, United States

Background: The association of TACI and CD38 expression may indicate the notable balance between the cell survival factors BAFF and APRIL, and their receptors BAFF-R (TNFRSF13C), TACI (TNFRSF13B), BCMA (TNFRSF17) in the tumor microenvironment. The two factors are produced by cancer cells and play an important role in tumor progression. The BCMA, TACI, BAFF and APRIL levels were measured at diagnosis using enzyme-linked immunosorbent assay (ELISA). The association with conventional prognostic markers and impact on survival were evaluated.

Methods: A total of 129 newly diagnosed CLL patients [median age: 64(39-88); M/F: 85/44] and 26 healthy volunteers were enrolled in this study. Serum BCMA, TACI, BAFF and APRIL levels were significantly lower in the patient group (p<0.05) (Table 1). Serum BAFF ([p=0.008; r=0.236]) and BCMA ([p=0.042; r=0.183]) levels were negatively correlated with Rai stage and serum BAFF level was higher in low-risk patients based on modified Rai staging system (p=0.059). The CD38+ positive patients ([p=0.06; 0.17(0.1-0.86) vs 0.13(1.0-1.07)]. Age ([p=0.002), Rai stage ([p=0.005) and Modified Rai stage ([p=0.051 were the significant factors which had an impact on overall survival in multivariate analysis.

Table 1.

Summary/Conclusions: As BAFF and APRIL display their main biological effects once they bond to their receptors and pass through the intracellular compartment, we consider that it may be more feasible to measure the intracellular levels of these molecules which may be more predictive for B-CLL prognosis. The association of TACI and CD38 expression may indicate the notable balance between proliferation and apoptosis, as CD38 is considered to be a proliferation marker in B-CLL. Further large and prospective studies analyzing the intracellular levels of these molecules are essential to validate the prognostic role of these particular biomarkers in CLL.

EXPERIENCE OF IBRUTINIB IN RELAPSED/REFRACTORY B-CELL CHRONIC LYMPHOCYTIC LEUKAEMIA AND MANTLE CELL LYMPHOMA IN A DISTRICT GENERAL HOSPITAL

J. Lalia1, A. Smith1,*, C. Millar2, G. Fellows1, A. Bryan1, J. Addada1

1Haematology, Derby Teaching Hospitals NHS Foundation Trust, Derby, United Kingdom, 2Haematology, Northern General Hospital, Sheffield, United Kingdom

Background: The specific determining factors for malignant progression in chronic lymphocytic leukemia (CLL), remaining unknown. Aims: To investigate the potential existence of unique cytogenetic profiles associated with specific IGHV repertoires that could be associated with an increased risk of progression in CLL.

Methods: For this purpose, molecular analysis of well-established cytogenetic alterations of chromosomes 11, 12, 13, 14 and 17 together with the pattern of rearrangement of the IGHV genes were performed in 100 CLL cases.

Results: Our results based on molecular analysis from 100 subjects living in the same geographical area, show the presence of three major groups of clones with distinct but partially overlying configurations of IGHV gene usage, IGHV mutual status and cytogenetic alterations. These included a group which mainly consisted of clinical advanced stage CLL with a skewed but different IGHV-associated IGHV gene repertoire (VH1-69 associated with HD3 gene and H6 gene). It is frequently associated with complex karyotypes and poor-prognosis cytogenetic alterations, a second group enhanced in clones expressing specific IGHV subgroups (VH3-23 associated with HD2 genes and HJ6 gene) with no or isolated good-prognosis cytogenetic alterations and a third group of clones with intermediate features, with prevalence of mutated IGHV genes, and higher numbers of del(13q) clones.

Summary/Conclusions: These findings suggest that the specific IGHV repertoire and IGHV mutual status of CLL patient cells may be predictive of the alteration they may undergo and their clinical significance. Further long-term follow-up studies investigating the IGHV gene repertoire of CLL clones in distinct geographical and clonal microenvironmental compartments are required to validate our findings and discard or confirm the potential role of some antigen-binding BCR specificities contributing to clonal evolution.
Background: Constitutive activation of B-cell receptor signalling appears to be essential for the proliferation of malignant B cells. Bruton’s tyrosine kinase (BTK) has been identified as an essential component of the B-cell receptor signalling pathway. Ibrutinib is an orally administered BTK inhibitor that antagonises B cell receptor, chemokine & integrin mediated signalling.

Aims: We report our experience of using ibrutinib to treat relapsed/refractory B-cell chronic lymphocytic leukaemia (B-CLL) and mantle cell lymphoma (MCL) in a busy U.K. District General Hospital (DGH) serving a population of 600,000.

Methods: 26 patients were commenced on ibrutinib for relapsed/refractory B-CLL or MCL between August 2014 & December 2016. 16 patients had B-CLL and 10 patients had MCL. Patients with B-CLL were commenced on 420mg daily; those with MCL received 540mg daily. The median age at which ibrutinib was commenced was 71.1 years (range 50-85). The median age of patients with B-CLL was 71.1 years (range 50-80) and for MCL was 71.6 years (range 54-85). The median number of prior lines of therapy decreased over the time period from 3.2 in 2014 to 1.2 in 2016. The mean interval between diagnosis and commencement of ibrutinib was 6.4 years (range 0.8-18). The number of co-morbidities in both groups was similar: 1.4 in B-CLL and 1.5 in MCL. After May 2015 all patients received aciclovir and co-trimoxazole prophylaxis. Response to ibrutinib was assessed by clinical examination and blood results; imaging and bone marrow examination were conducted at the clinician’s discretion.

Results: The median follow up was 15.5 months for B-CLL patients and 8 months for MCL patients. The median survival of all patients who did not receive anti-viral and pneumocystis prophylaxis was 5 months and the median survival for those who did receive prophylaxis was not reached (p = 0.0001). The median survival of patients who received chemotherapy in the period from 1-1-2000 up to 1-9-2010 was 17 months; the median survival in those who had received just one prior line of treatment was not reached (p = 0.0085). In the B-CLL cohort there was no difference in survival between those who with and without p53 deletion. 11/26 patients experienced side effects: 8 had grade 1 and 2 side effects (diarrhoea, drug rash, cardiac arrhythmias) which were easily controlled. 3 patients had grade 4 side effects (1 severe arthropathy, 2 intracranial haemorrhage - one of which was fatal). 4 of the 16 (25%) with B-CLL and 5 of the 10 (50%) with MCL died during the period of follow-up. Causes of death were: intra-cerebral haemorrhage (1), unrelated cancer (1), disease progression (2), disease progression+sepsis (2), sepsis alone (3). Of the remaining 17 patients, 14 continue to receive ibrutinib, 2 (B-CLL) were switched to idelisib+Rituximab (for grade 4 toxicity) & 1 went on to have an allogeneic transplant (MCL).

Summary/Conclusions: Though our cohort of patients is small, our experience shows that the use of prophylaxis with co-trimoxazole and aciclovir is associated with a low incidence of overall survival. Moreover, patients who received fewer lines of prior treatment had a better survival. Patients with p53 deletion were more likely to have treated disease than those without p53 deletion. 1/26 patients responded as well as those without a deletion. Ibrutinib is a very effective therapeutic option in patients with relapsed CLL and MCL.

Background: Chronic lymphocytic leukaemia (CLL) is characterised by frequent co-existent infectious complications. They stem from, among other things, hypogammaglobulinaemia, which is connected with CLL, and correlates with the disease duration and severity, as well as T-lymphocyte function disorders. The application of innovative therapies (chemoimmunotherapy) on the one hand facilitates considerable improvements in treatment outcomes and on the other hand it increases the risk of life-threatening infectious complications. The introduction of a new drug, ibrutinib (Bruton’s kinase inhibitor), has created a unique opportunity for CLL patients, especially those with prognostically unfavourable genetic aberrations (del17p), or in the case of whom previous chemotherapies have failed to give satisfying results. Previous observations have shown that ibrutinib therapy is associated with a lower incidence of infectious complications and an improved survival compared to conventional chemotherapy. The aim of this paper was to evaluate the risk of infectious complications in persons with CLL, and to determine potential correlations between possible infectious complications and selected clinical, morphological and biochemical parameters.

Methods: The study comprised 43 CLL patients aged 48-82 years (average age 67 years), 18 women and 25 men. At the beginning of ibrutinib therapy the patient’s disease was at the 2-4 clinical stage, according to Rai et al. Usually they were individuals who had received a couple of previous chemotherapies (from 1 to 7) which contained, inter alia, purine analogues, and the monoclonal antibodies (rituximab, alemtuzumab, ofatumumab). Ibrutinib was administered (before ibrutinib administration) and infectious complications during these therapies (p>0.05). The average IgM concentration in patients with complications was considerably lower when compared to people who did not experience any complications. The patients (n=3, 6.98%) with complications at the moment of ibrutinib treatment. This phenomenon was confirmed in 13 patients (33%) in the other group. The correlation was borderline significant (p=0.09). Infectious complications were observed more frequently in the patients with 3-4 stage CLL (according to Rai et al.) than in the individuals at the less-advanced clinical stages of the disease (0-2), and this correlation also showed borderline significance (p=0.08). No significant correlation was detected between the risk of infectious complications and earlier therapy with purine analogues and neutropenic episodes during the ibrutinib therapy.

Summary/Conclusions: 1) Ibrutinib is considered to be a real breakthrough in CLL treatment; but it has to be borne in mind that the drug gives possible side effects which might occur during therapy. They include infectious complications which are among the main causes of death in this group of patients. The results obtained by us indicate that the risk of infection during ibrutinib therapy relates mainly to patients with low IgM concentration in the blood serum and at more advanced clinical stages of the disease. In this case the occurrence of previous complications (before ibrutinib administration) is also relevant. We are aware of the limitations of our work related to the small number of patients. Yet, even at this stage, it is possible to select CLL patients with increased risk of such usually life-threatening complications.

PB1801 MONOCLONAL B-CELL LYMPHOCYTOSIS AND PROSTATE CANCER: AN UNEXPECTED, POSSIBLE ASSOCIATION

F. D’Auria1,*, L. Rago1, L. Valvaro1, T. Statuto1, A. Traficante1, V. Simeone1, V. Fusco1, P. Musto1

1IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture (PZ), Italy

Background: Monoclonal B-cell lymphocytosis (MBL) is a recently recognized entity characterized by the presence, in the peripheral blood, of a monoclonal B-cell population lower than 5000/µl, in the absence of any type of clinical features. MBL clones may have: a) chronic lymphocytic leukemia (CLL)-like phenotype (CD5+, CD19+, CD23+, CD20 dim); b) atypical CLL phenotype (CD5+, CD19+, CD23- or CD20 bright); c) non-CLL phenotype (CD5-). MBL can be also distinguished in “low-count” (<500/µl) and “high-count” (>500/µl) subtypes. High-count MBL frequently shows typical CLL phenotypic/genetic features and require adequate follow-up in order to detect their possible evolution into symptomatic CLL. MBL showing a clonal B-cell count higher than 1000-1500/µl are usually defined “clinical” MBL. Using highly sensitive (i.e. >6 colors and >5/10000 events) flow cytometry approaches, CLL-like MBL clones have been found at a frequency of 7-12% in healthy subjects, showing, however, very low median counts of clonal B-cell (10-170/µl), with only 0.14% being clinical MBL. Though several studies have described the association between CLL and various types of neoplastic disorders, only few data exist about the risk of non-hematologic cancer in individuals with MBL, in particular, no association between MBL and prostate cancer (PC) has been so far reported.

Aims: To study prospectively the frequency of CLL-like MBL clones in patients affected by PC compared to healthy males of the same ages, after our previous observational case of an apparently increased MBL incidence at baseline in a cohort of patients with PC originally studied to detect lymphocyte abnormalities possibly induced by radiotherapy (RT).

Methods: We enrolled 34 consecutive patients affected by PC (mean age 74 years, range 58-91), naive for chemotherapy (sixteen previously treated with hormone-therapy). All patients were planned to receive whole-pelvis RT with radical (n. 23) or salvage (n. 11) intent. Fifty-four healthy males (mean age 71 years, range 58-87) represented the control group. Immunophenotypic analysis of peripheral lymphocytes before RT was performed by BD FacsCanto II flow cyrometer, using a 5-6 colors approach and the following antibody combinations: CD19 FITC/CD5 PE/CD45 PerCP/CD20 PE-Cy7/CD3 APC, Kappa FITC/Lambda PE/CD19 PerCP-Cy5.5/CD20 PE-Cy7/CD5 APC/CD45 APC-Cy7. For each sample, 100,000 events were collected. CD45+ lymphocytes were gated on CD45 vs SSC dot plot, then B cells were isolated by gating on CD19 and CD19+ CD5+ cells were interrogated for intensity of CD20. Finally, CD19+ CD5+ CD20dim selected population was analyzed for light chain expression.

Results: Median (range) absolute counts of white blood cells (WBC), total lymphocytes and B-cells, as well as absolute single values of MBL clones are reported in Table 1. In PC patients we found 3 MBL (8.8%), two of which were “high count/clinical” MBL (5.8%). In contrast, in healthy subject group, only one “low count” MBL (1.8%) was detected, showing a very small clone (8 cells/µl). Such a difference was not statistically significant (p=0.2).

Table 1.

Summary/Conclusions: The preliminary results of our prospective study, performed using a routine, not highly sensitive flow cytometry approach, highlight a possible association between (clinical?) MBL and PC, never described before and probably warranting further investigation in a larger number of patients.
Chronic myeloid leukemia - Biology

IDENTIFICATION OF NOVEL MUTATIONS IN CANCER-RELATED GENES IN HUMAN ERYTHROLEUKEMIA K562 CELL LINE BY NEXT-GENERATION SEQUENCING
M. Pesenkova1,2,*, M. Karwowska1, M.M. Machnicki2, I. Solarska3, K. Borg3, M. Rydzanicz4, P. Stawinski2, R. Płoski2, T. Stoklosa1
1Department of Immunology, Medical University of Warsaw, 2Postgraduate School of Molecular Medicine, 2Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, 3Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland

Background: Chronic myeloid leukemia (CML) is a clonal hematopoietic stem cell disorder characterized by reciprocal chromosomal translocation (t(9;22)(q34;q11), resulting in the formation of the BCR-ABL fusion oncogene. One of the most common CML in vitro model in the K562 BCR-ABL1-positive human erythroleukemia cell line derived from a female patient with CML in blastic phase (CML-BP) and representing an important tool for the studies of malignant hematopoiesis in last decades. Although K562 karyotype was described several times, detailed genomic analysis of this cell line is not yet available and to our best knowledge there are no publications yet describing complex genomic landscape of K562 cells.

Aims: The aim of our study was to determine the mutational landscape of K562 cell line using next-generation sequencing (NGS). Additionally classical fluorescence in situ hybridization (FISH) with BCR and ABL1 probes was performed to confirm cytogenetics.

Methods: The K562 cell line was purchased from DSMZ (Braunschweig, Germany). We analyzed almost 1300 genes implicated in human cancer using custom designed capture (SeqCap EZ, NimbleGen, Roche) followed by high-throughput sequencing on Illumina HiSeq 1500. Common variants (>1%) gathered in ESP6500 and 1000 genomes projects and our internal exome database were filtered out and the subsequent analysis was focused on putative protein damaging variants with the frequency in the database from NHLBI GO exome sequencing project less or equal to 0.01. We used different bioinformatic tools for variant effect prediction (eg. PolyPhen-2, SIFT, IntOGen). Mutations were confirmed with Sanger sequencing. FISH was performed using commercially available probes (Vysis, Abbott, USA), that identifies BCR-ABL1 fusion genes.

Results: Sequencing and bioinformatic analysis revealed 88 variants with potential biological significance. We detected Q136fs*13 mutation in TP53, which has already been described in K562 cell line previously by ATCC, but we have also identified several new mutations in genes involved in tumorigenesis and drug resistance (Table 1). Moreover, cytogenetic analysis showed both multiplication of the BCR and ABL1 genes and amplification of the BCR-ABL1 fusion gene (Ph chromosome is present in at least four additional copies).

Table 1. Selected prominent mutations identified in K562 cells.

Summary/Conclusions: We describe several new mutations in such genes as ASXL1, BRCAL1 or MLH1 in one of the most frequently used cell line in leukemia research, K562 erythroleukemia. Our results confirm high level of genomic instability in the blastic phase of CML represented by the K562 cell line and add new, valuable information for researchers who want to employ this cell line. The awareness of the genomic aberrations present in the K562 erythroleukemia cell line is essential for further studies as those aberrations may have a significant impact on the observed results.

INVESTIGATION OF POLYMORPHISMS RELATED TO MIR-608 IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA
N. Ryabchikova1, G. Safuanova1,*, I. Minniakhmetov2, A. Sultanbaev1
1Department of Immunology, Medical University of Warsaw, 2Postgraduate School of Molecular Medicine, 2Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, 3Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland

Background: Chronic myeloid leukemia (CML) is a myeloproliferative disorder characterized by the expression of the BCR-ABL oncoprotein, which is essential for the pathogenesis of the disease. Imatinib, an ATP-competitive selective inhibitor of BCR-ABL, has unprecedented efficacy for the treatment of CML. Several cellular and genetic mechanisms of imatinib resistance have been proposed, including overexpression of the BCR-ABL gene, the tyrosine kinase domain mutations, pharmacokinetic and pharmacodynamic factors.

Aims: The purpose of this study was to investigate miRNA-608 role in response to tyrosine kinase inhibitors (Imatinib). In this study, we analyzed rs9762 SNP located in a miRNA-608 binding site of 3’UTR of BCR-ABL gene and rs4919510 SNP in the mature sequence of miR-608 in CML patients with different response to tyrosine kinase inhibitor therapy. These polymorphisms disrupt the negative effect of mir-608 on its target BCR-ABL. These polymorphisms could affect the expression of its target gene BCR-ABL1 and its effect on leukaemia cells. We also suggested that individual based investigations may be important to evaluate the BCR-ABL1 gene expression.

Methods: We conducted fluorescence in situ hybridization (FISH) on peripheral blood leukocytes from 81% in CML patients with effective therapy. We suggest that miR-608 could possess oncosuppressing activity as miR-203 but it should be confirmed by further experiments.

Summary/Conclusions: miRNAs could be a perspective tool for therapy and polymorphisms affecting its regulation should also be considered.

PB1804
TARGETED STRATEGY FOR ABL TYROSINE KINASE INHIBITOR RESISTANT PHILADELPHIA CHROMOSOME POSITIVE LEUKEMIA CELLS
S. Okabe1,*, T. Tauchi1, Y. Tanaka1, K. Ohyashiki 1
1Department of Hematology, TOKYO MEDICAL UNIVERSITY, Shinjuku-Ku, Japan

Background: Although ABL tyrosine kinase inhibitors (TKIs) such as imatinib have demonstrated the potency against Philadelphia chromosome (Ph)-positive leukemia patients, resistance to ABL TKI can develop in chronic myeloid leukemia (CML) patients. Therefore, new approach against ABL TKI resistant cells may improve the outcome of Ph-positive leukemia patients. It has already reported that ABL kinase domain mutations have been implicated in the pathogenesis of ABL TKI resistance, however, it is fully not known the molecular mechanism of drug resistance including second (nilotinib and dasatinib ) and third generation (ponatinib) ABL TKIs.

Aims: As leukemia is a genetic disease driven by heritable or somatic mutations, we hypothesized that ABL TKI resistance may often happen due to additional somatic mutations in the oncogene.

Methods: We established several TKI-resistant in vitro cell line models. We also investigated model to evaluate the next-generation sequencing (NGS) panel, NGS platform to screen mutational hotspots in 50 leukemia-related genes.

Results: We established ABL TKI resistant cell lines (K562 imatinib-R, K562 nilotinib-R, K562 dasatinib-R, K562 ponatinib-R), Ba/F3 T315I and Ba/F3 ponatinib-R) in this study. We conducted fluorescence in situ hybridization (FISH) analysis on parental K562 and ABL TKI resistant K562 cells. BCR-ABL expression levels were not increased in ABL TKI resistant K562 cells compared to parental K562. We next investigated the BCR-ABL point mutations direct sequence analysis. We could not detect the BCR-ABL point mutation in ABL TKI resistant K562 cells. However, the exon 4 deletion in the BCR-ABL gene was found in K562 ponatinib-R cells. In contrast, compound mutations in BCR-ABL were found in Ba/F3 ponatinib-R cells. K562 ponatinib-R cells were also highly resistant to imatinib, nilotinib and dasatinib. We examined several TKI-resistant ABL TKI resistant K562 cells. Phosphorylation of BCR-ABL and Crk-L was reduced in K562 dasatinib-R cells, however, MAPK activity was increased. In K562 ponatinib-R cells, MAPK activity was reduced. We next evaluated the NGS panel (GeneRead DNAseq Targeted Panels V2) to investigate the mutation. We found that several somatic mutations in TET2, FLT3, RB1, TP53, SETBP1, ASXL1, and BCORL1 in parental K562 cells. We also found that additional somatic mutations in K562 imatinib-R (IDH1 and KRAS), K562 dasatinib-R (IDH1) and K562 ponatinib-R (SF3A1). We could not detect additional mutation in K562 nilotinib-R cells. We next investigated the MEK inhibitor and IDH1 inhibitor activity against K562 with IDH1-R and K562 with MEK-R cells. MEK inhibitor did not induce cell growth inhibition directly. However, combined treatment of ABL TKI resistant K562 with imatinib or dasatinib and MEK inhibitor or IDH1 inhibitor caused more cytotoxicity than each drug alone. Because aberrant activation of PI3K signaling pathway and deregulation of HDAC activity may be a cause of malignant disease in humans, we examined the PI3K and HDAC inhibitor in ABL TKI resistant cells. We found 72 h treatment of oral inhibitor of class I PI3K as well as class I and II HDAC enzymes, CUDC-907 exhibits cell growth inhibition ABL TKI resistant K562 cells and Ba/F3 ponatinib-R cells in a dose dependent manner. In the mouse study, a dose of 20 mg/kg/day of ponatinib and 30 mg/kg/day of CUDC-907 inhibited tumor growth of T315I mutant cells compared with control mice and induced apoptosis in tumor samples.

Summary/Conclusions: Our study indicated that leukemia cells have acquired resistance through somatic mutation or exon 4 deletion in the BCR-ABL1 gene. Our study suggested that individual based investigations may be important to evaluate the ABL TKI resistant cells. We also provide the promising clinical relevance as a candidate drug for treatment of ABL TKI resistant leukemia patients.

FLUORESCENCE IN SITU HYBRIDIZATION SIGNAL PATTERNS AND INTRACHROMOSOMAL BCR-ABL1 AMPLIFICATION ANALYSIS IN IMATINIB-RESISTANT CHRONIC MYELOGENOUS LEUKEMIA PATIENTS USING TRICOLOR DUAL FUSION PROBE

K. Bommannan1,*, S. Naseem1, N. Varma, P. Malhotra2, J. Binotta1, S. Varma2
1Hematology, 2Internal Medicine, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Conventional cytogenetics is a common modality for tyrosine kinase inhibitor (TKI) response assessment in chronic myelogenous leukemia (CML) patients. There is no consensus regarding the use of conventional bone marrow (BM) cytogenetics or peripheral blood (PB) interphase fluorescence in situ hybridization (FISH) during follow-up. The routine dual colour FISH probes are less sensitive to reliably identify der(9) deletions during follow-up. BCR/ABL/ASS1 tri-colour dual fusion (TCDF) probe is highly sensitive and specific in identifying der(9) deletions.

Aims: Our aim was to identify the I-FISH fusion patterns of BCR/ABL/ASS1 TCDF probe and correlate the patterns with patient-specific molecular genetic parameters.

Methods: This was an ethically approved study conducted at a government-funded tertiary care institute. From January 2015 to June 2016, PB I-FISH analysis was performed on European LeukemiaNet defined imatinib-resistant CML patients using BCR/ABL/ASS1 TCDF probe (Abbott Laboratories, Abbott Park, Illinois, USA). The residual BCR-ABL1 transcript load was monitored in international scale (BCR-ABL1%) using an automated cartridge-based Generation Xpert system (Cepheid, Sunnyvale, CA, USA).

Results: On analyzing 37 adult patients, all had residual Philadelphia (Ph) chromosomes (100%). Classic Ph fusion pattern was seen in 33 (89%), derivative chromosome 9 (der(9)) deletions in 25 (67.5%) and supernumerary Ph chromosomes in 11 (30%) patients. Coexistence of classical fusion and der(9) deletions were seen in 21 patients (57%), whereas 8 patients (22%) had a mutual existence of classical fusion, der(9) deletions and supernumerary Ph chromosomes. None had Ph amplification. Figure 1 demonstrates the I-FISH patterns seen in a 43-year-old male diagnosed with CML-CP and had progressed to blast crisis at his 72nd month of imatinib therapy. In this Figure red, yellow and white arrows indicate blast cells without Ph chromosome, Ph+ blast cells with a loss of residual ABL1 on der(9) classical and random signal overlap, respectively. A mean (± S.D) of 29% (± 30) and 18% (± 17) der(9) deleted cells were seen amongst patients with b2a2 and b3a2 BCR-ABL1 transcript types, respectively and this difference was statistically significant (p<0.008).

There was also a significant difference in the disease transformation status according to the percentage of der(9) deleted cells (p=0.03). In this regard, patients with progressive disease (accelerated phase/blast crisis progression) had a mean (± S.D) of 47% (± 35) der(9) deleted cells in comparison to 19% (± 20) such cells in patients without disease transformation. In addition, patients with Ph duplication/triplication had a mean (± S.D) BCR-ABL1% levels of 49.478% (± 40.184), in comparison to BCR-ABL1% levels of 16.00% (± 19.993) in patients without these anomalies and this difference was also statistically significant (p=0.029).

Summary/Conclusions: Our work would be an appropriate reference material for I-FISH signal interpretation using BCR/ABL/ASS1 TCDF probe. We have demonstrated a high frequency of der(9) deletions, clonal heterogeneity and absence of BCR-ABL1 amplification in an imatinib-resistant Indian CML cohort. For the first time, a significant association of der(9) deleted cell percentage with b2a2 transcript type and disease transformation status has been identified and the same has to be tested in a larger cohort.

PB1806

ARE YOU ACTUALLY SUSPECTING A CHRONIC MYELOID LEUKEMIA WHEN ORDERING A BCR/ABL RT-PCR?

L. Abato Perez1,*, C. Guillon Rietena1, M. Sopera Corinos1, W.M. Torres Jimenez1, R. Guillon Santos2, J. Villamubia1, F.A. Gonzalez Fernandez1, F. Cava Valenciano2
1Hematology Department, 2Head of the Laboratory, Central Laboratory BRSalud Madrid. Infanta Sofia Hospital, Madrid, Spain

Background: Chronic myeloid leukaemia (CML) is a myelo proliferative neoplasm (MPN). It is characterized by a reciprocal t(9:22)(q34;q11.2) resulting in a fusion oncogene BCR/ABL in a hematopoietic stem cell. Clinical features are absent in nearly 20-40% of patients at diagnosis time. Hence, laboratory suspicion is crucial. Peripheral blood shows leukocytosis with left shift and "myelocyte bulge", absolute eosinophilia, and absolute basophilia invariably present1-3. The demonstration of the Philadelphia (Ph) chromosome with cytogenetic analysis, or BCR/ABL fusion gene by qRT-PCR will confirm the diagnosis (typical CML).

Aims: In order to gain accuracy when BCR/ABL PCR is ordered, we review myeloproliferative hematometric parameters, with special focus in basophilia, before performing molecular analysis.

Methods: We retrospectively reviewed 299 BCR-ABL PCR requests received at our laboratory between January 1, 2015 and January 1, 2017. 80% of the total requests were ordered by haematologists physicians, 13.46% by other medical specialties (11.5% internal medicine) and 7.7% from the laboratory. Complete blood cell count (CBC) were analysed by ADVIA 2120. Neutrophilia was defined in our laboratory as absolute neutrophil count of >7.7 x10 9/L, and basophilia was defined as absolute basophil count of >0.2 x10 9/L. A total of 299 requests for PCR of BCR-ABL were reviewed by laboratory hematology staff before performing them. We performed 235 test (78.6%) and 64(21.4%) were considered inadequate according former criteria. qRT-PCR p<0.05 was performed and if a negative result was obtained with high CML suspicion qRT-PCRp<0.19 and qRT-PCRp<0.230, such as cytogenetic studies were performed. The statistical analysis was performed with STATA.

Results: 235 BCR/ABL by PCR tests were performed and 24 (10.21%) resulted positive. 167 (71.06%) were placed for neutrophilia; 41 (17.87%) for thrombocytosis and 26 (11.07%) for other criteria (eosinophilia, monocytosis, splenomegaly or combined).Among 24 positive cases 100% presented basophilia at diagnostic time and 91.66% (22/24) presented basophilia and neutrophilia. Two cases without neutrophilia at diagnosis were CML with extreme trombocytosis. We found 33 cases with basophilia among 235 patients. 24 cases (72.73%) were diagnosed of CML and 9(27.27%) resulted in other MPN Ph- or unclassifiable MPS/MDS neoplasm. Our results show that basophilia should be carefully investigate when CML is suspected, with high sensibility (100%) and specificity (95.75%).

Summary/Conclusions: Our results show that basophilia should be carefully investigate when CML is suspected, with high sensibility (100%) and specificity (95.75%). In cases no CML with basophilia >0.3 x10 9/L, further investigation should be performed in order to diagnose a MPN Ph- or MDS/MPN. Even basophilia is well stablished as nearly universal in CML 1,3,4, this study reveals it is not always pursue enough, when clinicians ask for a molecular study.

PB1807

BCR-ABL DEL C.1086-1270 (PR362FS21) AND TKI RESISTANCE IN CML PATIENTS FROM RUSSIAN FEDERATION

A. Abdullaev1,*, I. Mikhailova2, O. Nesterova2, A. Odilov3, T. Makarik1, E. Stepanova1, S. Treglazova1, A. Sudarikov1
1Molecular hematology, National Research Center for Hematology, 2Faculty of Molecular Biology and Biotechnology, Lomonosov Moscow State University, 3Department of Hematology, Research Institute of Hematology, Moscow, Russia

Background: It is not always pursue enough, when clinicians ask for a molecular study.

Summary/Conclusions: Our results show that basophilia should be carefully investigate when CML is suspected, with high sensibility (100%) and specificity (95.75%). In cases no CML with basophilia >0.3 x10 9/L, further investigation should be performed in order to diagnose a MPN Ph- or MDS/MPN. Even basophilia is well stablished as nearly universal in CML 1,3,4, this study reveals it is not always pursue enough, when clinicians ask for a molecular study.
of fundamental medicine, Lomonosov Moscow State University, Moscow, Russian Federation. 3Medical faculty, Tashkent Medical Academy, Tashkent, Uzbekistan

Background: Data concerning the impact of BCR-ABL del. c.1086-1270 on TKI resistance in CML is still controversial. This mutation was first described by Curvo et al. (2008) and was thought to confer TKI resistance. However computer modeling performed by Meggynesi N. et al. (2012) revealed disruption of ATP binding site in mutated tyrosine kinase therefore abrogating enzymatic activity. Nevertheless pathogenic effect of BCR-ABL p.R362fs*21 could be attributed to the formation of heterodimer with “wild type” Bcr-Abl p210 as described by Poulikakos P.I. et al. (2011).

Aims: To assess the impact of BCR-ABL del. c.1086-1270 (p.R362fs*21) on TKI resistance in CML patients from Russian Federation.

Methods: 33 male and 49 female CML patients (age 24-80) with BCR-ABL transcript level >0.1% were included in the study. BCR-ABL del. c.1086-1270 was estimated by nested PCR followed by Sanger sequencing. Initial screening for deletions was performed by means of fragment analysis (Applied Biosystems 3130).

Results: 92 RNA (cDNA) samples isolated from peripheral blood of 82 CML patients were tested. BCR-ABL del. c.1086-1270 (p.R362fs*21) was found in 32 patients (39%). 15 out of 32 (47%) patients with deletion were TKI sensitive while 17 (55%) were TKI resistant. In one TKI resistant case BCR-ABL del. c.1086-1270 was accompanied by BCR-ABL c.844G˃C p.E282Q point mutation not described so far (Figure 1). This mutation was found in BCR-ABL del. c.1086-1270 transcript only and was absent in “wild type” Bcr-Abl p210 transcript amplified from the same patient.

Summary/Conclusions: BCR-ABL del. c.1086-1270 could be found in almost half of CML patients and have no evident impact on the induction of big molecular response in TKI sensitive cases. Our observation that independent c.844G˃C p.E282Q point mutation expressed on the same BCR-ABL transcript with deletion c.1086-1270 (p.R362fs*21) being absent in “wild type” transcript strongly contradicts the hypothesis, that del. c.1086-1270 could be generated by alternative splicing of “wild type” BCR-ABL transcript.

PB1808
PEROXIREDOXIN II ACTIVITY HAS IMPORTANT ROLES TO CONTROL ABL TYROSINE KINASE ACTIVITY IN STIS TREATED CML PATIENTS AND ITS POTENTIAL APPLICATION IN IMATINIB RESISTANCE
E.S. Yoo1, Y.-C. Mun1, J.-Y. Ahn1, J.-W. Huh1, C.-M. Seong1
1Ewha Womans University MokDong Hospital, Seoul, Korea, Republic Of

Background: Therapies targeting the redox environment such as over-expression of antioxidants or antioxidant treatment, could inhibit tumor cell growth even resistant cells. Bcr-Abl oncopgene is known to induce high levels of intracellular ROS which may further induce genomic instability with malignant transformation and even induce resistance of the patients’ body without the existence of leukaemic clone. Variable expression of antioxidant enzymes in leukemia, with limited studies with variable results so far. Altered redox biology in leukemia also has implications for therapeutics.

Aims: We investigated the roles of PRX II in CML primary cells at diagnosis and remission during signal transduction inhibitor (STIs), and tested the same roles in Ph+ cell lines.

Methods: Three BCR-ABL1 positive cell lines with different resistance to TKI and generating IM-resistant K562 cells by chronic exposure of increasing concentrations of IM were compared with cell growth by MTT assay. BCR/ABL expression by western blot analysis, changes of intracellular ROS level and antioxidant enzymes such as peroxiredoxin (Prx) 1, 2, 3 using immunoblot assay according to different concentrations of IM between 0 to 10 μM in time dependent manner (24 hours/48 hours). We also repeatedly investigated the effects of IM therapy using PRXII overexpressed K562 cells by transfection.

Results: Three BCR-ABL1 positive cell lines showed significant change in cell viability. Intracellular ROS level, eradication of BCR/ABL oncogene and levels of Prx2 during IM treatment with different response each other in degree and pattern by IM exposure. The levels of BCR-ABL1 oncogene were slightly decreased in Pnx2 overexpressed K562 cells. Moreover, Pnx2 overexpressed K562 cells showed further down-regulation of Bcr-Abl oncoprotein by IM treatment.

Summary/Conclusions: Our findings may contributes to find a new pathway on which TKIs are working besides the mechanisms of ATP binding competitively, blocking the binding of ABL-Bcr kinase and substract resulting apoptosis of Ph+ cells. In addition develop the new strategies to overcome the situation of the IM resistant 2010 BCR-ABL positive disease in the future. The importance of the roles of ROS and its PRX II, antioxidant enzymes in CML is further established by our work.
A CASE OF ATYPICAL CHRONIC MYELOID LEUKEMIA WITH LATE DISCOVERY OF JAK2

M. Dudez1,*, M. Daniel1, A. Belahbri2, B. Foucher3, S. Girard4, S. Hayette5, I. Tigaoud6, L. Viau7, 
1Laboratory of Hematology, GHOST Lyon, Bron Cedex, 2Service d’onc hematologie, Centre Leon Bérard, 3Laboratory of hematology, Hôpital Desenettes, Lyon, 4Laboratory of hematology, GHOST, BRON, 5Department of Cyto genetics and molecular biology, 6Department of cytogenetics and molecular biology, GHSUD, Lyon, France

Background: Myeloproliferative neoplasms (MPN) include on the one hand chronic myeloid leukemia defined by the presence of Philadelphia chromosome and BCR-ABL remodeling, and on the other hand MPNs without Philadelphia chromosome (Polycythemia vera [PV], essential thrombocythemia [ET] and primary myelofibrosis [PMF]). V617F JAK2 mutation is the main recurring genetic abnormality in these pathologies (1). It can be found in 28% of PV and 79% of ET and PMF (2). The 2016 WHO classification makes this mutation a key entity which would include BCR-ABL-and V617F JAK2+CML. However 28 of those cases were described in a 2013 literature review (9). Most patients developed either a V617F JAK2 mutation during treatment by tyrosine kinase for a BCR-ABL+CML, or a BCR-ABL+CML during treatment for a V617F JAK2+MPN (3,4,5,6,7). A very small number of patients showed coexistence of those two mutations (8).

Aims: We report a 62y old woman patient with chronic myeloid leukemia with late discovery of JAK2.

Methods: Clinical presentation: A 62-year-old man with no notable medical history was admitted in 2009 for CML. After failure of a first line treatment by Imatinib in 2009 (poor tolerance and incomplete molecular response), treatment by Nilotinib was initiated in 2012 allowing for, to this day, good molecular response despite poor digestive tolerance in the form of dyspepsia. Ever since diagnosis, the patient was under TKI treatment for essential thrombocytosis. In 2018, polycythemia followed then by polycythemia (Hb: 16.7–19 g/dL) that were first attributed to hemoconcentration and inflammation due to recurring bacterial urinary tract infections. Neither infiltration of the lymph nodes nor organomegaly had been noted. In 2014, the patient complained of abundant sweating in the absence of fever and, despite the ongoing complete molecular response, hyperleukocytosis was observed (see Figure 1A). In 2015 the patient, then aged 68, signaled weight loss of 10 kg despite decent overall state of health. Todemiosdometry found evidence of hepatitisplenomegaly. Taking into account the symptoms and persisting blood count abnormalities (WBC 27 G/L, Hb 182 g/L, Platelets 479 G/L, Neutrophils 22.4 G/L, erythrocytemia) a second MPN was suspected. V617F JAK2 mutation was found positive and treatment by Hydroxy for essential thrombocythemia was initiated. Adaptation of Nilotinib posology was decided to avoid possible cytopenia due to its association with Hydroxy.

Evolution: (see Figure 1B) As of the last follow-up consultation in 2017, BCR-ABL remains undetectable and the overall state of health was preserved. Hyperleukocytosis as well as myelosclerosis were persistent on the blood count whereas hemoglobin and platelets had normalized. To determine whether or not V617F JAK2 mutation was present at the time of CML diagnosis, a 2009 sample, in which JAK2 V617F had been estimated at less than 1%, was reanalyzed by means of molecular biology in January 2017. This exam found the mutation in quantities below the clinical significance threshold (1%). But this positivity, however small (0.19%), shows preexistence of that entity, which would include BCR-ABL-and V617F JAK2+CML. However 28 of those cases were described in a 2013 literature review (9). Most patients developed either a V617F JAK2 mutation during treatment by tyrosine kinase for a BCR-ABL+CML, or a BCR-ABL+CML during treatment for a V617F JAK2+MPN (3,4,5,6,7). A very small number of patients showed coexistence of those two mutations (8).

Aims: We report a 62y old woman patient with chronic myeloid leukemia with late discovery of JAK2.

Methods: Clinical presentation: A 62-year-old man with no notable medical history was admitted in 2009 for CML. E14A2 TRANSCRIPT IS ASSOCIATED WITH HIGHER PROBABILITY OF DURABLE TREATMENT FREE REMISSION IN CML PATIENTS

M. D’Adda1,*, F. Schieppati1, E. Morello2, G. Ruggeri3, E. Cerqui1, S. Ferrari1, C. Bottelli1, A. Passi1, G. Rossi1

1Hematology, 2USD Centro Trapianto Midollo Adulti, 3Laboratorio Analisi, ASST Spedali Civili di Brescia, Brescia, Italy

Background: TKIs discontinuation in CML-CP patients with deep molecular response (DMR) are feasible, safe and 40-60% of them maintain treatment free remission (TFR); sokal risk score and duration of TKI-therapy were significantly associated with molecular relapse, according to Euro-Ski and STIM1 trials. While it is known that patients with e14a2 achieve earlier, deeper and more durable responses compared to those with e13a2, few information is available on the influence of the type of bcr-abl transcript on TFR duration.

Aims: Here we describe our single center experience of TKI discontinuation in CML-CP patients with sustained DMR.

Methods: Bcr-abl transcripts were determined by RQ-PCR analysis performed in accordance with EAC protocol (Gabert et al., Leukemia 2003) and to the standards of the Italian national network Labnet. All 174 CML-CP patients presently followed at our institution according to ELN guidelines and treated with 1st or 2nd TKIs were analysed: 103 (59%) had e14a2 and 69 (40%) e13a2 transcript (in 2 pz bcr-abl were not detectable). Criteria for TKI discontinuation was sustained DMR (MR4 or better) for at least 2 years. After TKI withdrawal, RQ-PCR for BCR-ABL was performed every month during the first year and every 2 months thereafter. TKI treatment was reintroduced immediately if DMR loss occurred. TFR was defined as the time between the date of TKI cessation and the date of restarting treatment for DMR loss or, if TKI was not resumed, the date of the last contact.

Results: Forty-nine patients, 25 male and 24 female, discontinued TKI treatment. At the time of discontinuation median age was 63 years (43-85), median time from TKI start 113 months (30-172), median duration of sustained DMR 60 months (24-153). Sokal distribution was 49%, 29% and 20% for low, intermediate and high risk (one patient was not evaluable). Among our 174 patients 39% (40/103) of all e14a2 patients and 13% (9/69) of all e13a2 discontinued TKI (P 0.0002, chi square). Thirty-six patients discontinued imatinib (11 of them with previous INF treatment), 13 stopped nilotinib (8 in first line, 5 in second line treatment). Median follow up after treatment discontinuation was 19 months (3-76), including 31 patients with follow up > 12 months. Thirty-nine patients lost DMR. Median time off-therapy for these patients was 3 months (2-8), and only 1 lost DMR after 6 months. Therapy was restarted in all 13 patients (2 in MR1, 4 in MR2, 7 in MR3), 10 achieved a second DMR after a median interval of 2 months (1-7); 2/13 patients are in M3 after 7 and 12 months, 1 patient is not yet evaluable. Ten out of 11 patients treated with INF before imatinib remained in TFR. Of note, the type of bcr-abl transcript was significantly linked to DMR loss: after TKI discontinuation, 32/40 e14a2 patients (80%) maintained DMR vs 4/9 e13a2 patients (44%) (p 0.03). After 12 months 78% (+/-6% CI95%) of e14a2 and 41,6 (+/-17% CI95%) of e13a2 patients were still in TFR (log-rank: P=0.033) (see Figure 1). Using multivariate analysis the type of bcr-abl transcript and previous INF treatment correlated with DMR loss (p 0.012 and p 0.033). One patient died during follow up in DMR for CML-unrelated cause.

Figure 1.
Summary/Conclusions: In e14a2 CML patients the probability of discontinuation of sustained DMR is significantly higher as compared with e13a2 patients. Moreover, after discontinuation, e14a2 have significantly lower probability of DMR loss than e13a2. These data confirm that e14a2 transcript is as 0.45% (13 of 2,900 patients) in symptomatic patients treated with dasatinib. Dasatinib-related PH usually resolves after cessation of treatment, but it can be fatal, as two deaths in France and one in Japan have been documented.

Aims: To clarify the incidence of tyrosine kinase inhibitor (TKI)-related PH, we noninvasively screened CML patients who have been given imatinib, nilotinib or dasatinib by echocardiography.

Methods: 105 patients with CML in chronic phase (CP) who received TKI were enrolled in this study between 2014 and 2015. Nine patients with newly diagnosed CML in CP prior to TKI treatment were added as control. Patients underwent echocardiography to evaluate 36 values of tricuspid regurgitation pressure gradient (TRPG), which relates to severity of PH. Patients with TRPG values >31mmHg were suspected of PH onset according to European Society of Cardiology criteria. All patients gave informed consent.

Results: Patients were divided into 3 groups by the TKIs they used at the time of study enrollment: 37 patients on imatinib, 30 on nilotinib and 38 on dasatinib (Table 1). In imatinib group, patients’ age was significantly higher, and duration of treatment was also longer than those of the 2nd generation TKIs. Echocardiography revealed mean values of TRPG as 22.7, 23.1 and 23.4mmHg in imatinib, nilotinib and dasatinib groups, respectively (P=0.887), and these values were higher than that in the newly diagnosed CML patients (19.0mmHg), though without significance (P=0.38). Nine of the 105 patients (8.6%) presented with an elevated TRPG>31mmHg, suggesting the presence of PH; 1 of 37 (2.7%) in imatinib group, 3 of 30 (10.0%) in nilotinib group, and 5 of 38 (13.2%) in dasatinib group. Three patients complained of dyspnea, while the remaining 6 were asymptomatic. We found no apparent risk factors associated with TRPG elevation, however, there were trends toward correlation of age and TRPG values in nilotinib and dasatinib treated patients, and treatment duration and TRPG values in nilotinib treated patients. Imatinib dosage tended to inversely correlate with TRPG value, suggesting that imatinib might decrease pulmonary arterial blood pressure in a dose-dependent manner.

Table 1.
TKI resistance. Here we present our data concerning prognostic significance of BCR-ABL1 kinase domain mutations dynamics in Russian CML patients according the follow-up study having been performed during the last 10 years.

Aims: To determine the frequency dynamics of BCR-ABL1 mutations in CML patients and its prognostic significance.

Methods: In this study we have included 1077 TKI resistant CML patients from 112 hospitals in 77 Russian cities having been observed during the period from 2006 to 2016. BCR-ABL1 kinase domain point mutations in mRNA samples from peripheral blood cells were analyzed by means of PCR followed by Sanger sequencing. Statistical analysis was performed using SPSS 22.0 (IBM, USA) and Excel 2013 (Microsoft, USA). Critical p-value was set to 0.05.

Results: 1077 The resistant CML patients were analyzed, among them were 41.5% men (n=447) and 58.5% women (n=630), median age – 50 (from 15 to 74). BCR-ABL1 mutations were found in 30.8% (332/1077) CML pts. We have detected a total of 415 mutations in 332 patients, giving rise for 58 different mutation variants. Mutation associated resistance rate was higher in women to compared to men (63% vs. 55%, p=0.001). In 63% of patients with b2a2 transcript, the e13a2 transcript was present at a lower in frequency compared to e14a2 transcript. The e13a2 and H396R mutations were statistically more frequent in women, meanwhile T315I mutation prevailed in men (Pearson’s χ²=0.05). It was of a sudden that BCR-ABL1 mutation distribution significantly varied according the particular CML pts city location throughout the different regions of Russia. Although for the period from 2006 to 2016 there were no detectable changes in mutation frequency spectrum (Pearson’s χ² is 0.62), the total amount of mutations associated with TKI CML resistance has decreased from 36.6% in 2006-2008 to 24.96% in 2013-2016, but still remained significant. For particular mutations following dynamics were detected: frequency of imatinib-resistant mutations decreased gradually from 2006 to 2016, while the rate of F317L and F359V mutations underlying resistance to second generation TKI increased in 2013-2016. T315I mutation rate expanded to the maximal level in 2014 and abruptly decreased afterwards. This tendency change may be the consequence of the second generation TKIs and other therapeutic strategies involvement into clinical practice.

Summary/Conclusions: As far as different BCR-ABL1 kinase domain mutations are associated with various types of mutation associated resistance to TKI treatment, the detection of trends in mutation distribution in CML patients receiving TKI treatment is very important for long time treatment strategy decision making, and also for better analysis of resistance. We believe here that regional difference of mutation profiles should also be considered. Therefore, to enable correct triggering of particular types of TKI for CML treatment it is necessary to obtain data of when, which and where a particular type of BCR-ABL1 mutation is prone to appear in a distinguished cohort of CML pts.

PB1818

IMPACT OF BCR-ABL1 TRANSCRIPT TYPE IN CHRONIC MYELOID LEUKEMIA TREATED FRONTLINE WITH NILOTINIB

Three patients (2 IM/HU, 1 IM) were lost to follow-up. As prospectively designed, all available IM/HU patients (n=77) were included in the analysis. According to the study protocol, patients from the CML IV study were to be added to obtain equal numbers for analysis. To arrive at a total of 77 IM patients, from study IV another 49 patients were selected by propensity score matching. The median age of the 154 patients was 55 years (range 18 – 82). The ELTS prognostic score was available for 141 patients and was high in 8 (5.7%), intermediate in 35 (24.8%) and low in 98 (69.5%), with no significant differences between treatment groups.

Results: The 5-year overall survival (OS) / progression-free survival (PFS) probabilities were 90.4 and 66.7% in the IM/HU and twice 84.9% in the IM arm, respectively. IM/HU, the probabilities of complete cytogenetic response (CCR) at 6, 12, and 18 months were 54.3, 84.0, and 93.7%, In the IM arm, the corresponding numbers were 70.4, 84.9, and 83.3% (p-not significant). Primary endpoint was MMR rate at 18 months. There was no significant difference between IM/HU (65.8%) and IM (66.0%). At 6 months, MMR rates in the IM/HU group were 61.0% (p=0.0385) and at 12 months 41.9 (IM/HU) vs 58.9% (not significant). Time to event analyses of OS and PFS did not result in significant differences; neither did group comparisons between the probabilities of CCR and MMR. The median HU dose was 500mg (range 152-3000); the median IM dose was 400 mg (range 145-617mg) in both arms. The gross numbers of adverse events in general or of adverse events of grade 4 were not different between the two arms, but cumulative incidences showed an earlier occurrence in the IM/HU than in the IM arm (p= 0.0343, Gray test).

Summary/Conclusions: Compared to imatinib only, the combination of imatinib and HU resulted in a lower MMR rate at 6 months but a similar MMR rate at 18 months. Furthermore, IM/HU was associated with more early adverse events. There was no indication of a beneficial effect in the treatment of CML patients in 1st chronic phase using the combination of IM with HU.

A MULTICENTER, OBSERVATIONAL, AMBISPECTIVE STUDY EVALUATING EFFICACY AND SAFETY OF GENERIC IMATINIB COMPARED TO GLEEVEE IN CHRONIC MYELOGENOUS LEUKEMIA IN CHRONIC PHASE - 3 MONTHS RESPONSE ANALYSIS

K. Pagnano1,2, E. Miranda1, N. Clementino2, G. Magalhães2, A. Coelho3, E. Reis4, E. Sesma5, M. R. de Souza6, R. Teixeira4, J. Bortolini6, C. Pinna9, M. D. L. Chauffaille10, R. Centrone11, C. De Souza12

1Hematology and Hemotherapy Center, University of Campinas, Campinas, Brazil, 2Hospital das Clínicas-Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, 3Instituto Nacional do Câncer, Rio de Janeiro, Brazil, 4Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, 5Memoria, Rio de Janeiro, Brazil, 6Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil, 7Centro de Pesquisa Oncológicas de Santa Catarina, Florianópolis, Brazil, 8Universidade Federal da Bahia, Salvador, Brazil, 9Universidade Federal de São Paulo, Brazil, 10Instituto de Estudos e Pesquisas São Lucas, São Paulo, Brazil, 11University of Campinas, Campinas, Brazil

Background: The efficacy of branded imatinib (Gleevec) in the first-line treatment of chronic myeloid leukemia (CML) has been demonstrated in several clinical studies. However, there are few consistent data in the literature on the efficacy and adverse effects of generic formulations of imatinib. In Brazil, CML patients have been treated in the national public health system with generic imatinib since June 2013.

Aims: The present study aims to evaluate the efficacy and safety of generic imatinib in the treatment of CML in comparison with the reference drug (Gleevec) in the first three months of imatinib treatment.

Methods: This is a multicenter, observational, ambispective, cohort-type study. The study was initiated in January 2015 with the intended participation of 17 Brazilian centers. In the prospective group, were selected chronic phase CML patients who started their first-line treatment with generic imatinib between January 2015 and October 2016, whereas retrospective group was treated with imatinib between January 2010 and December 2010. All patients started imatinib less than six months from diagnosis. Study data were collected and managed using REDCap electronic data capture tools. Demographic data were collected at diagnosis: age, gender, Sokal, Hasford, EUTOS score, comorbidity, cytogenetics, BCR-ABL transcript type. The definition of the responses followed the European Leukemia Net (ELN) criteria. Adverse events were assessed based on the Common Terminology Criteria for Adverse Events (CTCAE) Version 4.0.3, 2010. Statistical analysis: SPSS version 21.0 was used applying the chi-square and t-test, when adequate. All analysis considered p-value <0.05 as significant.

Results: Ten centers were registered 177 patients in the retrospective group and 68 patients in the prospective group so far. For this preliminary analysis, response data from 132 patients were available (47 from prospective and 85 from the retrospective groups). The median age of patients was 54 years in the prospective group and 46 years in the retrospective group (P=0.012). Sokal score < and ≥ between 0.9 (n=38 and n=94). Median dose of imatinib was 42%/52%; intermediate risk 42%/31% and high risk 45%/67% (P=0.48). There was no difference between the groups concerning gender, Hasford, EUTOS scores, ECOG, blood cell counts at diagnosis and before starting imatinib and BCR-ABL transcripts. Responding rates, there was no difference between the hematology and complete cytogenetic responses and rate of BCR-ABL transcripts >10% at three months. However, there was a higher rate of failure at three months according to the ELN 2013 criteria in the retrospective group (14.9% versus 4.7% Gleevec group, P=0.04). There was no significant difference in grade 3 and 4 hematological and non-hematological toxicity, but there was one early death in the prospective group (acute peripheral arterial occlusion and renal failure). Four patients discontinued imatinib: one from Gleevec group (resistance) and three from the generic group due to intolerance (1) and resistance (2).

Summary/Conclusions: According to ELN-2013 criteria, there was a higher rate of failure in the retrospective group (generic imatinib) at three months, but no difference in toxicity. The register is ongoing; the confirmation of this data and the impact in prognosis will be evaluated in the long-term follow-up, after increasing the number of patients.

COMPLEX ADDITIONAL CHROMOSOME ABERRATIONS IN PH-POSITIVE CELLS IMPACT ON CHRONIC MYELOID LEUKEMIA PATIENTS' SURVIVAL IN THE ERA OF TYROSINE KINASE INHIBITORS

M. Fominykh1, O. Shuhov2, I. Martynevikich1, V. Shuvave1, E. Chelysheeva2, A. Turkina2

1Clinical department, Russian Research Institute of Hematology and Transfusionology, Saint-Petersburg, 2Clinical department, National Research Center for Hematology, Moscow, Russian Federation

Background: Additional chromosomal aberrations (ACA) as marker of clonal evolution in chronic myeloid leukemia (CML) patients were previously noted in association with resistance to therapy. The presents of ACA have been associated with a worse prognosis for survival in the pre-TKI era. The ACA classification proposed earlier was based only on its frequencies. Whereas ACA's clinical impact had not yet been clearly established.

Aims: The aim of our study was to evaluate the long-term impact of the ACA presence in Ph-positive cells in CML patients on TKI treatment results.

Methods: 30 patients with ACA in Ph-positive cells treated in our center from 2005 to 2015 years were included in this study. Cytogenetic analyses of at least 20 Giemsa-banded bone marrow metaphases were interpreted per ISCN 2013. We analyzed overall survival (OS) and cumulative incidence of CML-related death on TKI treatment. Cox regression was used for multivariate survival analysis, that included next covariates: number of ACA, type of ACA, age, TKI type, CP or AP at diagnosis. OS was estimated by Kaplan-Meier method with log-rank test for comparison. Cumulative incidence of CML-related death was estimated into consideration the presents of competing risks (CML-unrelated death) using Gray’s test for comparison between groups.

Results: Median follow-up period in ACA group (n=30) was 51 months (3-124). ACA at diagnosis were detected in 16 (53%) of 30 patients. Chronic phase was detected in 23 (77%) patients. CML-related death was 23%. Number of ACA(p=0.03, HR=13.2) and age (p=0.03, HR=1.14) had statistical significance influence on survival by regression analysis. 10-years OS was 31% and 77% (p<0.05) in patients with complex ACA and single ACA respectively, 10-years cumulative incidence of CML-related death was 54% for patients with complex aberrations versus 10% for single ACA patients (p<0.05) (Figure 1).

Summary/Conclusions: Our results showed that TKI treated CML patients with complex ACAs have a higher risk of progression and death in comparison with single-ACA patients.

Figure 1.
BCR/ABL1 TRANSLOCATION E13A2 IS ASSOCIATED WITH HIGHER CUMULATIVE PROBABILITY OF LOSS OF MAJOR MOLECULAR RESPONSE IN CML PATIENTS TREATED WITH NILOTINIB AS THE 2ND LINE THERAPY

I. Dmytrenko1, V. Fedorchenko1, Z. Martina2, V. Sholoyko2, T. Shlyakhchytenko1, Z. Minchenko1, I. Dyagii2
1Immunogenetic Laboratory, 2Hematology and Transplantology Department, National Research Center for Radiation Medicine, Kyiv, Ukraine

Background: Several types of transcripts can be produced during chromosomal translocation, which lead to formation of the BCR/ABL fusion gene in patients with chronic myeloid leukemia (CML). Previous results of a few large studies showed that patients with CML in chronic phase (CP) with e13a2 transcript have inferior responses to front-line imatinib therapy compared to patients with the e14a2 transcript.

Aims: To investigate the prognostic significance of e13a2 and b14a2 BCR/ABL1 transcripts in CML patients switched to nilotinib after suboptimal response or failure on front-line imatinib.

Methods: CP-CML patients (N=143) who did not achieve complete cytogenetic response (CCR) after imatinib therapy (600 or 800 mg once daily) and were switched to nilotinib 400 mg twice daily, were enrolled in present study (55 patients with e13a2 transcript and 88 patients with e14a2 transcript). The mean and secondary resistance before switching to nilotinib was 44 months (range 1-137). A qualitative RT-PCR for BCR/ABL1 transcript was performed at diagnosis. The patients who achieved CCR but did not have major molecular response (MMR) as well as patients with rare BCR/ABL1 transcripts and coexpression were excluded from the analysis. Probability of overall survival (OS), progression-free survival (PFS), event-free survival (EFS) and overall cumulative incidence of MMR were calculated using Kaplan-Meier method. Event in EFS was defined as death of a patient on treatment for any reason, progression of disease, or loss of CCR or MMR. Differences between groups were assessed using log-rank, χ2-tests and Mann-Whitney U-tests. Cumulative probability of CCR, MMR, MR4.0 (BCR/ABL<0.1%) and loss of CCR and MMR was assessed using Kaplan-Meier method.

Results: The median follow up was 23 (range 4 – 82) months. The groups with both of the BCR/ABL1 main transcripts were comparable for the disease phase, Sokal risk score and the proportion of patients with additional chromosomal abnormalities in Ph-positive cells. No correlation of transcript type with age or sex was observed. Transcript e13a2 was associated with higher WBC (120x10^9/L vs 95.3x10^9/L, p=0.02) and lower baseline percentage of eosinophils (p=0.041). No differences were found in other differential counts of peripheral blood, hemoglobin concentration, or spleen size. The time to CCR, MMR and MR4.0 and rate of CCR (52% and 52%), MMR (38% and 33%) and MR4 (23% and 22%) were comparable in patients with e13a2 and e14a2 transcripts respectively. Estimated probability of CCR, MMR and MR4.0 also did not differ in both groups. The rate of optimal response, primary and secondary resistance before switching to nilotinib was comparable in both groups. Whereas there were no differences in the estimated probability of CCR in both groups, but rate and cumulative incidence of MMR loss was significant higher (69% vs 11%, p=0.037) in patients with e13a2 transcript. No difference between groups was observed with regard to PFS, EFS and OS.

Summary/Conclusions: Analysis of the optimal response to nilotinib by transcript type of these drugs show that the 2nd-line therapy suggests that patients with e13a2 transcript have less stable therapy response and demonstrate higher cumulative incidence of MMR loss (molecular relapse). But outcome differences were not observed. Further analysis of a larger number of events and longer observation is required.

PB1824 ACHIEVING OPTIMAL RESPONSE AT 12 MONTHS IS ASSOCIATED WITH A BETTER HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA: A PROSPECTIVE, LONGITUDINAL, SINGLE CENTER STUDY

Q. Jiang1, H. Wang2, L. Yu1, D. Mili joystick1, X. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking University Clinical Research Institute, Beijing, China, 3Novartis Pharma AG, Basel, Switzerland

Background: Health-related quality-of-life (HRQoL) profile is now recognized as an important component in the management of Chronic myeloid leukemia (CML). Aims: To explore the HRQoL profiles of patients with CML in the chronic phase (CP) who were treated with front-line imatinib or nilotinib, in order to assess the relationship between early response and HRQoL outcomes.

Methods: A prospective, longitudinal, single center study was conducted to assess the response to treatment with imatinib or nilotinib and the HRQoL profile of patients who were newly diagnosed with CML-CP and enrolled into ENESTchina study. Health-related quality-of-life (HRQoL) profile was measured according to the European LeukemiaNet recommendations, and patient-reported HRQoL profile was measured by the SF-36 health survey.

Results: Fifty-nine patients were randomly assigned to receive imatinib (n=31) or nilotinib (n=28). In multivariate analysis, the use of nilotinib was identified as an independent factor affecting the achievement of optimal response at 6 months (OR=3.9, 95% CI, 1.0-14.9; P =0.043) and 12 months (OR=5.6, 95% CI, 1.7-17.9; P =0.004). With a median follow-up of 60 months, the probabilities of failure-free survival (all P Values <0.001) and progression-free survival (all P Values <0.05) at 5 years were significantly higher in patients who achieved optimal response at 3, 6, or 12 months than those who achieved non-optimal response (warming or failure), and overall survival rate at 5 years was significantly higher in those who achieved optimal response at 12 months (P =0.047). Achieving optimal response at 12 months was associated with better role limitation and emotional limitations due to physical health problems (P =0.0019) and role limitations due to emotional problems (P =0.0110) and was the sole factor associated with significantly improving physical component summary over time ( P =0.0160). In addition, achieving optimal response at 6 months had a tendency of high physical functioning (P =0.0674), social functioning (P =0.0571), and role limitations due to emotional problems (P =0.06) of CML patients who achieved optimal response at 6 months. Female gender, and higher education level were also associated with better HRQoL subscales.

Summary/Conclusions: Achieving optimal response at 12 months was associated not only with longer overall survival and less treatment failure and disease progression, but also better HRQoL in newly diagnosed patients with CML-CP on front-line tyrosine kinase inhibitor.

PB1825 MULTI-COUNTRY RETROSPECTIVE CHART AUDIT STUDY TO EXAMINE DEEP MOLECULAR RESPONSE (MR4.5) ASSOCIATED WITH DEEP MOLECULAR RESPONSE (MR4.5) ASSOCIATED WITH DEEP MOLECULAR RESPONSE (MR4.5) ASSOCIATED WITH
SECOND-LINE TYROSINE KINASE INHIBITORS IN CHRONIC PHASE - CHRONIC MYELOGENOUS LEUKEMIA (CML-CP)
J. Cortes1,2, L. Huyten2, P. Brandt3, M. Der Sarkissian3, G. Zaccarellile2, D. Dalal4, J. Hussein2, M. S. Duh2
1Department of Hematology, The University of Texas MD Anderson Cancer Center, Houston, 2Epidemiology, Analysis Group, Inc., Boston, 3Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: Achieving deep molecular response, ≥4.5-log reduction (MR4.5; BCR-ABL1 on the International Scale [IS] ≤0.0032%) is, one of the important prerequisites for achieving treatment-free remission. Limited information is available on comparative rates of MR4.5 between nilotinib and dasatinib in second-line (2L).

Aims: This study aims to investigate time to achieving MR4.5 and major molecular response (MRM; ≥3-log reduction or ≤0.1% in BCR-ABL1 on IS in CML-CP patients (pts)) treated with nilotinib vs dasatinib in 2L.

Methods: This retrospective panel approach was used to recruit oncologists (N=141) globally to conduct a retrospective medical chart audit. Physicians were instructed to select up to 4 pts who met the following criteria via a random letter generation scheme for the first letter of pt’s last name: diagnosed with CML-CP at age ≥18 years, initiated 2L nilotinib or dasatinib between 1/1/11 and 12/31/13, and had ≥12 mos of follow-up data after initiating 1L TKI. Multivariate Cox proportional hazards models accounting for country clustering random effects were used to assess the effect of nilotinib vs dasatinib on time to MR4.5 and MMR, adjusting for age, gender, Sokal risk score at diagnosis, hydroxyurea use before 1L TKI, 1st vs 2nd generation TKI as 1L, and reasons for 1L TKI discontinuation. Adjusted hazard ratios (HR) and 95% confidence intervals (CIs) were reported. Adverse events (AEs) were also described.

Results: The study included 236 pts from Australia, Brazil, France, Germany, Italy, and Netherlands treated with nilotinib (N=115[49%]) or dasatinib (N=121[51%]) in 2L. Both groups had a similar mean follow-up of 23 mos, median follow-up was 16 mos. There were 35% females and 65% Asian. 2L nilotinib pts were treated with the other 2nd generation TKI in 1L (p<0.01). A higher proportion of nilotinib pts had high-risk Sokal score (20.9% vs 11.6%, p=0.05) and received prior hydroxyurea (8.7% vs 3.3%, p=0.08) vs dasatinib. 85% and 11% of 2L nilotinib pts continued 1L TKI due to resistance and intolerance, respectively, prior to switching to nilotinib, vs 74% and 22% for 2L dasatinib pts (both p<0.05). The univariate Cox model showed that nilotinib had a non-significantly higher rate of achieving MR4.5 than dasatinib (32% vs 31% at 24 mos for 2L nilotinib and 2L dasatinib, respectively, based on the Kaplan Meier estimator; unadjusted HR=1.09, 95% CI [0.87, 1.38], p=0.46); however, after multivariate adjustment, nilotinib reached a significantly higher rate of achieving MR4.5 (adjusted HR=1.36, 95% CI [1.07, 1.73], p=0.01) than dasatinib. Among those who achieved MR4.5, 45% of nilotinib pts maintained MR4.5 for ≥1 year vs 39% of dasatinib pts (p=0.60). Additionally, higher-risk Sokal score (HR=0.31, 95% CI [0.14, 0.72], p<0.01) and resistance to 1L TKI (HR=0.60; 95% CI [0.24, 0.88], p<0.01) were inversely associated with achieving MR4.5. There was no significant difference in MMR achievement between 2L TKI groups. Over 3 times more dasatinib pts experienced pleural and pericardial effusion AEs than nilotinib pts (9.9% vs 2.6%, p=0.02). One nilotinib pt had ischemic heart disease-related AE

Summary/Conclusions: This retrospective chart audit study suggests that 2L nilotinib may be associated with a higher rate of MR4.5 than 2L dasatinib in CML-CP. Our results should be taken with caution as this study is susceptible to unmeasured confounding and biases due to its retrospective and observational nature. Rigorous clinical assessment in a prospective setting is needed to conclusively compare rates of patients achieving MR4.5.

PB1826
COMPUTATIONALLY INTELLIGENT PREDICTION OF CLINICAL OUTCOME IN CHRONIC MYELOCYTIC LEUKEMIA
Z. Cojbasic1, I. Cojbasic2, L. Macukanovic-Golubovic3, M. Vucic3,4
1hemato-oncology, Rabin Medical Center, Petah Tikva, 2Sackler School of Medicine, Tel Aviv University, Ramat-Aviv, 3Department of Hematology, Hadassah-Hebrew University Medical Centre, Jerusalem, 4Hematology Division, Chaim Sheba Medical Center, Tel-Hashomer, 5Bone Marrow Transplantation Unit, Soursacy Medical Center, Tel Aviv, 6Department of Hematology, Meir Medical Center, Kfar Saba, 7Bone Marrow Transplantation Unit, Rabin Medical Center, Petah Tikva, 8Hematology Institute, Soroka University Medical Center, Beer-Sheva, 9Hematology unit, HaEmek Medical Center, Afula, 10Department of hematology, Assaf Harofeh Medical Center, Zerifin, 11Department of hematology, Wolfson Medical Center, Holon, Israel

Background: Computational intelligence has been applied to a wide range of problems to assist in decision-making, especially artificial neural networks, fuzzy systems and powerful hybrid neuro-fuzzy approaches have already proven their strong potentials in medicine. Despite that, applications in hematology are still scarce.

Aims: In this study we have developed novel ANFIS neuro-fuzzy prognostic models, based on biochemical and morphometric diagnostic data, to enable better prediction of complete cytogenetic response (CCgR) for patients with chronic myeloid leukemia.

Methods: This prospective study included a consecutive series of patients with chronic myeloid leukemia (CML) who were started on imatinib therapy. Analysis was performed on the first 90 patients (1.6 ± 1.2, 12 and 18 months as the outcome variables. A total of 40 patients on imatinib therapy were included in the final analysis. Of these, 25 (62.5%), 29 (72.5%), and 32 (80%), respectively, achieved CCgR at 6, 12, and 18 months after initiation of imatinib. Computationally intelligent neuro-fuzzy models that were developed included EUTOS score on diagnosis and one of the following morphometric parameters: microvascular density, length of the minor axis, area or circularity of the blood vessel. Adaptive neuro-fuzzy systems represent a specific combination of artificial neural networks and fuzzy logic, thus combining the learning ability of artificial neural networks with the knowledge representation capability of fuzzy logic systems. ANFIS (Adaptive Neuro Fuzzy Inference System) consists of five layers of nodes (neurons), each of which performs a particular function on incoming signals as well as a set of parameters pertaining to this node. The basic architecture of ANFIS using hybrid learning algorithm is presented in Figure 1.

Results: All analysed patients have received imatinib mesylate as their first-line treatment for CML. Model predictions (0–1) for any individual patient were interpreted as probability of CCgR at 6, 12 or 18 months. The overall accuracy of the final model was determined by comparing the predicted values with the actual events. A probability cut-off point of 0.50 (50%) was used to classify observations as events or non events, and patients were divided in training, validation and testing groups. Best performing ANFIS model, including EUTOS score and minor axis morphometric parameter was better than a model that includes only EUTOS score and regression model based on the same inputs. Overall model correct classification achieved for EUTOS, two input LR model and two ANFIS model were respectively 75%, 75% and 75.5%, while areas under curve on ROC graphs were 0.776, 0.529 and 0.875 respectively.

Figure 1.

Summary/Conclusions: The major finding of this study is that ANFIS models using the morphometric parameters, available at diagnosis of chronic phase of the CML, may improve prediction of CCgR at 6, 12 and 18 months on imatinib therapy, in comparison to the EUTOS score being the standard prognostic scoring system and regression models using the same inputs. Using neuro-fuzzy computationally intelligent ANFIS models with morphometric parameters in conjunction with EUTOS score improves prediction of CCgR. Validation on larger groups of patients is needed, but these findings indicate that neuro fuzzy models could aid in individual CML patient risk stratification.
based regimens (N=28, 76%). Nine patients (25%) underwent hematopoietic stem cell transplantation (HSCT) prior to ponatinib. The time that elapsed from diagnosis until ponatinib initiation ranged considerably (from 1 to 215 months, median 47 months). *Indications for ponatinib switch*: 26% of patients (N=9) switched to ponatinib because T315I mutation was detected. The remaining switched either because of progressive disease, i.e. accelerated (N=5, 14%) or blastoid (17%, N=8, 17%) phases, and 19% (N=7) because they experienced loss of previous molecular or cytogenetics response. Only 5% (N=2) switched because of unacceptable side effects to previous treatments. *Treatment with Ponatinib*: Patients received ponatinib for a median time of 14 months (range: 1 to 51). The drug started at the recommended dose of 45 mg/day in only 60% (N=22) of patients and in 24% of them (N=9) the dose was reduced during treatment. The median survival time of patients with ponatinib was 38 months (95% CI: 30 to 47 months) (Figure 1). Patients died because of cerebrovascular event (N=1), sepsis (N=2) or graft vs host disease that developed shortly after HSCT (N=1). *Response assessment*: Response assessment as available for 32 patients (86%). Seventy percent (N=22) achieved molecular response, of which 60% (N=13) achieved at least major molecular response. The median time to maximal response was 7 months (range: 3 to 28 months). *Drug discontinuation*: Twenty four percent (N=9) discontinued ponatinib after a median of 7 months (range: 1 to 18 months) because of disease progression (N=6) or severe adverse effects in two patients (cerebrovascular event and severe pancytopenia).

**PB1829**

**BCR-ABL MOLECULAR RESPONSES AT 12-18 MONTHS USING THE QUANTIDEX QPCR BCR-ABL IS KIT PREDICT LONG-TERM EVENT-FREE SURVIVAL IN PATIENTS WITH TKI-TREATED CML**

**J. Brown1,*, A. Ruskin1, I. Beldorh1, M. Fahey1**

1Laboratory of Cytogenetics and Molecular Biology, 2National Specialised Hospital for Active Treatment of Hematological Diseases, 3Alexandrova University Hospital, Sofia, Bulgaria

**Background**: Generally, chronic myeloid leukemia (CML) and essential thrombocythemia (ET) are characterized by distinctive clinical and laboratory character-istics, including the spectrum of genetic abnormalities - Philadelphia chromosome (Ph) and BCR-ABL fusion transcripts in CML and JAK2, CALR or MPL gene mutations in ET. Therefore, even in the presence of overlapping fea-tures in some cases, the correct diagnosis can be assigned. However, in rare cases Ph chromosome and BCR-ABL1 fusion transcripts can be found in other cases typical for ET. The number of reported cases of this sequence of the disease and the response to tyrosine kinase inhibitors (TKI) in such patients with BCR-ABL1-positive thrombocytosis is largely unknown.

**Aims**: To report the clinical course and response to TKI in patients (pts) with CML presenting with isolated thrombocytosis at the onset.

**Methods**: In total, 31 pts with Ph(+) and/or BCR-ABL1(+) isolated thrombocyto-sis and a moderate or absent leukocytosis were retrieved from the hospital database. The cohort comprised 17 females and 14 males, at a median age of 47 years (range 23-86). Diagnosis was based on blood and bone marrow mor-phology and differential, cytogenetics and/or molecular testing according to the WHO criteria (2008). Molecular monitoring was carried out using Xpert BCR-ABL Monitor or Xpert BCR-ABL Ultra tests (Cepheid). In total, follow up data for at least 6 months (mean 65 months) are available for 25 patients treated with TKI as a first-line therapy.

**Results**: At diagnosis the median leukocyte count was 22 x10⁹ (range 6-36) and platelet count ~ 1316x10⁹/l (range 770-2815). Splenomegaly was found in 5 pts (16.1%). Only one patient was diagnosed in accelerated phase as the remaining presented in chronic phase at diagnosis. Interestingly, 4 pts (12.9%) had a history of an antecedent solid tumor. All patients enrolled in the study were BCR-ABL1(+): b3a2 (n=16) or b2a2 (n=15). Karyotypes were available in 16 pts and classical Ph was detected in 16 of them (69%), with in 41% of them (21.7%) a cryptic translocation was detected as well a variant Ph in the remaining 2 pts (8.7%). Imatinib was used as a first line therapy in 15 pts and optimal response was achieved in 53.3% (n=8), while 5 were switched to a second line, and 2 - to a third line therapy. First-line treatment with nilotinib in 10 pts resulted in optimal response in 80% (n=8). In optimal molecular response (MR) was achieved in 80% (n=20), including deep MR in 56% (n=14). One pt was lost of follow up after optimal response was registered. No response was documented in 4 pts (16%) and progression to blast crisis developed in 2 of them. The mean OS was estimated 143 months and the cumulative propor-tion surviving at 5 years was 91%.

**Summary/Conclusions**: Interestingly, CML presenting with isolated thrombo-cytosis at diagnosis in our cohort had high proportion of antecedent malignanties and high incidence of cryptic Ph translocation without any specific correla-tion with the transcript types. However, the clinical course and molecular response to TKI therapy was similar to the reported in CML in general.

SHOULD SWITCHING TO SECOND GENERATION TKIS BE A RULE IN PATIENTS WITH CP-CML AFTER 3-6 MONTHS OF IMATINIB TREATMENT? RETROSPECTIVE ANALYSIS OF CML PATIENTS TREATED IN A SINGLE BRAZILIAN CANCER CENTER

A.P.S. Ferreira1,2*, F.S. Seguro1,2, A.B. Medina3, A.N.R. Abdo2, F.V.R. Maciel4, L.Y. Okada1, I. Bendit1
1Hematology, Hospital das Clinicas da Faculdade de Medicina da USP, 2Hematology, Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil

Background: Early molecular response is an important predictor for survival and therapy-free remission in chronic myeloid leukemia (CML). The current guidelines define BCR-ABL1 <10% at 3 months and/or 1-10% at 6 months as warning signals; however, it is not clear if switching imatinib to second generation TKIs in this scenario improves responses and overall survival in patients outside clinical trials.

Aims: To analyze the proportion of patients with major molecular response (MMR) at 12 months according to the molecular response at 3 and 6 months in a cohort of CML population, not enrolled in clinical trials and treated only with imatinib. Also evaluate the incidence of molecular responses log3.0, log2.0, and log1.5 at any time in patients who did not switch to second generation TKIs.

Methods: Retrospective analysis of all 226 patients diagnosed with CML from January 2007 until January 2015 in our hospital. The exclusions criteria were: advanced phases, inclusion in clinical trial, treatment with second-generation TKI in the first 12 months (due to toxicity or failure). The molecular response was evaluated according ELN recommendations: RQ-PCR assessment of BCR-ABL1 levels every 3 months until achievement of MMR, with molecular evaluation every 3-6 months afterward. All samples were analyzed in the same laboratory which was standardized since 2007.

Results: In the first cohort, 150 patients with CML chronic phase were analyzed. Optimal molecular responses by the ELN at 3 and 6 months were predictors of MMR by 12 months (94% vs 6%, p<0.001 at 3m, 89.3% vs 10.7%, p<0.001 at 6m), but there was no overall survival benefit. A second cohort with 119 patients received only imatinib, with a medium follow-up time of 71 months (13-117m), MMR was achieved by 60% of this imatinib-only group after 12 months and by more than 90% after 36 months (Figure 1). Patients with BCR-ABL1 <10% at 3 months and/or <1% had a higher probability of achieving MMR3, MMR4 and MMR4.5 at any time.

Summary/Conclusions: Our study shows that around 30% of the patients that do not fail to imatinib at the first year of treatment may be late responders. Not all patients should change therapy, if they have not reached MMR at 12 months. Molecular response at 3 or 6 months might guide the decision to switch TKI, but patient’s comorbidities, possibility of discontinuation and cost of therapy should also be considered.
PB1833

COST-EFFECTIVENESS OF A THERAPEUTIC EDUCATION PROGRAM (TPE) FOR PATIENTS WITH CHRONIC MYELOID LEUKEMIA AND TREATED BY TYROSINE KINASE INHIBITORS

M. Régnier-Cordier1, A. Chan Hew Wai2, L. Cochard3, M.-L. Fontoura4, T. Gindina1,*, E. Morozova1, O. Shukhov2, M. Barabanshchikova1, T. Gindina1

Aims: Within our cancer centre, an TPE program on ITK in the management of CML has been authorized since 2011. We conducted a pharmacoeconomic study to evaluate the TPE clinical impact on responses to TKI in patients with CML (based on recommendations from European Leukemia Net) and also the costs in terms of use of care.

Methods: Over the 12-month follow-up period, the study population consisted of 2 groups of CML patients monitored in our centre: - Intervention group (n=18) (IG): Patients who benefited of TPE sessions on TKI between January 2013 and August 2015 - “Matched controls” group (n=18) (CG): Patients who benefited only from the usual care, matched to the “intervention” group. The method of pairing the 2 groups of patients according to the age at diagnosis, sex, the molecule used in first line and the prognostic risk of the MMR by 4.4 months.

Summary/Conclusions: As demonstrated in this audit, patients with CML on ITK who received a therapeutic education in ITK management showed a better response to treatment and reduced costs as compared to patients who received only the usual care. In addition, the study underlines the need for integrated care programs with a comprehensive design and an individualized approach to address the specific needs of patients with CML.
Methods: This cross-sectional study comprised 85 patients with CML in chronic phase, treated with imatinib, nilotinib, and dasatinib. A Clinic for Hematology, Clinical Centre of Vojvodina, Serbia. Thyroid function was assessed by analyzing the serum FT3, FT4 and TSH levels. Hypothyroidism in relation to TKI therapy was defined as newly diagnosed hypothyroidism (while the patient was already on TKI therapy) requiring hormone substitution therapy or serum FT4 level <11.5 pmol/l and serum FT3 level <1.9 pmol/l. Patients with previous medical history of thyroid dysfunction were excluded. The duration of TKI treatment varied from 2 month to 10 years. The dose of imatinib was 400mg daily, while nilotinib was dosed 800mg a day.

Results: From the total number of patients included, 37 (43.53%) were female and 48 (56.47%) were male. The age of the patients ranged from 21-84. The prevalence of hypothyroidism (clinical, and subclinical) was 8.23% (n=7) which is in accordance with the prevalence in general population. Three patients (3.53%) were diagnosed to have subclinical hypothyroidism (defined as normal serum FT4 and TSH >5.50 mIU/l). Hyperthyroidism was more common in males (71.5%, p=0.29, not statistically significant). In patients treated with imatinib, 2 (3.4%) had subclinical, while 3 (5.01%) had clinical hypothyroidism. Of the 26 patients treated with nilotinib, subclinical hypothyroidism was detected in 1 (3.85%), as well as clinical hypothyroidism (3.85%). Other thyroid dysfunctions were not detected.

Summary/Conclusions: Hypothyroidism was the only thyroid dysfunction in our study. The prevalence of hypothyroidism in our study did not differ from general population. Additional study on a larger sample size and evaluation of antibodies is required.

PB1836

RESPONSE RATES AND SURVIVAL OF PATIENTS WITH CHRONIC MYELOID LEUKAEMIA INITIALLY TREATED WITH IMATINIB: 11 YEAR EXPERIENCE OF A TEACHING HOSPITAL GOSPORT, UK

M. Ruparelia1,*, P. George1, D. Brownings1, K. Marshall1, A. Hunter1, M. Martin1, K. Hodgson1
1University Hospitals Leicester, Leicester, United Kingdom

Background: In large trials, patients with chronic myeloid leukaemia (CML) treated with Tyrosine Kinase Inhibitors (TKIs) have relative survival rates of up to 90% that of age-matched controls. Patients achieving complete cytogenetic responses (CCyR) within 2 years of starting Imatinib have survival rates equivalent to the general population. Newer TKIs are associated with faster and deeper treatment responses, but have a more toxic side effect profile as well as being more costly.

Aims: This study looks at the 11 year experience of a single teaching hospital treating a population of almost one million and presents the response and survival data of this unselected population of patients with CML treated with imatinib as initial therapy.

Methods: A retrospective case record review was undertaken on CML patients identified from the regional cytogenetics department. Imatinib was available for routine prescription in the UK from 2003, so a 11-year period from 2003 to 2013 was selected to allow for adequate follow-up.

Results: In total 83 patients were newly diagnosed in this time period. Four patients, treated on SPIRIT2 with dasatinib as initial therapy, have been excluded from the subsequent analysis, leaving 79 patients treated initially with imatinib 400mg daily. The median age at diagnosis was 53 years (range 13-95) with 48 (60.7%) being males. The median follow up was 75 months (range in living patients 29-163 months). Fifteen patients have died (19%). The median age at diagnosis of these was 73 years. Two deaths were transplant-related, both in patients who had failed available TKIs and had mismatched transplants. The only treated patient who died of accelerated disease was intolerant of all TKIs and unfit for transplant. Three patients died of other malignancies (ovarian, bowel and melanoma). Seven patients were transplanted. Of the surviving 5, 2 had sibling transplants early in the TKI era, 2 had MUD transplants after failing imatinib prior to the availability of second line drugs, and one failed to make an adequate response to imatinib then nilotinib and received a second transplant.

Summary/Conclusions: This data shows the real life experience of patients treated for CML in the TKI era. At six years follow up, the overall survival was 86% which is remarkably similar to that of the IRIS trial patients. Using an intention to treat analysis, 11% of the unselected population patients are in good partial or complete cytogenetic response (BCRABL1 ratio <0.01, MMR). An MMR was achieved by 60/79 (76%) patients. Of the 19 without MMR, 1 is lost to follow-up, and 9 have died, of which only one death was due to accelerated CML in a patient intolerant of all TKIs. Of those 9 patients living not in MMR, 8 have a CCyR. Three are elderly and frail and have taken an pragmatic approach; three are quoted to patient compliance, two to treatment limited by severe side effects and one had TKI interruption to facilitate cancer treatment. Of the sixty patients in MMR, 40 achieved this on standard dose imatinib. Four patients required increased dose of imatinib, 11 were switched to second line TKI and 5 were transplanted. A complete molecular response (BCRABL1 ratio <0.003, CMR) was achieved by 10 patients, six on standard dose imatinib.

PB1837

FRONTLINE Nilotinib IS A BETTER CHOICE THAN FRONTLINE IMATINIB FOR CML PATIENTS WITH DELAYED TREATMENT: 11 YEAR FOLLOW-UP

I. Cojbasic1,*, E. Islamagic2, S. Kurtovic3, A. Hasic4, V. Bijedic3, F. Colakovic5, N. Skobic Bovan6
1Clinical pathology, cytology, and human genetics, Clinical Center of the University of Sarajevo, 2Faculty of Natural Sciences, University of Sarajevo, 3Hematology, Clinical Center of the University of Sarajevo, 4Genetics, University of Sarajevo, 5Hematology, Clinical Center Zenica, Sarajevo, 6Hematology, University Clinical Hospital Mostar, Mostar, Bosnia and Herzegovina

Background: CML patients in developing world had to wait for the start of TKI treatment, from several months to years. The significant delay in proper treatment of CML has had drastic consequences on patient outcomes including survival, CCyR and MMR. Nilotinib was introduced in 2011 as front- and second-line therapy for newly diagnosed as well as patients who waited for TKI treatment for a long time.

Aims: In this study we compared the long-term real life clinical outcomes (OS, CCyR and MMR) of patients receiving frontline imatinib and frontline nilotinib therapy in Bosnia and Herzegovina in the period from 08/2005 to 08/2016, categorized based on delayed start of therapy.

Methods: All newly diagnosed CML patients in CML-CP (n=149) who started their TKI treatment in period from August 2005 to August 2016 were included in this multicentre retrospective cross-sectional study. The duration of TKI treatment varied from 2 month to 10 years. The dose of imatinib was 400mg daily, while nilotinib was dosed 800mg a day.

Results: We analyzed 149 patients (median age was 54.5 years; 57% were males) in chronic phase of CML. The median follow-up from time of diagnosis and start of therapy was 45 months and 39 months, respectively (range 3-145 months). The median wait period before the start of TKI therapy in patients who waited less than 6 months was 0 months (range 0-6) vs 15 months in the waiting group (range 9-63). At 11 years, overall survival for patients on frontline imatinib (Group 1) and frontline nilotinib (Group 2) was 83% and 87%, respectively. According to ITT principle, achievement of CCyR and MMR at 24 months was higher in Group 2 compared to Group 1 (81% vs 66% and 74% vs 37%, respectively). Rate of death was similar in both studied groups (20/118 vs 4/31). When we analysed delayed treatment at 24 months, CCyR for patients who received therapy immediately, who waited 6-13 months and more than 13 months, was 74% vs 64% vs 40%, respectively. Regarding nilotinib treatment at 24 months, patients on 1st line immediate nilotinib vs 1st line delayed nilotinib achieved 83% vs 77% for CCyR and 78% vs 69% for MMR, respectively.

Summary/Conclusions: Our results after 11 years of follow up suggest that nilotinib demonstrated improved efficacy over imatinib therapy. Achievement of CCyR and MMR at 24 months was higher in patients on front-line nilotinib therapy. Patients who waited for therapy had optimal response regardless the wait period on nilotinib therapy.

PB1838

THE INFLUENCE OF AGE ON TREATMENT OUTCOME OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA RECEIVING FRONTLINE IMATINIB I. Cojbasic1,*, L. Macukanovic Golubovic2, M. Vucic3, A. Kurtovic-Kozaric1, E. Islamagic2, N. Govedarovic1, F. Colakovic5, N. Skobic Bovan6
1Clinical pathology, cytology, and human genetics, Clinical Center of the University of Sarajevo, 2Faculty of Natural Sciences, University of Sarajevo, 3Hematology, University Clinical Hospital Mostar, Mostar, Bosnia and Herzegovina

Background: The tyrosine kinase inhibitor (TKI) imatinib was the first targeted therapy for patients with chronic-phase chronic myeloid leukemia (CP-CML), and its introduction has had drastic consequences on patient outcomes including survival, CCyR and MMR. Nilotinib was introduced in 2011 as front- and second-line therapy for newly diagnosed as well as patients who waited for TKI treatment for a long time.

Aims: The aim of this study was to evaluate impact of age on the treatment outcome in patients with chronic myeloid leukemia treated with frontline imatinib.

Methods: A newly diagnosed CP-CML patients treated and followed in our institution were surveyed retrospectively from August 2006 to August 2016. Patients <5 years of age were excluded from this group. Fourteen children (18-45 years) (YA), middle aged adults (46-64 years) (MA) and elderly persons (65 and more years) (EP). Patients' demographics, disease risk scores, duration of imatinib therapy and follow-up, cytogenetic and molecular responses,
adverse event (AEs), the 5-year event-free survival (EFS) and 5-year overall survival (OS) were all evaluated. Clinical features of the patients in different age groups are summarized in Table 1.

**Results:** The patient cohort consisted of 94 patients with median age of 53.4 years (range 18-78), with a slight predominance of females of 53.2%. There were more patients with intermediate and high Sokal scores in the EP group than in the groups MA and YA (p<0.001). To the contrary of that, most patients with high EUTOS score were observed in the group YA compared to MA and EP groups (p<0.001). The three groups were balanced regarding Euro score. The median duration of imatinib therapy was the longest in MA group (61.4 months vs 40.6 months in YA and 38.2 months in EP patients p<0.001). Furthermore, median follow-up duration was also the longest in MA group (64.3 months vs 48.5 months in YA and 44.7 months in EP patients p<0.001). The rates of complete cytogenetic response (CCyR) were similar in all three analysed groups (80.6% in YA, 86.5% in MA and 75.9% in EP, p=0.328) while rate of major molecular response was the highest in the MA group (83.3% vs 63.3% in YA and 57.1% in EL, p=0.001). The percentages of patients who switched to second-generation TKIs were similar in all three groups (36.7% in YA vs 30% in MA vs 32.1% in EP, p=0.559). There were the most of non-hematological AEs all grades in EP group (25% vs 13.3% in YA and 13.8% in MA, p=0.005). Hematological AEs also were common in EP group but not statistically significant (17.8% vs 10% in YA and in 12.1% in MA, p=0.156). The 5-years EFS in the MA group (88% (95%Ci 82.1-96.9)) was significantly higher than in YA group (65.3% (95%Ci 59.1-78.1)) and in EP group (60.2% (95%Ci 49.5-73.7)). The 5-years OS in the EP group (74.7% (95%Ci 65.9-89.0)) was significantly lower than in YA group (93.1% (95%Ci 87.2-99.5)) and in MA group (90.8% (95%Ci 85.8-97.8)). The number of deaths, both CML related or not was the largest in the EP group (25% vs 13.3% in YA and 13.8% in MA, p<0.001).

**Table 1. Clinical features of the patients in different age groups.**

**Summary/Conclusions:** Results of this study indicate that age at diagnosis impacts the course of chronic myeloid leukemia treated with imatinib. The best clinical outcomes have middle age patients in terms of the highest rates achieved optimal therapeutic response and longer survival without events and overall survival. The degree of therapeutic responds in the elderly is comparable with that observed in younger patients, but the presence of comorbidity and more frequent occurrence of adverse events were affecting relatively lower overall survival. Although it might be expected that younger patient population has a better clinical outcome than patients middle age, a possible cause of poor outcomes is probably a late diagnosis at an advanced stage of the disease.

**Enzymopathies, membranopathies and other anemias**

**CHARACTERIZATION OF HEMATOPOIETIC SAMPLES FROM PYRUVATE KINASE DEFICIENCY PATIENTS**

1LACISEP (Advanced Therapies Unit), CIEMAT/CIBERER, 2LACISEP (Advanced Therapies Unit), 3Hematopoietic Innovative Therapies, CIEMAT, MADRID, Spain, 4SFondazione IRCCS Ca' Granda, UO Oncoematologia, UOS Fisiopatologia delle Anemie, Ospedale Maggiore Policlinico, Milan, Italy, 5Insti- tuto de investigacion contra la leucemia Josep Carreras, 6Hospital de Sant Pau, Barcelona, 7Hematologia y Hemoterapia, Hospital Infantil Universitario Nino Jesus, Madrid, Spain

**Background:** Pyruvate Kinase Deficiency (PKD) is an autosomal recessive disease caused by mutations in the PKLR gene. PKD produces chronic non-spher- ocytic hemolytic anemia, which can be fatal during early childhood and may result in lifelong transfusion dependence that in some instances persists despite therapeutic splenectomy. Although not considered a standard-of-care, allogeneic bone marrow transplantation has been curative in a limited number of cases. These findings, and the evidence that PKLR gene mutations are likely the sole etiology of the disorder, make PKD a candidate for gene therapy. Our lab has developed a therapeutic Orphan Drug lentiviral product (EMA: EU/3/14/1330; FDA: DRU-2016-5168) for the treatment of PKD and is working to develop an efficient and safe gene therapy clinical trial for the treatment of PKD.

**Aims:** In order to improve this new treatment, a more deep knowledge of the disease and its associated pathophysiology is necessary.

**Methods:** To characterize the hematopoietic profile of this disease, we have standardized flow cytometry protocols to perform both a qualitative and quantita- tive study of different population subsets. These included subsets of the hematopoietic stem cell compartment, erythroid progenitors, reticulocytes, mature erythrocytes and other mature lineages. Human routine samples con- sisted of peripheral blood, bone marrow and cord blood from PKD patients. In addition, xenogenic engraftment studies in immunodeficient (NSG) mice were also performed.

**Results:** Flow cytometry studies showed a clear imbalance in the erythroid populations. On the other hand, human PKD progenitors were able to engraft into NSG mice demonstrating that the disease does not likely impair hematopoietic stem cell capabilities.

**Summary/Conclusions:** Pyruvate Kinase Deficiency (PKD) is an autosomal recessive disease caused by mutations in the PKLR gene. Our lab has recently developed a therapeutic Orphan Drug lentiviral product for the treatment of PKD. In order to improve this new treatment, we are also working to deep into the knowledge of the disease and its associated pathophysiology. Flow cytom- etry studies have shown a clear imbalance in the erythroid populations. Func- tionally, results in NSG mice we have demonstrated that the disease does not likely impair hematopoietic stem cell capabilities.

**OSMOTIC GRADIENT EKTACYTOMETRY: A VALUABLE SCREENING TEST FOR HEREDITARY SPHEROCYTOSIS AND OTHER RED BLOOD CELL MEMBRANE DISORDERS**

M.D.M. Martí-Pereira1, E. Lliaudet Planas1, V. Rizzuto1, J.L. Vives Corrons1

1Red Blood Cell Pathology and Hematopoietic Defects, Josep Carreras Leukaemia Research Institute, Barcelona, Spain

**Background:** Red blood cell (RBC) membrane disorders constitute one of the major causes of chronic hereditary hemolytic anemia. Main RBC membrane dis- orders, namely hereditary spherocytosis (HS), hereditary elliptocytosis (HE) and hereditary stomatocytosis (HSt), alter membrane cohesion, membrane mechan- ical stability, and RBC volume, respectively. As a consequence, RBC deformability is compromised leading to their premature removal from circulation, manifested as hemolytic anemia. New generation osmotic gradient ektacytometry has become a powerful procedure for measuring red cell deformability and therefore for the diagnosis of red blood cell membrane disorders.

**Aims:** The aim of this study is to evaluate osmotic gradient ektacytometry as an adequate assay to perform screening of membranopathies, focusing on the different diagnostic between HS and non-spherocytic membrane defects such as HE and dHSt.

**Methods:** A total of 75 patients with chronic hemolytic anemia oriented as hereditary RBC membrane disorders (hemoglobin disorders discarded and negative Coombs test) were included during a period comprised between January 2015 and August 2016. Normal controls were obtained from blood donors. Osmotic gradient ektacytometry was performed using the osmoscan module of the Laser-assisted Optical Rotational Deformability Cell Analyzer: LoRRCa MaxSis (RR Mechanotronics). Evaluation of osmscan parameters
robustness for HS diagnosis was performed using the receiver operating characteristic (ROC) curve analysis. The optimal cut-off was determined as the one with the highest likelihood ratio. Statistical analysis was operated with GraphPad Prism.

Results: Specific patterns of osmolar LoRRa MaxSiS were observed for each individual membranopathy. All HS curves were bell shaped but two different profiles were identified both presenting increased Omin, and decreased Exmax and AUC. HE curves showed a characteristic trapezoidal shape with a decreased Exmax, Omax and AUC. DHST curve was bell shaped with a specific decrease in Ohtyper and a slight increase in Elmin. Reference ranges for each osmolar parameter were established with 171 healthy subjects and compared with the values of the parameters obtained from the different RBC membrane disorders. ROC curve analysis was performed for HS and each one of the non-HS groups separately. The results determined that Elmax was the parameter that better separated HS from normal controls and dHST, while the Omin was the best to separate HS from HE. The optimal Elmax cut-off to differentiate HS from HE was: Omin <0.5975 (sensitivity 98.46%, specificity 99.42%), while the optimal Omin cut-off to differentiate HS from HE was >159.0 (sensitivity 95.38%, specificity 85.71%). Expressing the results as% of variation in relation to the mean of our normal controls, the best combination of parameters for HS diagnosis would be Elmax <3% and Omin >5.2%. This combination of parameters (sensitivity 99%, specificity 98%) was used as criteria to classify all the 246 samples included in the present study, and the result showed 62 samples detected as HS and 184 as non-HS. Of the 62 patients identified as HS, 61 were real HS (specificity 98.38%) and 1 was an HE. On the other hand, 4 HS patients were identified as non-HS (sensitivity 93.85%).

Summary/Conclusions: We can conclude that, the inclusion of LoRRa as a screening test in RBC membrane diagnostic workflow will signify an important advance for the accurate diagnosis of HS patients, as well as for the identification of HE and specially dHSi patients.

PB1841
RARE RED BLOOD CELL ENZYMOPATHIES INDUCED CHRONIC NONSPHEROCYTIC HYEMOLYTIC ANEMIA: NEXT GENERATION SEQUENCING BASED MOLECULAR DIAGNOSIS
M. Jamwal1,*, A. Aggarwal1, P. Sharma1, D. Bansal2, P. Malhotra3, A. Maitra4, R. Das4.
1Hematology, 2Pediatrics (Hemato-Oncology), 3Internal Medicine, Postgraduate Institute of Medical Education and Research, Chandigarh, India

Background: Red blood cell enzymopathies are mostly inherited autosomal recessive monogenic disorders. Mutations in the genes encoding red blood cell enzymes could lead to chronic nonspherocytic hemolytic anemia (CNSHA). The clinical manifestations are jaundice, cholelithiasis, splenomegaly, with usually normocytic normochromic hemolytic anemia. Phenotypes vary from having fully compensated hemolysis (without anemia) to severe hemolytic anemia requiring regular transfusions. Definitive diagnosis is difficult when biochemical test results are not consistent/fail to identify defects. Molecular diagnosis by gene-by-gene approach is expensive, time consuming and cumbersome as testing for multiple genes is required.

Aims: Use of targeted resequencing can expedite the molecular diagnosis when the cause for hemolysis remains unexplained after routine laboratory tests.

Methods: Ten patients with clinical and laboratory evidence suggestive of hemolytic anemia were enrolled. Various biochemical and molecular tests were used to exclude Glucose-6-phosphate dehydrogenase (G6PD) deficiency, thalassemias, hemoglobinopathies, autoimmune hemolytic anemia, hereditary spherocytosis and pyruvate kinase deficiency. Common G6PD and PKLR variants were excluded by molecular tests. Family history was negative in all the cases. Libraries were prepared using TruSeq One sequencig panel and sequenced on MiSeq™ Sequencing System. MiSeq Reporter™ and Variant studio™ v2.1 were used for analysis, classification, and reporting of genomic variants.

Results: Two patients with G6PD deficiency, six patients with pyruvate kinase (PKLR) deficiency and two patients with Glucose-6-phosphate isomerase (GPI) deficiency were found. Unexpected pyruvate kinase defects were found on target resequencing for six patients. Pyruvate Kinase (PK) enzyme activity assay were within normal limits in all these cases. All the mutations were predicted deleterious by PolyPhen/ SIFT/ Provean/ mutpred and Mutatontaster. Mutations were validated in the parents/siblings (where available) to prove the molecular inheritance.

Summary/Conclusions: Unexpected PK deficiency were found after next generation sequencing analysis in the patients where PK enzyme levels were within normal limits. PK deficiency may be missed by conventional testing approaches. Our data demonstrates the clinical utility of next generation sequencing for molecular diagnosis. Timely detection of the cause in our patient is likely beneficial for future HS patients as the results demonstrated a specific congenital erythrocyte defects. Thermogravimetric analysis (TGA) coupled with chemometrics has recently been proposed as a rapid and cost effective diagnostic tool for β-thalassemia screening. This model, consisting of Partial Least Square-Discriminant Analysis (PLS-DA), permitted the discrimination of thalassemic patients and healthy individuals, using thermogravimetric curves of blood samples [1].

ADVANCES IN DIAGNOSIS OF HEREDITARY HEMOLYTIC ANEMIAS: THERMOGRAVIMETRY COUPLED WITH CHEMOMETRICS
R. Risoli1,*, S. Maternozzi1, F. Sorrentino2, L. Maielli3, C. Bozzi3, P. Caprari4,1
1Department of Chemistry, Sapienza University of Rome, 2Thalassemia Unit, S. Eugenio Hospital, 3Haematology, Oncology and Molecular Medicine, Istituto Superiore di Sanità, Rome, Italy

Background: The differential diagnosis of hereditary hemolytic anemia is generally carried out by applying different diagnostic protocols depending on the specific congenital erythrocyte defects. Thermogravimetric analysis (TGA) coupled with chemometrics has recently been proposed as a rapid and cost effective diagnostic tool for β-thalassemia screening. This model, consisting of Partial Least Square-Discriminant Analysis (PLS-DA), permitted the discrimination of thalassemic patients and healthy individuals, using thermogravimetric curves of blood samples [1].

In this study, the capability of thermogravimetry in conjunction with a mut-
tivariate statistical analysis was investigated for the screening of hereditary hemolytic anemias due to different erythrocyte defects.

**Methods:** Whole blood samples collected in K$_2$EDTA were obtained, after informed consent, from patients suffering from congenital hemolytic anemias and were analyzed using the thermobalance TG7 (Perkin Elmer) without any pretreatment and the resulting curves were compared with those of healthy individuals. Two groups of hereditary hemolytic anemias were considered: the hemoglobinopathies (sickle cell anemia and thalassemia) and the erythrocyte membrane defects (hereditary elliptocytosis and hereditary spherocytosis).

**Results:** The characteristic profile of the blood sample thermal decomposition and the first derivative (DTG) of the TG curve showed that blood samples from anemic patients were clearly distinguished from those of healthy individuals as a result of different amounts of water and corpuscular fraction. The chemometric approach based on Principal Components Analysis (PCA) allowed a quick identification of differences between healthy and anemic patients in order to point out a model of prediction in patients with heterogeneous congenital hemolodal disorders.

**Summary/Conclusions:** The achieved results allow to consider the coupling TGA/Chemometrics as a promising diagnostic approach to provide a high-throughput and sensitive tool to obtain an early detection of hereditary hemolytic anemias using only a few microliters of blood without any pretreatment and with an hour of analysis time.

**PB1844**

**DEVELOPMENT OF A POINT-SCORING SYSTEM FOR EARLY DIAGNOSTIC TESTING IN GAUCHER DISEASE: APPLICATION OF FINDINGS FROM THE GAUCHER EARLIER DIAGNOSIS CONSENSUS DELPHI INITIATIVE**

S. Salek1*, J. D. Kuter2, A. Mehta3
1School of Life and Medical Sciences, University of Hertfordshire, Hatfield, United Kingdom, 2Center for Hematology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, 3Department of Haematology, Royal Free Hospital, UCL School of Medicine, London, United Kingdom

**Background:** In the Western hemisphere, Gaucher disease (GD) type 1 is the most common GD phenotype, but the prevalence of GD type 3 is increasing. The major signs and symptoms of the different GD phenotypes ranges from fatal perinatal to asymptomatic adult disease, and the heterogeneity of its presentation contributes to both misdiagnosis and delays in diagnosis by clinicians unfamiliar with the disease. The Gaucher Earlier Diagnosis Consensus (GED-C) Delphi initiative determined which signs and patient co-variables were regarded by experts in GD as most indicative of GD types 1 or 3 in the early stages.

**Aims:** From the findings of the GED-C expert consensus, to generate a simple web-based point-scoring system (PSS) suitable for use across clinical specialties, that provides guidance based on patients' presenting signs as to whether GD diagnostic testing is appropriate.

**Methods:** An anonymous three-round Delphi process, conducted among a global panel of 22 expert physicians, established consensus on which signs and co-variables may be important in early GD type 1 and, separately, in early GD type 3. In round 1, free-text responses provided by the panel were categorized and consolidated into summary factors by the non-voting co-chairs. In round 2, the factors were rated for importance by the panel using a 5-point Likert scale (1 = not important, 3 = important, 5 = extremely important). Any factors assigned an importance score of ≥3 by >75% of respondents were then rated for agreement in round 3, using a 5-point Likert scale (1 = strongly disagree, 3 = neither agree nor disagree, 5 = strongly agree). Consensus was defined as a score of ≥4 by >67% of respondents. Factors meeting this threshold were classified as major; all other factors were classified as minor. The co-chairs defined value ranges corresponding to mild, moderate or severe forms of five of the major signs of GD (anaemia, hepatomegaly, hyperferritinaemia, splenomegaly and thrombocytopenia). Panel members indicated whether they regarded each range as consistent with a GD diagnosis. This information was used in combination with the classifications of signs and co-variables as major or minor to create a prototype PSS.

**Results:** The consensus 100% response rate in each round. Factors identified as major or minor in GD types 1 or 3 are given in the Table 1. There was 100% agreement that splenomegaly (≥3-fold enlargement) and disturbed occlu- lomotor function (slow horizontal saccades with unimpaired vision) are major signs in GD, and these were assigned a score of 3 in the prototype PSS; other major signs and co-variables were assigned a score of 2. The panel was divided about whether severe anaemia, hepatomegaly, hyperferritinemia and severe thrombocytopenia were consistent with a GD diagnosis, so these were assigned a score of 1. All minor signs and co-variables were assigned a score of 0.5.

**Summary:** PB1844 A prototype PSS to inform GD diagnostic testing has been developed from the GED-C Delphi initiative. The PSS will be validated with retrospective patient data. Total patient scores based on presenting signs and co-variables will be used to determine empirically a minimum threshold score that captures positive tests for GD. Abstract submitted on behalf of the GED-C panel and the EHA Scientific Working Group ‘Quality of Life and Symptoms’. Administration of the GED-C initiative was funded by unrestricted educational grants from Shire International GmbH.

**Table 1.**
CHARACTERISTICS AND MANAGEMENT OF AUTOIMMUNE HEMOLYTIC ANEMIA: A SINGLE CENTER STUDY WITH 32 CASES

A.F. Yilmaz1, H.D. Kiper Unal1, T. Yuksel Karsali2, M. Klinic2, F. Gediz2, K.B. Bayman Payzin1

1Hematology, 2Internal Medicine, Izmir Katip Celebi University Ataturk Research and Training Hospital, Izmir, Turkey

Background: Autoimmune hemolytic anemia (AIHA) is characterized by red blood cell destruction mediated with autoantibodies against RBC antigens. Most common type is warm AIHA which can be either idiopathic or secondary to underlying disorders with immune disturbance. Determining the optimal therapy is a challenge because of insufficient data from prospective controlled trials.

Aims: To evaluate the clinical characteristics, treatment responses and outcomes of our AIHA patients.

Methods: The clinical data of 32 patients with AIHA diagnosed and treated in our center between 2008 and 2016 were retrospectively analyzed.

Results: Median age at diagnosis of AIHA was 45 years (range:20-74). Male/female ratio was 1/1.3. 24 of 32 patients (75%) had primary AIHA and 8 (25%) had secondary AIHA with underlying disorders as SLE in 2 patients, mixed connection tissue disease (MCTD) in 2, psoriatic arthritis in 1, chronic lymphocytic leukemia (CLL) in 1, marginal zone lymphoma in 1 and, chronic HCV infection in 1. Median Hemoglobin (Hb) level was 7.4 g/dl and 5 patients also had thrombocytopenia (<150000) beside hemolytic anemia. Mean LDH level was 544, indirect bilirubin was 2.7, reticulocyte was 11.3%. 18/32 patients (56%) required transfusion. In all patients who required treatment (94%) corticosteroids were the first-line therapy with an initial response rate of 93%. Median steroid duration was 3 months range between 1.5 to 96 months. Relapse was occurred in 15 of 30 patients who received steroid (50%) with the median time to relapse (TTR) of 12 months (range:5-72 months). 11/30 patients (37%) required second-line therapy; seven had undergone splenectomy, three received rituximab, and one received dasanais. All of the patients who underwent splenectomy had CR in first month and relapse after splenectomy was seen in 5/7 patients (71%) with a median duration of 60 months. Of 3 patients who were treated with standard dose of Rituximab; two achieved CR and one did not achieve any response. One of two rituximab-responsible patients relapsed at 26. and 60 months and re-treated by rituximab; still following with CR for 16 months.

Summary/Conclusions: Although corticosteroids are the first choice of initial treatment of AIHA, most of the patients relapse at follow up. Steroid dependency and intolerance are also challenging. Splenectomy is still a considerable option for second-line therapy because of its high response rates and long remission durations. Rituximab is the other effective second-line therapy option with similar response rates to splenectomy. Until prospective studies will be performed, retrospective data would help the clinicians to choose best treatment algorithm for AIHA.

THE IMPACT OF THE REORGANIZATION OF THE PATIENT CARE PROCESS FOR GAUCHER DISEASE IN HEALTH SYSTEM

CMN-SXXI, Instituto Mexicano del Seguro Social, Ciudad de México, 9Jefe de Servicio de Prestaciones Médicas delegación Jalisco, Instituto Mexicano del Seguro Social, Guadalajara, México.

Background: Gaucher disease (GD) is a multisystemic disease of lysosomal storage that is caused by deficient activity of the glucocerebrosidase enzyme resulting from a recessive autosomal hereditary mutation in the β-glucocerebrosidase gene. The accumulation of glucocerebrosidase in the lysomes damages the hematological, skeletal, and nervous systems and leads to three varieties of the disease: type 1, which is non-neuropathic, and types 2 and 3, which are neuropathic. In Mexico, the process by which patients with lysosomal disease are cared for was recently characterized by the Clínicas de Referencia Nacional y Grupos de Expertos en Enfermedades Lísocromas (National Reference Clinics and Expert Groups on Lysosomal Diseases [EGLDs]), who created the Guías de Práctica Clínica (Clinical Practice Guidelines) for GD

Aims: This study aimed to evaluate the results obtained for 39 patients diagnosed with type 1GD (25 women and 14 men) through the National Reference Clinics and EGLDs.

Methods: The clinical case of 39 patients was analyzed and punctual mutation of the β-glucocerebrosidase gene was determined. The patients were treated with imiglucerase enzyme at 60 UI/Kg for every 14 days. The enzymatic activity of the β-glucocerebrosidase and the chitotriosidase was determined. We determine concentration of hemoglobin and platelets. The degree of hepatosplenomegaly, bone density and skeletal pain was evaluated.

Results: Four of the 39 patients were found to have been incorrectly diagnosed with GD, the remaining 35 patients completed the treatment goals, which included remission from hepatomegaly, splenomegaly, and skeletal pain. Additionally, increases in the hemoglobin and platelet concentration and bone mineralization were achieved, thereby attaining the patients’ therapeutic goals, reducing the therapeutic dose required, and achieving the expected impacts on their health.

Summary/Conclusions: This reorganization of patient care successfully reduced complications, improved care, and optimized the use of resources and costs of GD treatment.

NORMOCYTIC ANEMIA IS MORE COMMON THAN MICROCYTIC ANEMIA IN GASTRO-INTESTINAL CANCERS: A LARGE SINGLE CENTRE STUDY

F. Lourenco1,*, F. Alibeygi2, L. Barton2, J.M. Yeung3, S. Kadri1, R. Krishna2

1Hematology, 2Haematology, 3Colorectal Surgery, University Hospitals Leicester, Leicester, United Kingdom

Background: Microcytic anemia is traditionally associated with GI cancers and led to endoscopic investigations to evaluate for GI cancers. Aims: We evaluated the haematological profile of a large series (855) of consecutive GI cancer patients at diagnosis in a university hospital.

Methods: This retrospective study analysed the full blood count of 265 colorectal (CRC) patients over one calendar year and 590 patients with esophago-gastric cancers (OGC) over 3 calendar years. WHO guidelines were used to define anemia (Hb <130 g/L in males and <120 g/L in females). Further analysis was done based n severity of anemia (mild>110 g/L, moderate 80-110 g/L and severe<80 g/L), sex, age and tumour location. Results: Among the 265 CRC patients, 116 (44%) were anemic, of which 72 (37%) were normocytic, 44 (23%) were microcytic, and 1 was macrocytic. 67/152 (27%) were normocytic, 43(16%) were microcytic and 1 was macrocytic. 67/152 (27%) were normocytic and 43(16%) were microcytic and 1 was macrocytic. The causes may be multifactorial including anemia of chronic disease secondary to malignancy. This highlights the fact that GI cancers must be considered as a cause in normocytic anemia irrespective of iron deficiency.

Summary/Conclusions: There is a higher prevalence of normocytic anemia than microcytic anemia in Gastro-intestinal cancers almost at a ratio of 2:1. Normocytic anemia is more common in elderly patients and those with mild to moderate anemia. The causes may be multifactorial including anemia of chronic disease secondary to malnutrition. This highlights the fact that GI cancers must be considered as a cause in normocytic anemia irrespective of iron deficiency and symptoms of GI cancer should be carefully explored and investigations triggered.
Gene therapy, cellular immunotherapy and vaccination

DEMONSTRATION OF FUNCTIONAL SIMILARITY OF PROPOSED BIOSIMILAR ABP 798 TO RITUXIMAB
H. McBride1, G. Maher1, H. Sweet1, I. Foltz2, J. Cannon1, S. Kuhns1
1Biosimilars Development, Amgen Inc., Thousand Oaks, United States, 2Biosimilars Development, Amgen British Columbia, Burnaby, Canada

Background: Proposed biosimilars undergo comprehensive structural and functional characterization before they can be studied in confirmatory clinical trials. ABP 798 is being developed as a biosimilar to rituximab. The originator is approved for treatment of non-Hodgkin’s lymphoma, chronic lymphocytic leukemia, severe rheumatoid arthritis, granulomatosis with polyangiitis, and microscopic polyangiitis.

Aims: ABP 798 was compared with rituximab sourced from the European Union (EU). Quality attributes assessed included binding properties (CD20, C1q, FcRn, and Fc receptors), antibody-dependent cell-mediated cytotoxicity (ADCC), complement-dependent cytotoxicity (CDC), and induction of apoptosis.

Methods: Binding of ABP 798 and rituximab to the CD20 antigen was characterized using a cell-based CD20 binding assay utilizing the human B-lymphoblastoid, WIL2-S, cell line. A direct binding ELISA was used to assess the binding of the Fc domain of ABP 798 to C1q. Binding of the Fc moiety of ABP 798 and rituximab to FcγRI, FcγRIIA, FcγRIIB, and FcγRIIIA (158V) were evaluated in AlphaLISA® competitive binding assays. ADCC activity was evaluated in a functional cell-based assay, with CD20-expressing WIL2-S cells used as target cells and NK92-M1 cells, stably transfected with human CD16 (FcγRIIA [158V]), used as effector cells. CDC activity was evaluated in a functional cell-based assay using a CD20 expressing human B-lymphoblastoid WIL2-S cell line and baby rabbit complement. Induction of apoptosis was assessed by measuring activation of caspase 3/7 in SU-DHL-4 cells, a CD20-expressing human B cell lymphoma cell line.

Results: Relative binding (%) was comparable between ABP 798 and rituximab (Table 1).

Table 1.

MYD88 IN PRAIME GENE ACTIVATION
V. Misyurin1, N. Lyzhko1, A. Misyurina2, J. Finashutina1, V. Tikhonova1, L. Kesaeva1, O. Solopova1, N. Kasatkina1, M. Baryshnikova1, E. Misyurina2, A. Prokopiev1, A. Misyurin1
1National Cancer Research Center of Russia, Moscow, Russian Federation, 2Biosimilars Development, Amgen British Columbia, Burnaby, Canada

Background: PRAME is the most frequently expressed non-X-chromosomal cancer-testis gene in solid and hematological cancer. It is important, because PRAME often has a bad prognostic significance. In early studies was found that PRAME frequently coexpressed in translocation-harboring (like t(8;21), t(15;17) and t(9;22)) haematological diseases. Authors supposed that chimeric genes are activators of PRAME expression. But in large cases with normal karyotype PRAME is also expressed. Another reason for PRAME expression is promoter demethylation. But demethylating agents cannot activate PRAME expression in hematological cells taken from healthy donor. So presence of chimeric genes and methylation status only are not enough to explain why PRAME can be expressed in high level. Wadelin et al. found that PRAME expression level was increased in cell during lipopolysaccharide-treatment conditions. Role of MYD88 in this process still be unknown.

Aims: To check if MYD88 participates in activating PRAME expression in leukemia cell lines.

Methods: Three cell lines were used for incubation with anti-PRAME antibody: chronic myeloid leukemia cell line K562 with high PRAME expression level (645%), acute monocytic leukemia cell line THP-1 with intermediate PRAME expression level (2.92% relative to ABL) and acute myeloid leukemia cell line NOMO-1 with low PRAME expression level (0.46%). All cell lines were incubated in RPMI 1640 with addition of LPS in final concentration 10 ng/ml. After 1 and 4 hour of incubation total RNA was extracted and PRAME and MYD88 expression levels were measured.

Results: After 1 and 4 hours of experiment in K562 cell line PRAME expression level increased in 2.7 and 7 fold under control, respectively, and MYD88 expression level increased in 1.1 and 2.5 fold under control. In THP-1 line PRAME expression level was increased in 20 and 25 fold, respectively, and MYD88 expression level was increased in 5.5 and 6.5 fold. In cell line NOMO-1 PRAME expression level was increased in 10 fold after 1 hour and in 14 fold after 4 hours, and MYD88 expression level was increased in 2.4 and 3.2 fold after 1 and 4 hours of experiment, respectively. Strong correlation between MYD88 and PRAME expression levels was observed (Pearson correlation coefficient 0.98).

Summary/Conclusions: We conclude that LPS after binding with TLRs initiates activating signal to PRAME gene via MYD88.

PD-1 IS HIGHLY EXPRESSED ON MEMORY T-CELLS RESIDING IN BONE MARROW BUT NOT IN PE-RIPHERAL BLOOD IN HEALTHY INDIVIDUALS

N. Popova1,*, M. Drokov1, A. Kuchmiy2, A. Vdovin3, J. Davydova3, L. Kuzmina1, D. Dubnayk1, E. Mikhailova1, V. Vasilyeva1, O. Koroleva1, Z. Konova1, I. Galtseva2, G. Efimov2, E. Parovichnikova1, V. Savchenko1

1Bone marrow transplant department, 2Laboratory of post-transplant immunology, 3Laboratory of immunophenotyping, National Research Center for Hematology, Moscow, Russian Federation

Background: Recently memory T lymphocytes were shown to be a highly heterogeneous cell compartment comprising different phenotypes, functional activities, gene expression profiles and survival capacities. Phenotypically due to the differentiation stage and functional activities memory CD8+ T cells can be divided into central memory (Tcm), terminal memory (Tt), effector memory (Tem) and terminal effector (Tte) and reside in bone marrow (BM) as long-lived persistent T cells [Mahnke YD et al., 2013]. Programmed cell death protein 1 (PD-1) is well known as a negative immune regulator of T cells that has detrimental effects on anti-viral, anti-tumor immunity, mediates tissue tolerance to protect against immune-mediated tissue damage. Currently anti-PD1 immunotherapies are among the most effective anti-cancer immunotherapies available. PD1 pathway blockade is a key pathogenetic mechanism [Bousc et al., 2014]. Understanding the influence of PD-1 pathway on memory T cells homeostasis in BM might be critical for improving treatment of patients with cancers and hematological malignancies, but is still not well understood.

Aims: To evaluate PD-1 expression on distinct memory T cell subsets in BM and PB of healthy donors.

Methods: The first portion of BM and a sample of PB were obtained from healthy donors (n=10, m=6, f=4) with age 37.5 (22-53) years old. Numbers of white blood cells (WBC) in BM and PB samples were evaluated by SysmexXE-2100 hematology analyzer. 1*10^6 of WBC (excluded nucleated red blood cell) from BM and PB were stained using “lyse-wash-stain” standard protocol. The CD8-APC-Cy7, CCR7-PE-Cy7, CD28-PE, CD45R0-FITC, PD1-APC antibodies on PB and CD45-FITC, CD8-APC-Cy7, CCR7-PE-Cy7, CD28-PE, CD45R0-PE, PD1-APC antibodies on BM were used for T cell staining and 7-AAD was used for to discriminate dead cells during flow cytometry.

Results: PD1 expression by T memory cell subsets is shown in the Table 1 (median with interquartile range). The percentage of PD1+ cells within Tcm CD8+ subset was 34.2%, 8.03% in BM versus 10.4%, 2.13% in PB. Similar trend was observed in Tem cell subset. Tcm, Tem, Tt, T fluorescence activation and staining 7-AAD was used for to discriminate dead cells during flow cytometry.

Summary/Conclusions: We found higher frequencies of PD-1 expressing memory BM T cells comparing to PB. This might point to the important roles of PD-1 in regulation of memory T cells homeostasis in BM. In physiological conditions PD-1 is thought to neutralize self-reactive naive T cells that in its turn leads to restraining T cells excessive activation and blockade the development of autoimmunity in BM. On the other hand low expression of PD1 on T cells in PB can be explained by needs the opportunity for prompt reactivity with pathogens that also provide normal “robust control” and prevent developing of a disease.

PB1853

BONE MARROW STROMAL CELLS MAY HAVE GENETIC ABERRATIONS AND ARE CAPABLE TO GAIN THEM IN A CULTURE

I. Barkhatov1,1, N. Tsveletk1, D. Ershov1, T. Gindina1, A. Shakirova1, M. Nikolaeva1, A. Potter1, L. Zubarovskaya1, B. Aftanasyev1

1R.M. Gorbacheva Memorial Institute of Children Oncology, Hematology and Transplantation, Folia med Pat, Pauls Riga, Riga, Latvia; 2Pediatric hematology, University of Tartu, Tartu, Estonia; 3St.Petersburg State Medical University, St.Petersburg, Russian Federation

Background: Stromal microenvironment plays a key role in the regulation of both normal hematopoiesis and its reconstitution after hematopoietic stem cell transplantation (HSCT). Recent data supports the idea that bone marrow stromal cells (BMSC) also have genetic aberrations and may tightly involved in the pathogenesis of HSCT complications. These findings justify the need for more detailed study of genetic aberrations in BMSC.

Aims: The aim of this study was to evaluate genetic aberrations in BMSC and check the ability to gain them in coculture system.

Methods: The interaction of BMSC with hematopoietic tumor cell lines bearing specific genetic aberrations (BCR-ABL fusion transcript for K-562 and JAK2 V617F mutation for Uke-1 cell line) was investigated in stroma cells harvested from 17 patients and 8 healthy donors. We performed cultivation of BMSC monolayer and tumour cells in coculture using semipermeable membrane plates inserts with different pore size (0.4, μm and 3.0 μm) in order to exclude direct cell-to-cell contact. We looked also for existing specific genetic aberrations (point mutations and fusion transcripts) in BMSC of patients with the respective aberration in their leukemic clone. For this purpose we used both karyotyping (FISH) and RT-PCR method. BMSC were assayed by flow cytometry to evaluate the possible contamination with cells of hematopoietic lineage.

Results: We investigated the BMSC karyotype in seven patients and only one case led to a remarkable finding. The chromosomal rearrangement t(1;7) was detected in 25% of BMSC metaphases. Interestingly, this aberration was not detected in patient’s leukemic cell. We also examined BMSC from leukemia patients bearing recurrent genetic abnormalities and in one case the leukemia-specific marker was detected by RT-PCR - we observed expression of ETV6-RUNX1 gene (0.02%) in BMSC by patient with (12;21) acute lymphoblastic leukemia. At the moment of BMSC culture initiation ETV6-RUNX1 expression in patient’s bone marrow was detected at high level (ETV6-RUNX1/ABL>100:211). Before carrying out DNA extraction BMSC were harvested after the second passage and no contamination with CD45+ cells by flow cytometry was observed (50,000 events collected from the sample). When BMSCs and Uke-1 cell line were cocultured by using of BCR-ABL fusion transcript for K-562 BMSC population gained the Jak2V617F mutation (allelic burden = 30.39%). We reproduced similar experiments with the K-562 cell line and got similar results - CD45+ cells were also detected in BMSC population (> 30%). Moreover we detected CD45+ non-cellular particles by flow cytometry analysis. Imiting K-562 cells are not likely to cross the semipermeable membrane (3.0 μm pores versus 20.0 μm cells as measured during microscopy). Besides BCR-ABL gene expression in BMSC was detected by RT-PCR (BCR-ABL/ABL*100%=89%). We repeated same test with 0.4 μm pore inserts and without them in order to check implication of cell-to-cell interaction. We didn’t obtain any similar results with smaller pores, but the fusion transcript was detected in all BMSCs. BMSC culture initiated from 17 patients and 8 healthy donors. We performed cultivation of BMSC monolayer and tumour cells in coculture using semipermeable membrane plates inserts with different pore size (0.4 μm and 3.0 μm) in order to exclude direct cell-to-cell contact. We looked also for existing specific genetic aberrations (point mutations and fusion transcripts) in BMSC of patients with the respective aberration in their leukemic clone. For this purpose we used both karyotyping (FISH) and RT-PCR method. BMSC were assayed by flow cytometry to evaluate the possible contamination with cells of hematopoietic lineage.

Summary/Conclusions: Our data stands for the existence of horizontal gene transfer between leukemic clone and BMSC. This process seems to be mediated by membrane vesicles larger than 0.4 μm in size, though cell fusion can also take place. We also confirmed the fact BMSCs can bear clonal genetic rearrangements which are not specific to tumor cell populations. These findings show tight interaction between tumor and microenvironment cells and can partly explain nature of PCR-based MRD persistence in complete remission.

CIRCULATING ENDOTHELIAL PROGENITORS CELLS AND METABOLIC FACTORS IN CHILDHOOD CANCER SURVIVORS

E. Athanassopoulos1, G. Martimianaki1, H. Kounournaki1, M. Stratigaki1, E. Eftaxiakis1, N. Katzililarou1

1Pediatric Hematology - Oncology, University Hospital of Heraklion, University of Crete, Heraklion, Greece

Background: Circulating Endothelial Progenitor Cells (CEPCs) play a significant role in the maintenance of vascular integrity, balancing the anti-coagulation mechanisms and modulating the immune system by regulating the leukocyte trafficking, as well as controlling the vascular tone. Additionally, it is well-established, that patients who underwent chemotherapy have increased incidence of hypertension and obesity. Nevertheless, numerous studies have shown a negative correlation between CEPCs and obesity, underlining their vascular regulatory role.

Aims: The study of CEPCs in children who received chemotherapy for Acute Lymphoblastic Leukemia (ALL) and solid tumors (ST) and the investigation of their levels in correlation with patients Body Mass Index (BMI) and blood pressure (BP) regarding the time following treatment.

Methods: Children with blood cells from children with ALL (n=77), ST (n=81) and children without malignancies as control group (n=71) were studied. Four colour flow cytometry was performed to determine the subpopulations CD34+CD45negdimCD133+, CD34+CD45negdimVEGFR2+ and CD34+CD45negdimCD133+VEGFR2+ of CEPCs. The BMI of the patients was calculated and the percentiles were established specific by the age and gender. Normal weight defined with BMI percentile over 5th and below 85th percentile, overweight/obesity over 85th percentile. The systolic blood pressure (BP) was measured and the percentile was calculated specified by the age, gender and height.

Summary/Conclusions: Children with ALL and ST had significantly lower CEPC levels in correlation with patients Body Mass Index (BMI) and blood pressure (BP) regarding the time following treatment.

Conflict of Interest: None
Results: The mean values of CEPCs subpopulation CD34+CD45negdimVEGF-R2+ estimated in ALL, ST and Controls were 0.00380 (SE=0.00072), 0.00613 (SE=0.00146) and 0.002953 (SE=0.00004) respectively. The mean percentage of CD34+CD45negdimCD133+VEGF-R2+ in ALL, ST and Controls was 0.00331 (SE=0.00072), 0.00499 (SE=0.00113) and 0.002663 (SE=0.00037). The correlation of CEPCs showed statistical significant difference of CD34+CD45negdimCD133+VEGF-R2+ between the ST and controls (p<0.001). The mean MCHC value in the ST group was 33.78±2.31% at >15 yrs of age. The variations among the age groups are significant for hematocrit, mean corpuscular volume (MCV) and MCHC.

In ALL the levels of CD34+CD45negdimVEGF-R2+ the 1st year after treatment completion were 0.00458(SE=0.0026), during 1-3years 0.00331(SE=0.00066) and >3 years 0.00342(SE=0.00081). The levels of CD34+CD45negdimCD133+VEGF-R2+ during the 1st year after chemotherapy was 0.0092 (SE=0.0037), 1-3 years 0.0027(SE=0.00063) and >3 years 0.00331(SE=0.00081). In the ST group the mean value of CD34+CD45negdimVEGF-R2+ the 1st year after treatment was 0.0114 (SE=0.0048), 1-3 years 0.0047(SE=0.0013) and >3 years 0.0036(SE=0.0008). Whereas the percentage of CD34+CD45negdim CD133+VEGF-R2+ the 1st year after chemotherapy was 0.0092 (SE=0.0037), 1-3 years 0.0034(SE=0.00097)and >3 years 0.00336(SE=0.00085).Statistical significant results were calculated for the levels of CD34+CD45negdimVEGF-R2+ in ST group between the groups <1 year and over years’ post treatment(Mean Diff 0.007747, 95 CI of diff 0.000241 to 0.01525). The study of body weight in ALL and ST groups in relation with CEPCs showed no statistical significant difference, although a negative trend between obesity and CEPCs was found in the ALL group and a positive one in the ST group. The same trend also appeared in BP between ALL and ST regarding the CEPCs, with hypertensive patients in ALL group having higher levels of CEPCs than the ST hypertensive individuals.

Summary/Conclusions: The higher levels of CEPCs were estimated in ALL and ST just after treatment completion with a gradual decrease as time passes. The highest percentages of CEPCs were evaluated in ALL patients with normal weight and blood pressure in contrast with the solid tumor group. Further investigation is necessary to highlight the importance of these data.

PB1855

HEMATOLOGICAL PARAMETERS IN NATIVE HIGHLANDERS OF LADAKH AGED 4-19 YEARS

S.K. Das1*, V. Uday1, D. Katoch1, V. Nair2

1Hematology, Army Hospital (Research & Referral), New Delhi, India
2Department of Pediatrics, Army Hospital (Research & Referral), New Delhi, India

Background: High altitude (HA) has always intrigued physiologists because of the remarkable ability of man to adapt to the hostile environment. Hematological changes associated with HA exposure is believed to be driven by hypoxic hypoxia of HA. Majority of the studies on HA physiology and hematological adaptation have focused on the hematological adaptation in lowlanders visiting HA or have compared the hematological profile of native highlanders from Andes and Tibet with those of the neighboring lowlanders. These studies have mostly been directed towards adult population with no or little reference to children and adolescent age groups. Moreover these studies have been done mostly on the highlanders of Andes and Tibet with no data on Indian highlanders.

Aims: We aimed at assessing hematological parameters in native highlanders in the age group of 4- 19 yrs and compare the same with Indian lowland population as well as the native highlanders from Andes and Tibet.

Methods: A total of 390 native highlanders of Ladakh in the age group of 4-19 yrs with no history of travel to lowland were taken for the study. A written informed consent was taken from the parents of all the subjects before starting interviewing them for the laboratory investigations. After taking antiseptic precautions, blood samples were drawn from the ante-cubital vein and complete blood counts were done. The study subjects were stratified into five age groups (less than 5y, 5-8y, 8-10y, 10-12y, 12-15y and children more than 15y). Appropriate statistical analysis was done to compare the hematological parameters between the stratified age groups as well as between boys and girls.

Results: A total of 197 girls and 193 boys were included in the study. The mean age of the subjects was 128±80 (means±SD) months. The mean hematocrit value increased with age (38.68±2.51% in <5 yrs age group to 43.84±2.04% in >15 yrs age group). Similarly the mean corpuscular volume (MCV) was significantly higher in highlanders than in TB (39.36±3.36 fl in <5 years vs 38.56±2.72 fl in >15 yrs age). In contrast to the rising values of hematocrit and MCV we found that the mean corpuscular haemoglobin concentration (MCHC) decreased with age from 36.91±2.85% at <5 yrs of age to 33.78±2.31% at >15 yrs of age. The variations among the age groups are significant for hematocrit, mean corpuscular volume (MCV) and MCHC (p<0.01). On comparison of hematological parameters between boys and girls we found that the mean hemoglobin concentration in girls (13.99±0.29 g/dL) was significantly lower than boys (15.43±0.28 g/dL). The same findings were replicated in the mean RBC count (4.79±0.08 in girls vs 5.07±0.08 in boys). Although the distribution of mean MCHC was normal for a rising trend with age (79.07±1.39 g/dL in <5 yrs vs 78.5±3.5 g/dL in >15 yrs age). The mean MCHC in boys (37.23±0.93%) was significantly higher than those in girls (35.69±0.94%). The mean platelet count in boys was significantly higher than in girls (p<0.0003) (Figure 1).

Summary/Conclusions: The hematological adaptation of Ladakhi kids is different as compared to other native highlanders. There is also a significant difference in the hematological response to hypobaric hypoxia with growing age and between boys and girls.

PB1856

AGE VARIATION OF B-CELL PRECURSORS IN BONE MARROW: NORMAL VALUES AS A REFERENCE FOR MDS IN BRAZIL

I. Lorand-Metz1†, A.L. Longhini1, G. Oliveira-Duarte1, R.P. Correia2, M.C. Santos-Silva3, M.R. Ikoma4, E. Xisto Souto5, A. Sandes6, A. Frisano Oliveira7, K. Metz8

1Hematology - Hemotherapy Center, University of Campinas, Campinas, 2Laboratory of Hematology, Hospital Albert Einstein, São Paulo, 3Laboratory of Experimental Oncology, Federal University Of Santa Catarina, Florianópolis, 4Laboratory of Cytometry, Hospital Aamaral Carvalho, Jau, 5Laboratory of Hematology, DASA, 6Laboratory of Hematology, Laboratórios Fleurio, São Paulo, 7Laboratory of Hematology, Children’s Cancer Hospital, Barretos Cancer Center, Barretos, 8Pathology, University of Campinas, Campinas, Brazil

Background: Decrease of bone marrow (BM) B-cell precursors (BCP) is an important diagnostic feature in myelodysplastic syndromes (MDS). Moreover, their number is associated with patients’ overall survival. However, BCPs vary with age in normal BM.

Aims: In a multicenter study from the Brazilian Group of Flow Cytometry we analyzed the variation of BCPs in normal BM according to age, antibody combinations used for quantification and reproducibility after a centralized reanalysis. We set up a reference pattern of normal values for evaluation of patients with a suspected MDS.

Methods: In a retrospective study including 10 centers we retrieved analyses of BM donors and cases examined for elucidation of transitory reactive cytopneas presenting a normal BM immunophenotyping. BCPs were enumerated as CD19/CD34/CD45/CD10 cells (panel 1) or CD19/CD34/CD45 cells (panel 2), among the total nucleated cells and as percentage among CD34+ cells. Statistical multiple regression to analyse the dependence of BCS from the variables analysed.

Results: 134 cases were included. Panel 1 was applied in 106 cases (all centers) and panel 2 was used in 28 cases (3 centers). Age range: 10 months to 89 years. In the same age range, values for panel 2 were lower than those for panel 1. In multiple regression % BCP total cells-0.29 (log age)-0.313 (for panel 2)-correction factor for labs +1.873. The correction factor for labs was 0 to -0.40. Age explained alone 49.6% of the variance of % BCP total cells, while “labortory” explained 5.2% and panel used explained only 0.8%. Age explained only 24.9% of the variance of BCPs/CD34+ cells.

Summary/Conclusions: In a normal population BM B-cell precursors varied mainly with age, but were also dependent on technical peculiarities of operators and equipments. Analysis by phenotype and as percentage of total cells was more accurate and less susceptible to variation.
Background: Disrupted hematopoiesis is life-threatening complication of allo-genic hematopoietic cell transplantation (allo-HCT). The interactions of haematopoietic stem/progenitor cells (HSPCs) and bone marrow (BM) microenvironment, niche(s), control the homeostasis of BM. TGF-b induced gene 3 (BIG3), one of BM extracellular matrix (ECM) which is produced by niche cells maintain the homeostasis and regeneration of BM.

Aims: We analyzed the relationship between the idiopathic thrombocytopenia after allo-HCT and the BM expression of periostin as the only paralogue of BIG3.

Methods: We reviewed twenty patients who transplanted with matched sibling donor for acute myelogenous leukemia at Konya Burn Treatment University Hospital from January 2010 to August 2015. BM biopsy specimens at the time of day 28, day 90, day 180, and day 365 were decalciﬁed and stained with primary antibody of BIG3 and periostin. Expression of periostin in BM slides were reviewed by pathologist as follows: normal (0), minimal staining around blood vessels; (+1), sparse staining and/or focally staining; (+3), diffuse and strong staining; (+2), between (0) and (+3).

Results: The median age at transplant was 38.5 years (range, 17-68 years) and male was 13 patients (65%). Twelve patients (60%) were in CR1 (complete remission), 8 (40%) in CR2. Thirteen patients (65%) received myeloablative conditioning regimen. The median dose of CD34+ cell was 3.67±10^5/kg (range, 1.5-7.67×10^5/kg). All patients achieved the neutrophil engraftment with a median time of days (range 9-24 days). The median time of platelet engraftment was 15.5 days (range, 13-77 days). Idiopathic thrombocytopenia developed as follows; 13 patients at day 28, 16 at day 90, 6 at day 180, and 3 at day 365. There was no signiﬁcant difference between idiopathic thrombocytopenia and the expression of BIG3 or Periostin (p>0.128). However, BM idiopathic thrombocytopenia manifested the low periostin/BIG3 ratio (p=0.007). Acute GVHD was observed in 12 patients (60%) and chronic GVHD developed in 13 patients (65%). The development of thrombocytopenia dose not differ according to acute and chronic GVHD (p=0.847) (Figure 1).

Summary/Conclusions: The periostin/BIG3 ratio might represent the status of BM niche during the homeostasis and regeneration of hematopoiesis. High periostin/BIG3 ratio could predict the recovery of the idiopathic thrombocytopenia.

PB1858
ASSOCIATION WITH OMENN SYNDROME AND CYSTINURIA: CASE REPORT
T. Patiroglu1,2, M. Canserver2, S. Çoçkun2, M. Karakucuk1, N. Baydilli2
1Pediatric Hematology, 2Pediatric Immunology, 3Pediatric Nephrology, 4Urology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Omenn syndrome is one type of combined immunodeficiency, characterized with hepatoparesismegaly, lymphadenopathy, recurrent infections and has an autosomal recessive pattern of inheritance. T lymphocyte count can be normal in peripheral blood but their functions are impaired. B lymphocyte count 1560/mm3, absolute lymphocyte count 2270/mm3, absolute lymphocyte count 1560/mm3, absolute eosinophil count 2220/mm3, serum IgG level 171mg/dl, IgA level 5.81mg/dl, IgM level 24, 5mg/dl, IgE level 1270 mg/dl were found. Hemoglobin level was 8.7 g/dl and HbA2 was only coincidence. In Omenn Syndrome is known to be sequencing alteration of cysteine and tyrosine amino acids. Perhaps, cysteine stones took form as a result of this alteration.

Figure 1.

Summary/Conclusions: The periostin/BIG3 might represent the status of BM niche during the homeostasis and regeneration of hematopoiesis. High periostin/BIG3 ratio could predict the recovery of the idiopathic thrombocytopenia.

PB1859
LABEL-FREE IMAGING BY AUTO-FLUORESCENCE PERMITS IDENTIFICATION OF ERYTHROID PRECURSORS IN BONE MARROW AND DETECTS CHANGES OF SOLUBILITY OF HEMOGLOBIN IN ERYTHROCYTES
I. Lorand-Metze1,*, F. Borges da Silva2, M. Falconi, K. Metze2,3
1Hematology - Hemotherapy Center, 2National Institute of Photonics applied to Cell Biology (INFABIC), 3Pathology, University of campinas, Campinas, Brazil

Background: In the fluorescence lifetime imaging (FLIM) technique, the image contrast is created by determining the delay of the fluorescence photon emission at each pixel of the image and transforming it in pseudo-colors. This delay, also called lifetime depends on the type of molecules and their physicochemical characteristics.

Aims: We investigated the utility of this technique for the characterization of erythropoietic cell line and changes in the solubility of hemoglobin.

Methods: We used unstained BM smears of 24 normal BM and 8 megaloblastic anemia patients and unstained peripheral blood smears of 10 patients with sickle cell anemia. Images were captured with a confocal microscope HPM-100-40-Hybrid detector and excitation at 405 nm (diode laser,80 MHz). In order to create equivalent images of the cytological smears, pseudo-colors were attributed to different lifetime ranges. Images were compared with May-Grünwald-Giemsa (MGG) stained smears.

Results: FLIM created highly contrasted images, where different cell types could be easily recognized by their similarity with MGG images. Erythrocytes exhibited the shortest lifetimes (210.4±42.1 ps). Normal shaped erythrocytes in smears of sickle cell patients showed similar values (214.6±3.1 ps), whereas enucleated erythrocytes as well as drepanocytes revealed signiﬁcantly elevated values (314.2±66.7 ps and 312.5±67.0 ps respectively). Regarding erythropoiesis, the cytoplasm of erythroblasts showed signiﬁcantly shorter lifetimes (623.5±272.1 ps) than that of myeloblasts (835.9±198.4 ps) and the same was the case when comparing the nuclei (erythroblasts: 895.4±262.8 versus myeloblasts: 1166.4±287.9 ps). The same differences could be found in megaloblastic anemias. There was no signiﬁcant differences between the FLIM values of the different cell types between normal hemopoiesis and megaloblastic anemia.

Summary/Conclusions: The FLIM technique is easily applicable on unstained routine smears and revealed images of good quality permitting cell differentiation. It allowed also to distinguish between erythroid and myeloid precursor cells and indicates the major physico-chemical changes during the process of falcization.
There are three deaths because of refractory diseases. Five patients needed treatment for the first disease and nine patients needed treatment for the second disease. Four patients had treatment for both diseases.

**Summary/Conclusions:** occurrence of two malignancies in the same patient can be a challenge for the hematologist. Findings of the second disease can be attributed to the first disease or considering them to be results of treatment. Follow up and initiation of treatment in those patients can be more complex than usual. As far as origin is concerned there are conflicting reports in the literature supporting a common or different cells of origin. Recording of these cases and biobanking can be of great interest for understanding mechanisms of hematologic neoplasms.

**Background:** The prognosis of Hodgkin lymphoma (HL) has improved significantly with the implementation of a risk-adapted treatment that combines chemotherapy and radiotherapy. Although this approach has led to the greatest advance in disease response, the benefit in terms of overall survival (OS) has been jeopardized by long term toxicity.

The identification of risk factors is crucial to assign each patient to a well defined risk group and prevent under or overtreatment, minimizing the risk of relapse and long term toxicity.

**Aims:** To analyze the risk factors associated with survival in HL treated with an ABVD based regimen that restricted radiotherapy only to bulky disease.

**Methods:** We retrospectively analyzed HL patients diagnosed in 4 centers in Tarragona area (Catalonia, Spain), between 1995 and 2015, treated uniformly according to a local protocol.

Patients were assigned into 4 groups: G1: favorable early stage: ABVDx6 cycles, G2: Bulky early stage without other risk factors: ABVDx6+IFRDT. G3: unfavorable early stage (B symptoms) and advanced stage without bulky disease: ABVDx8, G4: Bulky advanced stage: AVBDx8+IFRDT.

**Results:** A total of 183 patients were analyzed with a median follow up of 82 months [range 1-244]. Male/female ratio was 1.29. Median age was 36 years [range 16-82]. Complete response was achieved in 160 patients (87.4%). The estimated OS at 20 years for the whole group was 62.7%. Kaplan–Meier method and log rank test were used for survival analysis. Cox proportional hazard model was used for univariate analysis to identify predictive factors for OS. Factors with significance (p <0.05) were considered for multivariate Cox regression. In univariate analysis, worse OS was found in patients with increased LDH, non-NS subtype, albumin <3.5 g/dL, B symptoms, HIV+, advance stage and ESR >50 mm (log rank p=0.012; p=0.049; p=0.024; p=0.002; p=0.005; p=0.004 and p=0.001 respectively). The multivariate Cox regression analysis identified B symptoms and ESR >50 mm as independent prognostic factors for OS (p=0.002; p=0.006 respectively). These variables allowed us to identify 3 patient groups: low (no risk factors), intermediate (either B symptoms or ESR>50 mm) and high risk (both risk factors), with significant differences in OS. Estimation for OS was uniformly analyzed at 216 months (18 years), which is the shortest follow up period for patients in the low risk group. Patients in the low, intermediate and high risk groups had an estimated OS of 85.7%, 65% and 40.1% (p<0.001) (Figure 1).

**Summary/Conclusions:** B symptoms and ESR>50mm are independently associated with OS. The combination of these factors can stratify patients in low, intermediate and high risk groups with significant differences in OS, regardless their clinical stage.
ADVANCED HODGKIN LYMPHOMA PATIENTS WITHOUT LARGE TUMOR MASS – A NEW PROGNOSTIC SCORE IDENTIFIES PATIENTS WITH FAVORABLE OUTCOME

Background: ABVD and escalated BEACOPP are still the standard of care in patients with advanced Hodgkin Lymphoma (HL). The use of escalated BEACOPP gives better disease control but it is associated with more acute and late toxic effects. The identification of patients who require more or less aggressive initial approach remains the main goal for many investigators in the field of HL.

Aims: The aim of this study was to identify among patients with diagnosed advanced HL, with large tumor mass, the subgroup which should not be considered for more aggressive approach than ABVD.

Methods: A retrospective study was performed on 149 patients classical HL, diagnosed in the period June 1997-December 2011. All the patients were in clinical stage III or IV and didn't have any tumor lesion of 5 cm or more in its largest diameter. The standard of initial care was 6-8 cycles of ABVD followed by radiotherapy. Prognostic relevance of age more than 45 years, gender, CS IV, presence of B symptoms, IPS score, ESR>50 mm/h, Hgb <10.5 g/dL, WBC>15,000 mm³ and lymphopenia (lymphocytes <600/mm³ or <8% of WBC count) were examined.

Results: The median age of analysed patients was 37 (range 17-80). The median follow up was 98 months. For the whole group 5-year event free survival (EFS) was 63.1% and 5-year overall survival (OS) was 80.6%. In univariate analysis, worse OS was found in patients older than 45 years (5-year OS 66.7% vs 87.8%), patients with CS IV (5-year OS 70.2% vs 87.0%), B symptoms (5-year OS 77.1% vs 89.1%), ESR>50 mm/h (5-year OS 75.0% vs 89.5%), lymphopenia (5-year OS 65.6% vs 84.6%) (log rank; p=0.001, p=0.006, p=0.303, p=0.714, p=0.522, respectively). Worse EFS was found in patients with CS IV (5-year EFS 50.0% vs 70.7%, kog rank p=0.002), IPS>3 (5-year EFS 53.8% vs 73.2%, (log rank; p=0.006) and lymphopenia (5-year EFS 50.0% vs 66.7%, kog rank p=0.025), while age, gender, B symptoms, ESR>50 mm/h, anemia and leukocytosis didn’t influence OS (log rank; p=0.303, p=0.078, p=0.437, p=0.068, p=0.151, p=0.384, p=0.158, respectively). The multivariate Cox regression analysis identified age more than 45 years, ESR>50 mm/h and lymphopenia as independent prognostic factors for OS, while only IPS was identified as an independent factor for EFS. Afterwards, we performed survival analysis with aggregate scores of identified negative prognostic factors for OS for each patient. Since there was no difference in OS in intergroup analysis, groups with 0, 1, 2, and 3 factors or worse, respectively, formed. Finally, we developed prognostic model for identifying patients at low (0 factor), intermediate (1 factor) and high risk (2-3 factors) for poor outcome (p=0.000). According to this model, in the examined group 34 (22.8%) patients had low, 64 (43.0%) intermediate and 51 (34.2%) high risk for poor outcome, with 5-years OS of 100%, 93.4% and 59.1%, respectively.

Summary/Conclusions: According to the score which we developed, ABVD is very effective in the subgroup of advanced HL patients without tumor mass and without identified risk factors.

PB1863
TREATMENT EscALATION IN CASE OF POSITIVE PET 2 AND IMPACT OF EARLY PET IN EXTENSIVE STAGE HODGKIN Lymphoma

Background: ABVD therapy has been for a long time the reference to standard chemotherapy. ABVD therapy has been for a long time the reference to standard chemotherapy, and antibiotic regime of the regimen, and delayed toxicity annually increased after BEACOPP. With the use of PET-scanner, escalation and progression-free survival of patients, in particular due to better initial control of disease and response assessment, is currently extremely useful in the standardization of treatment response. A score 1, 2, 3 is considered to represent complete metabolic response; score of 4, 5 – partial, no response or progressive disease.

Aims: To determine predictive possibility proapoptotic protein bcl-2 and CD30 expression in RS cells of classical HL, and antigenic profile of Reed-Sternberg (RS) cells. To determine the clinical significance of bcl-2 and CD30 expression in RS cells of classical HL, and antigenic profile of Reed-Sternberg (RS) cells. To determine the clinical significance of bcl-2 and CD30 expression in RS cells of classical HL, and antigenic profile of Reed-Sternberg (RS) cells.

Methods: Among the 102 patients with Hodgkin lymphoma treated between 2008 and 2016, 50 patients had advanced disease (Stage III or IV of Ann Arbor). The majority of patients were treated on front line by ABVD (47 patients), 2 by BEACOPP and 1 by VABEM. All patients underwent PET evaluation at diagnosis and after 2 cycles of treatment. The analysis of the metabolic response was carried out according to the Deauville criteria.

Results: The median age of the patients was 48 years (min-max: 19-85). 20 patients (40%) had an unfavorable prognosis, 24 (48%) had an intermediate prognosis. 11 patients (22%) were refractory to the ABVD protocol and had an escalation of treatment. The median PFS was 66 months (47-85). The median overall survival was not achieved; OS at 60 months was 65%. We found no difference in survival between patients with negative PET and those with positive PET with escalation of treatment. The study of PET 2 response, its impact on survival, as well as escalation of treatment will be presented to the EHA with update of follow-up.

Summary/Conclusions: This study evaluated the value of escalating treatment in patients with advanced PET 2 in patients with advanced Hodgkin lymphoma treated in first-line by ABVD. This management aims to reduce the toxicity of intensive treatments. The aim of our study is also to identify the higher risk patients for whom more intensive treatment could be used as first-line treatment.

PB1864
THE PROGNOSTIC IMPACT OF 18F-FDG PET/CT IN LYMPHOMA PATIENTS AFTER STANDARD CHEMOTHERAPY

Background: The lymphomas are a heterogeneous group of malignant diseases. The exact diagnosis, precise staging and follow up is very important for treatment and prognosis of these patients (pts). Accurate pretreatment evaluation and response assessment are critical to the optimal management of lymphoma pts. Differentiation of post-therapeutic residual tissue from active lymphoma is unsatisfactory when using only morphological imaging approaches. Positron emission tomography/computed tomography (PET/CT) is the most sensitive and specific imaging technique for monitoring therapy response currently available for lymphoma pts after standard chemotherapy and determining which pts would benefit from additional treatment.

Aims: The aim of the study was to assess the clinical value of 18F-FDG PET/CT for staging and response evaluation in lymphoma pts with Hodgkin’s disease (HD) and non-Hodgkin’s lymphoma (NHL).

Methods: Two hundred and twenty six pts with biopsy proven lymphoma – (HD n=92 and NHL n= 134), aged 18-76, were retrospectively reviewed. These pts were examined 4-6 weeks after the completion of the standard chemotherapy. 18F-FDG PET/CT, according to the accepted protocol. PET/CT was used to assess response in FDG-avid histologies using 5-point scale, both for interim analysis and treatment end assessment. The Lugano classification has proved extremely useful in the standardization of treatment response. A score 1, 2, 3 is considered to represent complete metabolic response; score of 4, 5 – partial, no response or progressive disease.

Results: By applying PET/CT results two pts' groups were formed: 1.group (n=153 pts) with negative PET/CT results (Deauville score 1-3) and 2.group (n=73 pts) with PET/CT positive results (partial metabolic response or progressive disease). By applying PET/CT results two pts' groups were formed: 1.group (n=153 pts) with negative PET/CT results (Deauville score 1-3) and 2.group (n=73 pts) with PET/CT positive results (partial metabolic response or progressive disease). By applying PET/CT results two pts' groups were formed: 1.group (n=153 pts) with negative PET/CT results (Deauville score 1-3) and 2.group (n=73 pts) with PET/CT positive results (partial metabolic response or progressive disease). By applying PET/CT results two pts' groups were formed: 1.group (n=153 pts) with negative PET/CT results (Deauville score 1-3) and 2.group (n=73 pts) with PET/CT positive results (partial metabolic response or progressive disease). By applying PET/CT results two pts' groups were formed: 1.group (n=153 pts) with negative PET/CT results (Deauville score 1-3) and 2.group (n=73 pts) with PET/CT positive results (partial metabolic response or progressive disease).

Summary/Conclusions: Using 18F-FDG PET was useful in HD and NHL pts after standard chemotherapy not only for determination of those who need additional therapy, but for the choice of the further management: radiotherapy, chemotherapy, or ASCT. A negative PET/CT study after the completion of therapy is an excellent predictor of good prognosis.

PB1865
BCL-2 AND CD30 EXPRESSION IN HODGKIN AND REED-STERNBERG CELLS OF CLASSICAL HODGKIN’S LYMPHOMAS AS A POORER PROGNOSIS CRITERIA

Background: There are a lot of prognosis criteria for risk stratification of Hodgkin’s lymphoma (HL). The most applicable is the IPS-7, however this score is ignoring a tumor cells phenotype. There are data about dependence survival and antigenic profile of Reed-Sternberg (RS) cells. To determine the clinical significance of bcl-2 and CD30 expression in RS cells of classical HL, we have correlated it’s expression with available IPS criteria and failure-free survival (FFS). Background: There are a lot of prognosis criteria for risk stratification of Hodgkin’s lymphoma (HL). The most applicable is the IPS-7, however this score is ignoring a tumor cells phenotype. There are data about dependence survival and antigenic profile of Reed-Sternberg (RS) cells. To determine the clinical significance of bcl-2 and CD30 expression in RS cells of classical HL, we have correlated it’s expression with available IPS criteria and failure-free survival (FFS).

Aims: To determine predictive possibility proapoptotic protein bcl-2 and CD30 antigen on RS cells aggregating with criteria IPS.
Methods: In study were included 85 previously untreated patients, presented with classical HL between 2002 and January 2016. This retrospective study did not require approval by the Local ethical committee. Inclusion criteria were: a histologically confirmed diagnosis of classical HL, the presence of a fixed in paraffin before treatment a lymph node sample or other diseased tissue, the minimum follow-up was not less than 18 months.

Results: In the study population (n=85) identified 30 (35%) histological samples bcl-2+ and 55 biopsies (65%), bcl-2. Group bcl-2+ patients had a lower response rate after ABVD chemotherapy - only 24 (28%) patients achieved CR or better result, as compared with 49 patients (57.6%) of the bcl-2 group. In the first-year liquid biopsy (EBUS) in bcl-2+ patients had lower 82% vs 96% CR in bcl-2 group (p=0.018). Multivariate analysis with the Cox proportional-hazard model with the inclusion of bcl-2+, CD34+, bcl-2+/CD30+, age 45 and older, B-symptoms, III-IV stage, anemia, increased serum albumin, increased LDH, leukocytosis revealed that the expression of bcl-2 on RFS was an independent factor of poor prognosis. 3 year EFS was 52% vs 90% in bcl-2 population (p=0.022; RR=1.4). The greater relative risk was observed in a population with double expression of bcl-2 and CD30, where the 3-year EFS was 47% (p=0.012; RR=1.6).

Summary/Conclusions: The expression of bcl-2 on HRS cells can be an independent prognostic factor, co-expression of bcl-2 and CD30 can be viewed as a more powerful factor of poor prognosis than bcl-2+ cells.

SURVIVAL ANALYSIS OF PATIENTS WITH CLASSICAL HODGKIN'S LYMPHOMA TREATED WITH ABVD: RESULTS FROM TWO REFERRAL CENTERS IN MEXICO CITY.

G.P. Agreda-Vásquez1, A.F. Ramírez-Ibargüen2, E. Crespo-Solís3,*

1Department of Hematology and Oncology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, 2Department of Hematology, Instituto Nacional de Cancerología, Mexico City, 3Department of Hematology and Oncology, Hospital Regional de Alta Especialidad de Ciudad Victoria, Victoria, Mexico

Background: Classical Hodgkin’s lymphoma (cHL) is a neoplastic disease with a favorable prognosis since 85% of patients can be considered cured with current treatment strategies. Combined chemotherapy with Adriamycin, Bleomycin, Vinblastine and Dacarbazine (ABVD) has been the standard therapy for over 20 years. Epidemiological information and the regimen’s results as first-line therapy in Mexico are limited.

Aims: The aim of this study was to conduct a survival analysis in adult patients from two referral centers in Mexico City.

Methods: This is a retrospective analysis of all patients with cHL treated at the Instituto Nacional de Cancerología and the Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, between 2009 and 2013. The study was approved by the local Ethics Committee.

Results: We included a total of 193 patients with a de novo diagnosis and initially treated with ABVD: 60.6% of cases were male, with a median age of 36 years (17-81 years), 71.5% were diagnosed in late clinical stages (CS). The most frequent histopathological subtypes were: nodular sclerosis and mixed cellularity (46.6% and 40.9%; respectively); the observed overall response rate (ORR) was 85.7% [Complete response (CR) was 78.2%.]. The RR was 90% in early CS vs 83.8% in late CS (CR rate was 84% vs 75.8%; respectively, p=0.23). Univariate analysis by logistic regression in the early CS group revealed that having a Lymphocyte:Monocyte ratio <1 presents an unfavored trend to achieve CR [OR 0.150 (95%CI 0.018-1.274; p=0.082)]. In the group in late CS, we found that the lymphocyte percentage tended to favor CR [OR 1.048 (95%CI 0.994-1.105; p=0.081)] and the opposite was observed in terms of the absolute monocyte count [OR 0.999 (95%CI 0.998-1.000; p=0.082)]. Median follow-up was 35 months (0-96 months), 10.0% of cases had died at last follow-up, and median overall survival (OS) of the entire cohort had not been reached at the time of analysis (5-year OS, 87.1%). However, at the time of this analysis, the group of patients in complete remission had a greater OS than the group that did not achieve CR (p=0.0001). With Cox multivariate analysis of OS according to CS, we detected that in the group in early CS, none of the analyzed factors were significant while in the late CS group, age >45 years was an independent risk factor [HR 6.9 (95%CI 1.80-26.60; p=0.005)] and achieving CR had a protective effect [HR 0.02 (95%CI 0.004-0.108; p=0.0001)].

Summary/Conclusions: Although OS medians had not been reached at the time of analysis, it is noteworthy that CR (84%) in early CS is lower than that reported in the literature and no related prognostic factor has been identified. The role of lymphocytes and monocytes may prove to be significant in larger series with a longer follow-up.

PB1867

OUTCOME OF PD-1 BLOCKADE IN PATIENTS WITH RELAPSED HODGKIN LYMPHOMA AND ACTIVE GRAFT-VERSUS-HOST DISEASE

A. Minson1,*, G. Douglas1, A. Grigg1

1Haematology, Austin Health, Heidelberg, Australia

Background: Efficacy of PD-1 (programmed death-1) inhibitors in relapsed/refractory Hodgkin lymphoma (HL) has been established, but their role in relapse after allogeneic stem cell transplant (alloSCT) remains controversial due to the perceived risk of exacerbating graft-versus-host disease (GVHD). The literature is largely limited to case reports in patients with no or quiescent GVHD.

Aims: To determine the outcome of PD-1 inhibitor therapy and subsequent management in patients with concomitant biopsy proven active GVHD and progressive HL after alloSCT.

Methods: We describe the treatment and management of two patients in our centre.

Results: Case 1 had both extensive bony, lung and nodal HL with active skin, pleuropediceral and liver GVHD 6 months after donor leucocyte infusion (DLI) and immunosuppression withdrawal and 24 months after sibling alloSCT. Fifty% of the standard pembrolizumab dose (100mg) produced a PET partial response after 5 weeks but with concomitant biopsy proven, severe exacerbation of liver GVHD. The latter was managed with prednisolone, everolimus, ursodeoxycholic acid (UDCA) and subsequently tacrolimus with gradual improvement in liver function over the next 5 months (Figure 1) in the absence of further PD-1 blockade, but with progression of lymphoma. Pembrolizumab 50mg was then given with lymphoma response but again a significant (but less severe) flare of liver GVHD occurred. Subsequent 25mg doses failed to prevent lymphoma progression. Reintroduction of 50mg doses approximately each 6 weeks for 4 doses with prophylactic everolimus, low dose prednisolone and ruxolitinib, has resulted in ongoing substantial but incomplete PET responses with associated stable liver GVHD. Case 2 had progressive mediastinal and pulmonary HL despite DLI-induced extensive liver and skin chronic GVHD 38 months post sibling alloSCT. Initial therapy consisted of optimisation of liver GVHD with 8 weeks of UDCA and prednisolone with improvement in liver indices (Figure 1). Pembrolizumab 50mg was then given, together with sirolimus and ruxolitinib as GVHD ‘prophylaxis’, resulting 5 weeks later in complete metabolic remission on PET. Concomitantly liver GVHD was aggravated (See Figure 1) together with pancycopenia and narrow hypoplasia attributed to an immune-mediated phenomenon. Despite addition of tacrolimus and increased steroids, he remains with severe liver dysfunction and pancytopenia 10 weeks after the single dose of PD1 inhibitor therapy.

Figure 1.

Summary/Conclusions: PD-1 inhibitors can exert powerful graft vs HL effects even in patients with progression in the context of active GVHD, but at the expense of substantial GVHD exacerbation. Further exploration of approaches such as individualised dose titration according to response and GVHD activity and prophylactic therapy with non-calcineurin based immunosuppression which may not mitigate the anti-lymphoma effect will help evaluate whether durable responses with tolerable toxicity is possible in this context.
PB1868

PROGNOSTIC VALUE OF THE RED CELL DISTRIBUTION WIDTH IN PATIENTS WITH CLASSIC HODGKIN LYMPHOMA

A. Knezović1, V. Periša2,3, L. Zibar4, J. Sinčić-Petričević2
1Community Health Centre Dončovo, Faculty of Medicine, University of Osijek, Osijek, Croatia, 2Department for Pathophysiology, Faculty of Medicine, University of Osijek, Osijek, Croatia, 3Nephrology, Department for Pathophysiology, University Hospital Centre Osijek, Faculty of Medicine, University of Osijek, Osijek, Croatia, 4Department for Pathophysiology, Faculty of Medicine, University of Osijek, Osijek, Croatia

Background: The current gold standard for risk stratification in Hodgkin lymphoma (HL) is the International Prognostic Score. There are certain molecular and immunohistochemical prognostic markers in patients with HL, but their cost and technical constraints make such an application in routine impractical and expensive. Therefore, prognostic models for classic HL (cHL) that are inexpensive, simple, and easy to perform and interpret are needed.

The red blood cell distribution width (RDW) is associated with short- and long-term outcomes of various malignancies. The prognostic value of the RDW in cHL remains unknown.

Aims: The aim of this study was to analyze the prognostic significance of RDW in cHL patients.

Methods: We retrospectively analyzed data from 54 cHL patients diagnosed from 2005 to 2016 at the University Hospital Center Osijek, Osijek, Croatia. We evaluated disease outcome, overall survival (OS) and event-free survival (EFS), and demographic, clinical and laboratory factors affecting outcome. Univariate analysis and Cox regression analysis were used.

Results: The median age of patients was 36 years, 29 were men (54%). Higher RDW levels (%) were found in patients with advanced Ann Arbor clinical stage (15.34 ± 2.28 vs 13.12 ± 1.3, P < 0.001) and in those with poor response to therapy (15.65 ± 3.37 (progression) vs 16.68 ± 2.09 (partial remission), 13.95±1.82 (complete remission), P = 0.008). Patients with RDW values of >14.5% (cutoff value calculated by receiver-operating characteristic) had a significantly worse two-year EFS (62.4% vs 90.4%, P = 0.009) but did not differ significantly in terms of OS (P = 0.2). Univariate analysis revealed that a high RDW (>14.5%) was correlated with poor EFS (P = 0.019). Multivariate Cox regression analysis showed that RDW >14.5% was an independent prognostic factor for EFS (hazard ratio [HR] 3.801, 95% confidence interval [CI] 1-14.45, P = 0.049). The RDW allowed further borderline statistically significant risk stratification in patients who were considered to be at low risk on the basis of an International Prognostic Score less than 4 (P = 0.053).

Summary/Conclusions: High baseline RDW is an independent prognostic marker of poor outcome in patients with cHL. RDW ratio is as simple, inexpensive, and independent prognostic factor for EFS that may improve the ability to identify high-risk patients with cHL. It could be an easily available and inexpensive marker for the risk stratification in patients with cHL.

PB1869

HIGH FREQUENCY OF SECONDARY MALIGNANCIES IN PATIENTS WITH LARGE GRANULAR LYMPHOCYTIC LEUKEMIA: A SINGLE INSTITUTIONAL EXPERIENCE

L. Iseman1, M. Van den Bergh 3, E. Wang2, B. Schaible 1, Z. Ma 1, L. Zhang 1, L. Sokol1
1Hematology-Oncology, H. Lee Moffitt Cancer Center and Research Institute, 2Internal Medicine, University of South Florida, Tampa, United States

Background: Large granular lymphocyte (LGL) disorders represent a spectrum of aberrant T-cell or natural killer cell lymphocytic proliferations. LGLL is classically associated with autoimmune conditions and bone marrow (BM) failure disorders. SM has been reported in association with LGLL in about 10%.

Aims: The aim of this study is to evaluate the impact of SM on the clinical course of LGLL.

Methods: This is a retrospective study of LGLL patients evaluated at Moffitt Cancer Center between January 1995 and May 2016. The diagnostic clinicopathological criteria consisted of LGL count > 0.5 k/µL with T-cell receptor gene rearrangement. Lower absolute number of clonal circulating LGLs with characteristic immunophenotype associated with BM involvement, cytopenias, myelodysplasia and/or associated symptoms were also diagnostic. Patients with myelodysplastic syndrome were excluded. Survival analysis was performed using the Kaplan-Meier method with log-rank test. Chi-square and T-test were used to analyze association among various variables. Significant P-value was considered < 0.05.

Results: Out of 668 screened patients with LGL expansions in peripheral blood, 261 met criteria for LGLL, of which 38% were hematological and 80% arose prior to onset of LGLL. Most common solid secondary malignancy included skin cancer (14%), prostate cancer (12%), and breast cancer (12%), while most common hematological secondary malignancy consisted of non-Hodgkin lymphoma (17%) and chronic leukemia (14%). 5-year overall survival (OS) for all LGLL patients was 75% and 10-year OS 63%. There was a statistically significant difference in 5-year OS between LGLL patients with a secondary malignancy compared to without (p = 0.049), but no difference between both groups in median OS or 10-year OS. Patients diagnosed with a secondary malignancy prior to LGLL had worse 5-year OS (p = 0.031) and 10-year OS (p = 0.05) compared to all other LGLL patients.

Summary/Conclusions: This study showed that the frequency of a secondary malignancy is higher than previously described, especially with onset prior to diagnosis of LGLL. Even though median age of LGLL is around 60 years, it appears that age itself cannot explain this phenomenon. Our results suggest that having a secondary malignancy is a poor prognostic factor in LGLL patients.

BENDAMUSTINE AND RITUXIMAB COMBINATION THERAPY WITH SUBSEQUENT RITUXIMAB SUPPORTING THERAPY IN RUSSIAN SUBJECTS WITH RELAPSED OR REFRACTORY INDOLENT B-CELL NON-HODGKIN LYMPHOMAS

1Russian Medical Academy for Postgraduate Education of Ministry of Health, 2Scientific Medical Surgical Center n.a.I.V.Pyrogov, Moscow, 3Regional Clinical Hospital, Tula, 4Regional Clinical Hospital, Orenberg, 5Moscow Scientific Research Oncology Institution n.a.P.A. Gertzon, Moscow, 6Volograd Regional Clinical Oncology Dispensary, 7Volograd Regional Clinical Hospital, Irkutsk, 8Atlas Medical Center, Moscow, 9Novosibirsk State Regional Clinical Hospital, Novosibirsk, 10Regional Clinical Hospital, Krasnoyarsk, 11Clinical Trial Support, Smolensk, Russian Federation, 12Astellas Pharma Europe, Middle East and Africa, Chertsey, United Kingdom

Background: Combination of bendamustine and rituximab has been established in many international guidelines as treatment for patients with indolent B-cell non-Hodgkin lymphoma (NHL).

Aims: Objectives of this study were to evaluate the effectiveness, safety, and tolerability of bendamustine/rituximab combination followed by rituximab maintenance therapy for relapsed or refractory (R/R) INHL patients in the Russian Federation.

Methods: Adult subjects (≥18 yr), diagnosed with R/R INHL according to local diagnostic standards, and were enrolled in this prospective observational study. Intravenous therapy was administered in 2 stages (Figure 1): a combination therapy stage followed by a rituximab supporting therapy stage for subjects who achieved complete response (CR) or partial response (PR) during the combination therapy stage. Overall response rate (ORR) was assessed after

Indolent Non-Hodgkin lymphoma - Clinical
3 (Evaluation 1) and 6–8 (Evaluation 2) 28-day cycles. Data from the full analy-
sis set (FAS) were used for the primary analysis and the per-protocol (PP) set for a subgroup analysis. Safety/tolerability was a secondary end point and was assessed in the safety analysis set (SAF). Response assessments used the LOCF method for substitution of missing data; overall survival (OS) and pro-
gression-free survival (PFS) were calculated using Kaplan–Meier estimates, safety/tolerability was assessed by adverse event (AE) frequency and described using descriptive statistics.

Results: Of the 102 subjects enrolled between June 2012 and October 2015, 83 subjects (52M/31F; median age 59 yr [range: 27–84]) with various NHL his-
tology; subjects with mantle cell lymphoma [n=4], diffuse large B-cell lymphoma [n=2], and follicular lymphoma transformation [n=1] were excluded from the PP population due to deviation from the iNHL inclusion criteria. Most study subjects were heavily pretreated with a median number of 2 prior lines of therapy before entering the study (range: 1–6). At Evaluation 2, ORR in the FAS was high (n=69/102 [67.7%]) with 35 (42.2%) subjects achieving CR (confirmed, n=20 [24.1%]; unconfirmed, n=15 [18.1%]) and 23 (27.7%) achieving PR; ORR (defined as [CR+CR unconfirmed +PR]) in the PP population was 70.8% (Table 1). For FAS patients, at follow up (17 mo) neither median OS nor PFS had been reached; 2-year OS was 88.9% (95% CI: 79.7–98.0%) and 2-year PFS was 87.9% (95% CI: 80.7–95.7%). In the SAF, 31 of 96 subjects (32.3%) reported ≥1 AE. Decreased neutrophil count, decreased white blood cell count, and infections were the most commonly reported AEs and serious AEs. Twelve deaths occurred: 5 due to disease progression (n=2) or relapse (n=3), 5 were not related to lymphoma or occurred during remission, 1 cause of death was unknown, and 1 subject died from hyperthermia and respiratory failure, which was the only death in the study considered related to combination therapy.

Figure 1.

Summary/Conclusions: Bendamustine plus rituximab therapy followed by rit-
ximab maintenance therapy was generally well tolerated and demonstrated clinical effectiveness in Russian R/R patients with iNHLs. Although a number of subjects with aggressive lymphomas were included in the FAS, the ORR rate was not considerably different from the PP population (ORR: 69.9% [FAS] vs 70.8% [PP]).

PB1871
PROGNOSTIC VALUE OF G8 SCREENING TOOL IN PATIENTS WITH INDOLENT B-CELL LYMPHOPROLIFERATIVE NEOPLASMS – A SINGLE CENTRE EXPERIENCE

Z. Cvetkovic1,2,3, A. Novkovic1, Z. Djamic1, T. Bibic1, A. Ivanovic1, N. Milutinovic1 1Department of haematology, Clinical Hospital Center Zemun, 2Medical Faculty University of Belgrade, Belgrade, Serbia, 3Department of haematology, Medical Faculty University of Belgrade, Belgrade, Serbia

Background: Indolent B-cell lymphoproliferative neoplasms (B-LPN) are malignant diseases of advanced age. The most common among them, follicular lymphoma (FL), marginal zone lymphoma (MZL) and chronic lymphocytic leukemia (CLL) together represent about 40% of all B-LPN. However, as indolent B-LPN are most often the slow-growing diseases, an approach “watch and wait” is often recommended. But, when treatment is necessary, the advanced patients’ age indicate the need for geriatric assessment (GA) in aim to indentify functional, cognitive, social, nutritional and psychological parameters of the general health status. G8 screening tool (G8) is recognized as fast, easy to perform and sensitive test for selecting the group of fit elderly patients capable for curative treatment approach. Although incorporated in routine oncological practice, GA and G8 are not widely evaluated in hematological practice, so far.

Aims: To evaluate the impact of G8 screening tool on clinical outcome and survival of elderly patients with indolent B-LPN ≥ 65. The most common among them, follicular lymphoma (FL), marginal zone lymphoma (MZL) and chronic lymphocytic leukemia (CLL) together represent about 40% of all B-LPN. How-
ever, as indolent B-LPN are most often the slow-growing diseases, an approach “watch and wait” is often recommended. But, when treatment is necessary, the advanced patients’ age indicate the need for geriatric assessment (GA) in aim to indentify functional, cognitive, social, nutritional and psychological parameters of the general health status. G8 screening tool (G8) is recognized as fast, easy to perform and sensitive test for selecting the group of fit elderly patients capable for curative treatment approach. Although incorpo-
rated in routine oncological practice, GA and G8 are not widely evaluated in hematological practice, so far.

Methods: Total of 89 consecutive elderly patients (45 males and 44 females with median age at diagnosis 74.6 years, range 65–88) with indolent B-

Results: Of the 89 patients median overall survival (OS) was 77 months, and disease free survival (DFS) in 58 (77.3%) patients achieving remission was 25 months. Among laboratory parameters, hemoglobin, platelet, neutrophil and monocyte count, as well as C-reactive protein, beta-2 microglobulin didn’t influence CR rate, OS and DFS. Elevated lactate dehydrogenase was found signifi-
cante for CR rate, and low albumin level (<40g/L) for predicting OS. Among clinical parameters, age, sex, presence of “B” symptoms, splenomegaly (>13cm), bulky disease (>10cm), extranodal (EN) disease, as well Charlson comorbidity index (CCI; ≥3), ECOG performance status (PS; ≤2) and G8 were considered to be independent functional, cognitive, social, nutritional and psychological parameters of the general health status. G8 screening tool (G8) is recognized as fast, easy to perform and sensitive test for selecting the group of fit elderly patients capable for curative treatment approach. Although incorpo-
rated in routine oncological practice, GA and G8 are not widely evaluated in hematological practice, so far.

Results: For all 89 patients median overall survival (OS) was 77 months, and disease free survival (DFS) in 58 (77.3%) patients achieving remission was 25 months. Among laboratory parameters, hemoglobin, platelet, neutrophil and monocyte count, as well as C-reactive protein, beta-2 microglobulin didn’t influence CR rate, OS and DFS. Elevated lactate dehydrogenase was found signifi-
cante for CR rate, and low albumin level (<40g/L) for predicting OS. Among clinical parameters, age, sex, presence of “B” symptoms, splenomegaly (>13cm), bulky disease (>10cm), extranodal (EN) disease, as well Charlson comorbidity index (CCI; ≥3), ECOG performance status (PS; ≤2) and G8 were considered to be independent functional, cognitive, social, nutritional and psychological parameters of the general health status. G8 screening tool (G8) is recognized as fast, easy to perform and sensitive test for selecting the group of fit elderly patients capable for curative treatment approach. Although incorpo-
rated in routine oncological practice, GA and G8 are not widely evaluated in hematological practice, so far.

Summary/Conclusions: According to our experience, the implementation of G8 is good prognostic parameter. Its incorporation into standard hematological indices may help in improving the optimal treatment approach decision in elderly patients.

PB1872
A PROSPECTIVE PHASE 2 TRIAL EVALUATING MONOTHERAPY WITH OFATUMUMAB FOR RELAPSED/REFRACTORY SPLENIC B-CELL MARGINAL ZONE LYMPHOMA (MORE TRIAL): SAFETY ANALYSIS RESULTS

L. Scarfo1,2,3,*, G. Gritti4, A. Tedeschi5, P. Ranghetti1, C. Scielzo1, P. Angiolillo1,2, M. Ponzoni3,4, F. Ronchi3, A. Ferreri1, P. Ghi1,2,3, 1B-cell Neoplasia Unit, IRCCS San Raffaele Scientific Institute, 2Strategic Research Program on CLL, IRCCS Ospedale San Raffaele, 3Università Vita-Salute San Raffaele, Milano, 4Hematology and Bone Marrow Transplant Unit, Ospedale Papa Giovanni XXIII, Bergamo, 5Department of Hematology, Niguar-
da Cancer Center, Niguarda Hospital, 6Unit of Lymphoid Malignancies, Department of Immunology and Transfusion Medicine Service, 7Unit of Lymphoid Malignancies, Department of Onco-Hematology, IRCCS San Raffaele Scientific Institute, Milano, Italy

Background: Due to the lack of prospective clinical trials, treatment guidelines for splenic marginal zone lymphoma (SMZL) are mainly based on chemotherapy expertise. Treatment options for progressive disease include splenectomy, chemo-immunotherapy, or anti-viral therapy in HCV-positive cases. As SMZL cells strongly express CD20 molecule, rituximab has been used in patients unfit for chemotherapy or splenectomy with high response rates. Ofatumumab is a fully humanized, high affinity anti-CD20 monoclonal antibody that induces a more potent complement-dependent cytotoxicity if compared to rituximab. We designed this multicenter, open-label, single-arm phase 2 trial addressing activity and safety of ofatumumab monotherapy in patients with relapsed/refrac-
tory (R/R) SMZL.

Aims: The primary objective is the activity of ofatumumab in terms of complete response (CR) rate. Secondary objectives aim at evaluating the safety and tol-
erability and exploratory endpoints investigate biological features potentially related with response to ofatumumab.

Methods: All patients provided written informed consent. Key eligibility criteria include R/R disease after ≤2 prior lines of chemotherapy or immunochemotherapy (including single-agent rituximab). Patients are treated with ofatumumab (1st dose: 300 mg, 2nd-8th doses: 1000 mg) up to 8 weekly doses. Response assessment is scheduled 3 months after the last dose. Sample size was defined assuming a P0 of 45% CR, and a P1 of 65% CR. Per protocol analysis (PP) is performed (amendment 1), if the number of 43 patients should be recruited. A safety analysis was planned after the enrollment of the first 10 patients. With an expected rate of adverse events (AEs) of 13%, if less than 3 AEs leading to withdrawal from treatment are reported, the accrual will
continue to the planned 15 patients (interim analysis). Here we present safety analysis results.

Results: Ten patients (6 males, 4 females; median age: 69.5 years, 9 ≥65 years, 1 <65 years) were analyzed for safety. Eight patients were previously treated with rituximab, 26 adverse events (AEs) occurred in 7 patients, with only 5 grade 3-4 AEs. Ten AEs were drug-related, 30% were of grade 3 (Table 1). Three SAEs occurred: hyperviscosity, n=2, both related, and anaphylaxis, n=1, unrelated to study drug. No AEs leading to treatment withdrawal were reported and no patients died on study. Hematological and biochemical abnormalities included: neutropenia (any grade 6 cases, grade 3-4; 4 thrombocytopenia (grade 1-2; 3 cases), lymphopenia (grade 1-2; 2 cases), leukopenia (grade 1-2; 5 cases), 1 case of GGT increase (grade 3, at baseline grade 2), 5 cases of ALP increase (all grade 1-2), 1 case each of AST, ALT and bilirubin increase (all grade 1). Preliminary response assessment in these 10 patients documented 5 CR, 4 Partial Responses (PR) and one patient with progressive disease (PD) at the end of treatment.

Table 1: List of AEs.

Summary/Conclusions: Ofatumumab is safe and generally well-tolerated even in elderly patients with R/R SMZL. No cases of unexpected adverse drug reactions were documented. In a series of patients largely pre-treated with rituximab, ofatumumab resulted in a 90% overall response rate, 50% being CR. Complete results of the interim analysis will be presented at meeting.

PB1873
TREATMENT PATTERNS AND RESPONSE TREATMENT IN PATIENTS WITH FOLLICULAR LYMPHOMA IN ROUTINE CLINICAL CARE – A UNITED STATES ELECTRONIC MEDICAL RECORD DATABASE STUDY

A. Galaznik1,*, J. Bell1, L. Hamilton2, A. Ogbonnaya2, K. Hennenfent2, M. Suarez2, A. Mestre2, M. Ferraro1, E. Abella1, L. Martinez1, C. Pedro1, E. Torres1, J. Maiques3, L. Colomo4, C. Besses1, A. Salar1
1Hematology department, Hospital del mar, Barcelona. Grup de recerca aplicada en Hematologia PSMAR, 2Nuclear Radiology department, 3Radiology department, 4Pathology department, Hospital del Mar, Barcelona, Spain

Background: FL represents 70% of all indolent non-Hodgkin lymphomas, and it is widely recognized that FL is a heterogeneous disease, with patients presenting with differing amounts of tumor burden and prognostic indicators. The NCCN guideline recommends using rituximab as a single agent or in combination with other chemotherapies as first-line therapy (1LT) or second-line therapy (2LT). No recommendations are provided beyond 2LT. The date of the first FL record was the index date. Patients were followed from index until end of continuous activity, progression to diffuse large B-cell lymphoma (DLBCL), death, or end of study period (09/30/15) and were evaluated for FL treatment patterns and treatment response. Possible remission was defined as no additional chemotherapies and no supportive care use or receipt of supportive care <30 days after end of line of therapy (LOT) for <30 days. Lack of remission was defined as receipt of supportive care >30 days after end of LOT for >30 days. Progression was defined as initiation of another LOT, transition to DLBCL, or evidence of supportive care >30 days after end of therapy (LOT) for >30 days.

Results: Of the 3,756 patients selected into the study, 1,346 (35.8%) initiated 1LT, and median (interquartile range [IQR]) time to therapy was 1.3 (0.5–5.9) months. Overall, treatment regimens were mainly rituximab-based. In 1LT, more patients initiated combination chemotherapy (61.4%) vs single-agent chemotherapy (38.6%). Bendamustine+rituximab (26.9%) and R-CHOP (15.1%) were the most common combination regimens, and rituximab (33.1%) was the most common single agent. Median (IQR) duration of 1LT was 4.3 (1.7–10.4) months. At the end of 1LT, 54.7% (n=736) had evidence of remission, 25.5% (n=344) progressed, and 1.6% (n=22) had no evidence of remission. Among AEs, 180 patients initiated 2LT, 32 patients received a single agent, and 65.7% received combination chemotherapy. 2LT regimens were similar to 1LT, with rituximab (18.9%) remaining the top single agent, while bendamustine+rituximab (25.9%) and R-CHOP (6.0%) remained the top combinations. Median (IQR) duration of 2LT was 3.6 (1.4–6.1) months. Of patients with progression after 1LT, 57% received 2LT; 31% received a single agent, and 64.4% received combination chemotherapy. In 3LT, rituximab (11.1%) was the most common single agent: bendamustine+rituximab (20.0%) and rituximab+vinblastine (8.9%) were the most common combinations. Median (IQR) duration of 3LT was 2.8 (1.4–4.7) months. Following 3LT, 26.7% (n=12) had evidence of remission, 39.9% (n=18) progressed, and 4.4% (n=2) had no evidence of remission.

Summary/Conclusions: FL treatment in routine clinical care aligns with treatment guidelines in 1LT and 2LT, with most patients receiving rituximab-based combination chemotherapy. Similar regimens were used in the 3LT setting. As expected, the rates of remission decreased with subsequent LOTs.

PB1874
PET-CT AND BONE MARROW BIOPSY IN STAGING FOLLICULAR LYMPHOMA IN A SINGLE INSTITUTION

I. Parraga1,*, E. Gimeno1, F. Garcia Palleros1, B. Sanchez Gonzalez1, M. Suarez2, A. Mestre2, M. Ferraro1, E. Abella1, L. Martinez1, C. Pedro1, E. Torres1, J. Maiques3, L. Colomo4, C. Besses1, A. Salar1
1Hematology department, Hospital del mar, Barcelona. Grup de recerca aplicada en Hematologia PSMAR, 2Nuclear Radiology department, 3Radiology department, 4Pathology department, Hospital del Mar, Barcelona, Spain

Background: Follicular lymphoma (FL) is an indolent lymphoid B neoplasm corresponding to 20–25% of non-Hodgkin lymphomas (NHL). Bone marrow biopsy (BMB) is part of standard work-up in indolent NHL since up to 40–70% of cases have bone marrow involvement. This fact important is one factor considered in the FL-IPI and FL-IPI prognostic index. Positron emission tomography/computed tomography (PET-CT) is a noninvasive technique that shows high sensitivity of detecting nodal and extranodal lymphoma involvement, specially in aggressive subtypes. Some studies have described a high specificity (62-100%) and sensitivity (95-100%) in the detection of bone marrow involvement in aggressive NHL. However, its role in low-grade indolent lymphomas such as follicular lymphoma remains controversial.

Aims: To analyze retrospectively the diagnostic accuracy of PET-CT in comparing BMB in the initial staging of new FL in a single centre in daily practice.

Methods: One hundred and thirty patients with de novo FL have been diagnosed in our institution from June 2005 to October 2016. Of them, 64 who underwent both BMB and PET-CT before treatment were evaluated. The BMB was evaluated by hemato-pathologist and the interpretation of PET-CT images was interpreted by a nuclear radiologist. Positive BMB was defined as the presence of CD20 + CD10 + B-cells lymphoid infiltration. No molecular biology techniques were done in the bone marrow tissue. PET-CT bone marrow involvement was defined as an elevated FDG uptake in the bone marrow more than those in liver or mediastinum.

Results: Thirty-five male and 29 female were included. The median age at diagnosis: 58 years (range 23-84). Thirty-four patients had grade 1-2 FL and 30 grade 3a FL. Bone marrow involvement was diagnosed in 33 of 64 patients (51.1%) by BMB. Out of the 17 patients with positive PET-CT, 4 had negative BMB. Out of 33 patients with positive BMB, 13 had a positive PET-CT (Table 1). The sensitivity and specificity of PET-CT was 39% and 87%, respectively. The positive predictive value and negative predictive value was 76.5% and 57%, respectively.

Table 1. Detection of BMO involvement: BMB and PET-CT results.

PB1875
SURVIVAL OUTCOMES AFTER FIRST-LINE THERAPY IN FOLLICULAR LYMPHOMA USING A UNITED STATES ELECTRONIC MEDICAL RECORD-BASED COHORT

A. Galaznik1,*, J. Bell1, L. Hamilton2, A. Ogbonnaya2, A. Raju2, K. Hennenfent2, M. Eddy3, Y. Shou1
1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Phar-

Summary/Conclusions: Our study shows a very low sensitivity of PET-CT in the daily practice. These results contrast with those reported in some recent studies in aggressive lymphoma. However, the high positive predictive value raises the question about the usefulness of BMB in these PET-CT positive cases. In our opinion, with the current data, BMB should be performed in indolent NHL patients.

PB1875
Background: FL is a heterogeneous disease, and clinical presentation is highly variable. The Follicular Lymphoma International Prognostic Index (FLIPI-2) identifies prognostic factors at diagnosis but does not predict in whom and when to initiate first-line therapy (1LT). 1 Recommended therapies for 1LT vary by stage, symptomatology, and tumor burden but include monotherapy with rituximab (R) or in combination with other chemotherapies. Survival of FL patients in the R era has greatly improved, but few studies have evaluated survival outcomes in patients seen in routine clinical care.

Aims: This study aimed to evaluate survival outcomes in a US population of newly diagnosed FL patients seen in routine clinical care.

Methods: A retrospective study was conducted in which the presence of ≥1 inpatient record or ≥2 outpatient records with FL diagnosis codes were used to identify newly diagnosed FL patients from several hospitals, a large US EMR database base, between 01/01/08 and 07/31/15. The study index date was the first FL record. Patients who subsequently initiated 1LT for FL were followed from the date of treatment initiation until death, loss to follow-up, or end of study (09/30/15) for the evaluation of the survival outcomes. Median progression-free survival (PFS) (defined as initiation of second-line therapy, evidence of supportive care >30 days after the end of a line of therapy, or death), median overall survival (OS), and PFS and OS rates at 2 years following initiation of 1LT were evaluated using Kaplan-Meier analyses.

Results: 1,346 newly diagnosed FL patients who initiated 1LT met the patient selection criteria. 47.7% were male, and the mean age was 65.4 years (SD: 12.7). At baseline, 16.6% of patients had a Charlson Comorbidity Index of ≥2, and the most common comorbidities were diabetes (14.5%) and chronic pulmonary disease (11.2%). 1LT consisted of both monotherapy (38.6%) and combination therapy (61.4%). For monotherapy, R was the predominant agent used (85.1%) for 1LT induction. Bendamustine-R (43.8%) and R-CHOP (24.6%) were the most common. Kaplan-Meier analysis revealed that the 2-year OS and PFS rates (from initiation of 1LT) were 86.9% and 64.6%, respectively. Median OS was not reached, and median PFS was 48.1 months (95% confidence interval: 39.4, 58.4).

Summary/Conclusions: The 2-year OS and PFS rates in this newly diagnosed FL patient cohort who received 1LT (the majority of which was R-based) were consistent with expectations in a post-R era. Future analysis will explore the differences in clinical characteristics and survival outcomes for patients who received R monotherapy and various R-combination therapies.

RITUXIMAB MAINTENANCE AFTER R.BENDAMUSTINE FOR PATIENTS WITH UNTREATED FOLLICULAR LYMPHOMA: A REAL LIFE STUDY IN SOUTHERN ITALY ON BEHALF OF RETE EMATOLOGICA PUGLIESE
G. Tarantini1,2, S. Capalbo2, F. Angriti3, N. Cascavilla4, M. Ciminiello5, C. Sillitano6, G. Guarini6, P. Mazzaf7, N. De Renzo10, V. Pavone11,1 Dipartimento Oncoematologico ASL BT, U.O.C. di Ematologia con Trapianto ASL BT Barletta - Italy, Barletta, 2Ematologia, Foggia, 3Ematologia, Pescara, 4Ematologia, S Giovanni Rotondo, 5Ematologia, Potenza, 6Ematologia, Reggio Calabria, 7Università di Bari, Cattedra di Ematologia, 8IRRCS Oncologico Bari, Ematologia, Bari, 9Ematologia, Taranto, 10Ematologia, Lecce, 11Ematologia, Tricase, Italy

Background: Results from phase 3 "Stil" and "BRIGHT" trials demonstrated the effectiveness of the combination Bendamustine-Rituximab (BR) compared to R alone as frontline treatment and as advanced Frontline Lymphoma (FL) (Bendamustine 90 mg/m2 8days 1+2), Rituximab 375 mg/m2 every 28 days. In the "Stil" study, the response rate (RR) was 84.4%, 7 pts had partial response, 5 pts (6.1%) had stable disease, whereas 3 (3.5%) showed no response to BR and had a progressive fatal disease. All of the pts achieving remission received the full planned 2 years Rituximab maintenance treatment and, among them, 24 pts (28.9%) were administered with R over the first two years. Primary adverse events recorded were of grade 3 and 4 in 25% of cases. Infectious (grade 3-4) and neutropenia (grade 3) were the most common adverse event, no additional unexpected toxicities were observed, whereas no occurrence of secondary malignancy was registered so far.

Aims: We study the value of F-18 FDG-PET/CT for the detection of bone marrow involvement in the initial staging of newly diagnosed patients with lymphoma was reviewed in the Recommendations of Lugano Classification. They conclude that if a PET/CT is performed, a bone marrow biopsy is no longer indicated for a routine staging of Hodgkin lymphoma (HL) and most diffuse large cell lymphoma (DLBCL). Data are insufficient in follicular lymphoma (FL) and bone marrow biopsy is always recommended.

Methods: Newly diagnosed patients with HL, DLBCL and FL who underwent F-18 FDG PET/CT and bone marrow biopsy for initial staging between January 2007 and June 2016 were included. We analyze sensitivity, specificity and concordance of PET/CT compared with bone marrow biopsy. In discordant cases, we review if there was any difference in the staging.

Results: 161 patients were included, 69 DLBCL (38 male, 31 female, median age 59 years), 44 HL (24 male, 20 female, median age 32y), 48 FL (23 male, 25 female, median age 56y). Four of the 44 patients with HL had bone marrow infiltration in bone marrow biopsy (BMB+) and PET/CT detected bone marrow involvement in all of them. Patients PET/CT was positive in bone marrow biopsy in 7 of the 40 patients without bone marrow infiltration in bone marrow biopsy (BMB-), these patients had bone marrow lesions on locations other than iliac crest. Six of the 7 patients were in advanced stage regardless of bone marrow involvement and a patient had sternal involvement by contiguity. Seven of the 69 patients with DLBCL had BMB+, 6 patients with DLBCL and 1 patient. DLBCL and FL PET/CT had detected bone marrow involvement in all of them. Sixty-two patients of 69 DLCL did not have bone marrow infiltration by biopsies (BMB-), but nine of them had BMMET+. Seven of the 9 patients were in stage IV because of extranodal involvement of other organs. One patient had primary brain involvement of jaw bone and splenic involvement by contiguity. Forty-four patients of 48 patients with FL had BMB+. Of these 14 patients with bone marrow involvement by biopsy, 5 patients had BMMET+ and PET/CT could not detect another extranodal involvement in three of these five patients. Of the 34 patients without bone marrow infiltration by biopsy BMOM- 8 patients had PET/TAC+, and 6/8 could be classified in stage IV regardless of bone marrow involvement (Table 1).

Summary/Conclusions: Our series confirms that PET/CT is useful to detect bone marrow involvement in the initial staging of Hodgkin Lymphoma and DLBCL. PET/CT can avoid bone marrow biopsy in these histological variants of lymphoma. In follicular lymphoma, PET/CT did not detect more than one third of patients with bone marrow infiltration by biopsy. These results support the histological assessment of bone marrow in the initial staging of follicular lymphoma.
PB1880

PREDICTIVE FACTORS FOR INFECTIONOUS ADVERSE EVENTS IN PATIENTS WITH B-CELL NON-HODGKIN LYMPHOMA TREATED WITH BENDEMASTURINE-RITUXIMAB (BR)±R MAINTENANCE. RESULTS OF A RETROSPECTIVE ANALYSIS

A. Di Rocco1, F. De Angelis1, L. Petrucci1, F. Vozzella1, D. De Benedittis1, R. Foa1, M. Martelli1

1Department of Cellular Biotechnologies and Hematology, University of Rome Sapienza, Rome, Italy

Background: The combination of bendamustine (B) and rituximab (R) is an effective and well tolerated treatment for B-cell malignancies. However, previous reports have shown a higher incidence of lymphopenia and secondary infectious complications in patients treated with BR than in patients treated with other chemoinmunotherapy regimens.

Aims: We performed a retrospective analysis at our institution in patients treated with BR with or without R maintenance, with the aim of determining the incidence of the infectious adverse events (AEs) and of identifying potential predictors factors.

Methods: We collected data from 65 patients with B-cell non-Hodgkin lymphoma (NHL) who received at least two cycles of BR±R maintenance between 2010 and 2016 at our institution. The AEs – including neutropenia (N), neuphenic fever (NF), lymphopenia, infections episodes and the occurrence of second tumors - were recorded according to the CTCAE v4.0 grade scale. We compared the patients with or without infections occurring during the study, and evaluated what did not. Univariate analysis with Fisher’s exact test was used to evaluate the potential risk factors.

Results: The median age at the first treatment cycle was 66 years (range 36-89), 33 patients (50%) were ≥65 years, 27 (41%) were male, 53 (82%) had advanced disease and 37 (56%) had bone marrow involvement. Thirty (46%) of patients had follicular lymphoma, 17 (26%) mantle cell lymphoma, 11 (17%) marginal lymphoma, 5 (7%) diffuse large B-cell lymphoma and 4% other indolent lymphomas. Twenty three patients (49%) received BR as first line treatment, 51% as second line and above. Bendamustine was administered either at the dosage of 90 or 100 mg/sqm iv on days 1, 2 and R was administered at a dose of 375 mg/sqm iv or sc, on day 1. Therapy was administered every 4 weeks up to 6 courses. Twenty nine patients (46%) received R maintenance every 8-12 weeks for two years. The mean number of cycles administered was 5 (range 2-6), 13 patients (20%) discontinued treatment due to toxicity: 8/13 for non-hematologic toxicity. Primary or secondary G-CSF prophylaxis was adminis- tered to 25 patients (38%), while the prophylaxis with trimetopin-sulfametox- azole against Pneumocystis jiroveci pneumonia was given to all patients. Twenty two patients (34%) had at least one infection. Bacterial pneumonia was identified in 622 patients, varicella zoster virus infection in 4/22, cytomegalovirus reactivation in 2/22 and other infections in 10 patients. At univariate analysis, the infectious AEs were associated only with lymphopenia during the second cycle (p=0.043) and with neutropenia during the second, third and fourth cycle (p=0.026, p=0.003, p=0.018, respectively). No correlation with age, line of treatment and G-CSF administration was documented. Other AEs were: grade 3/4 neutropenia in 4/22, grade 3/4 lymphopenia in 37 (60%) patients. We reported also a 5% incidence of second tumors after treatment (lung cancer in 2 patients and prostate cancer in 1).

Summary/Conclusions: In our analysis, BR±R maintenance confirms a toxicity profile similar to that reported in previous experiences. According to our results, an early lymphopenia and neutropenia (after two cycles) are predictive factors for infectious AEs and for premature treatment discontinuation. Twenty% of patients discontinued treatment mostly because of the early withdrawal due to infectious complications. These data raise the question on the role of antibacterial, antiviral and primary G-CSF prophylaxis in all patients treated with BR.

PB1881

CAUSES OF DEATH OF FOLLICULAR LYMPHOMAS. MONOCENTRIC AND RETROSPECTIVE STUDY WITH A LONG PERIOD OF OBSERVATION

L. Rigiacci1, S. Kovalchuk1, F. Lancia2, G. Mannesci1, P. Bucchi1, G. Benelli1, L. Mannelli1, A. Bosi1

1Haematology, AO Careggi University of Florence, Florence, 2Oncology, Ospedale di Ferrara, 3Istituto per la Prevenzione Oncologica, ISP, Firenze, Firenze, Italy

Background: Follicular lymphomas are usually defined as incurable diseases with a natural history characterized by continuous relapses.

Aims: Our aims were to evaluate after a long observation period the causes of death during follow-up.

Methods: All patients with histologically confirmed diagnosis of follicular lymphomas grade I-II or IIIa were selected from our data base starting from January 2000 until December 2004 in such a way to have more than 10 years of observation for the patients. We considered all patients with this diagnosis regardless to treatment and considering also patients followed with watch and wait. Patients were followed with ambulatory evaluation and for those lost to follow-up consulting the regional cancer registry.

Results: One hundred and forty-six patients were diagnosed and treated at our Institution. The median age at diagnosis was 61 years (range 21-92), large I in 47 patients, III-IV in 86. Bone marrow biopsy was positive in 87 patients, FLIPI 0-1 in 40, FLIPI 2 in 48, FLIPI 3 in 40 and FLIPI 4 in 18 patients. According to treatment 98 patients were treated with antiracantane containing regimens, 34 with fludarabine containing regimens and 14 were observed or treated with rituximab only. 95 patients (85%) received R on a day 1. Eighty patients (64%) were treated with rituximab chemotherapy combined in 24; 48 patients did not use rituximab. The median observation period for alive patients was 13,4 years (range 11-15 years) and 8 years (range 0,09-15 years) for dead patients. Sixty-five patients dead during this long period of observation and the causes were: 35 due to lymphoma pro-gression (50%), 16 second neoplasms (25%), 12 other disease (18%), 1 car accident and 1 unknown. The overall survival with a median period of obser- vation of 127 months (range 2-196) was 71%. In univariate analysis the best overall survival was statistically associated with low FLIPI score, the use of Rituximab and the obtainment of complete remission. In multivariate analysis by Cox model the obtainment of complete remission maintained the significance. Exactly the same results were observed if we considered the cause specific mortality.

Summary/Conclusions: In conclusion this retrospective monocentric study confirms that after a long follow-up period about half patients died of lymphoma and the other half died for complications related to therapy or to lack of immunolo- gical control (second neoplasm or other diseases). Follicular lymphoma con- firms to be a good prognosis lymphoproliferative disorders and in the long observation period of patients clinicians must have maintained a careful evalua- tion of concomitant pathologies.

INDOLENT NON-HODGKIN LYMPHOMA AND RISK OF TRANSFORMATION TO AGGRESSIVE LYMPHOMA: A SINGLE JORDANIAN CENTER EXPERIENCE

D. Zahren1, M. Ayesh (Haj Yousef)1, T. Kewan1, S. Al Bashir2

1Internal Medicine, 2Pathology, King Abdullah University Hospital (KAUH), Irbid, Jordan

Background: Indolent Non Hodgkin Lymphomas (INHL) are slow growing lymphomas that usually arise from B-cells. They are characterized by slow appearance and progression of symptoms compared to aggressive non Hodgkin lym- phoma (NHL) namely Diffuse large B-cell Lymphoma (DLBL). Small percentage of INHL might transform to aggressive NHL.

Aims: We aim to describe the clinical characteristics, prognosis and risk of transformation to aggressive lymphoma in patients with INHL in North Jordan as a model for other Middle East countries in which such data is lacking.

Methods: All patients diagnosed with INHL between Jan 2003 to Jan 2017 were retrospectively reviewed. Clinical and laboratory data at time of diagnosis including gender, age, lactate dehydrogenase level (LDH), pathological sub- type, histological grade (IGC, FL, MCL) were documented. Extranaodal involvement was confirmed either by histopathological studies or CT and PET/CT scan. Transfor- mation to aggressive lymphoma was confirmed by histopathological studies. Patients were followed and overall survival rate was calculated. Mean survival times were calculated using Kaplan-Meier method.

Results: A total of 428 patients were diagnosed with INHL. Among these 88 patients (33.20%) confirmed to have INHL 54 patients (61.4%) were males and 34 patients (38.6%) were females. Their ages at diagnosis ranged from 29-83 years with a mean (SD) of 59.26 (12.39). Among these patients, 45 patients (51.1%) had small lymphocytic lymphoma / chronic lymphocytic leukemia (CLL), 20 patients (22.7%) had follicular lymphoma (FL), 15 patients (17%) had marginal zone lymphoma (MZL), 6 patients (6.8%) had mantle cell lymphoma (MCL) and 2 patients (.78%) had unspecified INHL. Mean age of MZL (53.2 years) and FL (55.3 years) were significantly lower than mean age of MCL (58 years) and CLL (62.77 years). 22 patients (23.9%) had extra nodal involvement. There was significant association between INHL subtypes and transformation to aggressive NHL. (P-value=0.001). 60% of patients with MZL, 50% of patients with MCL, 20% of patients with FL and 8.9% of patients with CLL had extranodal sites involvement. (P-value=0.004). There was no significant association between mean age and mean albumin level with risk of transformation to DLBL. The overall survival rate was 56.8%. 10 years and 5 years survival rates were 47% and 60% respec- tively. Mean survival time in patients with MCL (31.8 months) was significantly lower than mean survival time in patients with follicular (85.48 months), MZL (90.6 months) and CLL (103.6 months) patients , (P-value=0.0004). There was type of NHL and extranodal sites involvement with transformation to DLBL. The distribution difference between patients who transformed and patients who didn’t transform to DLBL.

Summary/Conclusions: Prevalence of INHL among patients with NHL in North Jordan is 33.2%. The most common INHL subtypes in our patients were
CLL (51.1%) and FL (20.7%). These findings are significantly different from Saudi Arabia and Western Countries in which FL is the most common subtype. FL and CLL are associated with higher risk of transformation to DLBCL. High LDH level is considered a risk factor for transformation to DLBCL in our patients. MCL is associated with significantly lower mean survival time than other INHL subtypes.

PB1883

OCULAR ADNEXAL LOW GRADE LYMPHOMA TREATMENT OUTCOMES AND LONG TERM FOLLOW UP: A SINGLE CENTRE EXPERIENCE

N. Elmusharaf1,*, C. Bloodworth1, B. Skippen2, M. Hourihan3, T. Parmar2, D. Morris3, C. Lane3, C. Rowntree1

1Haematology, 2Ophthalmology, 3Radiology, University Hospital of Wales, Cardiff, United Kingdom

Background: Ocular adnexal lymphoma (OAL) accounts for 1-2% of Non-Hodgkin Lymphomas (NHL) and 8% of all extra-nodal sites. The majority of cases, >95%, are of B cell origin and 80% are low grade lymphomas. Secondary ocular involvement occurs in approximately 2.4-5.3% of patients with advanced systemic NHL. Marginal zone lymphoma or mucosa-associated lymphoid tissue (MALT) lymphoma is reported in approximately 50% of patients. Current treatment options for low grade OAL include radiotherapy and chemotherapy. Chlamydia Psittaci DNA has been reported in up to 80% of tumor biopsies from patients with OAL suggesting a possible value of anti-Chlamydia Psittaci antibiotic therapy.

Aims: To report a single centre’s experience in the outcomes of patients diagnosed with OAL over a 13 year period.

Methods: A Retrospective cohort of patients with low grade OAL treated in a single Centre between 2003 and 2016 was analyzed. Chemotherapy was the first choice of therapy until 2008, afterwards radiotherapy became the first line treatment for OAL.

Results: A total of 20 patients with OAL were identified. 60% (12/20) of patients were females with a median age of 61.5 years (range 45-85 years). 80% (16/20) had unilateral disease at presentation. MALT lymphomas comprised 75% (15/20), Follicular NHL 15% and CLL/SLL 10%. Only 10% (2/20) had a prior diagnosis of NHL. At presentation 20% (4/20) had evidence of systemic involvement: 19% (3/16) had bone marrow involvement and 1 patient had small volume lymphadenopathy on CT scan. 45% (9/20) were treated with first line chemotherapy, single agent Chlorambucil in 78% (7/9) of patients. A total of 5/9 had disease control with minimal long term side effects but 2/9 relapsed, 3/5 local recurrence and 2/5 extra-ocular relapse. 3 patients experienced ≥2 relapses, 2 patients had disease transformation to high grade and 1 patient subsequently died as a consequence of their disease. 33% (2/6) patients treated with radiotherapy experienced disease recurrence, mainly extra-ocular and 50% (3/6) suffered complications following radiotherapy in the form of dry eyes and cataracts. Median follow up was 9.5 years (range 1-14 years). Overall survival was 95% (19/20) with an event free survival of 65% (13/20) (Table 1).

Table 1. Summary of the management modalities of ocular adnexal low grade non-Hodgkin lymphoma.

Summary/Conclusions: The majority of patients in our cohort had favorable outcomes. Currently there is no national guideline for the management of OAL in the UK. Several treatment options exist including chemotherapy, radiotherapy, immunotherapy, observation or more recently the use of eradication treatment for Chlamydia Psittaci. Factors to consider when choosing a treatment include a patient’s co-morbidities, risk of visual impairment, need for systemic therapy, histological diagnosis and anticipated side effects. As treatments are so effective the long term consequences and possible late effects need to be acknowledged and avoided if at all possible. Observation is an acceptable approach in asymptomatic patients when there is no immediate risk of visual impairment. Radiotherapy is an effective first line treatment in symptomatic patients localized OAL. The exact role of radiotherapy in achieving disease control with minimal long term side effects is yet to be determined. Reviews with larger number of patients are needed to inform a practical approach to the management of OAL.

PB1884

AGE AS A POTENTIAL NOVEL PROGNOSTIC INDICATOR IN PRIMARY CUTANEOUS B-CELL LYMPHOMA

F. Desai1,2,*, M. Van den Bergh3,4, H. Zhang2, X. Zhang2, B. Schaible6, Z. Ma6, L. Sokol7

1Internal Medicine, University of South Florida, 2Internal Medicine, 3Hematology and Oncology, H. Lee Moffitt Cancer Center and Research Institute, 4Hematology and Oncology, University of South Florida, 5Oncologic Sciences, Pathology, and Cell Biology, BioStatistics and Bioinformatics, 6Malgratnik Hematology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, United States

Background: Primary Cutaneous B-Cell Lymphoma (PCBCL) comprises a rare group of cutaneous Non-Hodgkin’s lymphomas (NHLs) with an estimated annual incidence of 2.5 per 1,000,000 persons. They usually present with papules or nodules on the head, trunk, and/or extremities. The International Society for Cutaneous Lymphoma (ISCL) and the European Organization for Research and Treatment of Cancer (EORTC) developed a new way to classify PCBCL into three different subtypes. Indolent subtypes include Primary Cutaneous Marginal Zone Lymphoma (PCMZL) and Primary Cutaneous Follicular Center Lymphoma (PCFCL). Primary Cutaneous Diffuse Large B-Cell Lymphoma (PCDCLBL) is an aggressive subtype with a fatality rate of 50%. The Cutaneous Lymphoma International Prognostic Index (CLIPi) can risk stratify indolent subtypes, but criteria do not include age. Here we present our single institution analysis of clinicopathological features and outcomes of patients with PCBCL.

Aims: To analyze clinical and laboratory characteristics such as age, lesion characteristics, hematological parameters, and treatment modalities in order to determine their impact on progression free survival (PFS) in PCBCL.

Methods: This is a retrospective study of patients treated at the Moffitt Cancer Center between January 1990 and December 2016. Patients were identified using our PCBCL database and diagnosis was verified by independent hematopathologists and dermatopathologists. Staging was determined according to ISCL/EORTC recommendations. Demographics, lymphoma subtype, staging, disease course, and CLIPi scores were collected. Kruskal Wallis ANOVA and Fisher’s Exact tests were used to compare differences among the four subtypes for continuous and categorical variables, respectively. Kaplan Meier curves were produced to estimate PFS for different strata, and differences among the strata were tested using the log-rank test.

Results: We identified 37 patients who met diagnostic criteria for PCBCL (35% PCFCL, 40.5% PMZL, 13.5% PCDCLBL, and 11% indolent, unspecified). Male:female ratio was 2.4:1. 51% of patients were >60 years old (yo) and 49% were <60 yo. 94% had stage T1 disease, 27% T2, and 19% T3. Median PFS for patients >60 was 1.1 years, but was not reached for those <60. Mean follow-up time was 2.6 years for all patients. Log rank test showed a statistically significant difference in PFS between the two age groups (p=0.01). This was consistent when comparing PFS by age in both high (PCDCLBL) and low grade (indolent) subtypes. PFS according to stage in indolent subtypes showed a marginally statistically significant difference (p<0.06). Stratification of patients according to CLIPi did not show a significant difference in PFS among indolent subtypes.

Summary/Conclusions: We found that age is a highly statistically significant prognostic parameter in PCBCL, as patients >60 years old had a longer PFS compared to younger patients, even after adjusting for stage and CLIPi. This is an interesting finding as most NHL studies demonstrated a negative impact of advanced age on PFS. Our results suggested that age is a possible novel prognostic indicator in patients with PCBCL, however validation on a larger sample set is needed.

PB1885

EPIDEMIOLOGY, CHARACTERIZATION AND THERAPEUTIC MANAGEMENT OF MARGINAL ZONE LYMPHOMA: A SINGLE-CENTER EXPERIENCE

C. De Miguel1,*, B. Navarro1, J. Martín2, P. Martín2, R. Forés1, C. Bellas2, J.R. Cabrera1

1Hematology, 2Pathology, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain

Background: Marginal zone lymphomas are a group of relatively uncommon lymphomas whose cells are derived from B lymphocytes of the “marginal zone” of the secondary lymphoid follicles.

Aims: The objective of this study is to review our series evaluating the epidemiology, clinical presentation, morphological, immunohistochemical and molecular characterization and therapeutic management in a tertiary hospital.

Methods: We evaluated a total of 56 patients diagnosed between May 2008 and February 2017. We collected the epidemiological and clinical data, including location, clinical stage, FLIPI and associated risk, antigenic stimulus, symptomatic behavior, distribution of nodal and extranodal sites, and response to treatment. We reviewed the levels of LDH, beta2microglobulin, ER, serosal blood (PB) immunophenotype and studied the morphological, immunohistochemical and molecular characteristics (MALT1 translocation and

PB1886

haematologica | 2017; 102(s2) | 753

Madrid, Spain, June 22 – 25, 2017
immunoglobulin heavy chain rearrangement (CDR2 / CDR3 of IgH) in PB, bone marrow and affected organs. All diagnoses were classified according to WHO (2016 revision). In addition, we performed an autonomy test in most patients.

Results: Among the 56 patients, 26 were men (46.4%) and 30 women. The median age at diagnosis was 64 years (37-92). The most frequent subtype was mantle zone lymphoma (17 patients, 30.4%), followed by MALT: 10 pulmonary (17.9%), 10 gastric (17.9%), 5 cutaneous (8.9%), 5 O RL (8.9%), 2 (3.6%), 1 hepatic, 1 thyroid and 1 lacrimal gland (1.8%) and nodal marginal zone lymphoma (3 patients, 5.4%). Five of them presented with multifocal disease (8.9%). Fifty percent (28) had a clinical stage III / IV and 32 patients (57.1%) had a low risk of diagnosis (FLIPI 0-1). We found an antigenic stimulus in 11 patients (Helicobacter pylori, Sjögren’s syndrome, Hashimoto’s thyroiditis). The molecular study of MALT1 was performed in 25 patients and 3 presented the translocation (12%). Six of seventeen cases (35.3%) showed IgH rearrangements. Antinuclear antibodies were positive in 15 of 32 patients (46.9%). Of 32 patients, 82% (26) received some treatment and 36 achieved a complete remission (CR) (76.1%) and 10 partial remission (PR) (21.7%) after the first line of treatment. Among these, 17 received immunochemotherapy (37%), 10 immunotherapy (21.7%), 8 surgery (17.4%), 7 antibiotics (15.2%) and 4 radiotherapy (8.7%). We observed 7 relapses (16.7%), 3 patients (7.1%) achieved a CR in 7 (70%) and PR in 3 (30%) after rescue treatment. There was just one case of high grade transformation (1.8%), who was the only patient deceased in the series (1.8%), with a median follow-up of 70 months.

Summary/Conclusions: Marginal zone lymphoma is an indolent lymphoma, with a good prognosis and very good response to current therapy. It is sometimes associated with autoimmune phenomena and infectious agents. It is essential a correct staging and characterization to optimize its therapeutic management and outcome.

PB1886

HAIRY CELL LEUKEMIA AND B-RAF MUTATIONS
A. Olguin1, Y. Baskın2, S. Solmaz Meden3, I. Alacacioglu1, M. Akbapour2, T. Uysal2, O. Birge1, S. Ozkal4, H. Elidokuz2, M.A. Ozcak1.
1Dokuz Eylul University Hematology Dept., 2Dokuz Eylul University Oncology Institute, 3Bozyaka Training and Research Hospital, 4Dokuz Eylul University Pathology Dept., Izmir, Turkey

Background: Hairy cell leukemia(HCL) is a B cell lymphoproliferative disorder, presenting with splenomegaly, hepatomegaly and bone marrow infiltration. HCL accounts for 4-5% of non-Hodgkin lymphomas, more commonly seen in man. Diagnosis is based on the examination of peripheral blood smear, flow cytomtery and the bone marrow aspiration-biopsy. Recently, B-RAFV600E mutation was demonstrated in 10% of Tiacci HCL case series.

Aims: Aim of our study is to investigate the frequency of B-RAFV600Emutation and other rare mutations of B-RAF (B-RAFG464E, B-RAFG466E, B-RAFG469V) and their relation with clinical data and treatment responses.

Methods: Charts of 13 patients diagnosed with HCL were analyzed retrospectively. Patients’ clinical parameters were evaluated. HCL variant type patients were excluded. Paraffin blocks of spleen or bone marrow tissues are obtained from the pathology archives. One thin section (10 micron) of bone marrow or three sections of spleen are cut and DNA extracted by spin column technique, using DNA extraction kit. (QiAmp DNA FFPE Tissue Kit, Qiagen) After spectrophotometric measurement of DNA; common and uncommon mutations of B-RAF were investigated. (Qiagen PyroMark Q24 system, Therascreen BRAF Pyrokit 24, V1 (1/2) kit) Mutation and clinical data analysis were conducted using the SPSS 15.0 software. The study was approved by the local ethics board of Dokuz Eylul University.

Results: Male/female ratio was 9/4. Median age at diagnosis was 48 (37-59). Median follow-up time was 59 (3-96) months. At the time of diagnosis, 46.2% (n=6) of patients were asymptomatic. All of the patients had splenomegaly (96%), 30% liver involvement and 26% bone marrow involvement. Approximately half of the patients (%46.2) diagnosed with splenectomy. Only one patient was pancyctopenic at diagnosis. Four patients were anemic (Hemoglobin<10 gr/dL), six were thrombocytopenic (Platelets<150000/µl). Leucopenia was seen in 84.8% (n=11) of the patients). Monocytopenia was commonly seen in HCL was detected in 61.5%. One of the patients was diagnosed and treated due to Mantle cell lymphoma (MCL) a year ago and found in remission for both MCL and HCL; one was diagnosed Kaposi carcoma just before the diagnosis of HCL and lost in follow-up. Twelve patients were hospitalized and treated with one cycle of chemotherapy (the mean day IV for 7 days). One of these patients received SC IFNa at a dose of 4.5 mg/IV day prior to cladrribin therapy. Treatment responses could be evaluated in eleven patients and all of the patients gained CR. Survival analysis couldn’t be determined due to non of the patients had progressed or died. B-RAFV600E mutation was positive in 10 (76.9%) patients. Three (%23%) of the patients had B-RAF 464-469 codon mutations, and two had B-RAF G464E, one B-RAF G466E, one B-RAF G469E. Two patients were positive for both mutations. No relation could be determined between clinical findings and mutation state.

Summary/Conclusions: B-Raf mutations are variable and common mutations in HCL patients. B-RAFV600E mutation could be a supportive test for the diagnosis of HCL due to high incidence of mutation. Also it can be used as an indicator for patient selection that are appropriate for target therapies.

PB1887

BENDAMUSTINE-RITUXIMAB IN PATIENTS WITH RELAPSED FOLLICULAR LYMPHOMA PREVIOUSLY EXPOSED TO RITUXIMAB.

E. Gonzalez1,*, L. Diaz1, M. J. Macias1, V. Diaz1, I. Villanego1, S. Garduño1, C. Salas1, L. Gutierrez1, J. Jaen1.
1Radiation Oncology, H.U. Puerta del Mar, Cadiz, Spain

Background: Follicular lymphoma (FL) is characterized by a course of relapses and increasingly shorter responses to the consecutive treatments. In first relapse after immunochemotherapy, in patients who are not considered refractory to rituximab, there is no standard treatment. In Spain, bendamustine in association with rituximab (BR) has not been approved for the indication of FL; nevertheless this combination has shown high efficacy and excellent tolerance in patients previously treated with and without rituximab.

Aims: To evaluate the efficacy and safety of the bendamustine-rituximab association in a group of patients with follicular lymphoma previously exposed to rituximab.

Methods: Retrospective analysis of patients with relapsed FL treated with BR in 7 spanish hospitals on behalf of the Spanish Lymphoma Group (GELTAMO). The study was approved by the reference Ethic Committee and by all of the participating centres. All patients acceded to the treatment through the compassionate use program.

Results: 41 patients were valid for analysis. Characteristics: 70% males with a mean age of 62 years (30-87). ECOGs 2 in 95% of cases, 73.2% in stages III-IV and FLIPI ≥3 in 48%. Bulk mass in 13% of patients, LDH and β2-microglobulin increased by 12% and 41.2% respectively and bone marrow involvement in 60% (68%) had received only one previous treatment, with an average of 1.7 (1-5) and the most frequent was CHOP-R in 66% followed by CVP-R in 11%. All patients had previously received rituximab and only 3 patients (7.3%) could be considered refractory. All patients received BR (B-90 mg / m2 D1-2, R-375mg / m2 D1). Median cycles 5.1 (1-8). Support with GS-CSF was used in 27.5% of cycles. Maintenance with rituximab after obtaining a complete (CR) or partial remission (PR) was administered in 42% of patients. Response: The overall response rate was 95.1% (65.8% CR-IR / 29.3% PR). With a median follow-up of 25 months (6-92) the median response duration was 41.9 months (32.8-51.1) and the median progression-free survival (PFS) was 57 months (27.4-86.5) with no impact neither by the number of previous treatments (1 vs 2) (P=0.69) nor by the age (<70 vs ≥70) (P=0.9). Patients who received maintenance with rituximab after BR had a significantly longer median PFS than without (NR vs 32) (p=0.004). Toxicity: No treatment-related death was recorded. 42% and 36.6% of the patients presented G3-4 neutropenia and G3-4 mucositis respectively, although all were可控. 43% received cotrimoxazole prophylaxis and 3 opportunistic infections were recorded (1 P. jirovecii pneumonia in a patient without prophylaxis).

Summary/Conclusions: BR has a high efficacy and a good safety profile in this series of patients with relapsed FL previously exposed to rituximab. The number of previous treatments (1 vs ≥2) and the age had no impact in the results.

PB1888

USE OF RADIATION THERAPY FOR THE TREATMENT OF GASTRIC MALT LYMPHOMA

E. Gonzalez1, L. Diaz1, M. J. Macias1, V. Diaz1, I. Villanego1, S. Garduño1, C. Salas1, L. Gutierrez1, J. Jaen1.
1Radiation Oncology, H.U. Puerta del Mar, Cadiz, Spain

Background: Gastric mucosa-associated lymphoid tissue (MALT) lymphoma is a rare disease however, the incidence is increasing and closely associated with helicobacter pylori (HP) infection. One choice of treatment of gastric MALT lymphoma refractory to HP sterilization is radiotherapy. Aims: Our aim was to analyze the response to treatment with definitive radiotherapy in our department.

Methods: Between January 2014 and January 2017, 8 patients with gastric MALT lymphoma were treated with eradication therapy of HP, followed by definitive radiotherapy. The average total dose was of 38 Gy to the stomach in a once-daily schedule. Follow-up included computed tomography scan and
endoscopy with biopsies at regular intervals. The median follow-up was 14 months.

Results: In all patients we got complete responses (CR) with no tumor detectable by endoscopy or biopsy after initial treatment, but after 2 years one of them relapsed and required immunochemotherapy. The most common acute toxicities were fatigue and nausea, in our patients. In any case late toxicities were observed. The overall survival was 100% after 2 years.

Summary/Conclusions: In selected patients who are not responsive to HP sterilization, definitive radiotherapy can be an efficient therapy with tolerable complications, preservation of stomach and sustained response over time.

Infectious diseases, supportive care

PB1889

USE OF LIPEGFILGRASTIM IN CLINICAL PRACTICE FOR THE PROPHYLAXIS OF CHEMOTHERAPY-INDUCED NEUTROPENIA IN LYMPHOMA PATIENTS: INTERIM RESULTS OF A PAN-EUROPEAN NON-INTERVENTIONAL STUDY

N. Cascavilla1,2, T. Wrobel2, E. Hatzimichael2, E. Wojciechowska-Lampka2, P. Mazz2, K. Kargar2, M. Lenzhofer7
1Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy, 2Wrocław Medical University, Wroclaw, Poland, 3University Hospital of Ioannina, Ioannina, Greece, 4MSC Cancer Center and Institute, Warsaw, Poland, 5SS Annunziata Hospital, Taranto, Italy, 6Hospital Center of Wallonie Picarde, Tournai, Belgium, 7Schwarzach Hospital, Schwarzach im Pongau, Austria

Background: Lipegfilgrastim (Lonquex®) is a long-acting fixed-dose glycopeylated granulocyte colony-stimulating factor administered once per chemotherapy cycle. It has been available in Europe since 2013. It was proven to be non-inferior with regard to duration of severe neutropenia compared with pegfilgrastim in breast cancer patients. However, data in patients with hematological malignancies are limited.

Aims: We aimed to evaluate the effectiveness of ligeprafilgrastim in the cycle following the first ligeprafilgrastim-supported treatment cycle in lymphoma patients.

Methods: This is a prospective observational cohort study. Patients with different tumor types treated with cytotoxic chemotherapy (CT) who received ligeprafilgrastim in primary prophylaxis (PP) or secondary prophylaxis (SP) are being included in this study. CT dose modifications and neutropenia-related events are recorded and analyzed. Evaluation of effectiveness in the cycle following the first ligeprafilgrastim-supported CT cycle in a lymphoma subpopulation is presented here.

Results: At the time of the interim analysis (December 2016), 249 patients diagnosed with lymphoma have been included. Mean age-standard deviation of lymphoma patients was 61.6±15.6 years and 56.6% were male. For the majority of patients (81.1%), intended use of ligeprafilgrastim was in PP. Exposure to ligeprafilgrastim has been documented for 228 patients with an average of 4.76 cycles per patient. Data on CT dose modifications and neutropenic events following the first ligeprafilgrastim-supported cycle were available for 144 and 167 patients, respectively. CT dose was never omitted. CT dose delays were observed in 8.0% (PP) and 18.8% (SP) of patients and CT dose reductions in 4.5% (PP) and 12.5% (SP) of patients. In the first ligeprafilgrastim-supported cycle, febrile neutropenia was recorded in 4.5% (PP) and 3.0% (SP) of patients; severe neutropenia was recorded in 7.5% (PP) and 9.1% (SP) of patients. Throughout the treatment, 22 (9.6%) patients exposed to ligeprafilgrastim reported at least 1 adverse drug reaction (ADR). The most common ADRs were myalgia and musculoskeletal pain. Serious ADRs were reported by 11 (4.8%) patients.

Summary/Conclusions: Lipegfilgrastim is effective and well tolerated in the real-world setting in lymphoma patients, administered either in PP or SP. The results suggest that ligeprafilgrastim administered in PP might give better outcomes in terms of dose delays and dose reductions than when administered in SP.

PB1890

TUBERCULOSIS IN ACUTE LEUKEMIA: AN ANALYSIS OF CLINICAL CHARACTERISTICS AND IMPACT ON MANAGEMENT IN 25 PATIENTS

C. Singh1,2, A. Jain2, G. Prakash2, P. Malhotra2, S. Varma1
1Internal Medicine, 2Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh, India, Chandigarh, India

Background: Patients with acute leukemia represent an immune-compromised population, with innate, humoral and cellular immune paresis. These patients are thus at high risk of development of new infections and reactivation of chronic infections. Despite the high prevalence of tuberculosis in the general population in endemic countries, it is rarely suspected and diagnosed in patients with acute leukemia.

Aims: To study the clinical manifestations of tuberculosis in patients with acute leukemia, as well as the impact of infection in the management of leukemia.

Methods: A hospital database search was done to identify cases of acute leukemia and tuberculosis between a study duration of January 2013 to January 2017. All the medical records of the identified cases were retrieved from the central records department. A systemic analysis of characteristics pertaining to acute leukemia, treatment regimen, chemotherapy response, site of tubercular infection, mode of diagnosis and treatment response to anti-tuberculous therapy was conducted.

Results: A total of 25 patients with acute leukemia were identified who were also diagnosed with tuberculosis. 10 patients had Acute Myeloid Leukemia, 7 had Acute Promyelocytic Leukemia, 5 had Acute Lymphoblastic Leukemia, 2 had Mixed Phenotypic Leukemia while 1 had Myeloid Sarcoma. The mean interval between diagnosis of tuberculosis and acute leukemia was 37.2 weeks, with 2 patients being diagnosed after completion of therapy of acute leukemia.
and one patient was diagnosed post mortem. The most common organ involved was the lung, which was seen in 80% of patients and 20% of patients had disseminated tuberculosis. The development of tubercular infection led to alteration of therapy for the acute leukemia in 24% of cases, while it was postponed in 44% of cases. In particular, hypomethylating agents were used successfully in two patients with AML as bridge therapy to high dose chemotherapy. 76% of patients were cured of tuberculosis with effective combination therapy while 1 patient expired due to tuberculosis and 3 patients could not receive adequate therapy for tuberculosis. 3 patients went on to undergo HSCT post treatment for tuberculosis, and none had a flare of the disease post transplant.

**Summary/Conclusions:** The presence of tuberculosis infection in patients of acute leukemia has an impact on the overall management of the patient and strategies such as utilization of hypomethylating agents as bridge therapy may help in successful management of the leukemia. A high index of suspicion is required to suspect and diagnose the presence of tuberculosis as the manifestations are more commonly attributed to fungal infections or to the leukemia per se. These patients usually have a failure of empirical antibiotic therapy and the presence of tuberculosis infection does not forego treatment options such as HSCT or high dose chemotherapy for these patients.

**Figure 1.**

**Summary/Conclusions:** - Current antimicrobial resistance, especially concerning G- in our study, is particularly worrisome due to development of resistance to all available antimicrobial agents. The incidence of multi-resistant G+ is not very high. - Clinical presentation in MRB infections is more serious in our experience, and the mortality doubles in relation to the difficulty to establish appropriate treatment. - Severity sings at infection diagnosis in MRB carriers had led us to a change of empirical antibiotic therapy. - As reported in previous literature, prevention of transmission, a quick establishment of diagnosis and an effective treatment, along with a correct and limited use of antibiotic therapy could decrease the development of MRB.
Overall mortality rate was 46.9%. The mortality for hematologic cancer was septic shock (17.8%) were the most frequent indications for ICU admissions.

**Results:**

excluding scheduled perioperative admissions, the records of 81 admissions <21 years old between May, 2004 and Aug, 2016 at Chonnam National University Hospital were reviewed retrospectively.

**Aims:**

that result in admissions to the intensive care unit (ICU).

**Background:**

the utility of bone marrow biopsy trephine (BMT) as a diagnostic tool in patients with fever of unknown origin (FUO) is a subject of controversy and debate. BMT has been shown to be safe and useful in patients with HIV/AIDS but its value in immunocompetent patients has not been sufficiently assessed. It's reported the use of diagnostic BMT as a rapid decision-making tool in patients with HIV/AIDS and FUO in the proper clinical setting. A BMT demonstrated infection-related evidence prior to positive bone marrow culture in 75% of cases. Special stains and blood cultures had similar diagnostic yield, but BMT offers faster results. Thus, this procedure assists in clinical decision-making and the refinement of treatment in a more timely manner.

**Methods:**

We reviewed retrospectively the bone marrow biopsy results of the patients who underwent BMT from January 2010, to December 2016. Demographic, laboratory, diagnostic and outcome data were collected and retrospectively analyzed. We identified 31 patients who fulfilled the accepted classic Petersdorf criteria for FUO. The cohort included immunocompromise and immunocompetent patients.

**Results:**

The BMT contributes to the diagnosis in only four cases (12.9%). In two patients (6%) the histology revealed the presence of granuloma and/or lymphohistiocytic aggregates; one secondary hemophagocytosis (3.2%) and one mastocytosis infiltrate (3.2%). Six patients had a previous diagnosis of HIV/AIDS (19%). Sub analysis in HIV/AIDS patients revealed positive BMT culture in 2 of the patients (6.4%). Cultures demonstrated Mycobacterium tuberculosis and Mycobacterium avium intracellulare. There was one case in which a pathogen was grown in culture but that had a negative of 'direct examination'. The associations most likely related factor to contribute to the diagnosis in HIV/AIDS was male predominance (58% odds ratio [OR] 2.95; 95% CI, 1.19-4.25), clinical lymphadenopathy (OR 4.97; 95% CI, 1.90-2.44) or anemia (OR, 2.21; 95% CI, 1.26-3.84). Reactive myeloid hyperplasia was represented 15 cases (48%). Non-hematological diagnosis (lymphoma, Leukemia) was made on the exclusive bases of biopsy results.

**Summary/Conclusions:**

Bone marrow examination is an integral part of investigation of FUO, however, morphological finding alone would not be sufficient to ascertain the diagnosis. In present study only two cases of established infections were found. Both were present in HIV/AIDS. These results are explained because a highly active antiretroviral therapy has reduced incidence of opportunistic infections. The percent of opportunistic infections diagnosed by BMT was very low and did not justify an invasive procedure. The presence of granulomas in trephine biopsy incriminates non-hematological diagnosis in these patients. Bone marrow biopsy is still a useful ancillary procedure for establishing the diagnosis of FUO, only if used in the adequate context.

**PB1894**

THE OUTCOME OF PEDIATRIC CANCER PATIENTS ADMITTED TO THE INTENSIVE CARE UNIT OF A TERTIARY HOSPITAL IN Gwangju-chonnam, KOREA

H. Kook1, G. Kim1, J.-S. Choi1, H.-J. Cho1, H.-J. Baek1

1Pediatrics, Chonnam National University Hwasun Hospital, Hwasun-gun, Korea, Republic Of

**Background:**

Recent advances in supportive care have considerably improved the prognosis of pediatric cancer patients. However, the use of aggressive cancer treatment is also associated with complications and life-threatening events that result in admissions to the intensive care unit (ICU).

**Aims:**

To determine the utility of bone marrow biopsies in ICU patients.

**Methods:**

A retrospective analysis of 84 ICU admissions of cancer patients <21 years old between May, 2004 and Aug, 2016 at Chonnam National University Hospital (CNUNH) was undertaken. The risk factors for short-term outcome (survival at the time of discharge from the ICU) were analyzed. After excluding scheduled peripoperative admissions, the records of 81 admissions (75 patients) were reviewed.

**Results:**

Hematologic cancer patients represented 71.6% of admissions. The mean duration of ICU stay was 10.7 days. Respiratory failure (39.5%) and septic shock (17.8%) were the most frequent indications for ICU admissions. Overall mortality rate was 46.9%. The mortality for hematologic cancer was 51.7% as compared to 34.8% for solid cancer (P<0.05). Mortality for individual indication was as follows: bleeding, 66.7%; respiratory failure, 59.4%; systemic infection 57.5%, anterior mediastinal syndrome, 50%, neurologic disorders, 37.5%, renal disorder, 37.5%, and so on. ICU mortality after hematopoietic stem cell transplantation was 66.7%, mostly within 100 days post-transplant. The median Pediatric Risk of Mortality Score (PRISM) III score of survivors was lower than that of non-survivors (11.3±5.1 vs 19.9±10.9, P<0.001). The mortality rates were 70.3% and 27.3% in patients with high (>15 points) and low (<15 points) PRISM III score, respectively (P<0.001). Mortality rate was significantly related to the presence and number of organ system dysfunction (P<0.01 and P<0.001, respectively), positive inotropic support (P<0.01), and mechanical ventilation (P<0.001). By using multivariate logistic regressions, the independent risk factors were mechanical ventilation (OR, 8.0; 95% CI, 1.7-73.1; P<0.01), and 3 or 3 organ system dysfunction (OR, 18.5; 95% CI, 4.4-77.0; P<0.001). Hematologic cancer patients had higher mean PRISM3 score (16.6±4.9 vs 12.2±8.6; P=0.51) and higher risk of sepsis (39.3% vs 13.0%; P<0.05) compared to solid organ malignancies.

**Summary/Conclusions:**

These results revealed the current status of ICU care for pediatric cancer patients in a tertiary hospital in Korea. Further improvement of supportive care and earlier effective intervention should be translated in gradual reduction in mortality rate in these population.

**PB1895**

EFFICACY AND SAFETY OF TIGECYCLINE IN FEBRILE NEUTROPENIC PATIENTS WITH HEMATOLOGIC MALIGNANCIES AND CARBAPENEM RESISTANCE: A MULTICENTRE RETROSPECTIVE STUDY FROM CHINESE PEOPLE

X. Bing1, H. Long2, C. Guoshu3, L. Zhifeng1, S. Pengcheng2, G. Xutao4, W. Yamin1, L. Jie2, L. Jiaobao2, Z. Yong1

1The First Affiliated Hospital of Xiamen University, Xiamen, 2Nanfang Hospital, Southern Medical University, Guangzhou, 3Huizhou Municipal Central Hospital, Huizhou, 4Nanfang Hospital, Southern Medical University, Xianmen, China

**Background:**

Tigecycline has broad spectrum activity against multidrug-resistant (MDR) bacteria, but few investigations of tigecycline in febrile neutropenic (FN) patients with malignancy are available.

**Aims:**

This study attempts to investigate the efficacy and safety of tigecycline in FN and carbapenem resistant patients with hematologic malignancies.

**Methods:**

The study of 109 patients with hematologic diseases and FN were retrospectively analyzed. They are unresponsive to carbapenems for 3~5 days before receiving tigecycline (loading dose 100 mg; then 50 mg every 12 hours). Clinical response to treatment was defined as clinical cure, improvement or failure. Meanwhile, the adverse events were documented.

**Results:**

The median duration of neutropenia was 15 days (ranged from 1 to 83d). Out of 109 patients, 96 (88.1%) had respiratory infection, while 33 (30.3%) had bloodstream infection. The total response rate of tigecycline was 65.1%. The bacterial eradication rates and bacterial pathological eradication were 25.9% and 24.1%, respectively. The clinical effective rate was 85.7% when tigecycline was administered for more than 9 days, while just 48.3% when administered for less than 9 days (p<0.001). Patients with bloodstream infection got a worse efficacy than those without (41.2% vs 69.6%; p=0.024). For patients whose absolute neutrophil counts were less than 0.1×10⁹/L, the clinical effective result was 68.8% vs 86.4% (p=0.019). The side-effects were well tolerated. No lethal adverse events were observed.

**Summary/Conclusions:**

Our results demonstrated tigecycline was effective and safe for patients unresponsive to carbapenems with FN, combination and prolonged duration of tigecycline is recommended, and these results need to be further studied.

BONE MARROW CYTOTOLOGICAL CHARACTERIZATION OF PATIENTS WITH HYPREACTIVE MALARIAL SPLENOMEGALY

E. De La Vega1, F. Gómez-Aguado1, M.T. Corcuera1, M.D.M. Lago3, M. Gasior1, V. Jiménez1

1Hematología y Hemoterapia, 2Microbiología, 3Medicina Interna, Hospital Universitario La Paz, Madrid, Spain

**Background:**

Hyperactive malarial splenomegaly (HMS) is a common cause of massive splenomegaly in malarial-endemic areas. At present, diagnosis of patients with suspected HMS in tropical medicine departments of European hospitals is relatively frequent due to immigration and the return of missionaries and NGO workers after long periods in tropical countries. Diagnostic tools for HMS usually include a cytological study of bone marrow, because clinical similarities between HMS and lymphoproliferative disorders have been reported. However, there are no large series in the literature that estimate a bone marrow cytological standard for HMS. Another important issue is that patients with HMS are often multiinfected by other parasites and bacteria, which may be attributable to infections.

**Aims:**

The aim of this study was to define the bone marrow cytological pattern of patients with confirmed HMS, as well as of HMS patients with associated viral (HIV, HBV, HCV) or parasitic diseases.

haematologica | 2017; 102(s2) | 757
Methods: A retrospective cytological study of bone marrow aspires from 95 patients with HMS (n=27), HMS+HIV (n=8), HMS+HCV/HEV (n=11) and HMS+intestinal parasitosis (n=49) has been performed.

Results: Bone marrow cellularity was normal in all the groups studied except in HMS+HIV patients, in which the cellularity was very diminished (statistically significant difference, p<0.01). Most frequent alterations observed in all samples (HMS and HMS+other entities) that could define the HMS-bone marrow cytological pattern, were: - Erythroid hyperplasia with dyserythropoiesis, which is reflected in a decreased myeloerythroid ratio. - Increased eosinophils percentage. - Increased lymphocytes percentage. - Increased plasma cells percentage and detection of Mott cells in a significant proportion of samples from all series (48.1% of HMS samples). Quantitative results for these variables are summarized in Table 1. Lymphocytosis was significantly increased in HMS+HCV/HIV bone marrow (p=0.04). Significant detection of atypical lymphocytes (%4) varied widely between the groups, ranging from 14.8% of HMS bone marrows to 75.0% of HMS+HIV bone marrows (statistically significant difference, p<0.01). There was no lymphoid evidence in any case. No quantitative or qualitative alterations were detected in megakaryocytes, except for a slight decrease in HMS+HCV/HIV bone marrows (statistically non-significant difference) (Figure 1).

Table 1. Quantitative results (mean±standard deviation).

Summary/Conclusions: As far as we know, this is the largest series of HMS bone marrow analyzed. Identification of common cytological findings in all the groups studied allows defining a characteristic cytological pattern for HMS. The reason for these findings could be related to an aberrant chronic immune response caused by a continuous exposure to malaria parasites. Only bone marrows of HIV coinfected patients present additional specific alterations (decreased cellularity and high proportion of atypical lymphocytes). Some authors hypothesize that HMS could eventually evolve to chronic lymphocytic leukemia, hairy cell leukemia or splenic lymphoma with villous lymphocytes, so a special follow-up would be advisable for those patients with a high proportion of atypical lymphocytes.

ACUTE APPENDICITIS IN LEUKEMIA PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION DURING THE NEUTROPENIC PHASE
Q. Zhang1,*, Q. Jiang1, Y. Zhou1, Q. Mai1, K. Tsui1, Z. Wei2, J. Majaw2, C. Zuo2, Y. Zhang1, F. Huang1, Z. Fan1, J. Sun1, Q. Liu1
1Department of Hematology, Nanfang Hospital, Southern Medical University, 2First Clinical Medical College, Southern Medical University, Guangzhou, China

Background: Infectious complications arising from the gastrointestinal tract is common in neutropenic patients with hematologic malignancies, especially during HSCT.

Aims: Sequential analysis of 776 HSCTs in single center, totally 10 cases of acute appendicitis was found out, the treatment and outcome were further analyzed.

Methods: The HSCT patients who occurred acute appendicitis during -10d~+60d in the Hematological Department of Nanfang Hospital from Jan. 2005 to July 2016 were analyzed. Patients were enrolled in our study based on the Modified Alvarado Scoring combined with ultrasonography (the MASS total score of 1-4: acute appendicitis very unlikely; Score 5-7: acute appendicitis probable; Score 8-10: acute appendicitis definite. #: negative; +: positive).

*Reference standard by the Modified Alvarado Scoring System, Total scores were 10, Score 1-4: acute appendicitis very unlikely; Score 5-7: acute appendicitis probable; Score 8-10: acute appendicitis definite. #: negative; +: positive.

Summary/Conclusions: Acute appendicitis occurring during the neutropenic phase in HSCT patients could be diagnosed by the MASS and ultrasonography, and such cases could be cured by conservative therapy. This study could provide a further choice for the diagnosis and treatment of acute appendicitis in leukemia patients of HSCT.

PB1898
EPIDEMIOLOGY OF BLOODSTREAM INFECTIONS IN NEUTROPENIC AND NON-NEUTROPENIC PATIENTS WITH MALIGNANCY
N. Raja1, S. Gupta1, B. O’Neill2
1Pathology, 2Microbiology, 3Haematology, East Sussex Healthcare Trust, Hastings, United Kingdom

Background: Blood stream infections (BSI) in patients with malignancies remain associated with significant morbidity and mortality. The choice of an empirical antibiotic regimen is usually based on the local epidemiology of the microorganisms and their antibiotic susceptibility profile. Antimicrobial guidelines for the management of sepsis in cancer patients in East Sussex Healthcare Trust (ESHT) recommend piperacillin/tazobactam as monotherapy and gentamicin is added in case of septic shock. Vancomycin is also added as a first line therapy if there is a suspicion of central line sepsis. Alternative therapies are ceftazidime or meropenem plus aminoglycosides. Aims: We intend to review the aetiology of BSI and check the effectiveness of the antibiotics used in ESHT in cancer patients.

Methods: This retrospective study was conducted at ESHT from January 2006 to December 2015. Demographic and laboratory data were collected from the Pathology information system.

Results: A total of 640 episodes of BSI occurred in 297 patients (159 male). Of the 297 patients, 239 had haematology malignances while 54 had solid organ tumour. Four patients had both. The neutrophil count was <1 cells/103 in 383 episodes and majority of BSI occurred in this group. A total of 802 organisms (477 and 325 organisms from neutropenic and non-neutropenic respectively) were isolated. Of 802, 406 Gram positive and 386 Gram negative organisms were isolated. Seven Mycobacterium species and three Candida species were isolated. Most common organisms in neutropenic patients were Coagulase negative Staphylococcus (CoNS) (22%), Klebsiella species (14%), Escherichia coli (13%), Streptococcus species (10%), Pseudomonas species (10%), Enterococcus species (8%) and Staphylococcus aureus (4%). In non-neutropenic patients, CoNS (29%), Escherichia coli (11%), Pseudomonas species (8%), Streptococcus species (7%), and Klebsiella species (5%) were isolated. Twelve Glycopeptide resistant Enterococci were isolated, Four Methicillin resistant Staphylococcus aureus were isolated. In addition, 15 Extended Spectrum Beta-lactamase producing Gram negative bacilli were isolated. Among Gram negative organisms, more than 91% isolates were sensitive to piperacillin/tazobactam, ceftazidime and ciprofloxacin and higher sensitivity to amikacin and gentamicin and meropenem were recorded (96%) were recorded in gentamicin and meropenem, Table1 summarises the effectiveness of antibiotics used.

Summary/Conclusions: This study shows an on-going trend towards Gram positive organisms causing BSI in cancer patients. The antimicrobial regimens used in ESHT are highly effective against commonly isolated organisms. An early diagnosis and timely administration of appropriate antibiotics are imperative in managing BSI. The identification and the antimicrobial susceptibility of the microorganisms causing BSI in cancer patients remain important to develop antimicrobial treatment strategies, and to prevent the spread of antimicrobial resistance.

CHANGING TREND IN LOCAL BACTERIAL EPIDEMIOLOGY: EXPERIENCE IN ACUTE LEUKAEMIA PATIENTS HOSPITALIZED IN A SINGLE HEMATOLOGY UNIT

C. Buquicchio1, 2, L. Ciuffreda1, G. De Santis1, C. Germano1, M. Leo1, M.T. Santeramo1, R. Miccolis1, G. Tarantini1
1Ematologia, SC Ematologia con trapianto, Barletta, Italy

Background: The intense chemotherapeutic regimens and hypomielent agents to treat acute leukemia induce prolonged neutropenia with high risk of infections.

Aims: To analyze local microbial epidemiology we studied patients admitted to our ward.

Methods: All 100 cases of Acute Leukemia (AL) admitted in our ward from August 2013 to February 2017 received prophylactic antibacterial therapy with fluoroquinolones and were analyzed for weekly routine tissue culture screening and serial blood culture for fever. Six patients were Lymphoid AL and 94 were Myeloid AL. 41 patients were not eligible for intensive chemotherapy (for age and comorbidities) and were treated with hypomielent agents, while 59 were younger than 65 years and were treated with induction /consolidation chemotherapy 3 plus 7 regimen. Median age was 58 years with range from 27 to 88 years old.

Results: We found 28 patients (28%) bacterial septic shock during fever. of which 20 cases gram negative (71%) in particular 65% E.Coli, 15% Enterobacter, 10% Klebsiella, 5% Stenotrophomonas, 5% Pseudomonas; while 8 patients (29%) had a gram positive septic shock. During intensive chemotherapy and prolonged severe neutropenia we took over the major incidence of septic shock (23 patients 82%) than hypomielent treatment in particular decitabine (5 patients 18%). During 2014 we had 3 mortal septic shock for multiresistant gram-klebsiella and Pseudomonas. Since than we adopted in our ward, isolation of patients with gram negative (klebsiella or pseudomonas) tissue culture positive, hygienic and sanitary practices with closing room for 48 hours and hand disinfection before entering and after leaving any patients room. We noticed a change of bacterial infections incidence in these 3 years in our ward. Reduction klebsiella/pseudomonas multiresistant infections and emergency of E.coli and Staphilococcus septic shock not multiresistant.

Summary/Conclusions: More epidemiological analysis in several haematological ward are necessary to understand if it is a changing local microbial epidemiology or is the different management of neutropenic patients with acute leukemia and/or a different antimicrobial strategy to determine this changing trend.

PB1900

UK SINGLE-CENTRE SERVICE EVALUATION TO DESCRIBE THE IMPACT ON HEALTHCARE RESOURCE USE OF LOCAL ANTIFungal PROPHYLAXIS AND TREATMENT PROTOCOLS IN THE MANAGEMENT OF HIGH-RISK PATIENTS WITH NEUTROPENIA

D. Furry1, 2, H. Ahir1, G. Nock3, E. Taymor3
1Poole Hospital, Poole Hospital NHS Foundation Trust, Poole, 2Merck Sharp & Dohme Ltd, Merck Sharp & Dohme Ltd, Hoddesdon, 3pH Associates, pH Associates, Marlow, United Kingdom

Background: Patients with neutropenia, including those with haematologic malignancies, are at high risk of invasive fungal infections (IFI). Pre-2014, there were no formal written guidelines but the guidance at Poole Hospital NHS Foundation Trust specified the use of posaconazole oral suspension for primary prophylaxis in all high-risk patients except those with acute lymphoblastic leukaemia (ALL). In 2014 formal guideline changes included the introduction of the tablet formulation of posaconazole, use of micafungin as first line empirical therapy and a focus towards improving diagnostics to guide management.

Methods: We compared healthcare resource use data before and after changing trend.

Results: The evaluation included 24 patients in Cohort 1 (median age 66.8 years [interquartile range (IQR): 47.5–72.2] years; 16 [67%] male; 5 [21%] ALL) and 22 patients in Cohort 2 (median age 66.8 years [IQR: 51.7–73.4] years; 13 [59%] male; 1 [5%] ALL). At least one line of antifungal prophylaxis was recorded in 22 (92%) patients in Cohort 1 and 17 (71%) in Cohort 2. Posaconazole was the most commonly prescribed antifungal in Cohort 1 (18/24 [75%]) and Cohort 2 (17/22 [71%]). Other agents used included liposomal amphotericin B, fluconazole, and itraconazole. There were no patients in Cohort 1 and 2 (9%) patients in Cohort 2 (overall 4%) who experienced a BIFI: 1 was defined as confirmed and 1 as suspected. The mean 12 month costs per patient for all resource utilisation (including antifungal drug costs, hospitalisation costs [including admissions and attendances], investigations and tests) was £28,903 in Cohort 1 and £21,934 in Cohort 2 (Figure 1). Hospitalisation costs were a key determinant of overall costs, which is common in the management of people with complex underlying disease. There were 4 (17%) patients in Cohort 1 and 1 (5%) in Cohort 2 who had a period of ITU associated stay, which typically has greater costs than general wards. The most common investigations/tests were blood cultures (Cohort 1: mean 13.8; Cohort 2: mean 10.7) and chest x-ray (Cohort 1: mean 4.0; Cohort 2: mean 2.5), which are in-line with routine clinical practice. Once implemented, the guideline was adhered to in the management of 19 patients (86%) in Cohort 2.

Summary/Conclusions: These data show that rates of breakthrough IFI are low in complex patients receiving antifungal prophylaxis/treatment. Furthermore, the results in Cohort 2 indicate that the switch to recommending posaconazole tablets did not result in an increase in the mean cost per patient of antifungal prophylaxis and shows a lower overall mean cost per patient. A larger cohort study over a longer period is warranted to confirm these findings.

Figure 1. Breakdown of mean 12 month resource utilisation costs for cohorts 1 and 2.
Iron metabolism, deficiency and overload

PB1901
REAL-LIFE FEASIBILITY OF AN IRON CHELATION PROGRAM WITH DEFERASIROX IN MYELODYSPLASIA AND OTHER ACQUIRED CHRONIC ANEMIAS: A SINGLE CENTRE EXPERIENCE
G. Bertani1, M. Riva1, E.B. Volpato1, E. Ravano1, I. Cuppari1, A. Mazza1, P. Usardi1, R. Carli1
1Haematology, Ospedale Niguarda Ca’ Granda, Milano, Italy

Background: Prolonged red blood cell (RBC) transfusion support in patients affected by myelodysplastic syndrome (MDS) and other chronic anemias may cause vital organs damage due to accumulation of non-transferrin-bound iron with consequent increased oxidative stress. Retrospective studies have shown that iron chelation may prevent aforementioned mechanisms and improve survival in low-risk MDS patients. Iron chelation is usually recommended in patients who received at least 20 RBC units and/or have a serum ferritin level of 1000 ng/ml or higher. Deferasirox, an oral iron chelator, has widely replaced the use of deferiprone, due to its greater manageability, especially in the elderly. However, an high dropout rate of approximately 50% of patients within one year was observed in the majority of clinical studies, the leading cause of discontinuation being gastrointestinal toxicity, see flow-chart). Overall, 25/58 (43%) potentially eligible patients were not offered iron chelation without a specific clinical reason: half of them (3/6) were non-MDS patients. Furthermore, 13/38 (33.8%) patients were not offered deferasirox treatment, i.e. high transfusion burden, ferritin level ≥1000 ng/ml, and/or symptoms of IDA) at health screening visit.

Aims: We aimed at evaluating the real-life feasibility of a program of prolonged iron chelation in a population of acquired chronic anemia patients. Thus, we performed a retrospective analysis to evaluate which is the percentage of patients who in our centre actually receive and tolerate deferasirox treatment, among those potentially eligible.

Methods: Deferasirox treatment is considered at our centre in patients affected by MDS or other forms of chronic anemia (excluded chronic bleeding) who fulfill criteria for iron chelation (high transfusion burden, i.e. ≥20 RBC units and/or a serum ferritin ≥1000 ng/ml). Starting dose is usually 10 mg/kg, titrated up to 40 mg/kg as tolerated. The cohort of patients transfused at our centre during 2015 and 2016 was considered for analysis. Causes of unsuitability and of treatment discontinuation were extracted from our database.

Results: Our cohort consisted of 58 patients, mainly affected by MDS (45 pts); other diagnosis were myelofibrosis (6 pts), NHL (2) and multifactorial anemia, not related to blood cancer (7). Only 38 out of 58 potentially eligible patients were assigned to iron chelation (see the Figure 1). The leading cause of ineligibility in our cohort were a reduced life expectancy (5 pts), due to the hematologic disease itself or to comorbidities, and pre-existing renal failure (4). Importantly, in 6 cases patients were not offered iron chelation without a specific clinical reason: half of them (3/6) were non-MDS patients. Furthermore, 13/38 patients had to interrupt the treatment, due to toxicity (mainly renal failure, followed by gastrointestinal toxicity, see flow-chart). Overall, 25/58 (43%) potentially eligible patients, i.e. heavily transfused patients, initiate and continue an iron chelation program at our centre. The main cause for treatment discontinuation in our cohort was renal failure, while we had less difficulties in managing G.I. adverse events. Renal toxicity of deferasirox is known to be reversible; however, in patients with pre-existing compromise and those who concurrently take nephrotoxic drugs, treatment may be difficult to carry on.

Figure 1.

Summary/Conclusions: Our data are in line with literature. However, there is still room for improvement, especially in the category of non-MDS patients, who are often under-treated. Furthermore, the introduction of a new formulation of deferasirox, which is forthcoming, may hopefully reduce G.I. toxicity and improve tolerance and patients adherence to therapy.

NONINVASIVE TRANSUSTANEOUS SPOT-CHECKING OF TOTAL HEMOGLOBIN FOR THE SCREENING OF ANEMIA IN CAMBODIAN CHILDREN FROM REMOTE RURAL AREAS
J. Perez De Oteyza1,2, I. Fernandez de la Fuente1, C. Montero1, L. Trives2, A. Jayo3, R. Guiote2, V. Benito2, B. Santos2, A. Rodriguez2, J. Marin2, L. Sierra2, S.P. Gonzalez2, E. Martinez2, J. Rodriguez2, A. Perez2, A.I. Sanz2, X. Santos Heredero2
1Hematology, Hospital Universitario Madrid Sanchinarro, 2Clinical Sciences, 3Basic Sciences, Facultad de Medicina, Universidad CEU San Pablo, Madrid, Spain

Background: Previous studies have reported a high prevalence of anemia among school-aged children from Cambodia, ranging from 21 to 64%. Although iron deficiency accounts for the majority of cases, additional nutritional and non-nutritional etiologies have been identified. Children living in rural or remote areas, with limited access to health facilities, are at high-risk of developing anemia, and therefore, painless, fast, and reduced cost screening tests are needed.

Aims: The aim of our study is to evaluate the role of a portable device for transcutaneous noninvasive spot-checking of total hemoglobin (SpHb) in children living in remote locations.

Methods: Transcutaneous noninvasive spot-checking of total hemoglobin (SpHb) was performed in children attending summer-school camps at 12 different locations in Cambodia. SpHb was measured in fingertips by using size adapted optic sensors. For the purpose of the study, three age groups were defined as follows: Group 1=less than 5 years, group 2=5 to 11 years, and group 3=11 to 14 years.

Results: A total of 476 otherwise healthy children were analyzed. Mean SpHb value was 11.9 ±0.3 g/dl (range 9-16 g/dl). Overall, the prevalence of anemia in the entire population was 34.5%. Anemia was present in 5/31 (16.1%) of the children within group 1, 9/71 (12.6%) in group 2, and 54/81 (40%) in group 3. (p=0.039, two sided Pearson’s Chi square). There were no differences in the prevalence of anemia by gender in groups 1 and 2. In group 3, anemia was significantly more prevalent in females 32/65 (49.2%) than in males 22/48 (31.4%), p=0.035.

Summary/Conclusions: Taken together, our results demonstrate the feasibility of noninvasive transcutaneous spot-checking of total hemoglobin (SpHb) for the screening of anemia in children from remote rural areas with limited access to health services. Our results also confirm the high prevalence of anemia in this population.

PB1903
IRON DEFICIENCY ANEMIA IN INFANTS AND YOUNG CHILDREN
S.K. Park1,2, S.K. Kim2, E.Y. Joo2
1Pediatrics, Ulsan University Hospital, Ulsan, 2Pediatrics, Inha University College of Medicine, Incheon, Korea, Republic Of

Background: Iron deficiency anemia in infants and young children is easy to underdiagnose. Anemia and iron deficiency are usually corrected after aged 2-3 years old, but it causes complications. There is an association between IDA and impaired neurocognitive function and exercise intolerance, even after treatment of IDA. Therefore, preventing the progression of iron deficiency is especially important during infancy and early childhood. When increased vulnerability is associated with rapid growth and development, especially of the brain.

Aims: To detect iron deficiency anemia early and to reduce the adverse impact by IDA, we assessed the characteristics of infants and young children with IDA, those at risk for IDA and those exhibiting associated characteristics of severe anemia.

Methods: Among 1,782 children with IDA aged 6 months to 18 years-old, we retrospectively analyzed medical records and laboratory data of 1,361 subjects aged 6–23 months with IDA who had been diagnosed between 1996 and 2013. We excluded patients with CRP ≥5 mg/dL.

Results: IDA was predominant in boys (2.14:1) during infancy and young childhood. Peak incidence was at 9 to 12 months of age. Only 7% of subjects were brought to the hospital with symptoms and/or signs of IDA, while 23.6% in subjects with severe IDA. LBW infants with IDA shows low adherence with iron supplementation. In a multivariate analysis, risk factors of severe anemia in infants included prolonged breastfeeding without iron fortification [odds ratio (OR) 5.70] and low birth weight (OR 6.49).

Summary/Conclusions: Many clinicians did not consider IDA as a real problem, so many children with IDA were not followed up. LBW infants need more attention, as the increase adherence of iron supplementation. For early detection of IDA, nutritional assessment should be evaluated in every infants and iron batteries in high risk infants (LBW infants, prolonged breastfeeding, picky eater and/or symptoms of IDA) at health screening visit.
THE ROLE OF ZINC PROTOPORPHYRIN IN THE DIAGNOSIS OF SIDEROPENIC ANEMIA

M. Machaczka1,2,*, F. Lorenz3, E. Pawłowicz4, M. Gajewski5, M. Wolan2, M. Klimkowska6

1Department of Clinical Pathology and Laboratory Medicine, Medical University of Silesia, Katowice, Poland, 2Department of Laboratory Medicine and Hematology, Karolinska University Hospital Huddinge, Stockholm, Sweden, 3Medical Faculty, University of Rzeszow, Rzeszow, Poland, 4Department of Radiation Sciences, Section of Hematology, Umeå University, Umeå, Sweden, 5Medical University of Łódź, Łódź, 6Department of Clinical Pathology and Cytolgy, Karolinska University Hospital Huddinge, Stockholm, Sweden

Background: Sideropenic anemia (IDA) is the main cause of anemia worldwide. Even though, its diagnosis is quite straightforward with the use of red blood cell indices, peripheral blood smear (PBS) and ferritin measurements, there are still some pitfalls, namely in the presence of inflammation. The elevation of iron by proinflammatory cytokine constitutes the final reaction of heme biosynthesis. In the absence of iron, zinc becomes an alternative substrate for ferrochelatase leading to the formation of zinc protoporphyrin (ZPP). This compound can be quantified by fluorometry in blood samples, proving itself as a useful and easy parameter for the diagnosis of IDA. However, this technique is not broadly used in the clinical practice.

Aims: Determine the cut-off value of ZPP for the diagnosis of IDA. Evaluate the value of ZPP for the differential diagnosis between IDA and anemia due to inflammatory diseases (AID).

Methods: We have analyzed in our lab, from 1st to 15thFebruary 2017, all the consecutive samples (pediatric and adult) with anemia (as defined by WHO) which had sedimentation rate (SR) and serum ferritin evaluations. We have defined three different groups: IDA; Anemia and Ferritin <20µg/L; AID: Anemia, Ferritin ≥20µg/L and SR<20mm/h; Group control (GC): Normal levels of hB adjusted by age and sex, as defined by WHO, Ferritin 20-120µg/L and SR<20mm/h. ZPP measurement was performed by hemato-biospectrometry (AVIV, Biomedica, Inc). Data were analyzed by SPSS v20.0 using Wilcoxon W and Man-Whitney to examine differences between groups and receiver-operating characteristic (ROC) analysis to determine the cut-off values of ZPP. We considered the calculation of a p-value <0.05.

Results: We have identified 204 samples that fulfilled the inclusion criteria: 104 with IDA, 51 with AID and 49 from control patients. IDA group: 73% female (F); mean age 32.3y in F [1-78], 28y in males (M) [1-78]; mean Hb was 10.6g/dL [SD 1.4]; mean ferritin was 9.3 µg/L [SD 4.85] and ZPP was 214.1 µmol [SD 121.3]; mean SR was 20.0 mm/h [SD12.9]; AID group: 75% F; mean age 47y in F [2-91] and 22y in M [1-85]; mean Hb 11.0 g/dL [SD 1.2]; mean ferritin 150.3 µg/L[SD246.2] and ZPP 136.7 µmol [SD 107.8]; mean SR 47mm/h [SD 21]. GC: 69.4% F; mean age 44.8y in F [1-73], and 37y in M [2-65 years]; mean Hb 13.8 g/dL [SD 0.8]; mean ferritin 71.9ug/L [SD 49.9] and ZPP 77.8 µmol [SD 26.8]; mean SR 14mm/h [SD 4]. The mean serum ZPP in IDA and AID was significantly higher than in GC (95% CI; p<0.0005). The ROC analysis showed 83.7% sensitivity and 85% of specificity to identify IDA for ZPP ≥100.3 µmol (95% CI: 0.933) and 69% sensitivity and 70% of specificity to identify AID for ZPP ≥140 µmol (95% CI: 0.749) when compared with GC.

Summary/Conclusions: We have concluded that ZPP is a valid, quick, easy and cheap parameter to diagnose IDA in clinical practice, and we have defined in our cohort of patients a ZPP cut off of ≥100.3µmol as diagnostic of IDA with 83.7% sensitivity and 85% of specificity, independent of age. In AID patients we found a cut-off value of ≥140µmol, but with a low sensitivity and specificity. In conclusion, ZPP is a useful test for the differentiation of iron deficiency anemia from AID. This could be due to a sample selection bias (since clinical data were missing and the number of patient with AID was substantially lower than with IDA). It would be important to enlarge the AID sample in order to obtain a more reliable result. Since ferritin measurement can be performed in capillary blood and it is a very quick and cheap method to diagnose IDA, this could be a powerful tool in under-developed countries.

PB1905

HYPERFERRITINEMIA AND SERUM INFLAMMATORY CYTOKINES IN ADULTS WITH NEWLY DIAGNOSED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS ASSOCIATED WITH HEMATOLOGICAL MALIGNANCY

M. Machaczka1,2, F. Lorenz3, E. Pawłowicz4, M. Gajewski5, M. Wolan2, M. Klimkowska6

1Department of Clinical Pathology and Laboratory Medicine, Medical University of Silesia, Katowice, Poland, 2Department of Laboratory Medicine and Hematology, Karolinska University Hospital Huddinge, Stockholm, Sweden, 3Medical Faculty, University of Rzeszow, Rzeszow, Poland, 4Department of Radiation Sciences, Section of Hematology, Umeå University, Umeå, Sweden, 5Medical University of Łódź, Łódź, 6Department of Clinical Pathology and Cytolgy, Karolinska University Hospital Huddinge, Stockholm, Sweden

Background: Hemophagocytic lymphohistiocytosis (HLH) is an underdiagnosed but life-threatening syndrome of hyperinflammation which in adults is often caused by hematological malignancies. Release of inflammatory cytokines in HLH induces NK cells and cytokine production that cumulates in cytokine storm and hyperinflammation. Hyperferritinemia ≥500 µg/L is a diagnostic criterion for HLH. Prevalence of hyperferritinemia in HLH in the adult population is much less established than in children.

Aims: The aim of the present study was to evaluate the frequency and extent of hyperferritinemia as well as serum concentrations of selected inflammatory cytokines at the time of diagnosis of hematological malignancy-associated HLH (HM-HLH) in adults.

Methods: The study included 71 adults with HM-HLH, aged 22–84 years, and diagnosed between 2009 and 2016. Hematological malignancy was defined as a neoplasm of lymphoid or myeloid origin. In all studied patients, the diagnosis of HLH was based on the HLH-2004 criteria. Since the majority of patients in this study had severe lymphopenia, we decided to not perform functional analyses of NK-cells for HLH diagnosis. Thus, we included in this analysis all patients with hematological malignancies and suspected HLH who fulfilled at least four of seven HLH-2004 criteria as well as at least two of three additional features: sIL-2Rα ≥2400 U/mL, hemophagocytosis in BM, and hyperferritinemia ≥10,000 µg/L. Serum concentrations of inflammatory cytokines IL-1β, IL-6, IL-8, IL-10 and TNF-α were analyzed using chemiluminescence (IMMULITE® System, DPC Siemens). Serum levels of sIL-2Rα were determined by ELISA, using the quantitative ‘sandwich’ enzyme immunoassay, on the IMMULITE® 1000 Immunoassay System (DPC Siemens).

Results: Lymphoid malignancy was diagnosed in 42 patients and myeloid malignancy in 29 patients. Fifty-four (76%) patients developed HLH as a first manifestation of an unknown malignancy, during progressive disease, or at malignancy relapse. The remaining 24% of patients had a relapse of a previous lymphoma or leukemia. One-third of all patients received immunotherapy. Serum ferritin concentration (ref.: 30–350 µg/L) at the time of HM-HLH diagnosis was elevated in all but one patient (70/71, 98%). Mean ferritinemia was 37,281±84,440 µg/L, median value 14,727 µg/L, and ferritinemia range 96–645,291 µg/L. As HLH-2004 criterion, hyperferritinemia ≥500 µg/L was present in 69 of 71 patients (97%) at the time of HLH diagnosis. Hyperferritinemia of ≥2000 µg/L was noted in 67 (94%) patients, hyperferritinemia of ≥5000 µg/L in 56 (79%) patients, and hyperferritinemia of ≥10,000 µg/L occurred in 42 (59%) patients. Serum levels of sIL-2Rα (sCD25) were measured in 69/71 patients from whom 91% (63 of 69) had values ≥2400 U/mL. Moreover, in 3 more patients sIL-2Rα was clearly elevated to 2179, 2233, and 2345 U/mL, respectively. Concentrations of TNF-α, IL-6, and IL-10 in serum were in each elevated in over 85% of the examined HM-HLH patients. IL-8 concentration was increased in half of all tested patients at the time of HLH diagnosis. However, IL-1β concentration was above reference range only in 12% of patients (7 of 58). Results of the inflammatory cytokine analyses in patients with newly diagnosed HM-HLH are presented in Table 1.

Table 1. Inflammatory cytokines in patients with newly diagnosed HM-HLH.

Summary/Conclusions: Hyperferritinemia at the time of HLH diagnosis was common in Swedish adult patients with HM-HLH. Hyperferritinemia ≥500 µg/L was present in vast majority (97%) of them. We would like to emphasize that serum ferritin level fluctuates and can differ significantly from one day to another. Ferritinemia should be repeatedly measured in cases of suspected HLH. Serum concentrations of TNF-α, IL-6, IL-8, and IL-10 were frequently elevated in the examined HM-HLH patients and these can become important markers supporting HLH diagnosis in equivocal cases. On the other hand, IL-1β seems to be less useful in confirming a cytokine storm in this patient group.
blood films are iron deficiency pictures with the characteristic finding of reduced Haemoglobin (Hb), MCV and MCH. Above certain thresholds, the blood film adds little or no value to the CBC in these patients, apart from correlating with the iron studies results or suggesting iron studies when unavailable. One initiative used to manage the workload was based on this logic and aimed to reduce the blood film review rate using IT3000 technology (Roche).

Methods: An algorithm was designed in IT3000 to encourage testing and treatment for iron deficiency using a series of automated educational comments, while minimising unnecessary laboratory work. The impact that this algorithm had at WSCl was investigated by retrospective analysis of all the patient results from 1st November 2015 to the 1st of May 2016.

Results: In the first six months of operation, WSCl performed 232,192 CBCs and 30,204 blood films with an average review rate of 13.01%. Had this algorithm not been employed, 2,434 extra blood films would have been reviewed, bringing the review rate up to 14.05%.

Summary/Conclusions: Incorporation of an algorithm specific for iron deficiency in IT3000 has significantly reduced the review rate without any negative impact on patient care.

PB1907
THE RELATIONSHIP ENDOThelial MICROPARTICLES AND ASSYmETRIC DIMETIL ARGinine IN CHILDREN WITH IRON DEFICIENCY AND IRON DEFICIENCY ANEMIA
E. Kaygi Tarto1, Y. Altuner Torun2, C. Karakukcu3, S. Celi4, H.T. Hornet Oz5

1Pediatrics, 2Pediatric Hematology, 3Biochemistry, 4Pediatric Cardiology, 5Microbiology, Medical Health University, Kayseni, Turkey

Background: Iron deficiency anemia and iron deficiency without anemia increase the risk of atherosclerosis by increasing oxidative stress and inflammation. Endothelial dysfunction is an important factor of the pathogenesis of atherosclerosis.

Aims: Endothelial micro particles (EMPs) are considered as markers of endothelial dysfunction. Asymmetric dimetil arginine (ADMA) is known as another marker of endothelial dysfunction in this study; we aimed to evaluate circulating EMPs and ADMA in children with iron deficiency and iron deficiency anemia and to disclose iron deficiency with the strongest relation with EMPs, ADMA and carotid atherosclerosis.

Methods: This study included 30 children with iron deficiency anemia, 30 children with iron deficiency without anemia and 30 healthy children whose anthropometrics measurements were recorded. Hemoglobin, serum iron level, iron binding capacity, ferritin, and lipid profile were studied. Circulating EMPs (CD144, CD146, and CD105) were measured by flow cytometry. ADMA was measured by ELISA. The carotid artery intima media thickness (IMT) and left ventricular mass index (LVMl) were measured using echocardiography.

Results: CD144 and CD105 EMP levels were lower in the iron deficiency without anemia group than in the control group and statically lower than in the iron deficiency anemia group (p<0.05). There were no significant differences in ADMA levels between groups. Any significant variety in ADMA level was not observed between groups. IMT was negative correlated with ferritin and high density lipoprotein and positive correlated with body weight.

Summary/Conclusions: In this study, endothelial dysfunction which occurs as a result of iron deficiency were observed. According to our result, CD144 and CD105 EMP levels in the iron deficiency without anemia group were lower than the iron deficiency anemia and control group; these levels in iron deficiency anemia group were higher than control group. In addition, when the level of ferritin has decreased, IMT has increased. This study show that CD144 and CD105 may be related to endothelial dysfunction which occurs by iron deficiency.

PB1908
INVESTIGAtION OF IRON METABOLISM FOR REGULATING MEGAKARYOPoIESIS AND PLATELET Count ACCoUNtING TO THE MECHANISMS OF ANEMIA
S. Kim1, S.Y. Cho1, T.S. Park1

1Kyung Hee University Hospital, Seoul, Korea, Republic Of

Background: Iron deficiency anemia (IDA) is characterized by depletion of total body iron stores. By contrast, chronic inflammation makes iron unavailable for hematopoiesis through a cytokine-mediated cascade, resulting in anemia of chronic disease (AOC). However, the laboratory data regarding the regulatory role of iron metabolism on platelet count has not been fully discussed yet.

Aims: In this study, we investigated the relationship between iron status and platelet production according to different anemic mechanisms representing different iron metabolisms.

Methods: The study included total of 759 blood specimens from 537 different patients. The complete blood count with various CBC index were measured using Advia 2120 (Siemens, USA). Biochemical indexes including iron level were estimated using Toshiba chemical analyzer (Toshiba, Japan).

Results: We found a significant relationship between platelet count and serum iron level in AOC group (p=0.27), whereas there was no correlation in IDA group. In AOC group, platelet count was significantly correlated to serum iron level only in AOC group with decreased serum iron level (p<0.0001), unlike AOC group with normal serum iron level.

Summary/Conclusions: Reactive thrombocytosis in inflammatory states is a well-known phenomenon in AOC. Moreover, iron deficiency in AOC involves upregulated hepcidin production induced by increased inflammatory cytokines. It can cause increased iron sequestration in macrophage and decreased iron absorption for bone marrow. The condition of decreased megakaryocytic iron supply makes megakaryocytes with higher ploidy which can release more platelets than lower ploidy. These two features may enhance thrombocytosis in patients of AOC with decreased iron level. In the future, the further study should be performed to elucidate underlying mechanism involving the tight regulation between iron metabolism and megakaryopoiesis in anemic patients.
Myelodysplastic syndromes - Biology

PB1910
ROLE OF PRO-PHAGOCYTIC CALRECTICULIN AND ANTI-PHAGOCYTIC CD47 IN MDS AND MPN MODELS TREATED WITH AZACYTIDINE OR RUXOLITINIB
K. Kremens1, J. E. Bird2, J. Simmonds1, C.R. Rinaldi1
1School of life Sciences, Collage of Science, 2Lincoln Institute of Health, University of Lincoln, Lincoln, United Kingdom

Background: Myelodysplastic syndrome (MDS) and Myeloproliferative neo- plasms (MPN) are clonal myeloid disorders with the tendency to progress into acute myeloid leukaemia. Previous studies in solid tumours have shown an increase in expression of both pro-phagocytic calreticulin (CALR) and anti- phagocytic CD47, as they act in response to one another, reflecting a possible apoptosis vs survival mechanism in response to chemotherapy.

Aims: The aim of our study is to assess the changes in CALR and CD47 levels during treatment of MDS and MPN with azacitidine (AZA) or ruxolitinib (RUXO), in a series of model cell systems.

Methods: CALR and CD47 gene and protein expression was measured in MDS cell line models (MOLM-13 and SKM-1), MPN cell line models (HEL-92 and GDM-1) and in an intermediate MDS/MPN cell line (K562) before and after treatment with AZA and RUXO. Drug titrations were completed, resulting in dosing regimens of 0.05µM/ml for both AZA and RUXO, with re-drugging occurring at 24 hours. Cells were then harvested, cDNA was synthesized for use in qPCR and protein levels determined by Western blot analysis.

Results: When treated with AZA, MDS cell models showed a 7-10 fold increase in CALR expression and 4-6 fold increase in CD47 expression. In contrast, the MDS/MPN intermediate cell model (K562) showed a 4.5 fold increase in CALR but only a 0.5 fold decrease in CD47 expression. In the MPN model HEL-92, a 9-10 fold increase in CD47 expression was seen, whereas in the other MPN model (GDM-1 cells) expression was more evenly matched between CALR and CD47 (5.3 and 4.8 fold increases, respectively). After treatment with RUXO, MNX models showed a 9.5-16 fold increase in CALR expression and a 6-9 fold increase in CD47, which would be expected as RUXO is used to treat MPN in humans. When the MDS/MPN cell model or pure MDS models were treated with RUXO, the ratio of CALR/CD47 decreased substantially (with CALR expression only increased 2.4-3.7 fold compared to CD47 increasing 4.6-6.9 fold) showing resistance to treatment and a significant anti-phagocytic response. Interestingly one of the MDS cell line models (MOLM-13) showed an unexpectedly good response to RUXO therapy with high CALR/CD47 ratio (8 fold vs 4.8 fold, respectively).

Summary/Conclusions: In line with results in solid tumours, we have shown that treatment for MDS and MPN leads to an up-regulation of CALR and, to a lesser extent, CD47 in cell line models. The ratio of CALR/CD47 seems to correlate with specific treatment response, significantly increasing when given diseases models are treated with the appropriate drug. We postulate a role of CALR expression in leukaemia cell phagocytosis, with CD47 co-expression in synergy as a protective instinct within the cell to try and prevent apoptosis.

PB1911
GENETIC VARIANTS OF MSH3 AND BLM GENES MAY INFLUENCE MYELODYSPLASTIC SYNDROME SUSCEPTIBILITY AND PROGNOSIS
M.S. Melo1, L. Balanca2, A. Barbosa Ribeiro1,2, A.C. Gonçalves1,2, R. Alves1,2, J. Martínez-López1, A. Barbosa Ribeiro1, A.C. Gonçalves1,2, R. Alves1,2, 1Applied Molecular Biology and University Clinic of Hematology, 2CIMAGO, Centro Hospital e Universitário de Coimbra (CHUC), Coimbra, 3Molecular Genetics and Pathology Unit, Hospital do Divino Espírito Santo de Ponta Delgada, EPFR, Ponta Delgada - Azores, Portugal

Background: Myelodysplastic syndrome (MDS) is a heterogeneous group of hematopoietic stem cell disorders, characterized by peripheral cytopenias, ineffective hematopoiesis and frequent transformation into acute myeloid leukemia (AML). Several genetic alterations are involved in disease development and prognosis as a consequence of stepwise accumulation of DNA mutations, which infers a defect in DNA repair mechanisms. Mutations in DNA repair genes of the nucleotide excision repair (NER) group, and affecting the mismatch repair (MMR), and DNA crosslink repair genes, among others, are the cause of inherited diseases in other hematopoietic disorders. Therefore, in these mechanisms have been identified for their potential role in cancer susceptibility. However, in MDS, the relevance of these variants remains to be fully established and correlated with prognosis.

Aims: In the present study we investigate the influence of polymorphisms in DNA repair genes (XRCC5, RM1, RAD52, XRCC3, BLM, TOP3A, OGG1, LIG1, ERCC2, and MSH3) as risk factor for MDS development as well as prognostic factors of acute leukemia transformation.

Methods: We performed a hospital-based case-control study to investigate the association of DNA repair genes with MDS susceptibility and prognosis in a group of Portuguese patients. To that end, we genotyped 10 SNPs in the above-mentioned genes associated with DNA repair. The influence in MDS prognosis was evaluated by estimating, through Kaplan Meier analysis, the rate of MDS transformation into AML and the overall survival.

Results: There was no significant difference in frequencies of XRCC5, RM1, RAD52, XRCC3, BLM, TOP3A, OGG1, LIG1, ERCC2, and MSH3) in 460 MDS patients and 120 age- matched controls. Frequencies of alleles, genotypes, and genotypic profiles were estimated and compared between patients and controls. The role of these genes in MDS susceptibility was studied by logistic regression analysis. The influence of MDS was assessed by adjusting for covariates by multiple logistic regression analysis. The rate of MDS transformation into AML was estimated by using the Kaplan Meier analysis. The rate of MDS transformation into AML and the overall survival.

Summary/Conclusions: The present study suggests that MSH3 c.2655+5137C>G variant influences MDS susceptibility, and BLM c.-4-889A>C variant may be implicated in the propensity to AML transformation observed in MDS patients. Thus, these gene variants could be used as a risk and prognostic biomarkers for MDS, if these associations were replicated in a larger case-control study and/or with other populations.
Background: A prospective study was performed over one year in order to investigate whether suspected myelodysplastic syndromes (MDS) could be detected on a complete blood counts (CBC), the fastest laboratory investigation, performed on the recently developed XN-10® (Sysmex, Kobe, Japan).

Aims: The primary end point was to discriminate MDS patients from normal samples and the secondary end-point was to distinguish MDS with excess blasts (MDS-EB), MDS with multilineage dysplasia (MDS-MLD), MDS with single lineage dysplasia (MDS-SLD) and MDS with ring sideroblasts and sideroblasts and ring sideroblasts within the MDS group and by comparison with controls as described by the WHO 2016 classification.

Methods: One hundred and thirty patients were enrolled in the study, for whom a diagnosis of MDS was concluded based on CBC, bone marrow smears examination and karyotype. All patients were free of treatment, including transfusions, at inclusion. They were 63 men and 50 women with a median age of 82 years (range 36-96 yo). CBC were performed on a Sysmex analyzer XN-10®, including classical parameters (hemoglobin level, Mean Corpuscular Volume (MCV), reticulocytes, platelets, neutrophils and extra-parameters i.e. platelets by florescence (PLT-F), immature platelets fraction (IPF%), immature reticulocytes fraction (IRR%) and the neutrophils median position on the three axes as well as their dispersion (Neut-WX). For comparison with normal values, results from 707 healthy subjects over 50 years old, for whom CBC were performed on the same analyzer and generated no flag, were used. All had parameters within the normal range according to age. According to the WHO, 37 patients had MDS-EB, 35 MDS-MLD, 12 MDS-EB with 5q- pathology and demonstrate the potential use of lenalidomide in this group of patients.

PB1914 PROGRESSION SCORE FOR ACUTE LEUKEMIA – A NEW PROGNOSTIC SCORE IN MDS

E. Cortesia, A.C. Gonçalvesa, A.R. Tenreiro2, A. Ribiero1, C. Geraldes1, N. Costa e Silva3, L. Ribiero2, J. Nascimento Costa5, A.B. Sarmento-Ribeiro1

1Applied molecular biology and clinic university of medicine, Faculty of Medicine of University of Coimbra, 2Hematology, 3Clinical Pathology, Centro Hospitalar e Universitário de Coimbra (CHUC), Portugal, 4Histology and Embryology, 5Clinic university of oncology, Faculty of Medicine of University of Coimbra, Coimbra, Portugal

Background: Since 1997, the International Prognostic Scoring System (IPSS) has been the standard for stratifying patients with Myelodysplastic Syndrome (MDS). Although other models were proposed to improve this stratification, some issues remain, notably the identification of low-risk patients with poor prognosis who may benefit from earlier and/or aggressive therapy.

Aims: The aim of our work was the conception of a new prognostic score in MDS, and in the cellular and extra parameter axis.

Methods: Our sample consisted of 102 patients diagnosed with MDS de novo. The median age was 74 years (22-89), with a 0.8 Male to Female ratio. The subtypes, according to the World Health Organization 2008, were Refractory Cytopenia with multilineage dysplasia (RCMD) (n=52), Refractory Cytopenia with Unilineage Dysplasia (RUCD) (n=12), Refractory Anemia with Excess Blasts type 1 (RAEB1) (n=8), RAEB-2 (n=8), Refractory Anemia with Ringed Sideroblasts (n=6), 5q- syndrome (n=4) and Chronic Myelomonocytic Leukemia (n=12). The IPSS based stratification was: low (n=37), intermediate-1 (n=39), intermediate-2 (n=10) and high (n=1). Several variables were analyzed: clinical parameters (hemoglobin, platelets, blasts and ring sideroblasts), biochemical (erythropoietin, β2-microglobulin, follic, vitamin B12, ferritin, LDH), immunophenotypic (hematopoietic stem cell characterization by flow cytometry, FC, using the markers, CD34 / CD117 / CD123 / GlioP / IL-6 / TNFa and molecular characteristics (methylisation profile of genes p15, p16, DAPK, R1, R2, R3 and R4 performed by PCR-MS, and evaluation of expression levels of regulatory molecules of apoptosis BCL-2, BAX, TRAIL, R1, R2, R3, R4, FAS, Survivin, Caspase 3, Cit C, Glycop and p53, by FC).

Results: In the 60-month follow-up, 11 patients progressed to Acute Myeloblastic Leukemia (AML), 7 with RAEB-2, 2 with RCMD, 1 patient with RAEB-1 and another with CMLM. These patients had a higher% of ring sideroblasts and blasts; higher scores on IPSS, IPSS-R and WPSS; lower platelet counts, higher erythropoietin levels and greater expression of CD34 / CD117 / IL-6. Assigning a value (+1) to each altered variable a new prognostic score was obtained, named Progressed Progression Score for Acute Leukemia. We observed that patients belonging to subtypes with the highest scores were those that progressed to AML, namely RAEB-1, RAEB-2 and RCMD.

Summary/Conclusions: In conclusion, we believe that this score may contribute to evaluate the risk of progression to AML, by reflecting the heterogeneity of MDS and its multifactorial pathogenesis. The coexistence of many altered variables not only contributes to the etiopathogenesis of MDS but also allows the assessment of potential leukemic transformation.

PB1915 CORRELATION OF PATIENT PROGNOSIS WITH PU.1 AND JDP2 PROVIDES POTENTIAL NOVEL PROGNOSTIC/DIAGNOSTIC MARKERS IN MDS

R. Simpson1, A. Goddard1, J. Lally1, M. Simmonds1, C. Rinaldi2, 1University of Lincoln, 2University of Lincoln and United Lincolnshire Hospital Trust, Lincoln, United Kingdom

Background: PU.1 is a key transcription factor in haematopoiesis that plays important roles in various haematological malignancies. Previously, significant down-regulation of PU.1 has been reported in high risk myelodysplastic syndromes (MDS) and acute myelogenous leukaemia (AML) patients.

Aims: We revealed both PU.1 and JDP2 expression relative to the housekeeping gene GAPDH using the 2ΔΔCT method. Western blot has been performed using anti-PU.1 and anti-JDP2 (Abcam) according to manufactures instructions.

Methods: Samples were enriched for the mononuclear fraction by Ficoll separation. Total RNA was extracted and analysed by Real Time PCR for PU.1 and JDP2 expression relative to the housekeeping gene GAPDH using the 2ΔΔCT method. Western blot has been performed using anti-PU.1 and anti-JDP2 (Abcam) according to manufactures instructions.

Results: We revealed both PU.1 and JDP2 were down regulated in MDS. In addition, our data suggests that PU.1 and JDP2 expression inversely correlates with disease, with expression of these genes consistently reducing according to IPSS-R groups. Furthermore, a positive correlation of PU.1 and JDP2 expression <R=0.9333, p=0.0004 >, provides additional evidence that suppression of PU.1 and JDP2 in MDS might be characteristic of AML pathophysiology. Notably, PU.1 and JDP2 do not correlate to the same extent in normal HSCs, indicating that cofactors are required for PU.1 to exert its JDP2-regulating function and that such cofactors are not present under normal conditions. To confirm that JDP2 suppression is a direct result of reduced PU.1, we performed PU.1-knockdown in K562 cells stably expressing PU.1 short interfering RNAs versus control cells. These analyses reveal only a partial reduction in JDP2 expression when analysed by RT-PCR and Western blot, suggesting a more complex regulatory mechanism. Additionally, both PU.1 and JDP2 expression was recovered by treatment with azacitidine, which is routinely used to treat MDS, suggesting an involvement of MDS-RS-SLD within the MDS group and by comparison with controls as described by the WHO 2016 classification.

Conclusion: We believe that this score may contribute to evaluate the risk of progression to AML, by reflecting the heterogeneity of MDS and its multifactorial pathogenesis. The coexistence of many altered variables not only contributes to the etiopathogenesis of MDS but also allows the assessment of potential leukemic transformation.

Summary/Conclusions: This study demonstrates that a simple CBC allows to screen for MDS using a multiparameter score including Neut-WX. Blood smear examination should be performed in this situation even if the XN-10® analyzer does not raise any alarm, especially in unknown patients older than 50.

PB1913 INTEREST OF THE XN-10® ANALYZER TO SCREEN FOR MYELODYSPLASTIC SYNDROMES ON COMPLETE BLOOD COUNTS

R. Boutaut¹, P. Peterlin², M. Bouby³, S. Tremblaïs¹, M. De Oliveira¹, Y. Le Bris¹, C. Godon¹, O. Theisien¹, M.C. Béne², M. Evillard³

¹Hematology Laboratory, ²Hematology clinic, Nantes University Hospital, Nantes, ³Clinical research, Avicenne University Hospital, Avicenne, France
**Background:** Myelodysplastic syndromes (MDS) are clonal disorders of the haematopoietic stem cells (HSCs) characterized by inefficient bone marrow (BM) haemopoiesis and increased risk for leukemic evolution. Ineffective BM haemopoiesis in MDS has also been linked with an abnormal microenvironment that may sustain or even induce the aberrations within the HSC compartment. We have previously shown that the stroma progenitor cells, namely the mesenchymal stem cells (MSC), in MDS patients display impaired clonogenic and proliferative potential, reduced haemopoiesis supportive capacity and down-regulation of the canonical Wnt-signaling pathway.

**Aims:** Decorin, a small leucine-rich proteoglycan, and galectin-3, a member of b-galactosidase specific lectin family, are components of the extracellular matrix of the BM microenvironment. Both proteins have been implicated in the canonical Wnt-pathway participating therefore in cell growth and proliferation. The aim of the study is to assess the expression of decorin and galectin-3 in MSCs of MDS patients, evaluating their implication in the abnormal Wnt-signaling previously reported in MDS.

**Methods:** BM MSCs were isolated from 12 patients with lower risk MDS aged 51 to 75 years (median 67.5 years) and 12 haematologically healthy subjects aged 50 to 73 years (median 63.3 years), after informed consent. The study has been approved by the Ethics Committee of the University Hospital of Heraklion. BM MSCs were characterized according to international system for human cytogenetic nomenclature (ISCN) criteria, expanded and re-seeded for two passages (P). Total RNA was extracted from culture-expanded P2 MSCs and amplified by real-time PCR for the evaluation of decorin and galectin-3. Relative gene expression was calculated by the ΔCT method.

**Results:** A statistically significant decreased expression of decorin was identified in MSC of MDS patients (mean 1.338, SD 0.84) compared to the healthy individuals (mean 1.830, SD 0.71), (P<0.05). Galectin-3 expression was also decreased in MDS patients (mean 0.6758, SD 0.50) compared to controls (0.9395, SD 0.50), although not at a statistically significant levels.

**Summary/Conclusions:** MSCs from MDS patients display statistically significant decreased expression of decorin and a tendency towards decreased expression of galectin-3 in BM MSCs compared to healthy individuals. These preliminary data indicate that extracellular matrix proteins may have a role in the disturbed Wnt-pathway signaling and abnormal MSC function in MDS patients. The underlying mechanisms are currently under investigation.
Myelodysplastic syndromes - Clinical

PB1918

CLINICAL EVOLUTION OF ACUTE MYELOID LEUKEMIA WITH MYELODYSPLASIA-RELATED CHANGES
G. Pinto1,*, P. Herrera1
1Hematology, HOSPITAL RAMON Y CAJAL, Madrid, Spain

Background: Acute myeloid leukemia (AML) with myelodysplasia-related changes (MRC) is usually classified associated to worse clinical course and poor prognosis compared other AML subtypes. Differences between treatment modalities according to age, and the response to treatment, would help to provide specific anti-AML treatment in this difficult scenario.

Aims: The objective of this study is analyze the clinical features and course of patients with AML with MRC, in order to evaluate the impact of different therapeutic regimens in this subgroup.

Methods: We report an unicentric retrospective study of 76 patients with AML with MRC, over the past ten years in a single institution in Spain. We analyzed the overall survival (OS) among the subgroup of patients with over or under 65 years, and the different types of treatment that has been offered.

Results: Median age was 69 years with a male predominance, and 66% was preceded by a known myelodysplastic syndrome with a median interval of 18 months to progress to AML. The more frequent genetic abnormalities in descending order were trisomies, del(5q), and del(7q)/-7. The patients aged >65 <65 and <65 were 70% and 30%, respectively. The patients aged >65 received DNA hypomethylating agents (40%), anthracycline-cytarabine combinations (9%), low-dose cytarabine or hydroxyurea (17%), and supportive measures (34%). The patients aged <65 received induction chemotherapy with anthracycline-cytarabine combinations so as to continue with post-consolidation management with allogenic transplantation, but the 44% died over the induction chemotherapy (OS: 2.2 months). The OS in patients aged <65 was 20.2 months in chemotherapy plus allogenic transplantation. The OS in patients aged >65 was 10.3 months in the group of anthracycline-arac combinations, 3.81 months in the DNA hypomethylating agents group, 2.8 months in the low-dose of AraC/hydroxyurea, and 0.5 months in supportive measures group (Figure 1).

Results: Between June 2012 and February 2015, 7 male and 2 female pts (median age: 70; range: 63-84) were enrolled, and 3 and 6 pts were eventually assigned to the 1,200 and 1,800 mg arms, respectively. According to the Fab classification, 6, 2, and 1 pts were categorized to RAEB, RAEB-T, and RA respectively. There were 17 cases in the Int-1 and 1 case in high risk groups, with 1 and 2 pts in each risk group in the 1,200 and 1,800 mg arms, respectively. The median number of delivered cycles in the 1,200 and 1,800 mg arms were 4 (2 to 4) and 2 (1 to 8), respectively. DLT occurred not in the 1,200 mg arm but in the 1,800 mg arm: 5 episodes of grade 3 non-hematological toxicities in 2 pts. One pt developed grade 3/4 infections, grade 3/4 neutropenia, as well as 1 case each of grade 3 lymphopenia, grade 4 thrombocytopenia, and grade 3/4 neutropenia, as well as 1 case each of grade 3 lymphopenia, increased C-reactive protein, erythrophagia, and hypochromia developed. Three cases of SAEs, including grade 4 meningitis, grade 4 sepsis, and grade 3 catheter-related infection, developed in the 1,800 mg arm. Stable disease was obtained in 2 pts in the 1,800 mg arm. Hematological remission, hematological improvement, and cytogenetic response were not obtained in the two arms. The Cmin values in the 1,200 and 1,800 mg arms were 5.99±1.50 and 6.74±2.39 μg/mL, respectively. The AUC0- values were 314.6±142.7 and 324.8±83.9 μg × hr/mL, respectively.

Summary/Conclusions: This Phase I study showed that intravenous rigosertib (1,800 mg daily) for consecutive 72 h was well tolerated, indicating that this is the RD for Japanese pts with MDS similar to a Phase III study in the U.S. Based on these clinical outcomes, Japanese pts with MDS are participating in a global randomized Phase III study to compare rigosertib with physicians’ choice of treatment.

PB1919

SAFETY, EFFICACY, AND PHARMACOKINETICS OF INTRAVENOUS RIGOSERTIB IN JAPANESE PATIENTS WITH RECURRENT/RELAPSED OR REFRACTORY MYELODYSPLASTIC SYNDROMES: A MULTICENTER, OPEN-LABEL, PHASE I STUDY
M. Ogura1,2,*, Y. Kobayashi1, S. Kuboishi1, M. Hidaka2, T. Uchida2, Y. Takamatsu2
1Department of Hematology, Tokai Central Hospital, Kakamigahara, 2Department of Hematology and Oncology, Nagoya Daini Red Cross Hospital, Nagoya, 2Department of Hematology, National Cancer Center Hospital, Tokyo, 3Department of Hematology, National Hospital Organization Okayama Medical Center, Okayama, 4Department of Hematology, Red Cross Society Himeji Hospital, Himeji, 5Department of Hematology, National Hospital Organization Kumamoto Medical Center, Kumamoto, 6Division of Medical Oncology, Hematology, and Infectious Diseases, Fukuoka University Hospital, Fukuoka, Japan

Background: Rigosertib, a novel phosphoinositide 3/polo-like kinase pathway inhibitor, selectively induces the apoptosis of cancer cells and is safe and well tolerated in pts with recurrent/relapsed or refractory MDS.

Aims: We conducted a multicenter, open-label, Phase I study of intravenous rigosertib to evaluate its safety, efficacy, and pharmacokinetics and to determine the recommended dose (RD) for Japanese pts.

Methods: The key eligibility criteria were as follows: recurrent/relapsed or refractory MDS; age: 20 or older; Fab classification (RA, RARS, RAEB, RABE-T, and CMML), excepting patients at IPSS low- or Int-1 risk with respect to RA; ECOG PS of 0 to 2; no major organ dysfunction; and written informed consent. Treatment was administered intravenously for 72 h, followed by 11-day monitoring in one 14-day cycle. The primary endpoint was dose-limiting toxicity (DLT). The secondary endpoints were 1) safety as assessed with adverse events (AEs) and laboratory results; 2) efficacy as assessed with the International Working Group 2006 criteria; and 3) pharmacokinetics.

Results: The objectives of this study were analyzed the clinical features and course of patients with AML with MRC, in order to evaluate the impact of different therapeutic regimens in this subgroup.

Methods: We report an unicentric retrospective study of 76 patients with AML with MRC, over the past ten years in a single institution in Spain. We analyzed the overall survival (OS) among the subgroup of patients with over or under 65 years, and the different types of treatment that has been offered.

Results: Median age was 69 years with a male predominance, and 66% was preceded by a known myelodysplastic syndrome with a median interval of 18 months to progress to AML. The more frequent genetic abnormalities in descending order were trisomies, del(5q), and del(7q)/-7. The patients aged >65 <65 and <65 were 70% and 30%, respectively. The patients aged >65 received DNA hypomethylating agents (40%), anthracycline-cytarabine combinations (9%), low-dose cytarabine or hydroxyurea (17%), and supportive measures (34%). The patients aged <65 received induction chemotherapy with anthracycline-cytarabine combinations so as to continue with post-consolidation management with allogenic transplantation, but the 44% died over the induction chemotherapy (OS: 2.2 months). The OS in patients aged <65 was 20.2 months in chemotherapy plus allogenic transplantation. The OS in patients aged >65 was 10.3 months in the group of anthracycline-arac combinations, 3.81 months in the DNA hypomethylating agents group, 2.8 months in the low-dose of AraC/hydroxyurea, and 0.5 months in supportive measures group (Figure 1).

Summary/Conclusions: The AML with MRC patients is a group with difficult treatment decisions and poor prognosis, in whom only the chemotherapy plus allogenic transplantation treatment manage long-term survival. In patients aged >65, there is not a significant difference among groups, although the chemotherapy with anthracycline-cytarabine seems to reach a better OS versus other available treatments.

IRON CHELATION THERAPY IMPROVES HEMATOLOGICAL RESPONSE IN HIGH-RISK MYELODYSPLASTIC PATIENTS TREATED WITH AZACITIDINE
G. Pinto1,*, P. Herrera1
1Hematology, HOSPITAL RAMON Y CAJAL, Madrid, Spain

Background: The goals of treating older patients with Myelodysplastic Syndrome (MDS) are different than for younger patients. Few elderly patients are able to pursue an allogenic stem cell transplant. Azacitidine (AZA) improves long-term outcomes of higher-risk MDS patients and is now the reference frontline therapy of higher-risk MDS not eligible for allogeneic stem cell transplant. Anemia is the most common symptom of MDS and most patients become transfusion-dependent with the risk of iron overload. Deferasirox is an orally available iron chelator administered once-daily in transfusion-dependent patients with various chronic anemias. Its efficacy has been established in controlled clinical trials.

Aims: We report our experience on using the azacitidine in patients with high-risk MDS, evaluating the efficacy and safety. Concomitant treatment with deferasirox was performed in a routine clinical setting following Consensus Guidelines on Iron Chelation Therapy.

Methods: In our Institution from October 2009 to January 2017 we have...
treated 32 elderly patients (19 male and 13 female, median age 76 years, r. 71-88) affected by HIGH-RISK MDS (IPSS INT-2/HIGH). Patients received subcutaneous azacitidine at 75mg/m2 daily for 7 days every 4 weeks. All patients completed at least 6 cycles of therapy, 12/30 (40%) patients underwent more than 8 cycles of therapy. 18/30 patients underwent as well iron chelation therapy with deferasirox receiving a starting dosage of 10 mg/kg/day, subsequently titrated according to serum ferritin (SF) measured monthly.

Results: Complete response (CR), partial response (PR), and hematologic improvement (HI) were observed in 2 (7%), 5 (17%), and 12 (40%) patients, respectively. The median number of cycles to clinical response was 4 (range 4-8). The 2-year rate of transformation to acute myeloid leukemia-free survival was 48%. Five serious adverse events occurred in five patients with one fatal outcome. 16 out of 18 patients who showed any hematologic response (CR+PR+HI) meeting International Working Group 2006 criteria had also performed deferasirox therapy. No increased toxicity was noted when deferasirox was used concomitantly with azacitidine.

Summary/Conclusions: Our results confirm the effectiveness of the therapy with azacitidine in HIGH-RISK MDS elderly patients with acceptable toxicity profile. Peripheral cytopenias were the most commonly occurring adverse event, with gastrointestinal adverse events and injection-site reactions among the most commonly occurring non-haematological adverse events. In conclusion, azacitidine is an important agent for use in the treatment of elderly patients with MDS. Furthermore concurrent use of deferasirox in patients with iron overload seems to significantly improve the hematologic response by reducing transfusion requirement.

PB1921

EXPLORING THE RISK OF RED CELL ALLOIMMUNIZATION IN MYELODYSPLASTIC SYNDROMES. TO WHAT EXTEND COULD CYTOTOGENIC ANALYSIS AT DIAGNOSIS PREDICT THIS RISK?

I. Koutsavlis1, J. Falconer2, J. Fleming3, H. Roddie1
1Haematology, 2Blood Transfusion Service, 3Cytotgenics Service, NHS LOTHIAN, Edinburgh, United Kingdom

Background: Red cell alloimmunization poses a huge burden for the blood transfusion services as it may be associated with crossmatching difficulties, haemolytic episodes and transfusion reactions for the transfused patient. Collectively, alloimmunization appears to be higher in patients with myelodysplasia (MDS) and chronic myelomonocytic leukaemia (CMML) with a rate somewhat around 15%. Identification of patients at risk of developing alloantibodies would be of clinical significance as antigen negative red cells could be crossmatched in advance for use in clinical practice. Largely, studies have failed to predict this cohort of patients and little is known regarding identifiable risk factors.

Aims: To this end, we focused on exploring the cytogenetic profile from patients with MDS and CMML along with demographic characteristics as risk factors for alloimmunization.

Methods: A retrospective analysis was performed in 360 transfused patients with MDS (74.4%) and CMML (25.6%) registered in our local database between 1980 and 2016. Prognostic variables (age, sex, disease subtype) were assessed using a multivariate prediction model in SPSS statistical software. Cytotgenetics at diagnosis were available in 228 of the above patients and uni-variate analysis was performed separately.

Results: The mean age at diagnosis was 73 years (range 20-95) with 58.3% male patients. Overall, 45 patients (12.5%) formed 76 antibodies [88 alloantibodies, 8 autoantibodies] with 42% of them developing more than 1 antibody. 5 additional patients developed autoantibodies without alloantibodies. Alloantibody specificities were as follows: E (22 cases), C (8), K (7), Cw/Jka/Kpa (5 cases each), Lu(a), fya (3 cases each), M (2), C, D/ Chido/ Bag (1 case each). Collectively, alloantibodies against the RH and Kell systems encountered in 69% of this cohort. 6 out of 8 patients with anti-C had also developed a second antibody. In a regression model, none of the following variables reached statistical significant level as predictors for immunization: age (p=0.59), sex (p=0.07), MDS WHO subtype (p=1.0). 228 patients had known cytogenetics at diagnosis. Normal profile (46, XY or 46, XX) was encountered in 58.8%. Similarly, univariate analysis of this cohort (normal versus abnormal cytogenetics) showed no significant difference (p=0.64). Further subgroup analysis was performed to explore whether the risk was increased in patients with poor or very poor cytogenetics as per IPSS-R. Descriptive statistics showed; very good/ good risk cytogenetics 69.7%, intermediate 12.7% and poor/ very poor 17.5%. Logistic regression analysis revealed no association between cytogenetic groups and risk of alloimmunization (p=0.89, p=0.96 and p=0.84 respectively).

Summary/Conclusions: The rate of alloimmunization in our cohort of patients was 12.5%, slightly lower compared to published studies. The most common alloantibody found was anti-E. Prognostic variables included in analysis (age, sex and cytogenetic profile) reached statistical significance in the univariate analysis. Further subgroup analysis of alloimmunization and further studies are needed to investigate other possible risk factors. Prophylactic RH and Kell antigen matched cells, when possible, would be a reasonable strategy until further knowledge is acquired.

PB1922

PROGNOSTIC MARKERS THAT PREDICT THE OUTCOME OF REDUCED INTENSITY CONDITIONING TRANSPLANT IN ADULT PATIENTS WITH MYELODYSPLASTIC SYNDROMES: A SINGLE CENTER EXPERIENCE

S. Elashwah1, S. Shama2, H. Kamel3, M. Samra4, E. Azmy1
1Clinical Hematology, 2Medical Oncology, Mansoura University, Mansoura, 3Clinical Hematology, 4Medical Oncology, Cairo University, Cairo, Egypt

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of hematologic diseases, characterized by a clonal abnormality of hematopoietic stem cells. The incidence of MDS is age-dependent. The treatment approach is to categorize patients into lower or higher risk MDS and to select a suitable treatment accordingly. HCT offers potentially curative therapy for patients with MDS. Reduced intensity conditioning (RIC) regimen was used to reduce the toxicities associated with transplant procedure. The main concept of RIC rely upon adoptive immunotherapy especially in the low risk patients allowing the graft versus leukemia to occur.

Aims: This study aimed to investigate the occurrence of allogeneic peripheral blood stem cell transplantation among the alloimmunized patients for adult patients with MDS, the effect of different prognostic factors on outcome and the effect of chronic GVHD according to IPSS risk.

Methods: A retrospectively study analyzed the fifty-one patients with MDS who underwent transplantation at the BMT unit at Nasser Institute during a period of time, between the RIC regimen from HLA non-matched related peripheral blood stem cell. Outcomes analyzed the incidence of acute and chronic GVHD, disease free survival (DFS) & overall survival (OS).

Results: They were 31 males (60.8%) and 20 females (39.2%). Their ages ranged from 17 to 60 years, with mean age±SD of 48±10.1 years, including reduced intensity conditioning (RIC) in 14 patients (27.5%), MDS–u in 13 patients (25.5%), refractory anemia (RA) in 12 patients (23.5%), refractory anemia with excess blasts II (RAEB II) in 6 patients (11.8%) and MDS with hypopcellular bone marrow in 4 patients (7.8%) and refractory anemia ring sideroblasts in 2 patients (3.9%). According to IPSS classification, 11 patients (21.6%) were low risk, 28 patients (54.9%) were intermediate-I risk group, and 9 patients (17.5%) were intermediate-II & 3 patients (5%) were high risk group. The incidence of acute and chronic GVHD were 51.1% and 28.6% respectively. The 5-year estimate for DFS of the whole group was 21.8%. In univariate analysis, covariates associated with a better OS were recipient age <40 years (p=0.02) and the presence of cGVHD (p=0.002). On multivariate analysis the presence of cGVHD is significant predictor of survival (p=0.04). Also cGVHD significantly improve the OS for low and high risk MDS group (p=0.02 and 0.03 respectively). While presence of acute GVHD, IPSS & interval between diagnosis and transplant weren't significantly affect OS (p>0.05). The 5-year estimate for DFS of the whole group was 28.6%. On multivariate analysis the presence of cGVHD significantly reduce relapse (p=0.029).

Summary/Conclusions: The presence of cGVHD significantly improved OS and reduced the risk of relapse in patients with MDS. We also found that the presence of cGVHD significantly improved OS especially in high-risk patient group, which suggests that the GVL effect may be beneficial in high-risk patients who do not receive intensive preparative regimens.

MANAGEMENT OF MYELODYSPLASTIC SYNDROMES WITH ERYTHROPOIETIC STIMULATING AGENTS IN REAL-LIFE EXPERIENCE: AN UPDATE FROM RECAMDS

C. Cerchione1, O. Viltagiano1, R. Della Pepa1, G. Cercoli1, A. E. Pareto1, M. Di Perna1, I. Soriente1, P. Danise1, A. M. D’Arco2, F. Afflinito3, F. Pane4
1Hematology, Ematologia e trapianto/au federico ii, 2Hematology, Ospedale Umberto I, Napoli, 3Hematology, Ospedale Umberto I, Nocera Inferiore (SA), 4Ematologia e trapianto/au federico ii, Napoli, Italy

Background: Erythropoietic stimulating agents (ESAs) are the frontline treatment in low-risk anemic MDS patients and an employment of this therapy in the recent years delayed the use of RBC transfusion, hypothesically by slowing the disease course. It’s matter of debate whether the clinical response is a result of proliferation and maturation of the dysplastic clone or stimulation of residual normal erythropoiesis by ESAs.

Aims: Macrocystosis is one of the cytological hallmarks of dyserythropoiesis in MDS; an analysis of the erythropoietic response to ESAs therapy in a cohort of anemic non transfusion-dependent MDS patients, enrolled in a retrospective register, RECAMDS, subgroup of Italian register, was performed.

Methods: 183 patients, treated with standard-dose ESAs, have been retrospectively analyzed (Table 1). Data analysis was performed, according to IWG 2006 criteria, at the baseline, after 3 and 6 months of continuous treatment, with a sub-analysis of the patients according to WHO and R-IPSS risk stratification. ESAs were started at mean Hb concentration of 9.3±1 g/dl, mean serum EPO concentration: 51 mU/L, after a mean time from diagnosis of 6 months (r.1-118).

Summary/Conclusions: The presence of cGVHD significantly reduce relapse (p=0.029).
PB1924
CHARACTERIZATION OF MYELODYSPLASTIC SYNDROMES WITH TRANSFORMATION TO ACUTE LYMPHOBLASTIC LEUKAEMIA
F. Martins1, J. Poux-Schouman2, R. G. Racila3, O. Sperti1, S. Blum1,1
1Haematology, 2Cytogenetics, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, 3Haematology, University clinics Freiburg, Freiburg, Germany

Background: Myelodysplastic syndromes are heterogeneous diseases with variable probability of developing a transformation to acute leukaemia. The vast majority of these cases present a transformation to acute myeloid leukaemia. We here describe a series of 4 cases of MDS/CMMML with evolution to acute lymphoblastic leukaemia. These events are very rare and are to date only published as single cases.

Aims: The aim of these study is to better define cases of MDS transforming to ALL.

Methods: We describe 4 cases of patients suffering from MDS who in the course of their disease presented with ALL. Three of these cases presented in 1 centre, 1 in the other. all cases were documented in a 17-year time span. We than performed a literature research including at the moment 37 cases of MDS transforming to ALL described as case reports.

Results: Subtypes of MDS are varying from low risk MDS with deletion (5q) (del(5q)) to refractory anaemia with excess of blasts in transformation (RAEB-T), classified as AML in newer WHO classifications (2008 and 2016) and CMMML, classified as MDS/MPN nowadays. Even if MDS subgroups are manifold, cytogetic results are less so. Two of the 4 patients described demonstrated KMT2A rearrangements, 1 already at MDS presentation, the other at ALL presentation. One patient presented with del(5q). Of the 37 cases we identified in the literature, 7 presented with del(5q) and 2 showed with anomalies of the 11q23 locus.

Summary/Conclusions: KMT2A is known to be a gene involved in myeloid neoplasms as well as in acute lymphoblastic leukaemia. In a single case like this one, it is not excluded that ALL following MDS is only by chance and “bad luck”, but at least in the patient showing the same translocation at MDS presentation and at ALL presentation, both diseases seem to be related. MLL as a cytogetic event enabling the disease a switch from one phenotype (myeloid) to the other (lymphoblastic) could be a possible explanation for this phenomenon. KMT2A rearrangement in MDS is an extremely rare event, but could explain part of the high risk of transformation into leukemia. MDS occurs in several myeloid malignancies that differ in frequency of appearance, duration of the course and the probability of transformation into acute leukemia. The choice of therapy for a particular patient is determined by the morphological variant of the disease, the prognostic group, age and comorbidity. In hypoplastic cases of MDS are often used immunosuppressive therapy.

Aims: Analysis of the effectiveness of immunosuppressive therapy in patients with primary MDS

Methods: The research included 19 patients with primary MDS from 22 to 58 years (median age 46 years, 11 male, 8 female). The diagnosis was made according to WHO classification of the MDS cases in 2008. The materials were taken only after signing by patients informed consent form to participate in the research. The calculations are performed in the R version 3.1.3 statistical package.

Results: There were patients with defined MDS subtypes: RA in 52.6%, RCM in 31.6, and RAEB in 15.8%. Hypoplastic forms of MDS were diagnosed in 63.2% patients. The increased number of lymphocytes in the bone marrow of patients was 52.6%, accumulation of lymphocytes in the bone marrow biopsy – in 36.8%. Cytogetic abnormalities were found in 21% of patients (in 5.3% complex and in 15.7% isolated. All patients used immunosuppressive therapy as a first-line treatment: Antithymocyte globulin and Cyclophosphamide (Cy) in 15.8%, monotherapy with CsA in 84.2%. CsA therapy started at a dose of 5 mg/kg per day. Dose correction performed depending on the concentration of CsA in the serum and toxicity. Median treatment was 143 days (36…1253 days). The response rate to CsA treatment was considered a complete remission (normalization of blood and bone marrow), partial remission (improvement of blood counts for more than 50% and no dependence on transfusions of blood components) or improvement (reduction in transfusion requirements by 50% or more). Complete remission was achieved in 10.5% of patients (only variant RA). Partial remission was obtained in 31.6% (variants RA and RCM) and in 36.8% (variants RA, RCM and RAEB). There was no response to treatment in 21.1% of patients (variants RCM and RAEB). Positive effect on immunosuppressive therapy significantly more likely achieved in patients with hypoplastic forms MDS (57.9%) and the presence of clusters of lymphocytes in the bone marrow biopsies (36.8%). Dependence of treatment efficiency and cytogetic abnormalities not detected.

Summary/Conclusions: The effectiveness of immunosuppressive therapy in MDS associated with a variant of the disease, bone marrow cellularity and the bone marrow lymphoid infiltration. The greatest effect of the immunosuppressive therapy can be expected in patients with hypoplastic MDS and accumulation of lymphocytes in the bone marrow biopsy.
“intermediate” (n=14), and 29.5 ng/ml in “(very) high” (n=6) with p=0.102. Regarding cytogenetic risk classification median serum 25(OH)D levels were 18 ng/ml in “(very) good” (n=48), 16 ng/ml in “intermediate” (n=14), and 29.5 ng/ml in “(very) high” (n=6). Median serum OCN levels (normal range 11-46 ng/ml) of 16 ng/ml (RA, RARS, n=35), 23 ng/ml (MDS/MPN, n=33) and 20 ng/ml (MDS/MPN, n=8) (p=0.273). When classified by IPSS-R, median serum 25(OH)D levels were 18 ng/ml in “(very) low” (n=20), 16.5 ng/ml in “intermediate” (n=14), and 29.5 ng/ml in “(very) high” (n=6) with p=0.102. Regarding cytogenetic risk classification median serum 25(OH)D levels were 18 ng/ml in “(very) good” (n=48), 16 ng/ml in “intermediate” (n=14), and 29.5 ng/ml in “(very) high” (n=6). Cytogenetic risk classification had no impact on median serum OCN levels (p=0.271). Summary/Conclusions: In summary, our cohort of patients with MDS, MDS/MPN and sAML show clearly decreased serum VD levels. The preliminary results suggest a tendency of serum VD levels to increase with higher risk MDS/sAML which is supported by positive Kendall’s tau (p=0.210). Serum OCN levels lie below normal limits, but seem not to be affected by disease risk. These results suggest specific hypotheses regarding the pathomechanism that shall be investigated on an enlarged data set, which we are continuously collecting.

JEUNILEUOMYELOCYTOCYTIC LEUKEMIA IN TURKEY: A RETROSPECTIVE ANALYSIS OF 65 PATIENTS

O. Tüfekçi1, Ü. Koçak2, Z. Kaya2, I. Yenicesu2, C. Albayrak3, D. Albayrak3

Methods: We analyzed 48 patients with IPSS-R very low/low risk (VL/L) and 37 patients with IPSS-R intermediate risk (INT) in the past 10 years in a single institution. We calculated the time of progression-free survival (PFS). We also performed a median split analysis for the patients above the median value of 0.1% in both groups. In the VL/L group, patients with a%PBC above the median had a median PFS of 2.3 years versus 1.99 years for the patients with an%PBC below the median. In the INT group, patients with a%PBC above the median had a median PFS of 1.1 years versus 0.83 years for the patients with%PBC below the median (Figure 1).

Joanella, Hospital Ramon y Cajal, Madrid, Spain

Background: We investigated the%PBC at diagnosis in IPSS-R very low, low or intermediate MS.

Aims: Our aim was to search for genetic mutations in a cohort of patients with IPSS-R very low, low or intermediate MS. We analyzed 48 patients with IPSS-R very low/low risk (VL/L) and 37 patients with IPSS-R intermediate risk (INT) in the past 10 years in a single institution. We calculated the time of progression-free survival (PFS).

Results: Median age in both groups was 69 years, and median of progression to RAEB-2 or AML was 1.96 years in VL/L group and 0.64 years in INT group.

Methods: We analyzed 48 patients with IPSS-R very low/low risk (VL/L) and 37 patients with IPSS-R intermediate risk (INT) in the past 10 years in a single institution. We calculated the time of progression-free survival (PFS). We also performed a median split analysis for the patients above the median value of 0.1% in both groups. In the VL/L group, patients with a%PBC above the median had a median PFS of 2.3 years versus 1.99 years for the patients with an%PBC below the median. In the INT group, patients with a%PBC above the median had a median PFS of 1.1 years versus 0.83 years for the patients with%PBC below the median (Figure 1).

Figure 1. Summary/Conclusions: Our results not provide evidence in order to establish a prognostic value between%PBC at diagnosis in IPSS-R very low, low or intermediate MS.

PB1928

THE PRECURSOR B CELLS AS A PROGNOSIS FACTOR IN MYELODYSPLASTIC SYNDROMES

G. Pinto1,2, P. Herrera1

Background: Myelodysplastic syndrome (MDS) constitutes a heterogeneous group of hematopoietic stem cell disorders, characterized by peripheral blood cytopenias in the presence of a dysplastic or hypercellular bone marrow. This biological heterogeneity is reflected in the clinical course, ranging from an indolent disease to entities with high risk of progression to AML and dismal prognosis. Genetic and epigenetic abnormalities are at the core of myeloid neoplasias development and despite the degree of dysplasia and blast percentages still being the main features for the WHO classification, a large amount of data has recently become available on recurring mutations in MDS, mainly due to mass parallel sequencing techniques.

Aims: Our aim was to search for genetic mutations in a cohort of patients with MDS.

Methods: We studied a total of 33 patients diagnosed with de novo MDS (WHO 2008 classification), using a Next Generation Sequencing panel comprising 45 myeloid genes.

Results: Patients were 15 male and 18 female, with a median age at diagnosis of 76 years (52 – 93 years). The MDS subtypes distribution was 16 patients (48,5%) with RAEB, 4 patients with PR, 4 with RAEB-1 and 4 with RAEB-2 (12,1% for each subtype), 3 patients (9,1%) with 5q-Syndrome and 2 patients (6,1%) with RCUD. These patients were stratified according to the IPSS as Low-risk (24,2%), Int-1 (33,3%) and Int-2 (18,2%) without any high-risk
patients. All patients required erythropoiesis stimulating agents and 9 patients received treatment with azacytidine (AZA). Among all the Int-2 patients and 3 lower risk patients who progressed to a higher risk MDS. Estimated cumulative survival at 46 months was 67% with a median OS not reached and median follow-up time of 34 months. Patients receiving AZA revealed a trend towards survival benefit (mean survival 54.2 vs 50 months), independent of IPSS and R-IPSS classification, indicating that it may be a significant. Multivariate analysis revealed that 75.8% of patients had at least one gene mutation and it was most frequently related to DNA methylation genes (n=14), particularly in TET2 (n=7 patients) and DNMT3A (n=6 patients, 7 different mutations). We found a statistically significant difference between mutations in these genes and lower absolute neutrophil count (ANC) (0.47±G/L; p<0.01). Considering only the most frequently mutated genes were related to signal transduction pathways (n=11; JAK1, JAK2, NRAS, BTL, GATA2, SH2B3, CSFR). Patients with these mutations had significantly lower serum EPO levels (p<0.01; median 32.35 vs 42.70 UI/L). Furthermore, patients with such mutations demonstrated a clear disassociation between IPSS and R-IPSS. Patients with OS of ≤12 months did not reach in patients without mutations (p<0.01), being these results independent of the IPSS and R-IPSS risk groups. We were also able to identify a trend towards worst survival in patients with previously described high risk mutations (TP53, EZH2, ASXL1, RUNX1 and ETV6 genes).

Summary/Conclusions: Our results are in agreement with those previously published regarding demographic features. The role of pre-existing cytogenetic abnormalities and prediction of survival. Myelodysplasias are among the most difficult hematological diseases to treat. Treatment of low risk and high risk myelodysplasia are completely different, the last group carrying a great risk of leukemic transformation. For all these reasons, application of the new tools to R-IPSS and R-IPSS was assessed in 84 patients (18% very low risk, 30% low risk, 22.5% Intermediate, 15.5% High risk, 14% very High risk). Leukemic transformation (IPSS-R was assessed in 84 patients: (n= 16), RAEB-1 (n=22), RAEB-2 (n= 13), RARS (n= 15), Isolated 5q- (n=4). Among 101 patients, cytogenetic abnormalities by R banding karyotype (n= 16), in patients with MDS with excess blasts. Median patient age was 63.5 years (range: 49-69), male/female ratio was 9:5. According to IPSS, 12 out of 14 patients were high-risk (2 int-2, 11,14 had >10% blasts cell count). IPSS was assessed in 84 patients: (n= 16), RAEB-1 (n=22), RAEB-2 (n= 13), RARS (n= 15), Isolated 5q- (n=4). Patients were stratified risk categories based on IPSS and IPSS-R scores; survival probabilities were estimated using the Kaplan-Meier method.

Results: Among these 101 pts, 58 were male with a sex ratio=1, 35; range in age is from 18 years to 94 years with a median of 61, 6 years. Median hemoglobin value was 80 g/L (29-150), more than 60% of patients had severe anemia mainly in the low risk group; the median absolute neutrophil count was 3 G/L (0.060-13.5), and the median platelet count was 144 G/L (5-659). Median bone marrow blast cell count was 4% (0-18). Cases were classified by myelodysplasia two types of cytogenetic abnormalities, as described in the literature, which was independent of the IPSS risk group, being observed in both low-risk and high-risk patients. These results raise the question whether hypomethylating agents may also be of benefit for lower-risk patients. We found that patients with these mutations were related to signal transduction pathways which was related to a clear survival disadvantage across all risk groups of the IPSS and R-IPSS. This unveils the question we may be facing a shift towards the molecular level in MDS risk stratification and if therapies targeted to such molecules may improve the outcome of these patients.

2Hematology, EHS ELCC CAC, Blida, Algeria

Background: Myelodysplastic syndromes (MDS) are heterogeneous disorders defined as clonal diseases involving hematopoietic stem cells and even characterized by cytopenias, with a high risk of leukemic transformation. Morphological analysis of peripheral blood (PB) and marrow aspirates or bone marrow biopsies is the first step that ensures a diagnosis of MDS. Cyto genetic studies are important means of defining different prognostic groups and even of showing how patients are eligible for this or that treatment. We conducted the first study including conventional karyotyping and fluorescent in situ hybridization (FISH) in MDS in our country.

Aims: Our study was aimed to evaluate outcome of MDS regarding IPSS and IPSS-R classification in an emerging country.

Methods: Between January 2012 to December 2018, 101 patients with MDS were consecutively diagnosed. Frequent genetic abnormalities in MDS were scored according to the 2017 classification. Cytogenetic abnormalities identified in 6 patients including three probes (5q-; 7q-; 20q-), del(17p13), MLL, inv(3) (t(3;3)). Patients were stratified into risk groups according to IPSS and IPSS-R scores; survival probabilities were estimated using the Kaplan-Meier method.

Results: Among these 101 pts, 58 were male with a sex ratio=1, 35; range in age is from 18 years to 94 years with a median of 61, 6 years. Median hemoglobin value was 80 g/L (29-150), more than 60% of patients had severe anemia mainly in the low risk group; the median absolute neutrophil count was 3 G/L (0.060-13.5), and the median platelet count was 144 G/L (5-659). Median bone marrow blast cell count was 4% (0-18). Cases were classified by myelodysplasia two types of cytogenetic abnormalities, as described in the literature, which was independent of the IPSS risk group, being observed in both low-risk and high-risk patients. These results raise the question whether hypomethylating agents may also be of benefit for lower-risk patients. We found that patients with these mutations were related to signal transduction pathways which was related to a clear survival disadvantage across all risk groups of the IPSS and R-IPSS. This unveils the question we may be facing a shift towards the molecular level in MDS risk stratification and if therapies targeted to such molecules may improve the outcome of these patients.

IRON CHELATION THERapy IN MEYLODYSPLASTIC SYNDROMES AND IN OTHER TRANSFUSION-DEPENDENT CHRONIC ANEMIAs: RETROSPECTIVE STUDY OF 69 PATIENTS FROM A SINGLE INSTITUTION.

C. Finelli1,*, C. Clissa2, M. Barraco1, G. De Maio1, M. Stanzani1, S. Parisi1, S. Paolini1, C. Bosi3, M. Cavo1

1Haematology, Ospedale Niguarda Ca’ Granda, Milano, Italy
2Internal Medicine, Ospedale Mauriziano, Torino, Italy
3Internal Medicine, Ospedale S. Filippo Neri Hospital, Roma, Italy

Background: Although several recent guidelines recommend iron chelation therapy (ICT) for iron overload in transfusion-dependent patients (pts) with lower-risk myelodysplastic syndromes (MDS), several barriers may limit the initiation or the continuance of ICT: older age, comorbidities, poor tolerance and compliance.

Methods: In our Institute, we treat all patients with a blast cell count of 10% or higher with a pre-debulking therapy pre-transplant. This is usually an AML-like, cytarabine and anthracycline based, intensive chemotherapy (I.C.). In selected cases fludarabine and cytarabine containing regimens are also used. In the last ten years, in the context of a clinical trial, a series of patients have received a less intensive, hypomethylating therapy (repeated courses of 5-azacytidine 75 mg/m²subcutaneously for 7 days), as bridge to transplant. Conditioning regimens used in MDS patients is busulfan based in younger patients (Bu-Flu, BU-Cy); in the elderly or less fit patients a RIC regimen (thiotepa 5 mg/kg e.v., fludarabine mg/m²x 3 and L-PAM 100 mg/m²) is administered.

Results: In the last ten years we performed 14 HCT (between June 2008 and 2018) with 6 patients from MDS in our patients with MDS with excess blasts. Median patient age was 63.5 years (range: 49-69), male/female ratio was 9:5. According to IPSS, 12 out of 14 patients were high-risk (2 int-2, 11,14 had >10% blasts cell count). According to our centre protocol, we treated 11 patients with EB-2 and 1 patient with EB-1 (with hypercellular bone marrow) with a debulking therapy. This was I.C. in 6 patients and 5-AZA in 6 patients. Two patients with EB-1 did not receive any therapy pre-transplant. However, both of them are not evaluable, due to early mortality. Transplant conditioning was RIC in 11/14 patients, myeloablative in 3 cases. The donor was a sibling in 9/14, MUD in 5/14. Four out of six patients treated with I.C. achieved a pre-transplant CR (83.3%), compared to one out of six in the 5-Aza cohort (17%). Four patients experienced a relapse post HCT, after a median of 8.5 months (4-11). With a median follow up of 21 months (6-68), post transplant RR was 4/12 (33.3%) and was not influenced by debulking therapy (I.C. vs 5-Aza, p=0.54), nor by pre-transplant disease state (CR vs noCR, p=0.22). In fact, 3 out of 6 patients treated with I.C. reached a CR, but only 1 out of 6 treated with 5-Aza relapsed after transplant. Three out of four patients who subsequently relapsed had received ICT transplant; type of transplant was not associated with relapse (P=1.0) The only variable that showed a trend for reduced RR was MUD transplant (p=0.08).

Summary/Conclusions: Extreme caution must be used in considering our data, given the very small patients number. In our cohort, pre-transplant intensive debulking chemotherapy, although obtained an high rate of CR, showed no effect in preventing relapse. Larger studies are necessary to assess the real utility of I.C. in this subset of frail patients.
Aims: Therefore, with the aim of assessing the safety and efficacy of ICT in the daily clinical practice, we retrospectively analyzed our single-center experience on ICT in MDS and other chronic anemias.

Methods: From October 1997, in our Institution, 69 pts (48 males), median age: 74 (23-96) yrs, with transfusion-dependent anemia, received ICT, because of a diagnosis of iron overload, i.e. both a transfusion history of at least 20 units of RBC and a serum ferritin (SF) higher than 1000 ng/ml.

Results: 40 pts (58%) were affected by lower-risk MDS (IPSS risk: low or intermediate-1), while 16 pts (23.2%) showed a higher-risk MDS (IPSS risk: high or intermediate-2) but were considered for ICT because of responsiveness to hypomethylating therapy and/or eligibility for allogeneic SCT. 16 pts (23.2%) were affected by other diseases (chronic myelomonocytic leukemia: 2 pts; idiopathic myelofibrosis: 3 pts; aplastic anemia: 9 pts; pure red cell aplasia (PRCA): 2 pts). 45 pts (65.2%) received deferasirox (DFX) as first-line treatment, 12 pts (17.4%) received DFX after a previous treatment with deferoxamine (DFO), while 9 pts (13%) received DFO and 3 pts (4.3%) received DFO after DFX because of contraindications to DFX or toxicity. Median time from diagnosis to the start of ICT: 18 months. Median number of RBC transfusions before the start of ICT: 37.5. Median SF level pre-ICT: 1964 ng/ml; median SF after ICT (last value): 1858 ng/ml; median duration of ICT: 12 (range 1-230) months. 36 pts (52.2%) continued ICT for a period ≥12 months, and 25 pts (36.2%) for a period ≥24 months. 27 pts (39.1%) showed a drop of SF <500, in spite of ICT, and 18 pts (26.1%) showed an increase of SF >5000. In conclusion, in our experience ICT appears feasible both a transfusion history of at least 20 units of RBC and a serum ferritin (SF) higher than 1000 ng/ml.

Summary/Conclusions: In conclusion, in our experience ICT appearsfeasible and effective, in terms of reduction of SF and OS, even in a population of elderly pts, if carefully selected.

VCAM-1 AS A NOVEL DRUG THERAPY TARGET OF BONE MARROW MESENCHYMAL STEM CELLS IN MULTIPLE MYELOMA

A. Ortiz-Ruz1,*, C. Alica2, L. Alejandrea3, M.M. Luze4, L. Maria5, G. Miguel1, M.-L. Jaoquin1

1Haematological Malignancies Clinical Research Unit, CNIO, 2Hematologia Translacional, Hospital Universitario 12 de Octubre, Madrid, Spain.

Background: Multiple myeloma is characterized by the clonal proliferation of malignant plasma cells in the bone marrow microenvironment. The pathogenesis of this neoplastic condition, in part, is due to pathological interactions between myeloma cells and the mesenchymal stem cells (MSC). The interactions between myeloma cells and bone marrow cells are establish through surface receptors (e.g. integrins, cell adhesion molecules, etc.), which determine tumor growth, survival, migration and drug resistance. Mesenchymal stromal cells modulate the pattern of myeloma markers on the cellular surface in vitro towards a less differentiated phenotype. However, the exact mechanism by which mesenchymal stromal cells carry out their functions is not yet fully understood.

Aims: To evaluate the effect of MSCs from healthy donors and myeloma patients over malignant plasma cells and the molecular changes produced for the interaction each other.

Methods: Interactions between both cell types were studied through different co-cultures studies. We evaluate differences between culturing primary MSC cells and MM cell line RPMi 8226. Pathological MSCs were extracted from the bone marrow of newly diagnose MM patients. On the other hand, purified healthy MSCs will be isolated from donor patients. Pathological or healthy MSCs were cultured and co-cultured 24h after seeding with MM plasma cells RPMi 8226 for duplicates at 24, 48 and 72h. The phenotypical and molecular effect of the interaction of both cells were characterized by viability through trypan blue, cell apoptosis percentage (7AAD) and variations on expression of cell surface proteins (MSCs: CD90, CD105, CD106 and CD54, MM cell: CD138, CD38, CD49d and CD11a) using flow cytometry, and statistically analyzed with GraphPad.

Results: We observed a decrease of apoptosis of MM plasma cells when are in co-culture with pathological MSCs at short-term (24h, 7AAD positive cells MM alone: 4.8%, MM in co-culture: 0.4%) and mid-term (72h, 7AAD positive cells MM alone: 16.4%, MM in co-culture: 10.7%) compared with MM plasma cells alone. However MM plasma cells not decreases the level of apoptosis at mid-term with healthy MSCs in co-cultures (72h, 7AAD positive cells MM alone: 16.4%, MM in co-culture: 18.0%). The molecular analysis showed a correlation between MSC lack of protection over MM plasma cells and the decrease in the levels of expression of VCAM-1 (CD106).

Summary/Conclusions: As reported in literature CD106 expression increase when MSCs are co-cultured with plasma cells. Adhesion of tumor cells to BMSC activates many pathways resulting in upregulation of cell cycle and anti-apoptotic proteins. MM pathophysiology is supported by a strong interaction between CD106/CD49d. Changes in VCAM-1 and VLA-4 expression have been demonstrated in cell lines assays, and were corroborated with primary cells in the context of MSCs protection over MM plasma cell. Thus, MM pathological MSCs did not change VCAM-1 levels and MM plasma cell protection be held. However, healthy MSCS have the capacity to modulate the VCAM-1 in mid-term to avoid the protection effect. Therefore, these results suggest MSCs VCAM-1 as potential drug therapy target in MM disease.

PB1934

RALA AND RALB MEDIATE CELL SURVIVAL INDEPENDENTLY OF ONCOCGENIC RAS AND PROVIDE POTENTIAL THERAPEUTIC TARGETS IN MULTIPLE MYELOMA

M. Seibold1,*, T. Stühmer1, N. Schmied1, D. Brünnert1, A. Mottok2, E. Leich2, A. Rosenwald2, C.-J. Scholz3, M. Chatterjee1, H. Einsele1, R.C. Bargou4, M.-L. Joaquin2

1Department of Internal Medicine II, University Hospital of Würzburg, 2Institute of Pathology, University of Würzburg, 3Life & Medical Sciences Institute, University of Bonn, Bonn, 4Comprehensive Cancer Center Mainfranken, University Hospital of Würzburg, Würzburg, Germany

Background: Genetic mutations and the bone marrow microenvironment contribute to disease progression, aggressive phenotype, and shorter survival in multiple myeloma (MM). Oncogenic RAS is one of the most common mutations in MM. Pathway activation through oncogenic RAS is associated with promotion of disease progression and shorter survival. Cell survival and proliferation in MM are mainly mediated via classical signaling pathways such as MEK/ERK and PI3K/Akt. Since there is a lack of specific RAS-inhibitors for clinical use, it is important to identify and analyze associated pathways, which may provide useful alternative targets for MM therapy. The small GTPaseRal has previously
been implicated in putative downstream signaling of RAS, and may therefore promote proliferation and drug survival of MM cells.

Aims: We used shRNA-mediated knockdown of RaIa and RaIB isofoms to appraise their role as potential therapeutic targets and to analyze their connection to important signaling pathways, which regulate MM cell survival and proliferation. Because oncogenic RAS is a potential activator of the RaI pathway, we investigated the role of oncogenic RAS on RaI activity.

Methods: Immunohistochemical stainings of bone marrow trephines of MM patients and Western analysis of primary MM cells and MM cell lines were performed to evaluate RaI protein expression. Transient or stable knockdown of RaIa or RaIb was achieved by electroporation of MM cell lines and the effect on cell proliferation assessed. Cell cycle was measured with flow cytometry using annexin V/propidium iodide staining. RaI pulldown assays were applied to test potential dependence of RaI activation on oncogenic RAS. Furthermore, RNA sequencing was performed to compare RaI and Ra gene expression signatures after respective knockdowns.

Results: Both RaI isoforms were expressed in primary MM cells and MM cell lines, with RaIa showing the most prominent and consistent protein expression levels. ShRNA-mediated knockdown of RaIa strongly induced apoptosis in two thirds of the tested cell lines, whereas RaIb depletion did impair MM cell survival in less than half of the cell lines. Western analysis revealed no alteration of classic PI3K/Akt pathway activation after RaI knockdown. RaI activity appears to be independent of oncogenic KRAS or NRAS. In addition, RNA sequencing revealed differing gene expression signatures for RAS and RaI.

Summary/Conclusions: RaI and its effector network constitute potential therapeutic targets in MM, which are activated independently of oncogenic K- or NRAS. Therefore, investigation of the functional network of RaI may be important to identify useful clinical targets.

CXCR4 MUTATIONS FOUND BY USING DEEP SEQUENCING WITHOUT SORTING B CELLS, AND PROGNOSTIC IMPLICATION IN WALDENSTROM MACROGLOBULINEMIA
S.-M. Kim1,2, D.W. Shin², K. Im¹, S.M. Hwang³, J.-A. Kim², H.S. Park², D.S. Lee²
1Cancer Research institute, 2Department of Laboratory Medicine, Seoul National University College of Medicine, Seoul, 3Department of Laboratory Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of

Background: Waldenstrom macroglobulinemia (WM) is a lymphoplasmacytoid lymphoma with IgM monoclonal gammapathy. Most of WM harbor MYD88 L265P and/or MYD88 mutation in correlation with high risk clinical characteristics. In addition, CXCR4 mutation in WM has been implicated in putative downstream signaling of RAS, and may therefore promote proliferation and drug survival of MM cells.

Methods: Allele-specific PCR for MYD88 was performed on 37 patients with WM, along with 161 patients with B-cell neoplasms (diffuse large B-cell lymphoma (DLBCL), B-cell acute lymphoblastic leukemia (B-ALL), chronic lymphocytic leukemia (CLL)). Deep-sequencing for CXCR4 and interphase fluorescence in situ hybridization (FISH) for 6q deletion was performed on 31 patients with WM. Clinicopathologic features were compared among 3 groups according to MYD88 and CXCR4 mutation status (Group 1, MYD88WT and CXCR4WT; group 2, MYD88L265P and CXCR4WT; group 3, MYD88L265P and CXCR4Mutation; statistical comparison, Fisher exact test, one-way ANOVA).

Results: MYD88 L265P mutation was detected in 81.3% (36/22) patients with WM, 10.8% (9/83) in patients with DLBCL, 9.5% (6/63) in patients with CLL, 0% (0/15) in patients with B-ALL, and 0% in 200 healthy persons. Among the 31 WM patients, 6 patients have CXCR4 mutation (19.4%) in the c-terminal domain (Figure 1), 1 frameshift mutation and 5 nonsense mutations. Two (28%) patients had T(14;16), and were also myeloma copy number loss (MCL) positive. Of all of them had MYD88 L265P mutation. FISH revealed 6q21 deletion in 14 patients (43.8%), and IGH rearrangement in 9 patients (28.1%). There was no correlation among cytogenetic aberrations and genetic mutation (MYD88 and CXCR4). IgM levels of group 2 (MYD88L265P and CXCR4WT) were significantly higher than that of group 1 (MYD88WT and CXCR4WT) (P=0.024). Meanwhile, IgG level was significantly lower in group 1, compared to group 3. Other clinical characteristics such as age, Hb, platelet, anemia, hyperviscosity showed no significant difference among 3 groups. Group 1 showed adverse survival and 1 year survival rate of group 1 (66.7%) was lower than group 2 (94.7%), though it was not statistically significant (P=0.24). There were no death events in group 3 (MYD88L265P and CXCR4Mutation) patients during the research period.

Summary/Conclusions: The frequency of CXCR4 mutation in Korean WM was similar to those of Caucasian. We suggest that ultra-deep sequencing using RNA sequencing can improve the detection rate of CXCR4 mutation. Patients with MYD88L265P and CXCR4WT showed higher IgM level and lower survival, suggesting an adverse prognostic implication. This is the first report on CXCR4 mutation in Korean WM patients.
THE ROLE OF NEUROTROPHINS AND ANGIOGENIC CYTOKINES IN THE PATHOPHYSIOLOGY OF PERIPHERAL NEUROPATHY IN PATIENTS WITH MULTIPLE MYELOMA
K. Łuczkowska1,*, Z. Litwińska1, E. Pius-Sadowska1, A. Sobuś1, E. Paczkowska1, B. Machaliński1
1Department of General Pathology, Pomeranian Medical University in Szczecin, Szczecin, Poland

Background: The introduction of new treatment modalities has changed significantly the prognosis of multiple myeloma (MM) patients. The novel drugs and schemes of treatment of MM have contributed to substantial extend of the overall survival time of patients. However, the administration of some of the treatments, such as bortezomib or bortezomib or carfilzomib is associated with occurrence of a serious and common side-effect problem, which is the drug-induced peripheral neuropathy. The mechanism of the development of the peripheral neuropathy is poorly understood. Nevertheless, one of its potential cause, could be inadequate concentrations of crucial trophic factors, including neurotrophic and/or angiogenic factors, which are responsible for proliferation, differentiation, survival and death of neuronal and nonneuronal cells.

Aims: The aim of this study was to elucidate the potential relationship between concentration of neurotrophic and angiogenic factors and development of peripheral neuropathy in the natural clinical course of the disease and, especially, induced by treatment regimen: VMP (bortezomib, melphalan, prednisone) or VTD (bortezomib, thalidomide, dexamethason) in patients with MM.

Methods: Peripheral blood samples were collected from patients classified into two groups: i) patients with multiple myeloma, without neuropathy and before therapy; and ii) patients with peripheral neuropathy 3or 4th induced in the course of treatment with VMP. VTD or other scheme of treatment. The control group consisted healthy age- and sex-matched subjects. Assessment of concentrations of neurotrophins (BDNF, NSE) and angiogenic factor (PDGF) were performed using Lumineux technology, which utilize microbeads coated with fluorescently labeled antibodies.

Results: Concentration of BDNF, PDGF and NSE were significantly decreased in patients after treatment regimen involving VMP or VTD who have developed peripheral neuropathy grade 3 or 4, compared with patients with newly diagnosed MM without neuropathy, before therapy and control healthy group. Additionally, plasma levels of both neurotrophins and PDGF in patients before therapy were higher than, cases of MM in control group. Obtained results may be caused by the changes in an activity of the transcription factor NF-κB during the treatment of MM, since reduction of NF-κB concentration is associated with decrease in the transcription of genes encoding BDNF, NSE and PDGF.

Summary/Conclusions: Alterations in the concentration of BDNF, PDGF and NSE suggest the cause and effect relationship between these factors and the development of neuropathy in patients with MM. Comprehensive elucidation of this phenomenon may contribute to the extension of the knowledge concerning the pathogenesis of neuropathy, and might well lead to reduction of the incidence of polyneuropathy in MM patients in the future.

SILENCE OF LONG NONCODING RNA MALAT1 BY RNA INTERFERENCE INHIBITS PROLIFERATION AND INDUCES APOPTOSIS IN MULTIPLE MYELOMA
H. Liu1,*, Z. Gong1,2, W. Yang1
1Hematology, Shengjing Hospital of China Medical University, Shenyang, China
2School of Clinical Medicine, The University of Texas, MD Anderson Cancer Center, Houston, United States

Background: Multiple myeloma (MM) is a neoplasic plasma-cell disorder characterized by abnormal proliferation of monoclonal plasma cells in bone marrow leading to various end-organ damages. Altered long non-coding RNAs (lncRNAs) levels can result in aberrant expression of gene products that may contribute to cancer biology. Metastasis-associated lung adenocarcinoma transcript 1 (MALAT1), an evolutionarily conserved mRNA-like IncRNA was originally identified with high expression in metastatic non-small-cell lung cancer and reported to be up-regulated in many other cancers. However, the function of MALAT1 in MM remains unknown.

Aims: Our study aimed to evaluate the role of MALAT1 on proliferation as well as apoptosis in MM cells in vitro and tumorigenic ability in vivo, following transfection with MALAT1-specific short hairpin RNA (shRNA) expression plasmids.

Methods: Levels of MALAT1 in human myeloma cell lines were detected by real-time polymerase chain reaction (RT-PCR) analysis. The effects of MALAT1 shRNA on viability of MM cells in vitro and vivo. were assessed by crystal violet staining and colony-forming unit assay. The effect of MALAT1 shRNA on cell proliferation was assessed by EdU incorporation assay and CCK8 assay. The effect of MALAT1 shRNA on cell apoptosis was detected by Annexin V/PI staining assay.

Results: We found that MALAT1 was high expressing in RPMI8226 and U266 cell lines. Silencing of MALAT1 by shRNA significantly inhibited the proliferation through cell cycle arrest at G1 phase and induced apoptosis, which was closely associated with activation of caspase-3/9, downregulation of Bcl-2 and upregulation of Bax. Study in vivo revealed that silencing of MALAT1 delayed the tumor growth and led to apoptosis in mice bearing myeloma xenografts.

Summary/Conclusions: MALAT1 may serve as a promising novel therapeutic target in human MM. Notably, the inhibition of MALAT1 by shRNA may prove to be an effective genetic therapeutic strategy for MM treatment.
The effect of MEG3 on cell apoptosis, cell proliferation and angiogenesis were gained from CDK-8, flow cytometric analysis and transwell invasion assays in MM cell lines ARP-1 and LP-1. Insights of the mechanism of competitive endogenous RNA (ceRNA) were gained from bioinformatic analysis, luciferase reporter assays and RNA binding protein immunoprecipitation (RIP) assay. Results: MEG3 expression was significantly decreased in MM patients with advanced stage III and IV disease, and RB, TP53 and NOTCH1 mutations. Overexpression of MEG3 promoted cell apoptosis and inhibited cell proliferation, migration and angiogenesis in MM ARP1 and LP-1 cell lines. Furthermore, MEG3 increase the expression of phosphatase and tensin homolog (PTEN) and consequently inhibit MM cell proliferation and angiogenesis through sponging miR-181a in a manner induced by PTEN by luciferase assay. Summary/Conclusions: MEG3 functions as a tumor suppressor in MM. High expression of MEG3 is a marker for good survival. We reveal a novel mechanism that MEG3 as a ceRNA of the PTEN gene by competing for miRNA-181a binding sites and thereby regulate the expression of the PTEN mRNA.

**IMPROVE RISK-STRATIFICATION OF MULTIPLE MYELOMA PATIENT WITH MICROFLUIDIC DEVICES**

C. Li¹, L. Gao¹, Y. Zeng¹, X. Zhang¹, J. Zhong¹.

¹University of Southern California, Los Angeles, United States

Background: Cytogenetic alterations are required for risk stratification of multiple myeloma (MM); however, current pathology assays performed on bone marrow samples directly can produce false negatives due to the unpredictable distribution and rarity of MM cells. A more accurate method is needed for MM diagnosis and risk-stratification. We develop a new microfluidic device to facilitate micropore depletion for enhancing the detection of cytogenetic alterations in plasma cells.

Aims: Improve accuracy of risk stratification for multiple myeloma patients.

Methods: Bone marrow samples from 48 MM patients were divided into two parts each. One part was directly detected by classical flow cytometry and FISH while the other part was first enriched by microfluidic size selection and then underwent CD45-depletion (MF-CD45-TACs). The enriched samples were then analyzed by flow cytometry and FISH and compared to the classical analysis.

Results: MF-CD45-TACs significantly increased the percentage of CD38+CD138+ cells to 37.7%±20.4% (P<0.001) compared to 10.3%±6.5% in the marrow. After the MF-CD45-TACs enrichment, the detection rate of IgH rearrangement, del(13q14), del(17p) and 1q21 gains rose to 56.3% (P<0.001), 37.5% (P<0.001), 22.9% (P<0.001) and 41.7% (P<0.001), respectively, all significant increases compared to untreated samples.

Summary/Conclusions: We have developed a rapid, simple assay for improved diagnostics and risk-stratification for MM. With more precise diagnostics, the clinical outcomes of MM will be significantly improved.

**SERUM FREE LIGHT CHAIN RATIO IS AN INDEPENDENT RISK FACTOR FOR PROGRESSION IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE**

R. Cherif1*, B. Salah Eddine1

1University of Southern California, Los Angeles, United States

Background: Monoclonal gammapathy of undetermined significance (MGUS) is a premalignant plasma cell proliferative disorder found in approximately 3% of the general population 50 years of age and older. MGUS is associated with progression to multiple myeloma or related malignancy at a rate of 1% per year. Thus the risk of malignancy for a 50-year-old patient with a 25-year life span is 25%. Aims: We hypothesized that the presence of monoclonal free kappa or lambda immunoglobulin light chains in monoclonal gammapathy of undetermined significance (MGUS), as detected by the serum free light chain (FLC) assay, increases the risk of progression to malignancy. Methods: 90 Patients seen at the Hematology consultation from 2010 to 2015 with MGUS have a serum M protein less than 30 g/L, bone marrow plasma cells less than 10%, and no anemia, hypercalcemia, lytic bone lesions, or renal failure that would be indicative of a malignant plasma cell disorder. The prognostic effect of abnormal kappa-to-lambda FLC ratio on progression of MGUS was studied. We also examined whether the risk of progression varied depending on the extent to which the FLC ratio was abnormal (the normal reference range of k/l ratio 0.26 to 1.65).

Results: The median age at diagnosis of MGUS was 59 years (35-92years). 62 Womans and 28 Mans Sex ratio=2.2. Serum electrophoresis and immuno- electrophoresis or immunofixation was done in 85 patients. Of these, The median serum M protein size at diagnosis was 12 g/L (1.7-28.5 g/L). IgG monoclonal - 89% (75%), and non IgG monoclonal - 22 patients (25%). A monoclonal serum M protein size at diagnosis was 12 g/L (1.7-28.5 g/L). IgG monoclonal - 89% (75%), and non IgG monoclonal - 22 patients (25%). An abnormal serum M protein size at diagnosis was 12 g/L (1.7-28.5 g/L).

Summary/Conclusions: An abnormal serum free light chain (FLC) assay increases the risk of progression to malignancy. An abnormal FLC ratio (kappa-lambda ratio <0.26 or >1.65) was detected in 27 (30%) patients. At a median follow-up of 5 years, malignant progression had occurred in 6 patients (6.6%) with an abnormal serum FLC ratio.

**INTENSITY OF EXPRESSION OF MULTIDRUG RESISTANCE GENES AFFECT ON THE OVERALL SURVIVAL OF PATIENTS WITH MULTIPLE MYELOMA WHO WERE TREATED WITH BORTezOMIB AND ASSOCIATED WITH THE INITIAL MULTIDRUG RESISTANCE**

Y. Chermykh1, A. Golenkov2, L. Vysotskaya1, K. Belousov1

1clinical haematology, Moscow Regional Research and Clinical Institute, Moscow, Russian Federation

Background: Bortezomib is an important drug in multiple myeloma (MM) treatment, but the resistance to this treatment exist. Many conflicting data suggests that cellular overexpression of multidrug resistance (MDR) genes may reduce the effectiveness of bortezomib - containing treatment. We have developed a rapid, simple assay for improved diagnostics and risk-stratification for MM. With more precise diagnostics, the clinical outcomes of MM will be significantly improved.

Aims: We evaluated the changes of intensity of expression of MDR genes in patients with newly diagnosed and refractory/relapsed multiple myeloma and the effect of expression of MDR genes such as MDR 1, MRP 1, BCRP, LRP on the overall survival of patients after treatment with bortezomib. Methods: We have developed a rapid, simple assay for improved diagnostics and risk-stratification for MM. With more precise diagnostics, the clinical outcomes of MM will be significantly improved.

Results: In both groups of patients had comparable expression of all studied MDR's genes. The development of clinical resistance to treatment with alkylating agents were accompanied by an increase in mRNA expression of all studied genes. However, the statistically significant increase the expression of the intensity obtained for LRP gene only (the average intensity of the expression of mRNA LRP gene in ND MM 0.9±0.24, with RR MM 1.93±0.34, p<0.05). The MDR 1 mRNA expression was 1.50±0.34 in the group of ND MM and 1.67±0.31 in the group of RR MM, p<0.05. The expression of mRNA of MDR 1 and BCRP were 1.07±0.21 and 1.63±0.15 respectively before treatment and increased to 1.73±0.31 and 2.13±0.35 respectively in the group of RR MM, p<0.06. OS was not associated with high LRP gene expression only in group of ND MM (median of OS in patients with high LRP gene expression was 43 months and in those with low expression was 62 months, p<0.05).

Summary/Conclusions: High expression of LRP gene is associated with worse overall survival in patients with newly diagnosed MM treated with bortezomib- containing chemotherapy programs. "Genetic resource MDR" in MM is due mainly to the initial multidrug resistance. The treatment of MM by alkylating drugs increase the existing at the time of diagnosis of MDR activity of genes.
typing (IL-4, TGF-β1, IL-1α, IL-1β) was performed by PCR-SSP; study of cytokine abnormalities was performed by standard GTG-method and interphase FISH analyses with DNA probes: LSI 13(RB1)13q14, IGH/CCND1, IGH/FGFR3. LSI TP53 (17q13.1); p-values less than 0.05 were considered statistically significant.

Results: Previous results allow us to describe some cytokine genotype markers associated with the development of MM (IL-1α -889 TT, IL-1β -3962 TT, IL-6 -174 GG and IL-6 n565 GG; gr. 1) as additional negative prognostic markers but IL-4 -33 CC and TGF-β1 codon 25 GG genotypes as additional positive prognostic markers (gr. 2). However, in some MM patients we found presence of negative and positive markers together (mixed markers; gr. 3). We analyzed cytokine profiles in MM patients with different prognostic markers in their genotypes (Table 1).

Table 1.

<table>
<thead>
<tr>
<th>Genotypes with prognostic markers</th>
<th>Abnormal cytokine profile</th>
<th>Normal cytokine profile</th>
</tr>
</thead>
<tbody>
<tr>
<td>CD14 (C-159T) and IL6 (C-589T)</td>
<td>0.779</td>
<td>0.222</td>
</tr>
<tr>
<td>2nd gr. - MM patients with mixed prognostic markers in genotype: IL-4 -33CC, TGF-β3</td>
<td>0.377</td>
<td>0.622</td>
</tr>
<tr>
<td>3rd gr. - MM patients with mixed prognostic markers in genotype: IL-1α -889 TT, TGF-β3</td>
<td>0.085</td>
<td>0.333</td>
</tr>
</tbody>
</table>

The frequency of abnormal cytogenetic transformations in the 2nd gr. was noticeably lower compared to patients from the 1st and 3rd gr. (0.11 vs 0.78 vs 0.67 respectively; p<0.05). Similarly, significant differences in the frequency between patients with positive prognostic markers and normal cytokine profile (0.89) compared to MM patients of negative or mixed (0.22) or mixed (0.33) genotypes but normal cytokine profiles were also observed (p<0.05). In the 1st gr. frequency of cytogenetic abnormalities was noticeably higher compared to patients with normal profile (0.78 vs 0.22; p<0.05). Vice versa, in patients with positive prognostic markers the frequency of normal cytokine profiles was remarkably higher (0.89) compared to patients with aberrations (0.11; p<0.05).

Summary/Conclusions: Thus, our results allow to describe IL-1α -889 TT, IL-1β -3962 TT, IL-6 -174 GG and IL-6 n565 GG as markers associated with the presence of cytokine abnormalities in MM patient cells. However, IL-4 -33 CC and TGF-β1 codon 25 GG genotypes as additional negative prognostic markers associated with the development of multiple myeloma (mixed genotype) it seems that the chance of finding cytokine abnormalities is much higher compare to patients with positive prognostic markers only.

CORRELATION DEPENDENCE OF CHRONIC LYMPHOPROLIFERATIVE DISORDERS, MULTIPLE MYELOMA FROM CHANGES OF IMMUNE RESPONSE GENES PROFILE

E. Nazarova1,2, V. Shardashov1, A. Nagovitsina1, E. Zotina2, I. Dokshina2, N.Y. Semenova1,*, S. Bessmeltsev1, V. Rugal1

1Laboratory of Immunology of Leukemia, 2Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: Hematological malignancies are multifactorial diseases in the development of which play a role as environmental factors and genetic determinants. Such genetic factors include the presence in human genome of allelic variants of the regulatory regions of the innate immune response genes. At present time, they are considered as real risk factors for these diseases in a person with a certain set of genetic variants. Their distribution among the population corresponds to the population laws and has its ethno-categorical features. Analysis of the individual associations of genes polymorphism variants involved in the implementation of the immune response does not sufficiently complete answer about their role in the formation of predisposition to the development of chronic lymphoproliferative disorders (CLD) and multiple myeloma (MM). It is noted that in the pathogenesis of hematological diseases contribute significantly to certain combinations of immune response genes.

Aims: Analysis of interactions between genes based on the distribution of immune response genes combinations in chronic lymphoproliferative disorders and multiple myeloma.

Methods: The study included 176 patients aged 22-86 years (median - 61 year), identifying themselves as Caucasians residing in one region in the north-east of the Russian Federation. This group consisted of 80 patients with chronic lymphocytic leukemia/small lymphocytic lymphoma (45%), 72 with multiple myeloma (41%), 10 with diffuse large B-cell lymphoma (6%) with marginal zone lymphoma (3%) four with mantle cell lymphoma (2%), three with lymphoplasmacytic lymphoma (2%) and one patient with follicular lymphoma (1%). Genotyping of polymorphism of the innate immune response genes TLR2 (rs5743708), TLR3 (rs3775291), TLR6 (rs3743810), TLR9 (rs3743836), IL1β (rs2856841), IL2 (rs2069762), IL4 (rs2243250), IL6 (rs1800795), IL10 (rs1800871), IL12(17q17.1) frequency of normal cytokine genetic profile (rs34424920), TNFa (rs1800629), FCGR2A (rs1801274) was performed by polymerase chain reaction with allele-specific primers (LifeTech, Russia). Analysis of interactions between genes was performed using nonparametric GMDR program (Generalized Multifactor-
Myeloma and other monoclonal gammopathies - Clinical

IMPACT OF RENAL IMPAIRMENT IN NEWLY DIAGNOSED MULTIPLE MYELOMA IN A REAL WORLD SETTING
V. Bove1,*, F. Villano1, L. Díaz1, E. Riva1
1Hematología, Hospital de Clínicas, Montevideo, Uruguay

Background: Renal impairment (RI) is a frequent complication of patients with newly diagnosed multiple myeloma (NDMM), reported in 15-40% with 10% requiring hemodialysis (HD). It is associated with higher early mortality (EM) and lower overall survival (OS). Early diagnosis and treatment with new agents improve these results.

Aims: Analyze renal response, OS and EM in NDMM with RI and compare them to patients with MM without RI.

Methods: All consecutive and unselected NDMM patients treated at Hospital de Clínicas, Montevideo, Uruguay, from January 2011 to June 2015 were included. Our database was completed prospectively and included clinical and laboratory characteristics of the disease, treatment, treatment-related adverse events, response, HD requirement, renal response and mortality. Diagnosis of MM, response to treatment and degree of renal function recovery was based on the International Myeloma Working Group criteria. RI was defined as an estimated glomerular filtration rate (eGFR) <40 ml/min/1.73m², calculated by MDRD (Modification of Diet in Renal Disease) equation. Patients whose RI was explained by other causes were excluded. Early treatment was defined by initiation within 7 days after diagnosis. EM was defined as death within 3 months of diagnosis.

Results: MM was diagnosed in 52 patients, median age was 67 years (range 39-90), 61.5% were male, 38.5% had RI. The characteristics of the patients and front-line treatment are shown in Figure 1.

Summary/Conclusions: RI was frequent in NDMM and was associated with advanced disease and higher tumor mass (>90% stage III Durie-Salmon and ISS3), revealing a late diagnosis. Prompt institution of treatment and use of bZ relates to higher recovery of renal function and dalysis independence. Although toxicity and dose adjustments were higher in patients with RI this was not associated with lower response to treatment. Reversal of renal failure associates with better OS, similar to those without RI at diagnosis. EM are more prevalent in patients with RI at diagnosis. Even when the number of patients is small, this real life data supports the need of planning local strategies that lead to early diagnosis and initiation of treatment, which are crucial to reduce morbidity and mortality associated to RI in NDMM.

PB1950
THE EXPRESSION OF THE TRYPTASE POSITIVE MAST CELLS AND THE LEVELS OF IL-17, CORRELATE WITH ANGIOGENIC FACTORS IN PATIENTS WITH MULTIPLE MYELOMA
M. Kokonozaki1, C. Pappa2, R. Vyzoukaki1, A. Stavroulaki3,*, M. Devetzoglou4, A. Papadopoulou1, I. Liapis4, A. Boula5, M. Alexandrakis5
1Laboratory of Haematology, University Hospital of Heraklion, 2Department of Internal Medicine, 3Department of Haematology, Venizelion Hospital, 4Department of Haematology, University Hospital of Heraklion, 5Medical School, University of Crete, Heraklion, Greece

Background: Angiogenesis in the bone marrow plays a very important role in the progression of multiple myeloma (MM). The procedure of angiogenesis is stimulated by several factors such as VEGF, FGF-2 and metalloproteinases that are secreted straight from the tumor cells. The presence of IL-6 in the microenvironment, induces the production and the secretion of several angiogenic factors that activate inflammatory cells of the matrix, like macrophages and mast cells to secrete more angiogenic factors. IL-17 is among the most important cytokines that have an important role in the development of myeloma tumor. IL-17 is a proinflammatory cytokine that is secreted primarily by CD4 (activated memory cells) and stimulate macrophages, fibroblasts and other cells that release several cytokines. It has been reported that IL-17, induces angiogenesis in humans by stimulating the migration of vessel endothelial cells and adjusting the production of various proangiogenic factors. In a previous study, it was found that increased levels in stage II and stage III, resolved after therapy. Additionally, blocking the receptor of IL-17, with an antibody, cancels the effects of IL-17.

Aims: Aim of this study is to assess the relationship of the MCD and IL-17, in angiogenesis of MM, as well as their correlation with known angiogenic factors in disease progression.

Methods: We studied 52 newly diagnosed patients with MM. 32 women and 20 men, aged 67.±9,6 years. According to the ISS stage, 19 were stage I, 17 stage II and 16 stage III. Regarding the type of paraprotein that had been found, 31 IgG, 17 IgA and 4 patients with light chains. 20 age and sex-matched healthy volunteers, were used as controls. Serum samples and bone marrow biopsy samples were obtained from all patients prior to the initiation of treatment. Patients with impaired hepatic and renal function, chronic or acute infections, chronic inflammatory or autoimmune disorders or other malignancies were excluded from the study. We also excluded patients who were taking anti-inflammatory drugs, corticosteroids or bisphosphonates. IL-17, bFGF and ANGIOI-2 were measured in patients’ serum with ELISA method according to the manufacturer’s instructions. The MCD assessed after immunohistochemical staining using monoclonal antibody to mast cell tryptase. The MCD was measured in three hot spots (maximum vasculature area) x 100 and then we measured mast cells x 400, using a graduated slide which corresponds to an area of 0.0625 mm². MCD was calculated as mean MCD / HPF.

Results: Statistically significant differences between patients and controls were observed in all measured parameters, MCD (p <0.001), bFGF (p <0.01) and ANGIOI-2 (p<0.01). All parameters were increased in parallel with ISS stages (p <0.001) in all cases. Finally, the MCD and IL-17 correlated significantly with all the measured parameters (p <0.001)

Summary/Conclusions: The mast cells increase in the bone marrow(BM) of patients with MM. They release several transmitters that promote directly and indirectly the development of angiogenesis of MM. The progression of MM also exacerbate by increased angiogenesis in BM. In conclusion, mast cells and angiogenic factors seem to be important elements in the development of MM and become potential targets for the treatment and prognosis of the disease.

Figure 1. Characteristics of patients and overall survival according to renal function.

Overall response to first line treatment was 70% for those with RI (CR 20%) and 68.8% in patients without RI (CR 15.4%). Treatment related adverse effects were higher in patients with RI (45% vs 28.2%), being polyneuropathy the most common side effect. Patients with RI required more dose adjustments (40% vs 6.3%). Renal response: 50% reversed RI, 10% achieved renal PR and 40% renal CR, all before the 4th month from diagnosis; 77.8% started early treatment and 70% received bortezomib (bz). Patients whose RI did not reverse had late initiation of treatment in 78% and 40% received bz. Six patients (30%) remained in chronic HD, all had late initiation of treatment. Two of the 6 patients who required HD at diagnosis obtained later independence; both received bz and one was consolidated with autologous stem cell transplantation. Impact of RI on OS and EM: median OS in patients with RI was not significantly different to that of MM without RI (35.3 vs 43.3 months, p=0.346). Patients without RI had higher OS compared to those who had reversible renal failure and those who never recovered (43.3 vs 12 months, respectively, p=0.031). OS was higher in patients with RI who received bz vs other therapeutic schemes (42.5 vs 25.8 months, p=0.137). With a mean follow-up of 26 months, mortality was 40% and 28.1% in patients with and without RI, respectively. EM were also higher in patients with RI at diagnosis (50% vs 22.5%). The main cause of EM was infection in both groups.

HEALTHCARE RESOURCE UTILIZATION ASSOCIATED WITH DIFFERENT TREATMENT MODALITIES OF RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS IN THE US: FINDINGS FROM PREAMBLE
D. Kuter1, C. Chen2,*, S. Khare3, S. Perez4, T. Zyczynski2, C. Davis2, R. Vij5
1Massachusetts General Hospital, Boston, 2Bristol-Myers Squibb, Lawrenceville, United States, 3Mu Sigma, Kamataka, India, 4Mu Sigma, Northbrook, 5Washington University School of Medicine, St. Louis, United States

Background: Proteasome inhibitors (PIs), immunomodulatory drugs (IMiDs) and treatments involving both a PI and an IMID (PI+IMID) are the principal therapies for treating relapsed/refractory multiple myeloma (RRMM). The widespread adoption of these treatments may come with high healthcare resource utilization (HCRU), of which key drivers are reported in past research. It is important to further understand HCRU by different treatment modalities in real-world practice settings.

Aims: To evaluate HCRU in patients receiving different treatment modalities for RRMM.

Methods: US patients with RRMM, aged ≥18 y, with at least one prior treatment who initiated treatment with a PI, IMiD or PI+PI within 90 d before or ≤30 d after study enrollment (index therapy), were identified from PREAMBLE, an ongoing, prospective, multinational, non-interventional observational study. Patient data collected at each healthcare provider (HCP) visit, over a 3-y period or until the end of patient follow-up, included clinic/physician office visits; home healthcare, hospital outpatient and emergency room visits; and hospitalizations. Demographics and baseline characteristics were summarized using descriptive statistics. HCRU and its associated costs were analyzed using a standard period 1000 patients-per-month metric.

Results: 287 patients (median age 66 y; 56% male) were enrolled in the US. At the time of data cut-off (Sep 2016), 136 (47%) were still in the study and 151 (53%) had withdrawn; 92 (61%) of those withdrawn had died. Median (range) follow-up was 12.7 (0.5–41.0) mo. At study entry, patients were divided into three cohorts based on index therapy: PI (n=162, 56%; carfilzomib n=82/162; bortezomib n=80/162), IMiD (n=74, 26%; pomalidomide n=32/74; lenalidomide/thalidomide n=42/74), and PI+IMID (n=51, 18%; carfilzomib and/or pomalidomide n=17/51; other n=34/51). The three groups were similar with regard to sex, race, disease status, ISS stage, comorbidities and number of prior therapies (Table 1).

<table>
<thead>
<tr>
<th>Table 1. Patient characteristics and risk stratification.</th>
</tr>
</thead>
</table>

The median duration of treatment (mDoT) was longer for patients on IMID (6.4 mo), but shorter for those on PI (4.2 mo) or PI+IMID (4.4 mo). In the PI cohort, carfilzomib had a shorter mDoT than bortezomib (3.5 vs 4.7 mo). Of 3220 total HCP visits, the most common type was clinic/physician office (2732, 85%), followed by hospitalization (210, 7%) and hospital outpatient (54, 5%). Mean per-1000 patients-per-month total visits were higher for PI+IMID (876) than for PI (750) and IMID (494). This remained true for clinic/physician office, hospital outpatient and home healthcare/other. Patients on PI had more visits for management of MM treatment-related events (16%) than those on PI+IMID (10%) or IMID (7%) (Table 1). Notably, among patients on PI, those on carfilzomib had high mean per-1000 patients-per-month total visits (827), with per-1000 patients-per-month emergency room visits (18) and hospitalizations (78) higher than any other treatment; 19% (175) of visits were made for management of treatment-related events.

Summary/Conclusions: Routine management of MM and treatment-related events drive HCRU, which may differ by treatment. Hospitalizations and hospital outpatient visits remain key drivers of HCRU in MM, which highlights an unmet medical need for effective therapy with better safety profiles.

ASSOCIATION OF SERUM HEAVY/LIGHT CHAIN PAIR SUPPRESSION WITH RISK FACTORS FOR PROGRESSION IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE AND SMOLDERING MYELOMA
I. Isola1,*, M.T. Sanz2, M.T. Cibeira1, L. Rosiñol1, E. Lozano1, J.I. Aróstegui3, M. Elena4, N. Tovar1, J. Yagüe3, E. Mogas2, J. Bladé3, C. Fernández de Larra4
1Hematology (Amyloidosis and Myeloma Unit), Hospital Clinic de Barcelona, 2Immunology, Hospital de la Santa Creu I Sant Pau, 3Immunology (Amyloidosis and Myeloma Unit), 4Biochemistry (Amyloidosis and Myeloma Unit), Hospital Clinic de Barcelona, Barcelona, Spain

Background: Monoclonal gammopathy of undetermined significance (MGUS) and smoldering multiple myeloma (SMM) are conditions that usually precede symptomatic multiple myeloma (MM). Risk stratification is crucial, considering the heterogeneous progression rate among these patients and the chemoprevention trials encouraged for high risk individuals. A number of prognostic factors for progression have been identified. In this sense, the novel Hevylite assay now enables us to accurately measure each isotype-specific heavy and light chain (HLC). Recently, isotype-specific uninvolved HLC pair suppression was described as an independent predictor of progression to MM in patients with MGUS. The role of Hevylite as a prognostic factor in SMM is less investigated.

Aims: The aim of the present study was to analyze the impact of HLC pairs in a series of patients with high risk MGUS and SMM and their relationship with other previously described risk factors.

Methods: Forty-four patients diagnosed with high risk MGUS or SMM at a single institution from March 2014 through April 2016 were prospectively included in the present study. Patients were stratified according to the Mayo Clinic and the Spanish PETHEMA group models. Samples at diagnosis were tested for HLC concentrations for the three pairs (IgG, IgM and IgA) by immunonephelometry.

Results: The clinical characteristics and risk stratification of patients are summarized in Table 1.

An abnormal HLC-pair ratio was detected in 96% of MGUS and 94% of SMM patients, with no differences depending on the heavy chain isotype. A highly abnormal HLC ratio (<0.02 or >45) was present in 9 patients (1 with MGUS and 8 with SMM). HLC-pair suppression (i.e., IgG-κ in patients with IgG-λ gammapathy) was more frequent in patients with SMM (83% vs 46%, p<0.02). Severe HLC-pair suppression (>50% lower than lower level of normal) was present in 12 (27%) patients, the majority of which had a diagnosis of SMM (83%). Severe HLC-pair suppression was significantly associated with a highly abnormal (<0.125 or >8) serum free light chain (FLC) ratio (p=0.004), abnormal/normal bone marrow plasma cell ratio >0.95 (p=0.001) and immunoparesis (p=0.005), being present in 6 (86%) of the 7 patients with high risk SMM. Suppression of the other isotypes (i.e., IgA or IgM HLC pairs in a patient with IgG gammapathy) was identified in 33 (75%) patients, namely in 18 (69%) patients with MGUS and 15 (83%) patients with SMM (p=0.48), and was not significantly
associated with other risk factors for progression. Severe suppression (>50% below lower level of normal) was significantly more frequent in sEMD patients (33% vs 8%, p=0.04) and was associated with highly abnormal FLC ratio (p<0.001), abnormal/normal plasma cell ratio >0.95 (p<0.001), severe HLC-pair suppression (p<0.001) and highly abnormal HLC ratio at diagnosis (p<0.005). The "evolving" pattern of the serum M-protein was identified in 12 patients (77%). It was significantly associated with either severe suppression of the HLC-pair or of the other isotypes. After a median follow-up of 18 months (range, 6-35) progression to symptomatic MM was observed in 3 patients. All 3 had a diagnosis of SMM with an "evolving" pattern, highly abnormal HLC-ratio and severe HLC-pair suppression.

Summary/Conclusions: The findings presented in this study indicate that highly abnormal HLC ratio, severe suppression of the HLC-matched pair and other isotype HLC pairs are associated with known risk factors for disease progression in patients with high risk MGUS and SMM. The HLC assay could become a valuable tool in the risk stratification of these patients.

EXTRAMEDULLARY MYELOMA IN THE “NOVEL AGENTS ERA”:
OUTCOME, HETEROGENEITIES AND PECULIARITIES OF A COHORT OF 84 PATIENTS RETROSPECTIVELY ANALYSED IN A MONOCENTRIC EXPERIENCE
L. Torti1, A. Morelli1, F. Bacci2, P. Di Bartolomeo1
1Department of Hematology and Bone Marrow Unit , Pescara, 2Section of Hematopathology, Department of Hematology and Oncological Sciences, S. Orsola-Malpighi Hospital, Bologna, Italy

Background: Extramedullary disease is an uncommon manifestation in multiple myeloma (MM) and can either accompany newly diagnosed disease or develop with disease progression or relapse. Extramedullary myeloma (EMM) seems to have a different pathogenesis from its much more frequently encountered medullary counterpart, showing often a poor prognosis. EMM clinical situations are extraordinarily heterogeneous and their management is challenging. This includes organ or tissue involvement resulting from hematogenous-spread and/or bone involvement originating from different kind of bones.

Aims: We evaluated the impact of this disease features on patients' outcome in the context of novel-agents.

Methods: We reviewed patients presenting EMM (median age 60, range 30-76) describing clinical and biological features (Figure 1B). Our aim was studying prognosis of bone-related extramedullary-disease (bEMD) and its relationship with soft-tissue related EMM (sEMD) in MM patients in our institution.

Results: 42 bEMD and 42 sEMD patients treated at Our Department between 2007 and 2016 were included in this study. Of the first group 10 presented EMM at diagnosis and 32 at relapse as well as 7 and 35 respectively of the second series. 31 among sEMD were dead and 11 were alive, 20 of bEMD patients were dead and 22 were still alive. EM was diagnosed using imaging techniques such as PET-CT (35%) or magnetic resonance MRI (65%). Biopsy was performed only if the lesion was accessible (82%). The treatment was heterogeneous and all patients had received either thalidomide or bortezomib in the first-line of therapy. We showed that sEMD cohort has a significantly poorer survival compared to bEMD patients (median OS from diagnosis of EMM of 13 versus 58 months, P<0.001). Finally, lung, liver (parenchyma-EM) and central nervous system-EM in sEMD patients has shown a poorer outcome when compared to skin and lymph nodes masses respectively median OS of 12 and 10 months versus 18 and 15 months P <0.001). Conversely among bEMD group there wasn't a significant advantage of outcome regarding the different bones involved. Kaplan-Meier estimates were used for survival analysis and differences between survival-times in patient subgroups were tested using the log-rank test (Figure 1A). Interestingly extramedullary-spread can be triggered by an invasive-procedures (surgery) or by a bone-fraction. In our population we have a case of breast-plasmacytoma diagnosed accidentally after reconstructive breast-surgery; where Polymerase Chain Reaction of immunoglobulin decreased after the lesion was excised, respect confirming monoclonal-CD 138/lamba plasma-cells. This patient was first treated with VTD-regimen followed by tandem-ASCT and after EM-relapse achieved complete remission with haploidentical-bone-marrow-transplantation. Allogeneic transplantation should however be remembered in the therapeutic-armamentarium against EM especially in high-risk-young-patients. Furthermore often it has been described in the literature association between EMM, IgD subtype and 4 FLC-escape, all of them were observed in relapse-setting and in sEMD group. Finally the mechanism of extramedullary spread are poorly establishe and expression of integrins and CD56 is involved. In our population absence of CD56 protein was shown in 56% of sEMD group and in 15% of bEMD case-series.

Summary/Conclusions: Clinical features of MM-patients with bEMD were different from the patients with sEMD. Outcome of this population was significantly better than the patients with sEMD, and was comparable to the patients without EMM. Even in the era of novel drugs extramedullary soft tissue has a poor prognosis especially in a relapse-setting. This work shows a significant difference in prognosis for different type of extramedullary-disease even between sEMD (better OS of skin and lymph nodes involvement) suggesting a different biological-behavior.

PB1954
DINAMIC PREDICTIVE FACTORS FOR A BETTER STRATIFICATION OF PATIENTS WITH R-ISS II NEWLY DIAGNOSED MULTIPLE MYELOMA
M. Offidani1,*, L. Corvatta1, L. Maracci1, K. Garvey1, S. Gentili1, S. More1, L. Torti1, P. Di Bartolomeo1
1Istituti di Ematologia AOUMO Riuniti di Ancona, Ancona, Italy
Background: Revised International Staging System (R-ISS), combining the ISS score with cytogenetics and serum LDH, represents the most recent prognostic model for stratifying newly diagnosed multiple myeloma patients into three different survival groups. Although data for R-ISS development have been obtained from patients enrolled in clinical trials, this prognostic score has been validated also in real-life scenario (Tandon et al., 2017). In both non-clinical trial setting and IMWG experience, the majority of patients (about 65%) belonged to the intermediate risk group (R-ISS II) that, probably, needs better prognostication.

Aims: The aim of this study was to search for a closer stratification of MM patients with R-ISS II, taking into consideration dynamic aspects, such as therapeutical strategy and response to therapy.

Methods: We investigated the impact of variables, such as initial therapy, response to therapy and maintenance therapy, on PFS and OS in 108 newly diagnosed MM patients classified as R-ISS stage II, diagnosed between 2005 and 2015, who received novel agents such as immunomodulatory drugs and proteasome inhibitors. Score weights of the prognostic factors, found to be significant according to Cox regression model, were determined based on the regression coefficients.

Results: Median age of the 108 patients was 69 years (range 44-93) and 35% of them were older than 75 years. Thalidomide- and lenalidomide-based regimens were administered to 12% and 28% of patients, respectively. Whereas 60% of the patients received bortezomib (54%) or carfilzomib-based (6%) regimens as induction therapy. Thirty-eight percent of the study population underwent ASCT and 40% received maintenance therapy. Regarding the response to the therapy, at least VGPR and PR were documented in 35%, 66% and 87% of the patients respectively. Five-year PFS and OS were 31% and 65%, respectively, similar to those reported by IMWG. Patients who did not achieve a CR, showed a significantly shorter 5yr-PFS (27% vs 50%; HR=2.9, 95%CI=1.6-4.5; p<0.0001) and 5yr-OS (53% vs 80%; HR=2.8, 95%CI=1.3-5.9; p=0.006) compared to those who did. Moreover, a significant better 5yr-PFS (71%) and 5yr-OS (93%) was observed in patients receiving maintenance therapy compared to those who did not receive maintenance therapy (48% vs 20%; HR=1.9, 95%CI=1.2-3.3; p=0.010) whereas initial therapy did not affect the outcome. Assigning a value to the variables found to be significantly related to survival measures, according to the above methods, patients were stratified into the following two groups: low-risk (LR), including 36 patients with score 0-1, i.e. patients achieving CR and receiving maintenance therapy (score 0) or achieving CR but not receiving maintenance (score 1); high-risk (HR) group, including 70 patients with score 2-3, i.e. not achieving CR, who underwent maintenance therapy (score 2) or not achieving CR and not receiving maintenance (score 3). Five-year PFS of HR patients was significantly shorter (fired in the LR group (20% vs 58%; HR=2.5, 95%CI=1.6-3.8; p=0.0001), whereas 5-year OS was 57% vs 80% (HR=1.9, 95%CI=1.1-3.3; p=0.021).

Summary/Conclusions: Our results suggest that in the R-ISS II MM patients,
the outcome of those achieving a CR and undergoing long-term therapy, is comparable with the outcome of the R-ISS I group. On the other hand, patients not achieving CR have a poor outcome, similar to those in the R-ISS III group. Therefore, these patients should require personalized therapy, aimed to achieve CR and to maintain therapy continuously.

PB1955
THE IMPACT OF THE UPDATED IMWG DIAGNOSTIC CRITERIA IN A REAL-LIFE SMM COHORT: A SINGLE CENTER EXPERIENCE
P. Vlummen1,*, F. Olofsson1
1Hematology, Ghent University Hospital, Ghent, Belgium

Background: Recently, an update of the diagnostic criteria for smoldering multiple myeloma (SMM) & multiple myeloma (MM) was published by the Internation Myeloma Working Group (IMWG). In addition to CRAB criteria, 3 biomarkers of disease were introduced being (i) the presence of >60% clonal bone marrow plasma cells (BMPC), (ii) a serum free light chain ratio (FLCRatio) > 100 & (iii) the prevalence of >1 focal lesion on whole-body MRI (WBMRI). The introduction of these biomarkers has been shown to identify patients having a 70-80% risk of progression to MM over a 2-year time period.

Aims: To evaluate the impact of IMWG criteria in routine practice, focusing on (i) the prevalence of these biomarkers, (ii) the diagnostic strength of BMPC estimation, respectively (p=0.001 and 0.009) & (iii) the addition of dynamic contrast-enhanced WBMRI (DCEMRI) in the evaluation of SMM patients.

Methods: We retrospectively identified 28 SMM cases diagnosed between 01/01/09-31/12/14. Sufficient data for analysis was available for 25 patients. All patients underwent standard clinical & laboratory evaluation, bone marrow examination & WBMRI (T1- (+/-Gd) & T2-weighted sequences, diffusion-weighted sequences & additional DCEMRI sequences using time intensity curves). Time to progression (TTP) is defined as time from diagnosis until MM development. Overall survival (OS) is defined as time from diagnosis until death from any cause.

Results: Sensitivity of bone marrow aspirate biopsy & (iii) the added role of dynamic contrast-enhanced WBMRI (DCEMRI) in the evaluation of SMM patients.

Summary/Conclusions: Our sample size of 3-10% of venous thromboembolic events (VTE). The introduction of these biomarkers has been shown to identify patients having a 70-80% risk of progression to MM over a 2-year time period.

PB1956
RISK FACTORS FOR VENOUS THROMBOEMBOLISM IN 401 MULTIPLE MYELOMA PATIENTS: OBSERVATION OVER A 25-YEARS PERIOD IN A SINGLE INSTITUTION
M. Fernández-Caballero1,*, F. de Arriba1, A. Jerez1, M. D. García1, V. Vicente1, V. Roldán1
1Servicio de Hematología y Oncología Médica, Hospital General Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Armazca, Murcia, Spain

Background: Patients with multiple myeloma (MM) have shown an incidence of 3-10% of venous thromboembolic events (VTE). The introduction of immunomodulatory drugs (IMiDs) in the treatment regimen has further increased the risk of VTE, especially when combined with steroids or chemotherapy (20-30%). Actual guidelines recommend thromboprophylaxis measures, but the proposed strategies are the results of expert consensus or derived from the extrapolation of data from many studies.

Aims: The aim of this study is to analyze the development of VTE in a large cohort of MM patients, treated for 25 years in a single institution, to assess risk factors identified in general population, actors suggested VTE risk population, also to confirm the existence of risk of IMiDs-based regimens and the relevance of anticoagulant thromboprophylaxis.

Methods: Four hundred and one consecutive patients diagnosed with MM in a tertiary University Hospital between 1991 to 2015 were included. Data about VTE development, patient characteristics, myeloma-related factors, treatment and thromboprophylactic measures were retrospectively recorded. Multivariable correlates of VTE were assessed using Cox proportional hazards analysis.

Results: The median age at diagnosis was 68 years (range 24-90 years), and 47% were males. The results concerning treatment are extracted from 374 patients that were symptomatic and received myeloma-based treatment. Among the 164 patients that received IMiDs-based regimen, 27% did not receive any antithrombotic treatment, due to the lack of strong recommendations at the beginning of the use of IMiDs-based regimens. On the other hand, the most common thromboprophylaxis was set with LMWH (54%), followed by low doses of aspirin (13%) and anti-vitamin K (VKA) (8%). Median follow was 40 months (range, 1-293) and VTE occurred in 11% of patients, with a median time from diagnosis of 10 months. IMiDs-based regimen demonstrated to be a risk factor associated on multivariate analysis, and the relevance of thromboprophylaxis has been proved, as the absence of this measure increased significantly the risk of VTE. Other factors that have also demonstrated to be independently associated with a higher risk for VTE were: BMI ≥30 kg/m2, prior Stroke or TIA, prior malignant neoplasm, and the use of high dose of dexamethasone.

Summary/Conclusions: Our data support the actual recommendation of antithrombotic prophylaxis in IMiDs-based regimens, especially in association with high dose of dexamethasone. We recommend the use of a risk factor model including obesity and previous history of thromboembolic disease or cancer, in order to guide the appropriate thromboprophylaxis measures.

PB1957
A PHASE III RANDOMIZED, OPEN-LABEL STUDY OF ISATUXIMAB (SAR650984) PLUS POMALIDOMIDE AND DEXAMETHASONE VERSUS POM AND DEX IN RELAPSED/REFRACTORY MULTIPLE MYELOMA
P. Richardson1,*, M. Attala2, J. San Miguel3, F. Campana4, S. Le-Guennec5, A.-M. Hui4, M.-L. Risse5, K. Anderson1
1Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, 2Insti- tut Univ. du Cancer Toulouse Oncopole, Toulouse, France, 3Clinica Universidad de Navarra, Navarra, Spain, 4Sanofi, Cambridge, United States, 5Sanofi, Vit- ry-Alfortville, France

Background: Treatment for refractory or relapsed and refractory multiple myelo- ma (MM) remains an unmet medical need. On this basis, belantamab mafodotin (bortezomib, carfilzomib, or ixazomib) alone or in combination. Patients will be randomly assigned in a 1:1 ratio to either ISA (10 mg/kg IV on Days 1, 8, 15, and 22 in the first cycle; Days 1 and 15 in subsequent cycles) plus Pom (4 mg on Days 1–21) and dex (15 mg/m2 on days 1, 8, 15, and 21) or Pom (4 mg on Days 1–21) and dex (15 mg/m2 on days 1, 8, 15, and 21) or Pom/dex (NCT02990338; ICARIA-MM) is being conducted to evaluate the clinical benefit of ISA in combination with Pom and low-dose dex (Pom/dex) versus Pom/dex for the treatment of adult patients with RRMM.

Methods: Eligible patients are those with RRMM and demonstrated disease progression within 60 days of the last therapy. Patients will have received at least 2 prior lines of therapy, including lenalidomide and a proteasome inhibitor (bortezomib, carfilzomib, or ixazomib) alone or in combination. Patients will be randomly assigned in a 1:1 ratio to either ISA (10 mg/kg IV on Days 1, 8, 15, and 22 in the first cycle; Days 1 and 15 in subsequent cycles) plus Pom (4 mg on Days 1–21) and dex (15 mg/m2 on days 1, 8, 15, and 21) or Pom/dex (NCT02990338; ICARIA-MM) is being conducted to evaluate the clinical benefit of ISA in combination with Pom and low-dose dex (Pom/dex) versus Pom/dex for the treatment of adult patients with RRMM.

Aims: This Phase III, prospective, multicenter, randomized, open-label study (SAR650984) PLUS POMALIDOMIDE AND DEXAMETHASONE VERSUS POM AND DEX IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

Results: Approximately 300 patients (150 in each arm) are expected to be enrolled in this study. Statistical analyses will be conducted according to a pre-specified plan. The first patient was recruited in January 2017.

Summary/Conclusions: This Phase III, prospective, multicenter trial will provide critical data for the risk-benefit assessment, safety and efficacy of treatment using the efficacy of the drug combinations compared to Pom/dex, a combination which has previously reported preliminary clinical activity and manageable toxicities in heavily pretreated patients with RRMM in a single-arm Phase Ib study.
PB1958
LONG TERM SURVIVAL OF IGM MULTIPLE MYELOMA AND WALDENSTRÖM’S MACROGLOBULINEMIA PATIENTS
M. Kraj 1, R. Poglod 2, B. Krusk 1, K. Warzocha 1, M. Prochorec-Sobieszek 1
1Department of Diagnostics for Hematology, 2Department of Transfusion Medicine, 3Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: IgM multiple myeloma (MM) and Waldenström’s macroglobulinemia (WM) are two hematologic malignancies with the common finding of monoclonal gammapathy. IgM MM is a rare and poorly characterized disease.

Aims: The paper presents clinical and laboratory results of long term observations of 15 IgM MM patients selected from a group of 889 MM patients (1.6%) diagnosed and treated for several years at the Institute of Hematology and Transfusion Medicine in Warsaw as well as 15 WM patients investigated and treated at the same period of time at our hospital.

Methods: For analysis of serum proteins new Heyviley and Freefile tests (Binding Site Ltd Birmingham, UK) were applied as well as immunofixation using Sebia (Lisses, France) reagents. Fresh and archived frozen serum samples were used for the study.

Results: The clinical presentation of IgM MM patients is heterogenic starting with typical form for non IgM MM through predominant form with characteristic hyperviscosity syndrome and severe disease course to slow and latent form with survival time up to dozens of years. In 2 patients diagnosis of IgM MM was preceded by a 3-year period of monoclonal gammapathy of undetermined significance (MGUS) while in 4 patients (27%) diagnosis of WM was preceded by a 108, 84, 78, 9 months period of IgM MGUS. Median real overall survival of IgM MM patients was 50 months, 5 patients (33%) survived above 7 years and 3 patients (20%) above 12 years. Median survival of WM patients was 108 months, 7 patients (47%) survived above 10 years, 3 patients (20%) survived above 15 years. Lytic bone lesions were found in 11 (73%) IgM MM patients and in 3 (20%) WM patients. Urine monoclonal free light chains (FLC) detected by immunofixation was present in 60% of IgM MM patients and in 13% of WM patients. Clonal Lambda light chains (LC) LCκ/LCλ ratio in serum (by Freefile) was in 75% of IgM MM patients. It was shown that IgM clonality in IgM MM and WM patients can be determined by using immunoglobulin heavy chain /light chain (HCL) immunoassays- Heyviley. Immunofixation and HLC ratios were concordant in all assessed IgM MM and WM patients. In IgM MM patients, detection of uninvolved polyclonal IgM (determined by using HLC HLC test - has prognostic significance. The evaluation of IgM HLC in 13 patients with IgM MM at diagnosis revealed a decreased concentration of uninvolved IgM (HLC IgM <0.33 g/l, HLC IgM <0.20 g/l) in 5 patients and normal values in 8 patients. Median overall survival in patients with a decreased uninvolved cell population was 15 months and in patients with normal polyclonal IgM 55 months (p<0.01).

Summary/Conclusions: 33% of IgM MM patients survive above 7 years and 13% above 12 years while 47% of WM patients survive above 10 years and 20% above 15 years. Suppression of uninvolved polyclonal IgM (detectable by using HLC test) at the time of IgM myeloma diagnosis is unfavorable prognostic factor.

PB1959
MULTI SITE PERFORMANCE EVALUATION STUDY OF THE BD ONEFLOW PLASMA CELL DISORDERS PANEL
B. Balasa 1,*, D. van Hoof 2, C. Fox 3, E. Deal Becker 2, J. Perkins 2, C. Green 2, C. Bessette 2
1Medical Affairs, 2BD Biosciences, San Jose, United States

Background: The BD OneFlow solution for plasma cell disorders incorporates a standardized flow cytometry approach based on the EuroFlow (EF) Consor- tium validated reagent system. The BD OneFlow solution enables reproducible identification and discrimination of distinct cell populations by combining standard- ized assays, setup reagents, and protocols. The plasma cell disorders (PCD) panel is composed of the BD OneFlow PCST (Plasma Cell Screening Test) and the BD OneFlow PCD. BD OneFlow PCST helps differentiate normal plasma cell populations from those requiring follow-up. The BD OneFlow PCD system is in 100% agreement (26 of 26) with the EF system in identifying patients with a plasma cell disorder. Furthermore, the BD OneFlow PCD system correctly identified 100% of patients who had a plasma cell dis- order based on clinical results.

PRACTICE GAPS AND BARRIERS TO OPTIMAL MANAGEMENT OF MULTIPLE MYELOMA PATIENTS: RESULTS FROM A MIXED-METHODS STUDY IN 8 EUROPEAN COUNTRIES
S. Murray 1, M. Mothty 2, S. Peloquin 1, N.W. van de Donk 3, S. Leitao 4, S. Labbé 5, S. West 6, E. Hofstätter-Thalmann 7, P. Sonnewald 8, C. de Brouwer 9, M. Kraj 1,*, R. Pogłod 2, B. Kruk 1, K. Warzocha 3, M. Prochorec-Sobieszek 1
1Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland, 2Department of Diagnostics for Hematology, 3Department of Hematology, Institute of Hematology and Transfusion Medicine, 4Department of Hematology, University of Antwerp, 5Hospital Antoine Béclère, 6Department of Hematology, University Pierre & Marie Curie, Paris, France, 7Department of hematology, VU University Medical Center, Amsterdam, Netherlands, 8Janssen Pharmaceutical, Barcarena, Portugal, 9Royal Mardsen, London, United Kingdom, 10Janssen Pharmaceutical, Vienna, Austria, 11Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands.

Background: Previous studies have identified gaps and barriers in Multiple Myeloma (MM) patient care, especially in relation to treatment decision making. This study aimed to: 1)Identify and better understand the practice gaps, from the healthcare providers’ perspectives, with the purpose to investigate the root causes of those gaps and find solutions to alleviate the challenges.

Aims: We conducted a study to identify the practice gaps and challenges in the diagnosis, treatment and management of MM patients, as experienced and reported by medical oncologists, haematologists and haemato-oncologists (HEM) and oncology nurses (NU) in 8 European countries between February 2016 and June 2016.

Methods: This mixed methods ethics-approved study included exploratory semi-structured interviews (phase 1) designed to generate in-depth discussion of common challenges in the diagnosis, treatment and management of MM, followed by a quantitative online survey (phase 2) designed to validate the findings from the interviews with a larger sample. Practice gaps were identified through combined analysis of data from the in-depth interviews and online surveys.

Results: A total of 364 participants (HEM=281, NU=83) from France (n=58), Germany (n=58), Russia (n=41), Spain (n=58), Italy (n=50), the UK (n=58), the Netherlands (n=16), and Belgium (n=25) participated in this study. Thirty-nine (39) interviews were conducted (HEM=28, NU=11) and 325 participants completed the online survey (HEM=253, NU=72). A majority (79%) of the sample had more than 10 years of clinical practice experience and over a third (39%) had over 20% of MM patients in their patient caseload. Three key findings were identified in the management of MM patients: 1) challenges in managing treatment side-effects. Forty percent (40%) of HEM reported lack of skills in managing cardiovascular side effects or symptoms. Over a third of HEM reported difficulties in managing fatigue (40%), skin toxicities (35%) or peripheral neuropathy (34%). NU reported that 1) managing hyperviscosity syndrome and severe disease course to slow and latent form 2) NU reported challenges in managing MM patients with 3 main areas, challenges in managing side effects, communication with patients and leverage of guidelines which show differences between HEM and NU but also between countries. The findings highlight the need for tools to aid in the training of educational activities and performance improvement interventions, adapted to the local context at a country level. Efforts should aim to address those current challenges before new therapies, such as immunotherapies, become available.
The expression of APRIL by multiple myeloma cells and their role in the evolution of multiple myeloma

Aims: Aim of this study was the study of APRIL expression in myeloma cells in the bone marrow of patients with MM and their possible association with cell proliferation and malignant behavior.

Methods: We studied 42 newly diagnosed patients with MM, 19 women and 23 men, aged 64±14.0 years. According to the ISS stage, 14 were stage I, 17 stage II and 17 stage III. Regarding the type of paraprotein that had been found, 23 cases were light chains. Serum samples with bone marrow biopsy samples were obtained from all patients prior to the initiation of treatment. Patients with impaired hepatic and renal function, chronic or acute infections, chronic inflammatory or autoimmune disorders or other malignancies were excluded from the study. We also excluded patients who were taking anti-inflammatory drugs, corticosteroids or bisphosphonates. 20 age and sex-matched healthy volunteers, were used as controls. The levels of IL-10 and IL-6 in the serum were measured by ELISA. Bone marrow infiltration by neoplastic plasma cells was calculated in%. The expression of cell proliferation index was calculated in BM biopsy sections with immunohistochemistry techniques. The expression of APRIL was also calculated with immunohistochemistry. For the control of the process we used positive control. The assessing of the staining was checked in the optical microscope, over the whole surface of each sample and had to do with the cytoplasms of tumor cells. It was dotted with brown twig. Non-specific staining was observed at the other cellular components of BM. The degree of staining was expressed as a percentage of the neoplastic plasma cells and according to the intensity of staining in four-grade scale 0: negative, +1 weak, +2 moderate and +3 intense staining. Then the proportion of plasma cells stained for each type of staining separately, was calculated using the H-score method (Histoscore), based on the formula: % / 1% +2%/3% +. Our aim is to prove if the intensity of expression is associated with disease stage.

Results: Statistically significant differences were observed between patients and controls for all parameters measured (p<0.001 in all cases). All values of the measured parameters increased in parallel with the ISS stages of the disease with the exception of Ki-67 and IL-6, which were higher in stage II (p<0.001, IL-6, p<0.001) in patients with MM compared with controls.

Summary/Conclusions: Increased expression of APRIL ligand plays an important role in development and pathology of MM and may be an important therapeutic target in the treatment of MM.
Risk groups were defined based on the overall score. To provide optimal patient treatment, combined therapy was the preferred option in the case of SPB (60%), whereas unimodal treatment strategies were more frequently used in EMP (86%). All of the 20 patients with SPB progressed to MM (55%) in a median time of 4 years, while none of the patients with EMP progressed (p<0.05). The 5-year PFS and OS was 61% and 90% respectively, 31% and 74% at 10 years. Although a tendency towards a higher PFE was observed in the EMP group, it was not statistically significant. No differences were found in PFS/OS between age groups (<60 or ≥60 years), axial vs appendicular skeleton location in SBP, type of treatment received, or the presence of MB. Furthermore, no association was found between the presence of MB at diagnosis and progression to MM (Figure 1).

**Figure 1.**

Summary/Conclusions: The age at diagnosis of SPB is significantly lower than EMP. Moreover, the progression to MM is notably higher in this group of patients. These distinct characteristics in clinical presentation and outcome could suggest a biological difference between both entities.

**RISK STRATIFICATION ALGORITHM USING REAL-WORLD DATA FROM PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA: DESCRIPTION OF CLINICAL OUTCOME BY TREATMENT REGIME**

R. Hajek1,*, M. Delforge2, M. Raab2, J. Radocha4, J. Straub5, W. Bouwmeester6, Z. Szabo7, L. Pour8, S. Gonzalez-McQuire7, V. Maisnar4

1Department of Haematology Oncology, University of Ostrava, Ostrava, Czech Republic, 2Department of Haematology, UZ Leuven, Leuven, Belgium, 3Department of Internal Medicine, University Hospital Heidelberg, Heidelberg, Germany, 44th Department of Medicine, Charles University Hospital and Faculty of Medicine, Hradec Kralove, 5Departments of Internal Medicine and Hematology, Prague General Teaching Hospital, Prague, Czech Republic, 6PharmRet International, Rotterdam, Netherlands, 7Amgen (Europe) GmbH, Zug, Switzerland, 8Department of Internal Medicine, University Hospital Brno and Faculty of Medicine, Brno, Czech Republic

**Background:** Estimation of survival for patients with RRMM, requires prognostic tools that define the relative risk of death after first relapse. We recently developed a risk stratification algorithm (RSA) using real-world data from the Czech Registry of Monoclonal Gamopathies (RMG). Our RSA uses patient and disease characteristics at diagnosis and at initiation of second-line treatment (2L), and presents outcomes to stratify patients based on their overall survival (OS) expectations from initiation of 2L treatment (Hajek et al. Blood 2016). The value of such an algorithm depends on its validation, but also on understanding the evidence that explains these differences in survival expectations.

**Aims:** To describe 2L treatment patterns by RSA group and to report OS, progression-free survival (PFS) and response by treatment received in 2L per RSA risk group.

**Methods:** Data were collected from the Czech RMG for patients aged ≥18 years who were diagnosed with symptomatic MM between May 2007 and April 2016 and in whom 2L treatment had been initiated. Predictors of OS from the start of 2L were identified using Cox regression analyses. Hazard ratios for each OS predictor were multiplied to obtain an overall score for each patient. Risk groups were defined based on the overall score. To provide optimal patient stratification, cut-offs of the score were estimated using K-adaptive partitioning for survival (KAPS) analysis.

**Results:** Data from 1418 patients were analysed. KAPS analysis defined four groups based on risk of death: low (LR; score ≤4.1; n=403), intermediate-low (ILR; score 4.2–10.3; n=635), intermediate-high (IH; score 10.4–20.1; n=237) and high (HR; score ≥20.2; n=143) risk. Median OS (months) was 57, 29, 13 and 5 for the LR, ILR, IH and HR groups, respectively. Following stratification, compared with patients in the lower risk groups, a higher proportion of those in the HR group had LDH levels above 360 U/L and an Eastern Cooperative Oncology Group Performance Status of 3–4 at initiation of 2L. Treatments received at 2L were similar across all risk groups, with bortezomib and lenalidomide being the most common 2L treatments. Patients who received bortezomib at 1L were often given lenalidomide or thalidomide at 2L and those who received thalidomide at 1L were frequently given bortezomib at 2L. This suggests that 2L treatment choice was not defined by the underlying risk of death for each patient, but rather by the type of previous treatment. For patients receiving lenalidomide at 2L (months) from start of 2L was 57, 29, 13 and 6 (Figure 1), and median PFS (months) was 18, 12, 8 and 3 in the LR, ILR, IH and HR groups, respectively. A very good partial response or better (VGPR+) was reported for 29.3%, 31.0%, 18.7% and 16.9% of patients in the LR, ILR, IH and HR groups, respectively. For patients receiving lenalidomide at 2L, median OS (months) was 48, 29, 14 and 5, and median PFS (months) was 20, 12, 10 and 3 for patients in the LR, ILR, IH and HR groups, respectively. A VGPR+ was reported for 33.6%, 22.9%, 26.0% and 7.1% of patients in the LR, ILR, IH and HR groups, respectively.

**Figure 1.**

Summary/Conclusions: The RSA effectively stratifies patients according to OS from initiation of 2L. However, these results must be validated in an external dataset. The outcomes of each risk group are mainly driven by the underlying risk of death at initiation of 2L; treatment with bortezomib or lenalidomide provided similar outcomes independent of risk group. Use of our RSA at 2L would support physician decision making to improve patient specific care.

**LACK OF CD56 EXPRESSION IN MULTIPLE MYELOMA PATIENTS WITH RISS 2 DISEASE IS ASSOCIATED WITH WORSE PROGNOSIS AND ABOLISHED WITH AUTOLOGOUS STEM CELL TRANSPLANTATION**

M. Skerget1,*, B. Skopeč1, H. Podgornik1, D. Zontar1, K. Rebersek1, T. Furlan1, P. Cerneck1

1Department of Hematology, University Clinical Center Ljubljana, Ljubljana, Slovenia

**Background:** Multiple myeloma (MM) is a hematologic disease in which accumulation of malignant plasma cells and high levels of monoclonal protein and free light chains lead to bone marrow failure, hypercalcemia, lytic bone lesions and renal failure. Myeloma cells are distinguished from normal plasma cells by an aberrant immunophenotype. They express CD56 in 70-80% and can be used to distinguish myeloma cells by flow cytometry. The expression of CD56 is constant throughout the course of the disease. The lack of CD56 expression in myeloma cells decreases the adherence of myeloma cells to the cell matrix and is associated with higher levels of bone marrow infiltration and peripheral blood involvement, higher incidence of extramedullary disease, renal insufficiency, Bence Jones protein, plasma cell leukemia and t(11;14). The lack of CD117 expression is associated with higher levels of bone marrow infiltration, renal impairment, elevated β2-microglobulin and cytogenetic.
There were 40% (2015) and 32% (2016) pts considered as eligible for ASCT. Results: Data from 515 patients from 51 centres were available for the first.

Methods: We retrospectively analyzed 110 newly diagnosed MM patients from our national registry that had data available at the time of diagnosis. Immunophenotype was determined using a panel consisting of CD19/CD38/CD45/CD56/CD138 to distinguish and to enumerate MM cells. Analysis of myeloma cells included t(4;14), t(14;16) and t(11;14) using commercially available DNA probes. Results: We found no association between CD56 expression and age, gender, elevated LDH, cytogenetic risk or RISS stage. We found a strong association between lack of CD56 expression and light-chain only or asecretory myeloma. There was an association between CD28 expression and female gender (Table 1). In multivariate analysis including age, elevated creatinine, RISS, ASCT, CD28, CD56 and CD117 expression, CD56 expression was associated with a 47% reduced hazard for progression (Exp(B)=0.527, p=0.03). Other factors with statistically significant impact on progression were ASCT and age. In patients not undergoing ASCT lacking CD56 expression in comparison to those with an aberrant CD56 expression, the difference in PFS was statistically significant with a PFS of 8 vs 18 Month (Log Rank p=0.088, Breslow p=0.046). When stratified according to RISS stage, only patients in stage 2 disease had a significant reduction in PFS with lack of CD56 expression compared to CD56 positive.

Table 1.

Summary/Conclusions: CD56 expression was prognostic for PFS only in the patient cohort not undergoing aHSCT. As previously reported aHSCT seems to aggravate the negative impact of CD56 negativity. We propose CD56 expression to be used as a prognostic marker in patients with RISS stage 2 disease and to use these patients should undergo ASCT.

PB1966

AUTOLOGOUS TRANSPLANTATION FOR MULTIPLE MYELOMA IN GERMANY – REAL-WORLD DATA FROM A NATIONWIDE, MULTI-INSTITUTIONAL SURVEY IN 2015-2016

M. Merz1,*, L. Kellermann2, W. Poenisch3, U. Mahlklecht4, S. Fries5, H. Goldschmidt6

1Klinik für Innere Medizin V, Universitätsklinikum Heidelberg, Heidelberg, 2Onkologische InformationService, Freiburg, 3Universitätsklinikum Leipzig, Leipzig, 4Immenre Medizin Hämatologie und Internistische Onkologie, Kplus-Gruppe GmbH - St. Lukas Klinik, Solingen, 5Onkologische Schwerpunktpraxis, Bamberg, 6Nationales Zentrum für Tumorerkrankungen (NCT), Heidelberg, Germany

Background: A nationwide, multi-institutional survey was performed in 2015 and 2016 to analyse routine practice for myeloma patients outside clinical trials in Germany.

Methods: We aimed to investigate implementation of autologous stem cell transplantation (ASCT) into treatment of patients with newly diagnosed or relapsed/multiple myeloma (MM) in Germany. We describe the effectiveness and tolerability of the 2 regimens among 33 patients with relapsed and/or refractory multiple myeloma (RRMM). Patients who received 1 cycle of mod-CVAD (n=15) or bort-CVAD (n=18) from Jan 1 2011 and Dec 31 2015 at the Knight Cancer Institute were included. Most patients were previously treated with refractory to proteasome inhibitors (97%/76%) or immunomodulatory agents (82%/68%) respectively. 13 received prior autologous stem cell transplant (auto-HCT), the median number of prior lines was 3 (range 1-8). High risk cytogenetic factors (t(4;14), t(14;16), or del 17p) were present in 8 and extramedullary disease in 13 patients overall. Regimens contained cyclophosphamide 300 mg/m2 IV every 12 hours for 8 doses; doxorubicin 9 mg/m2/day continuous IV infusion every 24 hours and dexamethasone 40 mg by mouth on days 1-4; vincristine 0.4mg continuous IV infusion every 24 hours on days 1-4 (mod-CVAD) OR bortezomib 1.3mg/m2 SQ on day 1 and 4 (bort-CVAD). All patients received MESNA 350 mg/m2 IV every 24 hours on days 1 through 4; granulocyte colony-stimulating factor 24– 48 hours following the completion of chemotherapy; and standard infectious prophylaxis. International Myeloma Working Group uniform response and European Society for Blood and Marrow for minor response (MR) criteria were used.

Results: The median number of cycles given was 2 (range 1–6). Cycles were followed by a 3 day break and the median follow up was 48 and 33 months in mod-CVAD and bort-CVAD respectively. The ORR was 40% in the mod-CVAD group: 6 partial (PR), 6 minor (MR), and 3 stable disease (SD) compared to 44.4% in the bort-CVAD group: 1 complete response, 7 PR, 2 MR, 6 SD and 2 progressive disease (Fishers exact p=0.80). A total of 13 patients proceeded to auto-HCT with a median progression-free survival for all patients of 12 months. The overall survival was 6 and 11 months respectively, which was comparable between arms (Log rank test p=0.6635 and 0.7369). New or worsening of peripheral neuropathy occurred in 2 and 4 patients in the mod-CVAD and bort-CVAD groups respectively. There was no significantly important association between treatment and febrile neutropenia, hospitalization, cumulative transplant-related mortality and overall survival (Fishers exact test P value >0.05). There were no statistically significant differences in safety and tolerability between treatment arms. There were no statistically significant differences in safety and tolerability between treatment arms. Three and 6 patients in the mod-CVAD and bort-CVAD arms discontinued therapy due to toxicity or treatment complications respectively.

Conclusions: Overall effectiveness and safety outcomes were similar between mod-CVAD and bort-CVAD, with both regimens demonstrating an impressive response rate among heavily pre-treated patients with relapsed/refractory disease. This is a useful salvage strategy to gain rapid dis...
PB1968

EFFECTIVITY AND SAFETY OF LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA: A REAL LIFE EXPERIENCE FROM TURKEY

Background: Lenalidomide, an immunomodulatory drug, was approved for treatment of relapse/refractory multiple myeloma (RR-MM). In Turkey, we have been used the combination of lenalidomide and dexamethasone (RD) for RR-MM patients after 2010. Therefore, we analyzed efficacy and safety of RD in Turkish patients with RR-MM.

Aims: We aimed to evaluate the outcome and the tolerability of the RD in patients with RR-MM who had been treated under the standard clinical practice between October 2010 and June 2016.

Methods: This is a retrospective, single center study. Patients’ clinical and laboratory data were collected from patient files. The overall and progression free survival (OS and PFS) were calculated on days 0, 1, 21, and 28 days after initiation of treatment. Log-rank test was used to evaluate the variables affecting OS and PFS (univariate analysis). Cox proportional hazards regression was used for multivariate analysis to analyze the independent variables affecting PFS and OS.

Results: One-hundred and twenty patients (71 male and 49 female) enrolled in the study. The median age at the start of RD was 64 years (29-84) and the median number of previous line of treatment was 1 (1-4). Seventy-two patients (60%) received RD as second-line therapy and 51 patients (42.5%) treated with autologous stem cell transplantation (ASCT). With regard to the initial dose of lenalidomide, 82 (68.3%) of the patients received the recommended dose of 25 mg per day for 21 days in a cycle of 28 days. Objective response (OR) was observed in 87 patients (72.5%); 23 patients (19.2%) achieved CR. The median follow-up was 14 months (range, 1-72 months), and the median DOR was 19 months (range, 12.4-25.6 months). Median OS and PFS were 32 months (95% CI, 15.8-48.1 months) and 21 months (95% CI, 15.8-26.1 months), respectively. In the multivariate analysis, the independent prognostic factors for OS and PFS were treated with previous ASCT, patients who achieved at least PR, patients receiving RD for more than 12 cycles. Adverse events occurred in 69 of patients (57.5%). Hematological and non-hematological adverse events were found at the same rate (n=47, 39.2%). The treatment discontinuation rate due to AEs was 11.7% (14 patients). The overall incidence rate (IR, events per 100 patient-years) of second primary malignancies (SPMs) was 0.93 (95% CI, 0.04-4.60). The rate of anemia was 12.5% and thrombocytopenia was 9.2% in all grades. Penumania (15.8%), fatigue (14.2%) and herpes infections (0.8%) have been reported as most frequent non-hematological side effects.

Summary/Conclusions: RD is a safe, well tolerated and effective treatment in patients with RR-MM. Good response, previous ASCT and using more than 12 cycles are associated with better survival. Higher OS and PFS and ORR seem to be related to using RD in the first relapse. Adverse events are manageable and lower with prophylaxis.

PB1969

OPTIMIZING THE MANAGEMENT OF NON-HEMATOLOGICAL ADVERSE EFFECTS RELATED TO LENALIDOMIDE IN RELAPSED MULTIPLE MYELOMA PATIENTS. ONE CENTER EXPERIENCE

Background: During many years, the combination of lenalidomide and dexamethasone (RD) has been an effective treatment for patients with relapsed or refractory Multiple Myeloma (RRMM). On the basis of the available evidence, treatment with RD may continue in responding patients until progression or unacceptable toxic effects. The data suggest full dose lenalidomide is important for optimal efficacy and to improve the progression free survival (PFS). Approaches to achieve higher doses of lenalidomide could include continuing therapy in responding patients and proactive adverse effects (AEs) management.

Aims: The main aim was to evaluate the incidence of two of most common non-hematologic AEs related to lenalidomide (rash and dystonia) in patients while receiving RD. The second end points were to evaluate the response of rash after switching the enoxaparin to bemiparin and to evaluate the response of the dystonia after treatment with clonazepam, instead of lenalidomide dose reduction.

Methods: We retrospectively reviewed a consecutive cohort of patients with RRMM receiving Rd (R: 25 mg on days 1 through 21, d: 40 mg on days 1, 8, 15, and 22) in 28-day cycles until progression or unacceptable adverse effects, from 2011-2016. All patients received thromboprophylaxis with low-molecular-weight heparin (LMWH) (Enoxaparin 40 mg subcutaneous daily) the first 4 cycles; thereafter, patients were switched to aspirin 100 mg in a day prophylaxis. Bemiparin 7500 anti-Xa IU once-daily dose was employed if enoxaparin was suspended. Clonazepam dose to treat dystonia was 0.5 mg twice daily. Data were analyzed with SPSS statistical v 22.0.

Results: Between 2011 and 2016 a total of 65 patients received Rd in our center. Baseline characteristics are shown in Table 1. Patients received a median of 2 previous regimens (range 1-6). 51.5% of the patients had undergone one previous autologous stem-cell transplant (ASCT). Rash occurring in 12.3% of patients (grade 2), all of them were concurrently receiving enoxaparin. All rashes resolved switching the enoxaparin to bemiparin, maintaining same dose of lenalidomide. Neither treatment with esteroids or antihistaminic were administrated. Dystonias were reported in 23, 1% of patients (grade 2), all of them dissapeared after treatment with clonazepam without lenalidomide dose reduction.

Summary/Conclusions: Rash and dystonias are frequent adverse effects of immunomodulatory drugs (IMiDs), particularly lenalidomide, often leading to treatment discontinuation and decreasing the potential benefits to patients. According to our data, the rash could be due to synergism between enoxaparin and lenalidomide. In most cases, switch LWMH letting not to reduce lenalidomide dose in order to optimize the benefit of the treatment. Clonazepam, a benzodiazepine, is useful to treat dystonias related to lenalidomide.

PB1970

PROLONGED THROMBOPROPHYLAXIS IN PATIENTS TREATED WITH LENALIDOMIDE AND DEXAMETHASONE DOES NOT SEEM STRICTLY MANDATORY TO PREVENT LATE THROMBOTIC EVENTS

Background: Venous thromboembolism (VTE) in general population is 1% annually, significantly higher in oncologic setting, in particular with Multiple Myeloma (MM). Treatment with Lenalidomide plus Dexamethasone represents an additional risk factor for VTE, with most of VTE events observed in the first six months since therapy starting. No definitive data are available on the more appropriate duration of thromboprophylaxis (TP) in patients treated with lenalidomide.

Aims: To explore: I) the incidence of late thrombotic events in a real world population of relapsed MM, addressed to Lenalidomide plus low dose Dexamethasone treatment (Len-dex), and concomitant TP with low molecular weight heparin (LMWH) performed for the first 4-6 months of therapy, without TP maintenance, II) the possible correlation between the presence of thrombotic risk factors and the occurrence of a late VTE.

Methods: We performed a retrospective analysis, after regular approval of local ethic committee, on chart data of 103 patients (pts) with relapsed MM treated with Len-dex according to label indication between January 2003 and December 2016 at our single centre institution. VTE prophylaxis was performed with daily dose of subcutaneous LMWH 4000 IU for 4-6 months, with no further TP, regardless the presence of thrombotic risk factors.

Results: Main features of patients on study were: median age 66.3 years (range 41.9-85.2 years), median previous line of therapy 3 (range 1-7), time from diagnosis to lenalidomide starting 33.3 months (range 0.3-159.9 months), median duration of Lenalidomide treatment 8 months (range 0.4-65.2 months) with the following response: sPR 96%, CR 7%. Table 1 shows type and distribution of risk factors for VTE. In details median number of VTE risk factors per patient was 2 (range 0-6), 58.2% of pts had ≥2 risk factors, 41.8% of pts (43 pts) had 0-1 risk factor for VTE. Median duration of TP is 4.8 months (range...
Table 1. Baseline distribution of risk factors for thrombosis in the population on study.

Summary/Conclusions: This study shows that LMWH is effective and well tolerated for early VTE prophylaxis during Lenalidomide plus low dose Dexamethasone. Incidence of late VTE without TP maintenance is similar to that reported with long-term antiplatelet therapy. We found no difference in factors predisposing for thrombosis among patients developing or not VTE, with a not negligible proportion of concomitant adverse events observed nearby VTE occurrence.

PB1971
ELDERLY PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA IN THE REAL WORLD
E. Yamazaki1,2,*, H. Takahashi3, D. Ishibashi2, K. Kishimoto3, K. Miyashita4, A. Numata5, Y. Hatono6, R. Kawasaki7, K. Kohara-zawa8, K. Fujimaki9, J. Taguchi9, H. Fujita10, R. Saka10, S. Fujisawa11, H. Harano10, H. Nakajima10, 1Clinical Laboratory Department, Yokohama City University Hospital, 2Department of Hematology and clinical Immunology, Yokohama City University School of Medicine, 3Department of Hematology, Saiseikai Yokohama Nakano Hospital, 4Department of Hematology, Yokohama City University Medical Center, 5Department of Medical Oncology, Kanagawa Cancer Center, Yokohama, 6Department of Hematology, Fujisawa City Hospital, Fujisawa, 7Department of Hematology & Oncology, Yamato Municipal Hospital, Yamato, 8Department of Hematology, Shizuoka Red Cross Hospital, Shizuoka, 9Department of Haematology, Yokosuka City Hospital, Yokosuka, 10Department of Hematology, Yokohama City University School of Medicine, Yokohama, Japan

Background: Many new agents for multiple myeloma (MM) were launched during the last decade, and the clinical trial using such new agents showed promising results for MM patients. However, clinical course of elderly patients with newly diagnosed MM (NDMM) in the real world is different from that reported in clinical trial.
Aims: We examined the clinical parameter to assess survival in elderly patients with newly diagnosed MM (NDMM) in the real world.
Methods: We performed a retrospective study involving 125 elderly NDMM patients from April 2012 to September 2015. Patients aged 60 years or older, who were ineligible for autologous stem cell transplantation, were selected. The study included 57 males and 68 females, with median age at diagnosis of 74 years (range, 60-95 years). ECOG performance status at diagnosis were 0-2, p=0.092).

Results: Of 125 patients, 76% received bortezomib based therapy (VMP: 49; VD: 21; VCD: 6), 6 patients received lenalidomide based therapy (Ld: 6), 10 patients were received MP therapy, 19 patients received dexamethasone therapy (high dose, 16; low dose, 3), 1 patient received radiation therapy as first line therapy, and 13 patients received only supportive care due to their fragility. After induction therapy, the overall response rate (at least partial response, PR) was 52.7% (stringent complete response (sCR) 0.3%, CR 4.5%, very good PR 16.1%, PR 29.5%). Overall survival (OS) was 74.5% at 1 year, 66.2% at 2 years with median follow-up of 19 months (range 1-52) for patients who were still alive at the date of last contact and 14 months (range 1-52) for entire cohort. Death occurred in 41 patients during the follow-up period: International staging system (ISS), with ISS1, 19; ISS2, 42; ISS3, 60; N/A, 4, can divide elderly patients into three distinct survival groups (P<0.001) (Figure 1A). Univariate and multivariate analysis showed a lower OS was associated with eGFR lower than 40 ml/min (HR 2.279, 95%CI 1.152-4.510) (Figure 1B) and serum calcium level greater than 11 mg/dL (HR 3.036, 95%CI 1.412-6.529) (Figure 1C). Among 80 patients with FISH data, survival of those with t(14;16) or del(17p) or t(14,16) was not statistically different (P=0.394). Survival of patients treated with bortezomib or lenalidomide as an induction therapy was better, while not statistically significant (P=0.066) than those who were not.

Summary/Conclusions: This study shows that LMWH is effective and well tolerated for early VTE prophylaxis during Lenalidomide plus low dose Dexamethasone. Incidence of late VTE without TP maintenance is similar to that reported with long-term antiplatelet therapy. We found no difference in factors predisposing for thrombosis among patients developing or not VTE, with a not negligible proportion of concomitant adverse events observed nearby VTE occurrence.

PNB1972
RETROSPECTIVE ANALYSIS OF 121 MULTIPLE MYELOMA PATIENTS USING THE R-ISS PROGNOSTIC STAGING SYSTEM AND RESPONSE TO FIRST LINE OF TREATMENT
R. Ghonema1,*, S. AlShemmari1, R. Pandita2, M. Hasaneen1, M. Al-Drees1
1Hematology, Kuwait cancer control centre, Kuwait, Kuwait

Background: The International Myeloma Working Group has developed the R-ISS (Revised International Staging System) as a simple and powerful prognostic staging system. We collected the LDH level and the cytogenetics of a group of patients and studied the difference between the ISS (International Staging System) and the R-ISS (Revised International Staging System) for those patients.

Aims: To evaluate and compare between the ISS and the R-ISS for a group of patients treated in Kuwait Cancer Control Centre.

Methods: A retrospective analysis of the data collected from 121 patients registered as multiple myeloma from 2011-2015. Of the patients presented to our centre after initial work up and starting the right treatment abroad. Those patients were categorised according to age, gender, ISS stage, R-ISS stage, first line therapy and response.

Results: We recognised increase of the number of the yearly diagnosed patients with myeloma 2.48% of patients the actual date of diagnosis was before 2011 but30% of patients registered in 2015. Median age of patients at presentation is 56 years old , 3.33% between30-40 years old, 18.33% between 40-50 years old , 35% between 50-60 years old , 31.67% between 60-70 years old and 11.67% between 70-80 years old. Male to female ratio 1.75:1 (Table 1). According to ISS stage patients were categorised into14 stage I, 31% stage II, 47% stage III. Restaging using the RISS revealed10% stage I, 26% stage II, 56% stage III. Almost half of our patients are diagnosed in the third stage, and more patients were shifted from stage I or II were categorised in the third stage due to either high LDH level, high cytogenetic risk or
even both. First line treatment 56% of the patients received Bortezomib based triple therapy, 22% received melphalan and prednisone (CTD) (Cylophosphamide, Thalidomide, Dexamethasone), 7% RD (Lenalidomide, Dexamethasome), 3% CyBord (Cylophos- phamide, Bortezomib, Dexamethasone), 3% RV (Lenalidomide, Bortezomib), 2% Thal-Dex (Thalidomide, Dexamethasome), 2% RT (local Radiotherapy), 2% WatchfulWait, 1% MP (Melphalan, Prednisone) and 3% refused for treatment and lost follow up.

Summary/Conclusions: Applying the RISS system to myeloma patients is a very effective and easy method to categorise myeloma patients, a significant number of patients in Kuwait are diagnosed as stage III, with median age of 56 years although the use of novel therapies shows excellent response to most of them.

PB1974

EPIDEMIOLOGY OF MULTIPLE MYELOMA. THE GRANADA MYELOMA REGISTRY

R. Rios Tamayo1, D. Sánchez-Rodríguez2, J. Sainz Pérez3, J. J. Jiménez Moleón4, M. J. Sánchez Pérez5, M. Jurado Chacón1

1Hematology, University Hospital Virgen de las Nieves, 2Hematology, FIBAO, 3Hematology, GENYO, 4Medicine Preventive, University of Granada, 5Cancer Registry, Andalusian School of Public Health, Granada, Spain

Background: The Granada Myeloma Registry is the second largest single-institution population-based registry (Rios-Tamayo et al, 2015) of multiple myeloma (MM) referenced to date. Here we update and point out the epidemiological variables of interest.

Aims: To highlight the importance of the epidemiological perspective in the knowledge and outcome of MM.

Methods: From January 1985 to February 2017 all consecutive patients diagnosed with MM at our institution have been registered, including clinical, biological and socio-demographic variables, as previously reported. A comprehensive approach to comorbidity was recorded as well as diagnostic and treatment delay. Overall survival (OS) was estimated by the Kaplan-Meier method.

Results: 700 patients have been included in the registry, 343 men (49%) and 357 women. All cases have their place of residence in the Granada province. The median age was 67 years (range: 12-93). The race was Caucasian in 99.9%. In relation to occupation, 18.4% were skilled or elementary agricultural workers. Only 9% had a previously documented precursor disease (solitary plasmacytoma, monoclonal gammopathy of undetermined significance, or smoldering MM), and 14 patients (2%) remained alive with smoldering MM without progression. The subtype of MM is IgG 55.6%, IgA 24.8%, Light Chain only 15.9%, Non-secretory 3%, IgD 0.8% and IgM 0.2%. The International Staging System (ISS) is known in 378 patients (29.5%), 2 (25.7%), and 3 (48.4%). Baseline performance status (ECOG) was: 0 (4.7%), 1 (41.1%), 2 (26.7%), 3 (21.7%), and 4 (5.9%). Comorbidity was assessed in 498 patients. 30.6% of patients were obese at the moment of diagnosis. 8.2% had other previously known or synchronous neoplasms. 150 patients (30.1%) had three or more comorbidities. Treatment delay was 12.1 months (0.1-80) and median treatment delay was 13 days. 44 patients (6.3%) were very unfit and they did not receive active treatment. Information about stem cell transplant is available in 606 cases: 151 of them (24.9%) received a first autologous transplant. Median OS for the whole cohort was 43.1 and 22.4 months for patients younger than 65 years or 65 years or older, respectively (p=0.001). For patients younger than 65 or later, median OS is not reached for younger than 65 and 40.4 months for the elderly (p=0.001). Information about the main cause of death is available in 230 patients: 101 (43.9%) of them died by infection.

Summary/Conclusions: MM is a very heterogeneous disease from a clinical, biological and epidemiological perspective. The distribution by sex is identical. Farmer is the most frequent occupation. Almost one in three patients are obese, and one in ten had another prior or associated neoplasm. Infection is the leading cause of death. Information derived from population-based registries may help to complement data from clinical trials.

PB1975

REAL WORLD USE OF IXAZOMIB WITH LENALIDOMIDE AND DEXAMETHASONE FOR PATIENTS WITH RELAPSED AND RELAPSED REFRACTORY MULTIPLE MYELOMA

M. Ziff1, S. Cheeeman3, C. Kynaku1, A. Mehta1, X. Papankolou1, N. Rabini, A. Wechalekar1, K. Yong1, R. Popati1

1University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: Ixazomib (Ixa) is a novel oral proteasome inhibitor (PI) approved in combination with lenalidomide and dexamethasone (IRD) for the treatment of patients with relapsed or refractory multiple myeloma (MM). This was based on the TOUR-MALINE-MM1 trial which demonstrated a progression free survival benefit over RD. However real world use often differs to clinical trials due to heterogeneous patient selection, more flexibility with dosing intensity and country specific prescribing practices/funding restrictions. We therefore present our real world data on the use of Ixazomib in the real world setting.

Methods: This was a retrospective review of patients sequentially treated with IRD at a large UK Haematology Centre. Patients received Ixa 4mg D1, 8, 15 with lenalidomide (dose as per label) days 1-21 and dexamethasone 40mg weekly or as tolerated every 28 days until disease progression or intolerance. In some cases, Ixa was added later to RD. RR and PFS were assessed according to IMWG criteria and haematological toxicities graded by CTCAE 4.0 criteria.

Results: Up to 31st October 2016, 30 patients were treated with the IRD schedule. The median age was 65 years (32-75), male (57%), ISS: stage I 18 (60%), stage II 4 (13%), stage III 8 (27%). 27 patients had a median of 2 (2-5) prior lines of therapy. All patients had previous treatment with a proteasome inhibitor (PI) (29 bortezomib, 5 carfilzomib) and 8 (27%) were refractory to a PI. 3 (10%) had prior lenalidomide and all remained sensitive. 23 (77%) had a prior autol-
Efficacy and Tolerability of Lenalidomide and Pomalidomide in Relapsed/Refractory Myeloma Patients in a Real World Study

G. Adams1,*, M. Collins1, C. Kyriakou1, R. Ayto1
1Haematology, Northwick Park Hospital, London, United Kingdom

Background: New agents have revolutionised the treatment of multiple myeloma. Immunomodulatory drugs (IMiD) such as lenalidomide and pomalidomide are often added to multi-relapsed patients, raising the question regarding the benefit of IMiD therapy in the real-world setting.

Aims: In our study we aimed to describe the real-world experience of the use of lenalidomide followed by pomalidomide in a relatively elderly co-morbid cohort over a 4 year period and compare this to national averages. We reviewed IMiD efficacy, including sequential lenalidomide followed by pomalidomide, together with tolerance.

Methods: Records of delivered chemotherapy cycles were retrieved from local pharmacy data and national averages from Celgene ePAF data. Outcome data collected from clinical notes and laboratory results.

Results: We collected data on 46 patients treated between 2011-2014 with lenalidomide, 17 whom progressed to receive pomalidomide. The median age at initial presentation was 71 years, with median age at starting lenalidomide 77 years (range 36-94). This gave an average of 5 years from diagnosis to commencing lenalidomide (range 1-15 years). Myeloma subtypes included IgG 28/46, IgA 11/46, light chain disease 4/46 and 3 with Igd and non-secretory myeloma. High risk cytogenetics [17p-, t(4:16), t(4:20), hypodiploidy, chromosome 1 abnormal- ities] were identified in 9/46 and 16/46 were high-risk based on biomarker staging (ISS). All patients had at least 1 preceding line of therapy before starting lenalidomide, average 2 lines (range 1-6). Prior treatment included alkyating agents/steroid duets, thalidomide combinations, bortezomib-based therapy and autograft. National average for the% of patients reaching cycle 26 was 49% compared to 91% (P=0.01), reflecting better drug adherence. The median time to neutrophil engraftment in the Ixa group was 10(9-13) days, taking the same time on average (P=0.046).

Conclusions: The BUCY regimen is a safe and effective therapy for ASCT in patients with multiple myeloma. Besides, BUCY regimen is not inferior to HDM regimen. In conclusion, BUCY regimen may replace HDM regimen as a standard conditioning regimen for ASCT in multiple myeloma.

PB1978

Multiple Myeloma with Central Nervous System Involvement, 12 Cases and Review of the Literature

G. Varga1,*, G. Miklaia2, L. Ogoscat3, Z. Csukly2, P. Reményi1, G. Szombath1, J. Mihaly1, A. Andrikovics3, G. Balázs4, B. Timár5, A. Masszi1
1Department of Haematology, Soochow University, 2The First Affiliated Hospital of Soochow University, 3Department of Haematology, University of Budapest, 4University of Medicine, Semmelweis University, 5Third Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary

Background: Central nervous system (CNS) propagation is a rare event in multiple myeloma (MM), but may become more prevalent as newer treatment options allow patients to have a prolonged life expectancy and with this comes the selection of increasingly aggressive clones.

Aims: We reviewed 12 MM cases with CNS involvement treated in two hospitals. Methods: Statistical analyses were performed using the SPSS (version 20.0) software package.

Results: Between 2008 and 2015 twelve MM patient developed CNS involvement which presented in all cases at relapse. The median age at diagnosis and at CNS presentation were 55.5 and 57.4 years. At first presentation nine had ISS 3, one ISS 2 and two ISS 1 stage disease, two patient presented orig- inally as plasma cell leukaemia. FISH showed 1q amplification in 4, 13q deletion in 4, t(4:14) in 1, t(11;14) together with 17p deletion in 1, hyper- diploidy in 1 and complex karyotype in 2 cases. In 2 cases we demonstrated the development of new karyotypic abnormalities (one 1q amplification, one 17p deletion) at CNS progression. The median number of treatment lines prior to CNS progression was 4. The median CD4/CD8 ratio was seen 1.4 and thalidomide in all but one cases, two patients had lenalidomide. Six patients had ASCT before the CNS progression from which one had a second ASCT and one a reduced intensity allogeneic transplantation. The median time from diagnosis to CNS...
progression was 23.9 (3-65) months. Eight patients presented with cerebral nerve palsies, 2 with paraplegia, 1 with hemiparesis and 1 with headache. CSF cytospin or flow cytometry was positive in 7, MRI or CT supported the diagnosis in 4 patients. Treatment consisted of combination chemotherapy, intrathecal chemotherapy, cranio-caudal radiotherapy and imids with various success. The PFS and OS from CNS progression was 63 and 125 days. Two patients survived for over a year (427 and 776 days), both responded in terms of CNS symptoms to imid-based combination therapy and one had cranio-caudal radiotherapy (Figure 1).

Summary/Conclusions: CNS progression in MM has a particularly poor prognosis as it represents a late stage of an aggressive relapse which often shows chemo-refractoriness. The differential diagnosis includes infection, autoimmune or vascular diseases of the CNS as well as paraneoplasia and drug toxicity. The CNS penetration of the effective myeloma drugs is poor except for the imids, and drugs with CNS availability are usually not very effective in refractory MM.

PB1979 DARATUMUMAB; CHALLENGES OF INTEGRATING THIS NEW THERAPY INTO STANDARD CARE L. Little1,*, R. Powles1
1Haemato-Oncology, Cancer Centre London, Parkside, London, United Kingdom

Background: Daratumumab (Darzalex) is the first anti-CD38 human Monoclonal Antibody approved for Multiple Myeloma (MM). Targeting the CD38 antigen on the surface of MM cells it causes apoptosis, and has an immune modulating tumour lysis effect. Success in Clinical trials meant that this drug, administered as single agent, or in combination with other novel therapies (Lenalidomide or Bortezomib), received accelerated FDA Approval in the US. It is now being introduced into standard hospital care.

Aims: Daratumumab presents unique challenges to the delivery of risk managed care, due to effects on some blood and bone marrow testing, and to the Infusion Related Reactions (IRRs) seen at the outset of treatment. This poster will highlight important aspects of the treatment pathway for this new therapy, from a single centre perspective.

Methods: We outline the pathways integrated at MDT level; patient characteristics and adverse event profiles of the 15 myeloma patients we have treated with Daratumumab, in a standard service setting.

Results: Daratumumab affects certain pathologies; 1 so samples should be clearly identified. Relevant laboratory teams need to be aware of the methods used to process samples. Daratumumab binds to CD38 on Red Blood Cells, and therefore with Cross Match Compatibility testing and Antibody Screening. Obtaining RBC Products for patients receiving Dara will take longer, requiring up to 48 hours’ notice. Cross match samples taken prior to treatment provide the National Blood Service Laboratory with a baseline antigen profile to aid selection of suitable blood products. Dara is detected during Paraprotein Electrophoresis and drugs with CNS availability are usually not very effective in refractory MM.

设备和呼吸支持在高依赖性设置。工作人员被提醒患者报告所有新的症状，当灌注被中断并立即进行和IRR治疗并重新开始在较低的率当症状在患者消失。重新管理是在给药前一个给药周期后以及对有COPD的受试者提供额外的支持。患者特点。总计：15。(表1)

Summary/Conclusions: Education, to include Blood Transfusion, Protein and Histopathology laboratory, and High Dependency Unit staff, in the key aspects of monitoring and risk management are an important part of this new therapy to the treatment pathway for myeloma patients. Daratumumab is likely to become an important treatment for improving both Outcomes and Quality of Life for Myeloma patients going forward.

PB1980 MULTIPLE MYELOMA IN HIV+ PATIENTS LITERATURE REVIEW AND OWN CASE A. Leyghton1,2,*, A. Pivnik1, M. Tumanan1, G. Dudina1, E. Sergeeva1
1Oncohematology, MKNC, 2Internal Medicine, RUDN, Moscow, Russian Federation

Background: Multiple myeloma (MM) and HIV infection in AIDS stage until now its considered not to be associated. Recently new ideas appear in the literature such as influence of HAART on the treatment outcomes of MM in HIV negative patients.

Aims: To find literature sources on multiple myeloma in HIV positive patients and elucidate the problem of this association. evaluate the impact of HAART in multiple myeloma.

Methods: Patients were retrospectively identified out of 39 cases of MM and HIV from Pubmed/Medline from 1983 to 2017, and own case reported.

Results: Patients with MM and HIV infection did not differ significantly from the MM in HIV-negative with respect to age, gender, stages and renal function. Effects of HAART on levels of serum M-protein HAART itself has been reported to decrease M-protein in an HIV+ patient with MM. We determined whether HAART alone, in the absence of MM treatment, had any effects on the level of serum M-protein in HIV+MM patients. Depending on the interval between the discovery of the HIV infection HAART treatment initiation, and the diagnosis of MM and initiation of its treatment. The overall and progression free survival of HIV+MM patients on HAART appeared to be better prior to that of HIV-negative MM patients. The survival of the HIV+ MM patients were also superior to that of non-HIV MM patients reported in the literature. The majority of HIV+ MM patients who had long-term follow-up in our study did not show clinical symptoms of MM and were free of serum-M protein after primary MM therapy in the presence or absence of HAART and maintained treatment with HAART alone. Although MM is not an AIDS-defining illness, meta-analyses of large population studies reveal an increased risk of MM in HIV/AIDS patients. HIV infection is commonly associated with B cell hyperproliferation, as indicated by polyclonal hyperglobulinemia and the development of various autoantibodies. This is presumed to be usually due to these CD4 deficient patients’ inability to control Epstein-Barr virus infections, which immortalize B cells. This may help to explain the increased incidence of MM in HIV+ patients. However, HIV can neither infect B lymphocytes or plasma cells, nor drive their malignant transformation. Some authors are going to treat multiple myeloma in HIV seronegative patients with HAART in combination with chemotherapy (Geling Lia and co-authors, Leukemia Research, 2014). A 38 year-old Russian male presented at the Moscow clinical Center in 2015 with pronounced oasialgya and inability to move. Total protein 135 g/l of IgG-k M-protein and no presence of Bence Jones protein. Bone skeletal survey showed multiple generalized lytic lesions. Bone marrow aspirate and biopsy showed 46% plasma cells. Serum creatinine ~ 104 mkmol/l. HIV and hepatitis C (genotype 1a) screening test were positive, confirmed with Western blot analysis. The CD4 count was 290 cells, HIV viral load 11,000 copies/ml, hepatis C viral load 14.2 mln copies. He was started on HAART, combined with chemotherapy 5 courses of CP+VP+MP and 7 V- MP. In 2017 total serum protein ~ 97.3 g/l, M-protein 31.2 g/l, serum creatinine 63.0 mkmol/l. Now he is active without any bone pain receives Pegasys and lamivudine (Table 1).

Summary/Conclusions: Patients with MM and HIV infection did not differ significantly from the MM in HIV-negative with respect to age, gender, stages and renal function, and treatment with addition of HAART.Recently was reported that HAART itself may reduce and even remove m-gradient in HIV positive...
patients. It is considered to include HAART in HIV negative patients with MM. The problem of MM and HIV/AIDS association remains unclear and needs to be elucidated.

**PB1981**

**OPTIMIZATION OF APPROACHES FOR STEM CELL MOBILIZATION FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN ELDERLY MULTIPLE MYELOMA: PRACTICAL CONSIDERATIONS**

O.-L. Lee1,2*

1Haematology, Royal Adelaide Hospital, 2Haematology, SA Pathology, Adelaide, Australia

**Background:** Autologous stem cell transplant (ASCT) is a well-established treatment for myeloma. However, the optimal strategy for stem cell mobilization remains undefined. The goal of mobilization is to collect adequate stem cells for at least 2 ASCT (4x10^6/kg), with the minimum apheresis sessions and toxicities such as febrile neutropenia.

**Aims:** We aim to compare stem cell mobilization using granulocyte colony stem cell factor (GCSF) only (steady state), high dose cyclophosphamide (4 g/m2) with GCSF or low dose cyclophosphamide (2 g/m2) with GCSF.

**Methods:** We performed a retrospective analysis of 79 patients mobilized with GCSF only from mid-2014 to Aug 2016 with 32 patients mobilized using high dose cyclophosphamide and 23 patients with low dose cyclophosphamide during a similar period.

**Results:** Patients undergoing steady state collection required a median of 2 days for adequate collection, in comparison to 1 day for both high and low dose cyclophosphamide. Addition of plerixafor was required in 27.8% of patients on steady state collection, in contrast to 31.1% and 15% of patients on high and low dose cyclophosphamide respectively. The mean yield of CD34+ x 10^6/kg cells collected was 5.39, 9.14 and 8.5 for steady state, high and low dose. There was no significant difference in time to engraftment despite a lower dose of CD34+ cells reinfused for the steady state cohort. Admission for febrile neutropenia was observed in 60.7% patients with high dose cyclophosphamide, as compared to 13% of patients on the lower dose regime and none in the steady state cohort. Patients mobilized with cyclophosphamide had a longer interval between stem cell collection and transplant (median of 20, 42 and 34 days respectively for steady state, high dose and low dose). However, we observed that 60.7% patients with steady state mobilization had increases in their myeloma markers during this period, in contrast to biochemical improvement in 50% of patients mobilized with high dose cyclophosphamide and 26% with low dose cyclophosphamide.

**Summary/Conclusions:** All 3 strategies for stem cell mobilization have their merits. Steady state mobilization is safe and yields sufficient stem cells; however, patients require more apheresis sessions. Moreover, more than a quarter require additional therapy with plerixafor. Of concern, greater than half of these patients have increased myeloma markers during the interval between stem cell collection and mobilization which may potentially affect outcomes. Mobilization with high dose cyclophosphamide yield more CD34+ cells but with increased toxicities- 50% of patients required admission for febrile episodes. Conversely, half of these patients had improvement in their myeloma markers. The use of low dose cyclophosphamide for mobilization resulted in lower admission rates (13%), however, plerixafor is required in a fraction. In light of these findings, we propose that patients who have not achieved at least VGPR should be mobilized with cyclophosphamide, the dosage dependent on their individual risks.

**PB1982**

**MINIMAL RESIDUAL DISEASE MONITORING IN MULTIPLE MYELOMA PATIENTS BY FLOW CYTOMETRY: A SINGLE CENTER EXPERIENCE**

S. Sizikova1,*, N. Pronkina2, E. Batorov3, G. Ushakova1, V. Sergeevicheva1, A. Gilevich1, I. Kruchkova1

1Hematology and bone marrow transplantation, 2Laboratory of immunology, 3Laboratory of cell immunotherapy, Research Institute for Fundamental and Clinical Immunology, Novosibirsk, Russian Federation

**Background:** Multiple myeloma (MM) is a malignant disease characterized by an increased number of clonal (abnormal) plasma cells in the bone marrow (BM). High-dose chemotherapy followed by autologous peripheral blood stem cell transplantation (SCT) is used for the treatment of young MM patients and produces a high rate of complete remissions (CR). Recent trials with novel agent combinations alone have also resulted in high CR rates, even among old patients, high-risk patients and relapse/refractory MM. Unfortunately, most patients have a recurrences of the disease. This is due to the persistence of residual tumor cells, known as minimal residual disease (MRD), responsible for tumor relapse.

**Aims:** BM samples from 51 MM patients who had achieved partial or complete response or were resistant after chemotherapy, including autologous SCT, were evaluated by multiparameter flow cytometry (MFC). The study was conducted to assess the quality of remission, the correlation between the number of abnormal cells of BM and other signs of disease activity, readiness of patients for autologous SCT.

**Methods:** The study included 51 patients MM, average age - 54 years (36-70 years), who underwent assessment of MRD from November 2014 to February 2017. According to the classification Durie-Salmon the vast majority of patients (n=40) had III stage of disease, 8 patients – II and 2 patients – I. Response to treatment was assessed according to standard EBM criteria At the time of MRD assessment 20 patients were in CR, 8 had a partial response (PR) and 15 had a resistant disease; 5 patients had a primary MM, 3 patients were in the first relapse. Most of the patients were underwent high-dose chemotherapy with autologous SCT (n=42). Re-evaluation of MRD after therapy was managed to hold in 36 patients at a mean of 3.1 months (1.9-5.7, min-max). Analysis was performed using a FACSScantoll flow cytometer (BD) and FACS Diva software (BD). Instrument performance was checked daily by recording fluorescence intensity with calibrating beads (Cytometer Setup and Tracking from BD Biosciences). Whole BM was estimated using combination of surface and intracellular staining CD38/CD56/CD27/CD117/CD81/CD19/CD45/cytlambda/ CD138/cytkappa. The sensitivity of our panel MRD is 0.001% (i.e. 10^-4).

**Results:** Among patients in CR (n=20) confirmed the absence of MRD in 6 patients, but 14 CR patients were MRD positive. MRD was detected in all patients with PR and resistant disease (n=31). The relative content of abnormal plasma cells in CR patients with MRD positive (n=14) was significantly lower than that in PR/resistant patients (n=31): 0.0095% (0.026-0.271%) versus 1.3% (0.203-5.9%), pU=0.000092. PR patients (n=8) had a lower relative content of abnormal plasma cells (as expressed tendency), than patients with resistant disease (n=15): 0.286% (0.177-1.129%) versus 1.48% (0.90-8.0%), pU=0.053. Besides the relative content of abnormal plasma cells in PR/resistant patients (n=31) correlated with the serum M-gradient concentration (r=0.42, p=0.019) and low dose cyclophosphamide (r=0.54, p=0.0017).

**Summary/Conclusions:** Currently, it can be considered as the method of choice for MRD monitoring in MM. If the disease is measured, then, indeed, enough to evaluate only the M-gradient level of serum. If the M-gradient is not defined, it is necessary to assess the number of abnormal plasma cells in the BM and strive for the high-quality responses at the time of transplantation. And also it can help us to regulate duration of maintenance therapy.

**PB1983**

**AUTOLOGOUS STEM CELL TRANSPLANTATION IN ELDERLY MULTIPLE MYELOMA PATIENTS**

M. Staderini1,*, C. Nozzoli2, E. Antonioli1, I. Donnini2, E. Antonioli1, I. Cutini2, A.S. Guarrera1, M. Di Gioia1, A. Gozzini2, S. Guidi2, A. Bosi1, R. Saccardi2

1Hematology Department, 2BMT Unit, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

**Background:** Autologous stem cell transplantation (ASCT) is currently approved as a “gold standard” first line treatment for multiple myeloma (MM) patients (pts) under 65 year old but the procedure could also be feasible in fit elderly patients based on several retrospective studies. The aim of our study was to retrospectively evaluate the tolerability and the efficacy of high dose chemotherapy followed by ASCT in selected ≥65 year old MM population.

**Methods:** We retrospectively analyzed consecutive MM pts aged 65 or older who underwent upfront ASCT at our institution from January 2009 to November 2017. The patient receiving induction therapy is required for indolent and/or immunomodulatory drugs (bortezomib and/or thalidomide based), followed by high-dose cyclophosphamide plus G-CSF and subsequently underwent peripheral blood stem cells (PBSC) collection.
Results: Overall we analyzed 36 pts: 21 males and 14 females (median age 66, range 50-78); 23 had IgG MM, 4 had IgA MM and 5 had light chain MM. Induction therapy was bortezomib-based (bortezomib in combination with dexamethasone, VD, or VD plus thalidomide in 26 pts) for a median of 4 cycles (range 3-6). 2 patients received thalidomide plus dexamethasone (6-12 cycles). PBSC were collected after high-dose cyclophosphamide (2 g/sm² in 2 pts, 3 g/sm² in 11 pts, 4 g/sm² in 22 pts) plus G-CSF, plerixafor was administered in 4 pts. Three pts also received lenalidomide and dexamethasone to improve the depth of response before ASCT. At the time of conditioning, among 34 evaluable pts, 8/34 pts were in complete response/stringent complete response (CR/sCR). 19/34 had very good partial response (VGPR), 5/34 in partial response (PR) and 2/34 in stable disease (SD). The conditioning regimen consisted of melphalan 140 mg/sm² in 11 pts or 200 mg/sm² in 24 pts. A median number of 4.1 x 10⁷ CD34+ cells/Kg was reinfused (range 2.09-10.44). The most frequent complication was fever (9 pts) with gram negative bacteremia documented in 3/9 and gram positive bacteremia in 1/9. Other complications were represented by 1 case of atrial fibrillation and 3 cases of pneumonia and 1 case of VZV reactivation. All 35 pts achieved neutrophils recovery after a median of 12 days (range 8-25) and platelets recovery after a median of 13 days (range 8-45) after transplant. No grade 3-4 toxicities were recorded. No transplant-related mortality was recorded within 100 days post transplantation. Three months after ASCT, among 28 evaluable pts, 62% were in PR, 14/28 pts in VGPR and 4/28 pts in PR. Three pts underwent tandem ASCT. After a median follow-up of 32 months (range 3-96) among 33 evaluable pts, 20 experienced disease relapse and 7 deaths occurred. Median PFS and OS were 21 and 40 months.

Summary/Conclusions: Our data support the use of ASCT as an effective and safe first-line treatment approach also in elderly MM pts. A careful patient selection is needed to reduce the toxicity of the procedure.

PB1985
CHARACTERIZATION OF A SERIES OF PATIENTS WITH PLASMA CELL LEUKEMIA
P. Bettencourt Medeiros1,*, R. Bergan1, F. Trigo1, J.E. Guimarães1
1Servicio de Hematología Clínica, Centro Hospitalar de São João, EPE, Porto, Portugal

Background: Plasma cell leukemia (PCL) is a rare malignancy characterized by the proliferation of monoclonal plasma cells in the bone marrow and ≥2x10¹⁰ ≥20% plasma cells in the peripheral blood. It is an aggressive disease, with a median survival of 7 to 11 months. Due to its rarity, it is difficult to design prospective studies or randomized trials in PCL, so collecting and publishing data from the largest number of cases is essential for the understanding of PCL's pathophysiology and outcome.

Aims: To characterize a series of PCL patients, in order to obtain data with the potential to be used as prognostic factors and to improve clinical outcomes.

Methods: Single-center, observational, retrospective study including all PCL cases admitted in our hospital between 2007 and 2016. Data regarding demography, clinical characteristics, laboratory results, treatment, follow-up and mortality were collected and analyzed using Statistical Package for Social Sciences (21st version), searching for significant associations (p<0.05) with overall survival (OS) and progression free survival (PFS).

Results: 15 patients were included, with a median age of 58 years. Most patients were male (60%) and had PS ECOG 0-1 (93.3%) at presentation and primary PCL (80%). Median hemoglobin (Hb) and platelets values were 8.5 g/dl and 74x10⁹/L, respectively. Median plasma cell percentage was 37.3% (peripheral blood) and 60% (bone marrow). IgG heavy chain was present in 33.3% and lambda light chains in 53.3% of cases. Most patients had total serum calcium ≥4.5mmol/L (60%), total proteins ≥65g/L (66.7%), monoclonal component ≤30g/L (53.3%), albumin ≥35g/L (60%), creatinine clearance ≥50ml/min (66.7%), elevated β-2 microglobulin (93.3%), ISS III (80%), R-ISS III (73.3%) and at least 1 cytogenetic change associated with poor prognosis in multiple myeloma (86.7%). Ten (66.7%) patients received bortezomib-based chemotherapy and nine patients (60%) had at least one cycle of high dose intensity treatment with a median number of 2 cycles (range 1-6). Two (13.3%) patients underwent ASCT (2009 and 2016). Nine patients (60%) received an autologous stem cell transplantation (ASCT). Complete response (CR) or very good partial response (VGPR) were achieved, after chemotherapy, in 53.3% and, after ASCT, in 88.9% of patients. Mortality rate was 66.7%, with median PFS of 5 months and median OS of 4 months. In univariate analysis, OS was significantly associated with albumin ≤35g/L, splenomegaly and R-ISS III; PFS was significantly associated with platelets ≤100x10⁹/L, splenomegaly and lambda light chains. In multivariate analysis, only the presence of splenomegaly kept its association with OS; none of the characteristics associated with PFS kept their significance. Chemotherapy followed by ASCT and the achievement of, at least, VGPR after chemotherapy and ASCT were associated with longer OS and PFS.

Summary/Conclusions: This study’s retrospective design and the small sample limit the strength of our data and our conclusions. Interesting results were obtained regarding pre-treatment prognostic characteristics and the association of improved OS and PFS with treatment response and ASCT execution. More studies are necessary to determine the clinical relevance of this findings and the best treatment strategies in PCL.
The role of anthracycline remains to be demonstrated.

Background: Most outcome data for multiple myeloma (MM) come from clinical trials which can not necessarily be extrapolated to ‘real world’ patients. More information is needed on patients treated in the ‘real world’ and in a wider range of settings.

Aims: To compare and contrast baseline characteristics, investigations, and initial therapies in different geographical regions, Australia/New Zealand (ANZ) and Austria, through first analysis of data from two established MM registries on behalf of the steering committees of the Australian and New Zealand Myeloma and Related Diseases Registry and the Austrian Myeloma Registry.

Methods: Analysis of data from newly diagnosed MM patients enrolled on the Austrian Myeloma Registry (AMR) and the ANZ Myeloma and Related Diseases Registry (MRDR) from 2011-2015.

Results: Available data from 250 and 691 patients from the AMR and ANZ MRDR, respectively, were included. DEMOGRAPHICS: The AMR cohort was younger (median age m:f 63.5 yrs:64 years vs 65 yrs:66 yrs on the AMR and MRDR, respectively). The proportion of male/female patients was similar between the AMR and MRDR (m:f 56%:44% and 67%:33%, respectively). PRESENTATION: IgG myeloma was the most common subtype in both registries (m:f 64.5%:55% and 55%:58%, respectively) with more light chain only disease on the AMR (m:f 26%:33% vs 20%:19%). Presence of documented preceding plasmablastic myeloma cell dyscrasias was similar (m:f 21%:19% vs 21%:19% on the AMR and MRDR, respectively). INVESTIGATIONS: A higher proportion of patients underwent MRI (m:f 51%:58% vs 25%:27%) and skeletal survey (SS) (78% vs 60%) on diagnosis on the AMR than the MRDR, respectively. Baseline laboratory investigations were similar, however, patients on the MRDR demonstrated higher median LDH (m:f 176:178 vs 157:186 units/L) and serum calcium (m:f 2.34:2.28 vs 2.41:2.45 mmol/L) but decreased serum albumin (m:f 39:39g/L vs 35:35g/L) when compared to the AMR. STAGE: ISS staging was similar on both registries with ISS stage 2 being most common in both cohorts (m:f 42%:37% vs 40%:40%, on the AMR and MRDR, respectively) while ECOG performance status at diagnosis was lower in the MRDR cohort (ECOG1 m:f 43%:44% vs 81%:78%, on the AMR and MRDR, respectively). FIRST LINE THERAPY: First line therapy was predominantly bortezomib (Velasco - V) based on both registries (81% vs 85%). Videlmasethasone (D) was the most common on the AMR (29%) followed by V/Thalidomide/D (VTD) (25%) with both registries with substantial proportions of patients on bortezomib and lenalidomide containing regimens (35%:35% on the AMR and MRDR, respectively).

Summary/Conclusions: This pilot study between the AMR and ANZ MRDR demonstrates many similarities but also highlights significant differences, particularly in first line therapy and depth of response. Future studies between the AMR and MRDR will provide a platform for ongoing international benchmarking.
weeks and every 3 months later (minimum follow-up: 6 months). EBR was defined as 25% on M-protein increase (any amount for patients on CR/SR) and/or ≥20mg/dl FLC increase, and/or ≥25% involved HLC increase with abnormal ratios. For urine, an increase >500mg/24 hrs of involved free-chain protein.

**Results:** Fifty-five patients were registered. Median follow-up 47 months. MF ratio: 29:26, mean age 59.5 ± (33-71). Immunoglobulin subtype: IgG-Kappa: 41.8% (23), IgG-Lambda: 23.6% (12), IgA-Kappa: 16.4% (9), IgA-Lambda: 7.3% (4), Bence-Jones-Kappa: 3.6% (2), Bence-Jones-Lambda: 7.3% (4). Durie-Salmon Stage: IA: 13.5% (7), II-A: 32.7% (17), III-A: 44.2% (23), III-B: 9.6% (5), missing-data 3 case. All patients received Bortezomib based therapy and MEL200 as ASCT conditioning. Status pre-ASCT: minimal response: 12%, Partial Response (PR): 50.0%, very-good-PR (VGPR): 28.0%, complete response (CR): 6% and string response (SR): 4.0%. After ASCT, evaluation reveals that 13.0% achieved SR, 13.0% CR, 30.4% VGPR and 39.1% PR. During follow-up, 34/50 (68%) patients who achieved at least PR after ASCT, had a clinical relapse/progress, median PFS 41 months (31.5-50.5). EBR were detected in 28 patients, of them 22/34 (64.7%) clinically relapsed patients at median time 8.0 (2-22) months before symptomatic relapse. The EBR were detected by FLCr (36.7%), HLCr (22.7%), FLC+SPE (4.5%), FLC+IFX (9.1%), FLC+HLC+SPE (13.6%), FLC+HLC+SPE+UPE (13.6%).

**Summary/Conclusions:** Both FLC and HLC are useful tools to detect EBR in more than 50% of patients in our cohort ahead other techniques.

PB1991

**FIRST LINE USE OF NOVEL AGENTS BEFORE AUTOLOGOUS SCT HAS A POSITIVE IMPACT ON TIME TO SECOND PROGRESSION AND SURVIVAL IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA UNDER 70 YEARS**

S. Gassiot1,2,*, C. Moltó1,3, M. Morgades1, Y. Gonzalez4, M. Garcia-caro1, J.-M. Ribera1,2, A. Crispí1,2

1Hematology, Hospital Germans Trias i Pujol - ICO, Badalona, 2Universitat Autònoma de Barcelona, Cerdanyola del Vallès, 3Universitat Autònoma de Barcelona, Badalona, 4Hematology, Hospital Dr Josep Trueta, Girona, Spain

**Background:** Most clinical trials for multiple myeloma (MM) patients using novel agent-based regimens before autologous stem cell transplantation have shown improvement in response rates and progression-free survival, however they have failed to identify a significant overall survival (OS) benefit.

**Aims:** Our aim is to analyze the potential impact of initial induction in the feasibility of regimen choice on OS.

**Methods:** We performed a retrospective analysis of 263 newly diagnosed MM patients treated between 2006-2012 who had received first-line induction therapy with a novel agent before autologous stem cell transplantation (ASCT). Median follow-up was 7.4 years.

**Results:** We identified 2 groups: pre-ASCT conventional therapy (CC) and pre-ASCT novel agent (NA) regimens. Most clinical trials for multiple myeloma (MM) patients using novel agent-based regimens before autologous stem cell transplantation have shown improvement in response rates and progression-free survival, however they have failed to identify a significant overall survival (OS) benefit.

**Summary/Conclusions:** Infectious complications and progression of MM have been the main cause of early mortality in patients with NDMM. Identifying potential “modifiable” variables and acting on them improves the short-term prognosis of patients with NDMM like: Supportive treatment to prevent infectious complications (avoid unnecessary hospitalization, antibioprophylaxis) and rapid access to optimal antiMM treatments. These improvement of short-term

**EARLY MORTALITY (<6 M) IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS: COMPREHENSIVE INTERVENTION**

V. Martínez-Robles1,*, B. Ballina1, S. Cerdá1, N. de las Heras1, M. Fuentes1, L. Villar-Palasi1, S. Rodriguez-Corral1, F. Ríos1, F. Escalada1

1Hematología, Complejo Asistencial Universitario de León, LEON, Spain

**Background:** Early mortality in the first 6 to 12 months from diagnosis is well recognized in newly diagnosed multiple myeloma (NDMM) patients, with rates in the real-world between 2% and 10% mainly related to infections.

**Aims:** In a retrospective analysis of the causes of death performed by the end of 2012 we identify 2 different causes in the 2 consecutive periods analyzed. In the first period (1998-2006) the main cause was MM progression and in the second (2006-12) was secondary to serious infectious complications. Additional analysis were done after it can identify a patient and a infectious profiles. Main risk factors from the patient were: age (over 75), suboptimal treatment and renal failure (calculated CIcr=50 ml/min). The infectious mainly occurred in the first 3 months from diagnosis and principally polymicrobial and multiresistant infections.

**Methods:** After this analysis several measures were taken to reduce this high early mortality: 1) To promote the ambulatory regime both in diagnosis and for the rapid assessment of complications to avoid or shorten income and to reduce these nosocomial-behaviour infection complications. 2) Early initiation of “optimal” anti-myeloma treatment. 3) Get infectious prophylaxis in patients over 75 years and/or renal failure with Septrim®.

**Results:** Fifty-five patients were registered. Median follow-up 47 months. MF ratio: 29:26, mean age 59.5 ± (33-71). Immunoglobulin subtype: IgG-Kappa: 41.8% (23), IgG-Lambda: 23.6% (12), IgA-Kappa: 16.4% (9), IgA-Lambda: 7.3% (4). Durie-Salmon Stage: IA: 13.5% (7), II-A: 32.7% (17), III-A: 44.2% (23), III-B: 9.6% (5), missing-data 3 case. All patients received Bortezomib based therapy and MEL200 as ASCT conditioning. Status pre-ASCT: minimal response: 12%, Partial Response (PR): 50.0%, very-good-PR (VGPR): 28.0%, complete response (CR): 6% and string response (SR): 4.0%. Figure 1 (large graphic; legends: red: pre2013; blue: post2013).
Background: Multiple Myeloma (MM) is mainly a disease of the elderly and the very elderly patients (80 years of age or more) comprise one third about of all MM patients. This subset of patients suffer from comorbidities and/or conditions and require a different and a more individualized therapeutic approach, including the novel agents.

Aims: The aim of our study is to verify safety and efficacy of novel agents with the reliability to maintain a good quality of life and to obtain a maximal disease control.

Methods: Patients from 8 Hematology Centers of the “Rete Ematologica Pugliese” (REP)” were included in this study. Between January 2011 and December 2016, 71 patients (MF: 42/29) with a median age of 82 years (range 80-91) were diagnosed as newly symptomatic MM. Of the entire study population, 40 (65%) patients showed an ECOG score lower than 2. According to immunoglobulin heavy and light chain isotypes, patients had IgG-k (n=23), IgG-λ (n=16), IgA-k (n=14), IgA-λ (n=6), micromolecular κ (n=8) and λ (n=4) chains. On the basis of ISS, patients were classified as I(n=4) score, II (n=23) and III (n=44) score, respectively. When CRAB features were considered, bone lesions represented the most frequent (n=43, 60.6%) clinical manifestations, while anemia, hypercalcemia and renal failure were found in 35 (49.3%) patients and 2 (2.8%) and 2 (2.8%) patients, respectively. Majority of patients (n=49, 69%) showed at least 1 comorbidity requiring specific treatments, and 11 patients (15.5%) showed more than 3 comorbidities. Patients were treated according to Bortezomib-based regimens (VMP, VCD and VD) (n=45; 63.4%), Lenalidomide-based regimens (n=20; 28.5%) and Pomalidomide-based regimens (MPT) (n=5; 7%). Only 13 patients (18.3%) did not receive any novel agent.

Results: Based on IMWG criteria, patients (15% (21.1) achieved a CR, 15 patients (21.1%) were VGPR and 15 patients (21.1%) a PR. Fourteen patients (19.7%) and 12 (17%) patients experienced a SD and a PD, respectively. As second line of treatment, Bortezomib was used in 14 (33.3%) patients, Lenalidomide in 17 (40.5%) patients and Thalidomide in 3 (7.2%) patients. Height patients (19%) were treated with old drugs (Melphalan, Cyclophosphamide or Bendamustine). Pomalidomide was used as third line-therapy in 3 patients. After 72 months (median 32.5 months) of follow-up, 33 (46.5%) patients remained alive with a median overall survival (OS) of 22.8 months. Sixty-four (89.5%) patients received post ASCT maintenance with lenalidomide.

PB1994

Efficacy of Autologous Stem Cell Transplantation for the Treatment of Multiple Myeloma in HIV-Positive Patients – A Case-Series

Background: While hematopoietic malignancies are found at increased rates in individuals with acquired immunodeficiency syndrome (AIDS), the management of multiple myeloma (MM) and human immunodeficiency virus (HIV) is less common, leading to a paucity of expertise in the treatment of these co-morbid conditions. Prior to the advent of highly active anti-retroviral therapy (HAART), autologous stem cell transplant (ASCT) was relatively contraindicated for PM patients with HIV due to issues associated with stem cell harvest and the risk of opportunistic infections. With the widespread use of HAART for control of HIV, high dose chemotherapy and ASCT is now the preferred treatment for relapsed lymphoma and ASCT is now the preferred treatment for relapsed lymphoma, the leading hematopoietic malignancy for patients who were HIV-positive and on HAART undergoing ASCT for treatment of MM between January 2000 and June 2016 were collected and analyzed.

Results: The following Table 1 lists patient characteristics. All were male with average age 53.2 years. All were diagnosed with HIV prior to diagnosis of MM and were appropriately treated with HAART prior to ASCT. All patients had undetectable HIV viral titer prior to ASCT, and most remained undetectable after ASCT. Four of five patients had CD4 >200/uL and one patient had CD4 <50/uL prior to ASCT; however all patients recovered CD4 counts after ASCT (and most with improved CD4 count). Adequate CD34(+) stem cells were collected. Patients received high dose melphalan (200 mg/m2) followed by ASCT. HAART was continued during ASCT. Patients experienced usual ASCT toxicities including diarrhea, mucositis, and neutropenic fever. One patient developed sepsis and small bowel obstruction, which resolved with antibiotics and conservative management. All patients had normal neutrophil and platelet engraftments. Post-ASCT responses were complete remission (2 patients), very good partial remission (1 patient), partial remission (1) and minimal response (1). All patients are currently alive without relapse or progression 1-4 years from ASCT and receiving post ASCT maintenance with lenalidomide.

Table 1.

Background: Although bortezomib-melphalan-prednisone (VMP) therapy is a well-established standard treatment for patients with multiple myeloma (MM) who are ineligible for high-dose therapy, it is not clear whether very elderly patients should be treated with VMP in clinical practice, considering the toxicities.

Aims: The purpose of this case-control study was to compare the efficacy of VMP versus melphalan-prednisone or cyclophosphamide-prednisone (MP/CP) as initial therapy for elderly patients.

Methods: We retrospectively studied 233 patients aged 75 years or older with newly diagnosed multiple myeloma between March 2007 and February 2015. One-hundred thirty one patients received VMP and 102 patients received MP/CP regimen were enrolled from 15 institutions throughout Korea. Results: Patient characteristics were comparable in these two groups. Overall response rate was 70.2% in VMP patients and 48.0% in MP/CP patients (P=0.001). Complete response rate was 22.9% in VMP patients and 7.8% in MP/CP patients (P=0.002). After a median follow-up for survivors of 28.5 months, progression-free survival (PFS) and overall survival (OS) were significantly different between the two groups (PFS, median 11.8 months in VMP and MP/CP group, respectively, P=0.018; OS, median 34.9 vs. 22.8 months in VMP and MP/CP group, respectively, P=0.006). Nonetheless, for 61 patients who were aged ≥80 years, PFS and OS was not significantly different between the two groups (PFS, median 19.6 vs. 13.2 months in VMP and MP/CP group, respectively, P=0.376; OS, median 27.8 vs. 17.8 months in VMP and MP/CP group, respectively, P=0.443).

Summary/Conclusions: Although VMP therapy was associated with a significant improvement in overall survival among patients ≥75 years, there is no differences for patients aged 80 or older. Frailty and comprehensive geriatric assessment should be incorporated to guide treatment decisions for this population.
Summary/Conclusions: Multiple myeloma patients with concurrent HIV infection that is controlled on HAART tolerate ASCIT for treatment of myeloma as well as myeloma patients without HIV infection and have generally good outcomes.

PB1995

FEASIBILITY OF USING GLOBAL FDG UPTAKE IN BONE MARROW TO ASSESS TREATMENT RESPONSE IN MULTIPLE MYELOMA

1Hematology, Odense University Hospital, Odense, Denmark, 2Radiology, Hospital of the University of Pennsylvania, Philadelphia, United States, 3Nuclear Medicine, Zagreb, Croatia

Methods: Prospective FDG-PET/CT data of 23 MM patients between ages of 50 and 76 (mean=64.3, males=21, females=2) were collected from Odense University Hospital (NCT02187731) and included scans before initiation of treatment and at end of treatment (EOT) two months after high dose chemotherapy with stem cell support. All scans were conducted 60 min after intravenous injection of 4MBq of FDG. Images were analyzed using an iterative thresholding algorithm that delineates a continuous region based on Hounsfield units from the CT data (OsiriX software; Pixmeo SARL, Bernex, Switzerland), allowing for segmentation of the total skeleton on a fused PET/CT image. This enabled the quantification of FDG uptake representing the entire skeleton, providing a global SUVmean that considers all bone marrow involvement. Global SUVmean scores were compared before and at EOT using a two-tailed paired t test.

Results: A decrease in marrow FDG uptake was observed at EOT compared to baseline in most patients. The calculated global SUV/mean uptake decreased after initiation of treatment in 17 (73.9%) of the cases and increased in 6 (26.1%) of the cases. A decrease of 50% from base line was seen in 12 (52%) patients. Global assessment rather than focal analysis of discrete lesions represents a robust and straightforward method of determining total disease activity that potentially will be of value in treatment evaluation, disease monitoring and prognostication in multiple myeloma.

PB1996

VALUE OF MYELOMA PROGNOSTIC INDICES IN ERA OF NOVEL DRUGS IN TRANSPLANT SETTING

V. Zatezalo1, A. Hanžek1, N. Gredeļi-Sime1, V. Milunović1, M. Bogelič-Patekar1, M. Lukuć1, B. Jelić-Puškančič2, A. Štrčić3, D. Radič-Kristl1, O. Ostojić Konioni1, 1Department of Hematology, 4Department of Pathology, Clinical Hospital Merkur, Zagreb, 2School of Medicine, Osijek, 3School of Medicine, Zagreb, Croatia

Background: Despite the era of emerging novel agents, autologous peripheral blood stem cell transplantation remains backbone of myeloma treatment. 

Aims: The main aim of our study was to evaluate the role of tandem transplantation in myeloma treatment as well as prognostic indices in era of novel drug treatment.

Methods: We consecutively included all patients transplanted due to myeloma at our center from 2012 to the end of 2016. Patients were treated with either VAD or bortezomib based therapy. After induction treatment, all patients were eligible for tandem transplantation. Tandem transplantation is controlled on HAART and tolerated ASCIT for treatment of myeloma as well as myeloma patients without HIV infection and have generally good outcomes. 

Results: From January 2012 to December 2016 hundred and one patient with MM (49 male, 52 female), median age 55 (range 22-77), were transplanted. Bortezombased induction therapy was used in 55 (54,5%) and VAD induction was used in 46 (45,5%) patients. Median OS of all treated patients was 73 months; median OS of VAD group was 73 months while in bortezomib group median OS was not reached, but this difference was not statistically significant (p=0,19). TNT was significantly longer in bortezomib group than in VAD one (27,8 vs 17,5 months respectively; p=0,02). Interestingly prognostic indices could not discriminate patient groups according to OS (p=0,1), but could discriminate them due to TNT (p=0,008), possibly due to cross-over to bortezomib treatment after treatment failure. TNT had a significant correlation with levels of LDH (p=0,04) and no significant correlation with number of plasma cells in bone marrow. OS was significantly longer in those with longer duration of time to next treatment (p=0,0004). There was no difference in OS or TNT in patients treated with tandem transplant vs single transplant (p=0,68 and p=0,57 respectively), possibly due to heterogeneity of tandem group.

Summary/Conclusions: Even with the use of new anti-myeloma drugs it seems to converge risk groups to lower ones, prognostic indices remain relevant. Due to heterogeneity of patients and myriad of known prognostic factors further studies are needed so they may be translated into risk adapted therapy approach.

PB1997

WHICH ORGAN SHOULD WE BIOPSY TO DIAGNOSE ALAMYLOIDOSIS?

L. Llorente Gonzalez1, C. de Miguel Jiménez1, C. Salas2, P. García-Pavía3, E. Gonzalez3, J. A. López del Olmo4, J. M. Vázquez Cobos4, I. Krsnik1
1Hematology, 2Anatomical Pathology, 3Cardiology, Hospital Universitario Puer
ta de Hierro de Majadahonda, 4Cardiovascular Proteomics, Centro Nacional de Investigaciones Cardiovasculares Carlos III, Majadahonda, Spain

Background: Light chain (AL) amyloidosis is a deposition disease with can affect many organs and with a variable but usually bad, prognosis. Therapy requires a quick and correct diagnosis. Accurate identification of amyloid depo-
sition and of the amyloid subtype in tissue biopsies is thus, mandatory. Ran-
dom biopsies of easily accessible tissues such as subcutaneous fat, gingiva or rectum are usually recommended but sensitivity of this approach is low.

Aims: To present our experience with tissue biopsies performed in 62 consecu-
tive patients diagnosed of AL amyloidosis in our center.

Methods: We reviewed all tissue biopsies performed during the study period (2004-2017) in 62 consecutive patients diagnosed of AL amyloidosis at the same center. A bone marrow (BM) biopsy was performed per protocol in all cases. Decisions on biopsies were taken considering organ involvement and accessibility: skin, lymph nodes, lung or tongue biopsies were performed when lesions were seen on clinical or X-ray examinations, cardiac biopsies in the presence of increased NT-proBNP (N-terminal natriuretic peptide) levels and typical echocardiographic findings, kidney biopsies in patients with nephrotic syndromes. Biopsies were stained with Congo Red and read under polarized light with a Texas filter. Subtyping of the amyloid was done using anti-kappa, anti-lambda, anti-TTR and anti-A antisera. If any biopsy was positive for AL amyloid, no further biopsies were performed unless necessary for therapeutic decisions.

Results: A total of 152 biopsies were performed during the study period: see Table 1.

Summary/Conclusions: Prognosis in AL amyloidosis is slowly improving with the use of new anti-myeloma drugs and may improve further with new monoclonal antibodies. Therapy requires an early and accurate diagnosis. We do not perform random biopsies of tissues such as fat or gingiva due to low sen-
sitivity. In our hands biopsies of organs and tissues with amyloid deposition or radiological involvement shows higher sensitivity. A bone marrow biopsy is required for diagnosis of the neoplastic disease underlying AL amyloidosis and may show amyloid in up to 50% of the cases. Cardiac biopsy is also highly sensitive and in centers with a high degree of expertise such as ours, has no contraindications. Our data show that the pattern of biopsy approach to AL amyloidosis of what is usually published. Biopsies of clinically involved organs yields almost 100% sensitivity. Random biopsies of gingiva, subcutaneous fat or rectum should be discouraged.
PB1998

A COMPARISON OF CYCLOPHOSPHAMIDE-GLUCOCORTICOIDS AND LENALIDOMIDE-DEXAMETHASONE AS TREATMENT FOR MULTIPLE MYELOMA IN FIRST RELAPSE AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION

R. Sterrett1,2, A. Figueiredo2, R. Mallick3, N. Kekre1,2,5, H. Atkins1,2,5, A. McCurdy1,2,5
1Department of Medicine, University of Ottawa, 2Ottawa Hospital Research Institute, 3School of Epidemiology, Public Health and Preventive Medicine, University of Ottawa, 4Clinical Epidemiology Program, Ottawa Hospital Research Institute, 5Division of Hematology, The Ottawa Hospital, Ottawa, Canada

Background: The optimal management of relapsed Multiple Myeloma (MM) with respect to therapeutic combinations and sequence remains controversial and is actively evolving. Many commonly used regimens have not been directly compared. These agents vary widely in cost, and knowledge of their relative efficacy is of particular importance in regions where cancer medicines are publicly funded.

Aims: We sought to compare the efficacy and safety of two commonly used regimens for relapsed MM using historical cohorts from a single transplant center.

Methods: A retrospective observational study was performed between January 1991 and November 2016 to compare the efficacy of cyclophosphamide and dexamethasone/prednisone (Cyclo), or lenalidomide and dexamethasone (Len-Dex) for relapsed MM post autologous stem cell transplant (auto SCT). The primary outcome was Time to Next Treatment 2 (TTNT2), defined as time from first relapse requiring therapy after auto SCT to second relapse requiring therapy. The secondary outcome was overall survival, defined as time of diagnosis to death from any cause. Outcomes were assessed by Kaplan Meier methods and overall differences determined by log rank test. Hazard ratios were calculated for individual treatment groups and compared by univariate and multivariate logistic regression.

Results: A total of 243 patients underwent treatment for MM at first relapse post autologous transplant. Of these, 139 were included in this analysis: 88 Cyclo and 51 Len-Dex. Patient demographics and disease characteristics were similar between each group for age, sex, subtype of MM and ISS Stage (p>0.05). Vincristine, Doxorubicin and Dexamethasone (VAD) was the most common treatment at diagnosis for the Cyclo group (68%), whereas bortezomib-based therapy was the most common for the Len-Dex group (76%). First relapse requiring treatment after auto SCT was longer in the Cyclo group, although this was not significant (p>0.05). Vincristine, Doxorubicin and Dexamethasone (VAD) was the most common treatment at diagnosis for the Cyclo group (68%), whereas bortezomib-based therapy was the most common for the Len-Dex group (76%). First relapse requiring treatment after auto SCT was longer in the Cyclo group, although this was not significant (p>0.05).

The median initial dosage of Len was 15 mg and DEX 20 mg. The overall response rates were 68.6% and the 2-year progression-free survival was 70.8% at a median follow-up of 26.5 month. Grade 3 to 4 nonhematologic AEs were observed only in 8 patients. We estimated the AUC0-24 of Len by using formula as we previously reported (Ther Drug Monit 2014) and the cut-off value of the AUC0-24 of Len was 2033.5ng•hr/ml (sensitivity 81.8%, specificity 45.2%) and the non-hematologic AEs 3023.9ng•hr/ml (sensitivity 78.9%, specificity 62.5%). After Ld therapy, naïve subset of CD4 and CD8 T cells and monocytic MDSC were observed after Ld treatment.

Summary/Conclusions: In this observational study of patients with relapsed multiple myeloma post autologous stem cell transplantation, Lenalidomide-dexamethasone was associated with longer TTNT2 compared with Cyclophosphamide-glucocorticoids. However, there was no difference in overall survival. Cyclophosphamide is considerably less expensive than the novel agents. In an era when fiscally sustainable care for MM remains a challenge, further prospective studies are required to compare cyclophosphamide with novel agents in the management of relapsed multiple myeloma.

Background: Lenalidomide (Len) and dexamethasone (DEX) combination therapy is now the standard treatment of multiple myeloma (MM). Len has both a direct effect on MM cells and an immunomodulatory effect and recently many drugs are combined with Ld therapy to expect the synergistic anti-tumor immune response. However, adverse events (AEs) make continuation of Ld therapy difficult for some patients especially for elderly patients.

Aims: To investigate the safe and effective plasma concentration of Len and the anti-tumor immune response change in MM patients treated by Ld therapy.

Methods: Forty patients (18 men and 22 women) were enrolled in this study. Median age was 75.5 years old (range 61-86). Len was administered on days 1-25 of a 28-day cycle, and DEX, on days 1, 8, 15, and 22. The plasma concentrations of Len just before oral administration and 1, 2, and 4 hr thereafter were analyzed by liquid chromatography-tandem mass spectrometry. Before and after Ld therapy, Peripheral blood mononuclear cells (PBMCs) of MM patients were isolated from whole blood by Ficoll-Hypaque density-gradient centrifugation. PBMCs were stained with the fluorescent dye-conjugated antibodies against surface fluorescence-activated cell sorting (FACS) and intracellular cytokine proteins of IFN-γ, TNF-α, IL-2 and CD107a molecule was detected after stimulation with PMA/ionomycin for 5 hours in the presence of protein transport inhibitor Golgi stop (BD Biosciences). Analysis was performed using LSR Fortessa (BD Bioscience) and Flowjo version 10.2 software (TreeStar). This study protocol was approved by the Ethics Committee of Akita University Hospital, and all recipients gave written informed consent.

Results: 21 patients showed renal impairment (RI) necessary to adjust initial Len dosage. Adverse cytogenetics of del17p and t(4;14), detected by using fluorescence in situ hybridization, were found in 2 and 4 patients, respectively. The median initial dosage of Len was 15 mg and DEX 20 mg. The overall response rates were 68.6% and the 2-year progression-free survival was 70.8% at a median follow-up of 26.5 month. Grade 3 to 4 nonhematologic AEs were observed only in 8 patients. We estimated the AUC0-24 of Len by using formula as we previously reported (Ther Drug Monit 2014) and the cut-off value of the AUC0-24 of Len as a prediction marker of AEs. Enhanced cytokine production and increased memory subset of T cells was detected after stimulation with PMA/ionomycin for 5 hours in the presence of protein transport inhibitor Golgi stop (BD Biosciences). Analysis was performed using LSR Fortessa (BD Bioscience) and Flowjo version 10.2 software (TreeStar). This study protocol was approved by the Ethics Committee of Akita University Hospital, and all recipients gave written informed consent.

THE ROLE OF EXPRESSION CD56 ON BONE MARROW PLASMA CELLS AND EXTRAMEDULLARY PLASMA CELLS IN PATIENTS WITH MULTIPLE MYELOMA

M. Firsova1,2, L. Mendeleva1, A. Kovrigina2, M. Soloviev1, O. Pokrovskaya1, M. Nareiko1, L. Kuzmina3, V. Sivchenko1
1Department of High-Dose Chemotherapy of Paraproteinemic Hemoblastosis, 2Pathology department, 3Bone Marrow Transplantation Department, 4National Research Center for Hematology, Moscow, Russian Federation

Background: In multiple myeloma, the role of extramedullary plasma cells (EMP) is not well known. There are studies showing that EMP are involved in the development of extramedullary manifestations. Existing data about the expression of CD56 on EMP is controversial.

Aims: To determine the expression of CD56 on EMP in patients with multiple myeloma and to compare this with the expression of CD56 on bone marrow plasma cells (BMPC).

Methods: A total of 24 patients were included in this study. The expression of CD56 was evaluated using flow cytometry on BMPCs. CD56 expression on EMP was evaluated using IHC. The relationship between CD56 expression on EMP and BMPCs was analyzed using Fisher’s exact test.

Results: In comparison to BMPCs, CD56 expression on EMP was significantly higher (p<0.05). The expression of CD56 on EMP was not associated with clinical characteristics or disease stage. However, there was a trend towards higher CD56 expression on EMP in patients with more advanced disease (p=0.07).

Summary/Conclusions: The high expression of CD56 on EMP may indicate a role of EMP in the development of extramedullary manifestations in multiple myeloma. Further studies are needed to confirm these findings and to investigate the functional implications of CD56 expression in EMP.
Background: The myeloma cells interact with the bone marrow microenvironment by several adhesion molecules. One of them is CD56, a neural cell-adhesion molecule N-CAM – a membrane glycoprotein, a member of the immunoglobulin superfamily, expressed on the surface of malignant plasma cells of patients with multiple myeloma (MM). Decreased expression of CD56 is considered as one of the possible factors, that help tumor cells to spread outside the bone marrow.

Aims: To evaluate the impact of CD56 expression on the rate of overall survival (OS) in MM patients with extramedullary disease (EMD).

Methods: The study included 32 patients with primary MM (17 males, 15 females) 23-77 years old (median value: 52 years old). The disease was diagnosed in accordance with the IMWG criteria (2014). 17 patients had EMD including 14 patients with soft-tissue plasmacytomas associated with bone and 3 patients with extramedullary foci in the neck area, in the stomach, in the liver. In all cases a tumour biopsy and bone marrow trephine biopsy were performed, that confirmed the presence of malignant plasma cell infiltration. Paraffin block slices from trephine biopsy material and tumour biopsy material were used to perform an immunohistochemistry (IHC) analysis with an antibody to CD56. Kaplan-Meier survival curves were generated, statistical analysis was done using the program Statistica ver.10.

Results: In patients with plasmacytomas the IHC analysis of trephine biopsy material showed CD56+ in 59% cases vs 73.4% in patients without EMD. Five-year OS in patients with CD56+ in the bone marrow was 90%, which was significantly higher (p=0.04) than that of the patients with CD56- 0% with follow-up of 5 to 61 months (median 20 months, Figure 1). Expression of CD56 on the surface of extramedullary MM cells was found in 76.5% patients. OS in the group of patients with CD56+ in extramedullary MM cells and in bone marrow cells (n=9) was 67% which was significantly higher (p=0.04) than in the group of patients (n=4) with CD56+ in extramedullary MM cells and CD56- in bone marrow cells – 50%. Simultaneous lack of CD56 in extramedullary MM cells and in bone marrow cells was observed in 3 patients with 2 of them died of progression in 31 and 51 months. However simultaneous expression of CD56 in extramedullary MM cells and in bone marrow cells was observed in 9 patients with median follow-up of 40 months and 1 patient died of progression after 47 months.

Figure 1. Probability of overall survival in patients depending on CD56 expression in bone marrow.

Summary/Conclusions: CD56 expression in bone marrow plasma cells significantly increases the OS rate in MM patients regardless the presence or absence of plasmacytomas. Double CD56 negativity both in extramedullary and bone marrow MM cells is a poor prognostic factor with high risk of early relapse and death.

PB2001

BENDAMUSTINE-BORTEZOMIB-DESAMETASONE IN THE MANAGEMENT OF RELAPSED AND REFRACTORY MULTIPLE MYELOMA

C. Cerchione1,*, L. Catalano1, A. E. Pareto1, S. Basile1, L. Marano1, I. Peluso1, darelli, Napoli, Italy

Background: Bendamustine is a bifunctional alkylating agent, with low toxicity, proved to be effective in relapsed, refractory and in newly diagnosed Multiple Myeloma (MM).

Aims: It has been evaluated efficacy and tolerance of Bendamustine, in combination with bortezomib-dexamethasone (BVD) in patients with relapsed and refractory MM (rMM), whose prognosis is particularly severe. A regional prospective real-life analysis of patients with rMM who had been treated with BVD as salvage therapy has been performed.

Methods: 56 patients (31 M/25 F, Table 1), with rMM, median age at diagnosis 57.3 years (r. 25-82), median age at start of treatment 61.8 years (r.37-83) treated with several lines of treatments (median 6, r. 2-11), every refractory to all the drugs previously received (also Bortezomib), received BVD (Bendamustine 90 mg/sqm days 1,2, Bortezomib 1.3 mg/sqm days 1,4,8, Dexamethasone 20 mg days 1,2,4,8,9,11,12, Pegfilgrastim day +4) every 28 days, until progression. Endpoints were: a PR, a bridge to second auSCT, and for two patients a bridge to alloSCT. All patients were relapsed and refractory to last therapies received in SD, which can be considered as an impressive result in this subset of rrMM patients.

Results: According to IMWG, after a median follow-up of 14 months (r.3-62), ORR was 64% (36/56 : 4 CR, 7 VGPR, 16 PR, 9 MR) with 8 PD and 12 patients in SD, which can be considered as an impressive result in this subset of rrMM patients. In particular, for 11 patients, BVD was, after having achieved at least a PR, a bridge to second auSCT, and for two patients a bridge to alloSCT. Median time to response was 1.2 months (r.1-3), median OS from diagnosis was 62.7 months (range 6-151), median OS from start of Bendamustine was 9.8 months (range 2-36).

Table 1.

<table>

</tbody>
</table>

Median age, years at diagnosis, (range) 57.3 (36-82) at start of BVD, (range) 61.8 (41-73) months

Summary/Conclusions: BVD has shown significant efficacy in a particularly severe setting of patients, relapsed and refractory to all available therapeutic resources, and, in particular cases, it could be considered as a bridge to a second autologous or allogenic SCT.

PB2002

VE-CADHERIN IN MULTIPLE MYELOMA: AN INDEPENDENT PROGNOSTIC FACTOR FOR PROGRESSION-FREE SURVIVAL

B. Samuro1,2,*, Y. Kolesnisky2, V. Svolop3, A. Abramov3

1Department of Hematology, Zaporizhzhia Regional Clinical Hospital, 2Department of Internal diseases, 3Department of Pathophysiology, 4Department of Propedeutics of Internal diseases, 1Scientific medical-laboratory center, Zaporizhzhia State Medical University, Zaporizhzhia, Ukraine

Background: Endothelial damage and perivascular infiltrates are vital in the development of multiple myeloma. Recent studies have found that endothelial dysfunction might be result in multiple myeloma progression and adverse effects of drug implementation. On the other hand, there is a direct correlation between microvessels density in multiple myeloma and parameters of disease progression. Endothelial cells participate in inflammatory events leading to atherosclerosis by regulating endothelial cell permeability via the expression of VE-cadherin in their surface. VE-cadherin is a transmembrane protein probably modulates intensity of angiogenesis in multiple myeloma and may be useful in prognosis. However, the predictive role of VE-cadherin as a prognostic factor for survival of patients after treatment of multiple myeloma is not still clear.

Aim: To aim to evaluate the prognostic value of circulating VE-cadherin for progression-free survival in patients with multiple myeloma in complete or partial remission.

Methods: One hundred twelve out subjects with multiple myeloma were...
enrolled in the study. Diagnosis and staging of multiple myeloma were defined by current clinical practice guidelines. To be achieving remission chemotherapy with bortezomib, thalidomide, dexamethasone, cyclophosphamide, melphalan, anthracyclines was used accordingly contemporary clinical guidelines. All subjects were at complete or partial remission at baseline. Observation period was up to 12 months. ELISA method for measurements of circulating level of VE-cadherin was used.

Results: Medians of circulating levels of VE-cadherin in subjects without progression of multiple myeloma (n=89) and subjects with progression (n=23) during 12 months were 0.92 ng/ml (95% confidence interval [CI]=0.66-1.19 ng/ml) and 1.77 ng/ml (95% CI=1.47-2.07 ng/ml) (p=0.0002). The best VE-cadherin cutoff value for predicting disease progression risk was 1.31 ng/ml, with AUC value 0.833 (p=0.0001), the specificity and sensitivity were 77.8% and 61.5% respectively. The presence of high levels of serum VE-cadherin was significantly correlated to a shorter progression-free survival (PFS). In a multivariate analysis along with clinical and biologic prognostic parameters, high serum VE-cadherin level (>1.31 ng/ml) was an independent adverse prognostic variable for PFS (median PFS 9.93 (IC=14.16-11.71) months vs 7.35 (IC=5.75-8.95) months (p=0.02).

Summary/Conclusions: The serum VE-cadherin level is a valuable biomarker for predicting treatment response and an independent prognostic factor for progression-free survival for patients with multiple myeloma.

THE UTILITY OF FACS PURIFICATION OF PLASMA CELLS FOR FISH ANALYSIS IN MONOCLONAL GAMMOPATHIES

M. Pereira1,2, G. Marques3, J. Lima3, R. Reis3, A. Coelho3, L. Jorge3, S. Pedroso3, L. Ribeiro3, A. Paiva4, F. Rodrigues4

1Department of Hematology, Coimbra University Hospital Centre, 2Faculty of Medicine, University of Coimbra, 3Clinical Pathology Department, 4Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Despite the prognostic value of chromosomal aberrations, conventional metaphase karyotyping in monoclonal gammapathies (MG) is often uninformative due to the inherent difficulty of obtaining proliferating plasma cells (PC). Interphase fluorescence in situ hybridization (FISH) is a simple, quick and effective technique for the detection of cytogenetic aberrations that can overcome this limitation. However, the signal of interest is frequently diluted by the noise of the mixed cellularity of the sample, originating both false negatives and false positives. Fluorescence-activated cell sorting (FACS) of the target cells enables a focused application of FISH on pathologically significant cells – such as the PC in MG – reducing the confounding noise. This is particularly relevant when the percentage of pathologic cells in the sample is low, such as in monoclonal gammapathy of undetermined significance (MGUS) where, by definition, there are less than 10% PC in the bone marrow.

Aims: This study aims to analyze the utility and effectiveness of FACS purification of PC for the cytogenetic workup of MG by FISH.

Methods: We analyzed all FISH studies performed in our laboratory, in individual patients, on clonal interphase FACS-separated bone marrow PC, between the 1st June 2015 and the 15th September 2016. The probes used in our standard MG panel were del(1p32), amp(1q21), t(4;14) and del(17p13.1) (TP53 gene) and, starting in April 2016, t(14;16). We had previously established 20 000 cells per sample as the minimum (and sufficient) number of cells needed to get a confident application of all 5 probes in our lab.

Results: After the exclusion of samples diluted with peripheral blood, we identified 102 patients with FACS separated purified PC. An average of 165 393±270 516 PC were separated per patient, and 98 of the cohort (96.1%) had a sufficient number of cells for the hybridization of at least one FISH probe; all 5 probes were applied in 30% of patients, 4 in 50%, 3 in 12% and 2 in 8%; the reasons underlying the selection of fewer than all 5 probes in samples with a sufficient number (>20 000) of cells included the individual decision of the assisting physician and, for t(14;16), the date of the study. Considering only those studies performed after the introduction of t(14;16), all 5 probes were used in 67.0% of samples. It was possible to apply four or more probes in 80% of patients with 1% or less bone marrow PC according to flow cytometry. The median age of the 98 patients with a FISH result was 63.6 years old (37.8 to 87.3), and 56.1% were male; 41.8% eventually received a diagnosis of MGUS and 58.2% of multiple myeloma (MM), with an identical median age (64.2±16.9 vs 63.0±10.8 years old, P=NS). We found that 16.3% (of 92) were positive for t(14;14), 12.2% (of 90) for del(17p13.1), 6.8% (of 90) for del(1p32) and 41.1% (of 90) for amp(1q21); t(14;16) was not identified in any of the 30 patients in whom the probe was used. The t(4;14) translocation was present in 22.4% of MM and 7.7% of MGUS patients (p=0.055), and del(17p13.1) was found in 18.5% vs 2.8% (p=0.043) in the other. In the 9th, both del(1p32) (5.6% vs 5.8%, p=NS) and amp(1q21) (46.3% vs 33.3%, p=NS) were identically distributed across diagnoses. We observed that 40.4% of MM and 65.8% of MGUS patients were positive for 20% of less of the tested aberrations, while 54.4% vs 34.2% were positive for 20 to 50%, and 5.3% vs 0% were positive for over 50% of the aberrations evaluated.

Summary/Conclusions: We have found that the application of FISH probes in FACS-separated PC is highly efficient with a robust yield, providing a large enough sample for the application of at least two probes in over 95% of patients, irrespective of bone marrow plasmacytosis; in fact, we obtained an average of 165 000 pure PC per patient, which is more than 8-fold higher than the number we consider invariably sufficient to apply 5 probes, which we achieved in at least 80% of patients.

PB2004

CLINICAL SPECTRUM AND EVOLUTION OF MONOCLONAL GAMMOPATHY ASSOCIATED NEUROPATHY versus CHRONIC INFLAMMATORY DEMYELINATING POLYNEUROPATHY PATIENTS

1Seoul Metropolitan Government Seoul National University Boramae Medical Center, 2Seoul National University Hospital, 3Korea University Anam Hospital, Seoul, 1Inje University Haeundae Paik Hospital, Busan, 2Incheon Medical Center, Incheon , Korea, Republic Of

Background: Paraproteinemic neuropathy (PPN) refers to a disorder of the peripheral nervous system associated with a monoclonal gammopathy (MG). It is known that about 10% of idiopathic peripheral neuropathies are of this type. Unfortunately, PPN is often underdiagnosed or confused with chronic inflammatory demyelinating polyneuropathy (CIDP), subsequently leading to inappropriate management. Since progression of neuropathy is associated with possible malignant conversion of underlying monoclonal gammopathy, it is important to recognize underlying hematological conditions.

Aims: We aimed to determine whether the clinical characteristics and course differed in patients with PPN compared to those with CIDP in order to identify factors useful for differential diagnosis.

Methods: This study was carried out at Seoul National University Hospital, which is a tertiary academic center. During the period between January 2005 and December 2016, patients with 1) monoclonal gammapathy of undetermined significance (MGUS), and 2 CIDP were identified. Those with previous history of cancer or autoimmune disease requiring treatment with immunomodulatory agents were excluded from analyses. In the end, a total of 18 MGUS patients and 34 CIDP patients, with complete set of data including clinical physical examinations, electrodiagnostic studies, and laboratory test results, were enrolled.

Results: In both groups, males were predominant. IgG MG was most common (96.8%) in our cohort. PPN appeared to be mainly sensory regardless of heavy chain or light chain. Compared to PPN patients, CIDP patients were associated with motor symptoms manifesting as motor weakness (50.0% vs 91.2%, P=0.001) and ataxia (44.4% vs 61.8%, P=0.043) (Table 1). There were equal number of axonal type neuropathy and demyelinating type neuropathy in patients with PPN, and there were no differences in type of neuropathy between various immunoglobulin subclasses. However, demyelinating type PPN was associated with more severe clinical presentations, including more dysesthesia, pain and sensory symptoms. During median follow-up of 49 months, 2 CIDP patients developed overt hematologic malignancies: 1 case of Waldenström macroglobulinemia and 1 case of AL amyloidosis; both of them showed malignant transformation within 8 months of neuropathy development, and were associated with worsening neuropathic symptom at the diagnosis of hematologic malignancy. There were no differences between the two groups with regards to overall survival.

Table 1. Clinical characteristics of all enrolled patients.
Summary/Conclusions: Although both PPN and CIDP patients suffer from sensorimotor symptoms, CIDP patients were more often associated with superimposed motor symptoms. Among PPN patients, demyelinating type neuropathy seems to be associated with more severe clinical presentations. Worsening of neuropathic symptoms in PPN patients warrants a high level of suspicion of malignant transformation of underlying disease.

PB2005

MOLECULAR GENETIC CRITERIA PREDICTING THE EFFICIENCY OF PERIPHERAL BLOOD HEMATOPOIETIC STEM CELLS TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA

Z. Minchenko1, Z. Misharina2, O. Dmytrenko3, T. Liubarets3, I. Dmytrenko1, V. Khomenko4

1Institute of Physical Genetic Laboratory, National Research Center for Radiation Medicine of National Academy of Medical Science of Ukraine, 2O.O. Bogomolets National Medical University, 3Hematology and Transplantology Department, National Research Center for Radiation Medicine of National Academy of Medical Science of Ukraine, 4Kyiv Bone Marrow Transplantation Center, Kyiv, Ukraine

Background: Global gains in treatment of MM using auto-PBHSCT testify to heterogeneity of long-term outcomes of transplantation - different term of the achievement and duration of complete remission, progression-free survival (PFS), overall survival (OS). These facts determine individual approach to the approach and further PBHSCT.

Aims: Finding molecular genetic criteria of predicting the effectiveness of autologous peripheral blood hematopoietic stem cell transplantation (auto-PBHSCT) for improving of algorithm of multiple myeloma (MM) patients cure at various stages of treatment.

Methods: The study involved 61 patients with MM and relapse and primary therapy resistant patients. Molecular cytogentic, immunogenetic, hematological and statistical methods were used.

Results: Since appearance of genetic abnormalities in the malignant plasma cells one of the pathogenic mechanisms of the disease, genetic support of pathogenesis is essential. It was determined that the carriage of the allele HLA-DQB1*03: 02 in MM patients is associated with a high risk of high-dose chemotherapy resistance (F=4.83, p<0.028; OR=1.75, p=0.038), and achieving remission after auto-PBHSCT is associated with carriage of haplotype HLA-C*06 - HLA-DQA1*01: 01 (F=4.87, p<0.028; OR=1.75, p=0.038).

Abnormalities of chromosome 13 (23 patients (37.7%), Ro Spiranm=0.42, p < 0.05), deletion of chromosome 17 (17 patients (27.9%), Ro Spiranm=0.41, p < 0.05), deletion/monosomy of chromosome 13 (10 of 15 patients surveyed, Ro Spiranm=0.33, p < 0.05), the translocation t(4;14) (4 patients (6.6%), Ro Spiranm=0.50, p < 0.02).

Summary/Conclusions: The results indicate the necessity of introducing the molecular genetic support into protocol of examination MM patients on various stages of treatment with auto-PBHSCT.

PB2006

THE INFLUENCE OF MINIMAL RESIDUAL DISEASE AND TUMOR LOAD ON THE PROGRESSION FREE SURVIVAL IN MULTIPLE MYELOMA PATIENTS

A. Garifullin1, S. Volostshin1, A. Kuvshinov1, Z. Chubukina1, A. Schmidt1, S. Bessmel’sev1, A. Chechetkin1

1Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Use of modern drugs and their combinations in the complex antmyeloma therapy (induction, high-dose therapy (HDT) with autologous stem cells transplantation (ASCIT), consolidation and maintenance therapy) to improve efficacy of treatment and duration of responses. Despite the achievement of complete response (CR) many patients has a relapse which is caused by activation of residual clonal plasma cells.

Aims: To define influence of induction therapy regimens, HDT with ASCIT to the frequency of Minimal Residual Disease (MRD) negative status and estimate a role MRD in duration of Progression Free Survival (PFS) in multiple myeloma (MM) patients.

Methods: We analyzed 52 patients with MM (median age 55 years, male/female – 2:1). The induction therapy with Bortezomib-based regimens (VD, DVG, VMP, PAD) was used in 36/52 (69%) patients, Immunomodulator-based regimens (Thal+D, RD, VRD, PomD) – in 14/52 (27%), chemotherapy – in 25/52 (4%). ASCIT is carried out 31 (59.6%) patients. Primary tumor cells phenotype and MRD were detected by 5-color flow cytometry. Clonal plasmatic cells were detected by markers: CD38, CD138, CD45, CD19, CD20, CD27, CD56, CD117. MRD-negative status considered in identifying less than 1 tumor cell in 10000 (0.01%).

Results: MRD-negative CR was reached in 23.8% (10/42) patients after 4-6 cycles of therapy. The frequency of MRD-negative status in the Bortezomib group was 31% (9/29), in the “Immunomodulator group” – 7.7% (1/13) (Chi-square =0.1; p > 0.05). The general frequency of MRD-negative CR after HDT with ASCT was 33.3% (7/21). The carrying out HTD with ASCT allowed to MRD eradication in 36.4% (4/11) patients. One patient with a “light chain” myeloma lost MRD-negative CR after HTD with ASCT that led to development of a clinical relapse after 6 months. Carrying out a maintenance therapy with bortezomib or lenalidomide didn’t allow to achieve MRD-negative status in patients with MRD-positive response. On the contrary, achieve MRD-negative status promoted to increase of PFS. The PFS median in MRD-positive group of patients (n=36; 21 CR, 6 VGPR, 9 PR) was 21 months, in the MRD-negative group (n=16) – 66 months (p=0.004). The tumor load is also a strong prognostic factor like MRD status. Patients who attained low-level MRD had a benefit in the duration of PFS: <0.01% - 66 months, 0.01%-0.1% - 48 months at 0.1% - 1% - 22 months, >1% - 10 months (p=0.0009) (Figure 1).

QUALITY OF RESPONSE AS PREDICTOR OF SURVIVAL AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN REAL LIFE MULTIPLE MYELOMA PATIENTS IN A SINGLE INSTITUTION

A. Pinho1, A. Roque2, E. Cortesão1, A. Espadana1, A. B. Sarmento1,2, C. Gerais1,2, M. L. Ribeiro1

1Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra, 2Faculty of Medicine and Cimago, University of Coimbra, Coimbra, Portugal

Background: High dose chemotherapy (HDC) followed by autologous stem cell transplantation (ASCT) is the standard treatment approach for younger patients with multiple myeloma (MM). Since the introduction of proteasome inhibitors and immunomodulatory drugs in MM treatment more patients achieve durable and disease-free responses and better disease control before ASCT.

Aims: To evaluate the association between the depth of response before ASCT and survival outcomes in a cohort of patients with MM.

Methods: Retrospective analysis of patients with MM treated with HDT and ASCT between 2007 and 2016 in a single institution. All patients received at least one of the following regimens: VCD, D, RD, VRD, PomD and received HDC+ASCT. Patient characteristics were analyzed, the tumor load was also assessed and patients were divided in groups according to the achievement or not of MRD-negative status after ASCT.

Results: We included 185 MM patients, mainly males (57.9%) with a median age at ASCT of 61 years (28-71). The most prevalent subtype was IgG k (44%). The median number of previous therapeutic lines was 1 (1-4) and the majority of patients (61%) received bortezomib as part of first-line regimen. Patients undergone ASCT within a median of 10 months after diagnosis. With a median follow-up time from ASCT of 28.55 months (2.8-121.4), OS at 2 and
5 years was 83.8% and 68.9% and PFS was 74.8% and 37.3%, respectively. Before ASCT, 101 patients (51.8%) achieved very good partial response (VGPR) or better (≥VGPR) and 94 patients (48.2%) a partial response (PR). The patients in ≥VGPR presented significantly longer OS (median OS not reached vs 96.9 months, p=0.023) and PFS (58.5 vs 41.2 months, p=0.003) compared with those in PR. At 100 days after ASCT, 107 patients (54.9%) presented ≥VGPR, 79 (40.5%) PR and 7 (3.6%) progressive disease. Two patients were not assessed due to loss of follow-up. The group of ≥VGPR showed superior OS (median OS not reached vs 72.4 months, p=0.023) and PFS (58.5 vs 34.7 months, p=0.007) compared to the PR group. We did not found statistically significant differences in survival of patients who achieved ≥VGPR before or after ASCT. Univariate analysis indicates that depth of response before and after ASCT (≥VGPR vs PR) are significant predictors of OS (HR 0.49; 95% CI 0.31-0.80, p<0.004 and HR 0.49; 95% CI 0.30-0.81, p=0.005) and PFS (HR 0.50; 95% CI 0.27-0.92, p=0.026 and HR 0.49; 95% CI 0.27-0.90, p=0.021). Multivariate analysis confirmed that these factors retain their prognostic value after adjustment for age, International Staging System stage and number of previous lines of treatment.

Summary/Conclusions: These findings provide evidence for quality of response as a predictor of OS and PFS after ASCT in patients with MM. Outcomes after ASCT seems to be better for MM patients who achieve deep responses (at least VGPR) before or after transplant. Our results support the use of more effective induction regimens in order to improve initial response as this may correlate with higher response rates and survival post-ASCT.

PB2008
LEPTOMENINGEAL INFECTION SCREENING SHOULD BE PERFORMED IN PATIENTS DIAGNOSED WITH PLASMA CELL LEUKAEMIA
M.Q. Salas1,*, V. Clapes2, N. Garcia1, C. Baca3, R. Velasco4, E. Gamundi5, A. Sureña3
1Hematology, ICO-Hospitalitat, 2Hematology, ICO Duran i Reynals, 3Hematology, ICO-Duran i Reynals, 4Neurology, 5Hematology, Hospital Universitario de Bellvitge, Barcelona, Spain

Background: Plasma cell leukaemia (PCL) is a rare and aggressive plasma cell (PC) disorder characterized by the presence of circulating plasma cells. PCL can arise either de novo or as secondary PC (sPCL) in patients with relapsed/refractory multiple myeloma (MM). PCL has a more aggressive clinical presentation than MM with a more frequent extramedullary involvement, such as leptomeningeal infiltration. However, because of the low incidence of this entity, most clinical data come from small retrospective studies. Clinical diagnostic criteria of PCL are today under review and the incidence of leptomeningeal infiltration is unknown.

Aims: We aimed to study the clinical features with special emphasis in the incidence leptomeningeal infiltration in patients diagnosed with PCL in our centre.

Methods: Seventeen patients were diagnosed of PCL between 2008 to 2016 in our centre. PCL was defined based on criteria from the Chronic Leukaemia Myeloma Task Force, by the presence of 2x10⁹/L peripheral blood PC or plasmacytosis accounting for more than 20% of the differential white cell count. Medical records were retrospectively reviewed, Clinical response was evaluating per IWMG criteria. Clinical and biological features, progression free survival (PFS) and overall survival (OS) were analyzed. Survival curves were estimated using the Kaplan-Meier method and compared using the Log-Rank test.

Results: Seventeen patients with PCL were included. Six (35.3%) were pPCL and eleven (64.7%) sPCL. Median age at diagnosis was 57 years (range 35-78) and 8 (47.1%) were males. Clinical and analytical features at the moment of diagnosis are recorded in Table 1.

Five (29.4%) patients presented with leptomeningeal infiltration; in three of them it was diagnosed at the time of the diagnosis of PCL. All the patients had neurological features. Thirteen (76.4%) patients were able to start a curative treatment: VD in 7 (53.8%) patients, VTD in 2 (15.4%), VAD in 1 (7.7%), D-PACE in 1, MXR-ARAC in 1 patient and RD in the remaining one. Three patients received intrathecal treatment. The intention-to-treat response was: 2 (15.4%) CR, 2 (15.4%) PR, 7 (53.8%) refractory disease (progression and 2 non-evaluable). Only 2 (15.4%) patients achieved enough response (2 CR) to undergo an autologous stem cell transplant (ACST) and only 1 to undergo an allogenic-SCT. With a median follow up of 4 months for all the patients included, median of PFS was 3 (CI 95% 0.47-4.76) months and median of OS was 4 (IC 95% 0.47-7.53) months.

Summary/Conclusions: Prospective multicenter studies are required to provide a better understanding of the pathogenesis of PCL. Staging procedures should include lumbar puncture or magnetic resonance at diagnosis when extramedullary involvement is suspected. Intrathecal prophylaxis with cytarabine, metotrexate and dexamethasone is not today a standard of care for patients with PCL.

PB2009
MANAGEMENT AND OUTCOMES OF PATIENTS WITH MULTIPLE MYELOMA IN REAL-WORLD SETTINGS IN BULGARIA, CROATIA AND SLOVAKIA
1Clinic for Hematology, University Hospital Sofia, Sofia, Bulgaria, 2School of Medicine, Merkur University Hospital, Zagreb, Croatia, 3Department of Hema tology, Transfusiology, University Hospital, Bratislava, Slovakia, 4Kantar Health, Paris, France, 5Hemetsberger medical services, Vienna, Austria, 6Amgen (Europe) GmbH, Zug, Switzerland, 7Amgen (Europe) GmbH, Vienna, Austria

Background: The multiple myeloma (MM) treatment (Tx) landscape is rapidly evolving, with varying Tx practice patterns and access schemes across countries. However real-world (RW) data describing patient (pt) management, MM Tx use and outcomes in some Eastern European Countries are limited.

Aims: To understand the characteristics, management, Tx patterns and outcomes of pts with symptomatic MM in a RW setting in Bulgaria (BG), Croatia (HR) and Slovakia (SK).

Methods: Data were collected within a cross-sectional (X) and retrospective (R) phase of a chart review in 6 countries between June/15 and June/16 by (onco-)hematologists who managed at least 15 pts with MM per month (mo) and were responsible for initiating MM Tx. Data from 3 countries with limited access to MM Tx are shown. In the X-phase, data included characteristics and current Tx by line of therapy for all pts with MM seen during a 3-week observation period, regardless of pts’ Tx status and strategy. In the R-phase, data included pt and disease characteristics at diagnosis, Tx response, comorbidities and outcomes by Tx line. Pts were selected in reverse chronological order and those who had completed specific lines of active Tx within the past 3 mo were included as follows: 3 pts in first line (1L), 4 pts in second-line (2L) and 7 pts in third or higher lines. Analyses were descriptive.

Results: In the X-phase, 7 physicians from BG, 6 from HR and 5 from SK (combined). In the R-phase, 9 in BG, 69 in HR, and 89 in SK were analyzed. Survival curves were estimated using the Kaplan-Meier method and compared using the Log-Rank test. The proportion of pts that had received SCT at any point increased from 1L to 2L (3% to 19%, 7% to 35% and 9% to 54% in BG, HR and SK respectively). 82% of pts in BG, and 70% both in HR and SK were currently receiving Tx (Table 1), while 17%, 30% and 25% of pts respectively, were treated previously. Only 4 pts (1 in BG and 3 in SK) had never been treated. In the R-phase, 6 physicians from HR and 3 from SK provided outcomes from each of Tx and HR and SK included 43, 39 and 44 pts respectively. Only 2 (15.4%) patients achieved enough response (2 CR) to undergo an autologous stem cell transplant (ACST) and only 1 to undergo an allogenic-SCT. With a median of 4 months for all the patients included, median of PFS was 3 (CI 95% 0.47-4.76) months and median of OS was 4 (IC 95% 0.47-7.53) months.

Summary/Conclusions: These findings suggest a high unmet need for access to more effective and innovative Tx options with manageable safety profiles in these countries. In particular, in BG where bortezomib- and chemotherapy-based regimens are the only treatments used, pts might be re-treated with the same agents, which may explain why most do not achieve ≥VGPR from 2L. In HR and SK, sustained or increased rates of ≥VGPR in 2L may be due to the use of newer or different agents from those used in 1L and to the fact that most pts had previously received a SCT. These RW data provide useful input for economic evaluations of new MM agents to include in earlier Tx lines in these countries.
PB2010

SINGLE SHOT MEDIUM DOSE MELPHALAN IN RELAPSED MM PATIENTS: A RETROSPECTIVE, SINGLE CENTER EXPERIENCE

C. Clissa1, A. Isidori1, F. Coscocco1, E. Gabucci1, L. Malerba1, B. Guiducci1, G. Visani1

1Hematology, AORN M Parma, Parma, Italy

Background: Multiple myeloma (MM) patients refractory to proteasome inhibitors, IMiDs or both, have an extremely poor prognosis. Moreover, they frequently fail to respond to further therapies, and represent a major challenge in everyday clinical practice.

Aims: With this in mind, we treated 12 patient with relapsed MM with a single shot of medium dose melphalan (60 mg/m2) between October 2010 and January 2016.

Methods: The median age was 72 years (range, 62 – 79) and the median time from initial diagnosis to melphalan treatment was 61 months (range, 24 – 144). Patients were heavily pretreated with a median number of 3 prior lines of therapy. All patients were refractory to the previous therapeutic regimens and had failed to respond or were refractory to regimens containing bortezomib. Seven patients (84%) had previously received at least one IMiD, 8 (67%) autologous stem cell transplantation (ASCT) and 1 allogeneic stem cell transplantation. The patients included in the series were not eligible for any clinical trial available at the Institution. All patients gave informed consent.

Results: All patients had cytopenia (anemia, neutropenia and thrombocytopenia). We observed 3 cases of gastrointestinal toxicity (1 bleeding, 1 subcolonic fistula, 1 mucusitis). 3 cases of clinically documented infection (1 Escherichia coli bacteremia, 1 fever of unknown origin, 1 erysipela) and 2 deep vein thrombosis. Response was assessed between six and eight weeks after melphalan therapy. Overall, 10 out of 12 patients had a response (1 complete response, 3 very good partial response, 2 partial response and 4 stable disease). Median overall survival was 11 months (range, 2 - 37). 10 of 12 patients relapsed after a median time of 5 months (range: 2 -12). Concerning two patients not relapsed, 1 patient died in partial response 8 months after therapy of other causes; 1 patient is still alive, in complete remission 18 months after melphalan. He underwent ASCT and maintenance with lenalidomide.

Summary/Conclusions: Many patients refractory to proteasome inhibitors and IMiDs are probably still sensitive to alkylating agents and could be rescued with medium dose melphalan. We suggest therefore melphalan as a “bridge” strategy for further therapy, particularly in patients needing immediate disease control. Even in this era in which several novel drugs became available, single shot medium dose melphalan could be an affordable and safe therapy, able to control. Even in this era in which several novel drugs became available, single shot medium dose melphalan could be an affordable and safe therapy, able to control aggressive relapse, and to reduce disease burden prior to targeted therapy.

PB2011

LENALIDOMIDE AT THE DOSE OF TWENTY-FIVE MG EVERY OTHER DAY IN PATIENTS AFFECTED BY MULTIPLE MYELOMA AND RENAL FAILURE: A REAL-LIFE EXPERIENCE

C. Cerchione1, L. Catalano1, A.E. Pareto1, D. Nappi1, I. Peluso1, K. Ferrara1, M. Di Perna1, I. Zacheo1, F. Fane1

1Hematology, Ematologia e trapianto/au federico ii, Napoli, Italy

Background: Lenalidomide, available as oral compound, is an IMiD with both antiproliferative and immunomodulatory activity which is largely used in the management of newly diagnosed, relapsed or refractory MM and as maintenance therapy after autologous stem cell transplantation. Due to its renal route of excretion, it is mandatory to adjust lenalidomide dose in patients with RI, guided by Creatinine Clearance (CICr), in order to impede a systemic prolonged exposure that could boost myelosuppression. With normal renal function, lenalidomide reaches its maximal plasma concentration after a median time of 0.6-1.5 h, and its half-life in healthy volunteers is 28 days, with a serum half-life increasing up to hours if moderate/severe renal impairment is present (creatinine clearance <50 or <30 mL/min, respectively). In the latter cases a reduction of the daily dose is recommended. Dose adjustment based on RI severity decreases the daily amount of lenalidomide from 15 up to 5 mg (in patients undergoing dialysis); other studies include a schedule with 10 or 15 mg every other day. However, there is no theoretical assumption against the possibility that protracting the time of full standard doses can be equally effective and tolerated by patients requiring reduced doses.

Aims: In this report, we describe our retrospective experience on the administration of lenalidomide 25 mg every other day for patients with MM and RI.

Methods: From March 2014 to February 2016, 19 consecutive patients, 11 female and 8 male, with a median age of 63.3 years (range: 49-81) affected by advanced, resistant and progressive MM (median number of previous treatment lines: 3, range : 1-5, all including bortezomib) with concomitant renal failure not in dialytic support (median calculated CICr 36.4 mL/min, range: 18-66) were treated, after informed consent, with monthly 21-day courses of 25 mg lenalidomide every other day and dexamethasone (20-40 mg on days 1-8-15-22, every 28 days).

Results: Disappearance of urinary light chain and reduction of serum creatinine (complete response) were detected in 7 patients (36.8%); 3 patients (15.7%) had a very good partial response, 3 (15.7%) had a partial response, 4 of them (21.0%) were in stable disease, whereas 2 patients (10.5%) had signs of progressive disease. Overall response ratio was 68.2%. More than half of the patients (11/19, 57.8%) had a renal response (median calculated CICr 51.5ml/min, range 20-148). Median progression free survival was 23 months (range 3-18 months). No patient experienced grade 4 myelotoxicity; four patients required red cell transfusions for grade 3 anemia. No SAE occurred during treatment.

Summary/Conclusions: Dose adjustment RI-related of Lenalidomide is recommended in most guidelines, but there is no a leading scheme with a proven effectiveness more than others. These preliminary observations point to a significant therapeutic effect of lenalidomide, at the dose of 25 mg every other day for 21 days, in more than half of a small population of patients with advanced MM and renal impairment, with not negligible logistic and economic advantages. However, these results should be validated by controlled studies involving larger number of patients.

PB2012

A FEASIBILITY-STUDY ON IMPLEMENTATION OF THE INTERNATIONAL MYELOMA WORKING GROUP RECOMMENDATIONS FOR MULTIPLE MYELOMA PATIENTS IN ROUTINE CLINICAL PRACTICE: A PERIPHERAL CENTER EXPERIENCE

M. Torchio1,2, C. Cavalli1, A. Gazo2, R. Bellazzii2, M. Danova1

1Internal Medicine and Medical Oncology, 2Nephrology and Dyalisis , Ospedale Civile di Vigevano, ASST di Pavia, Vigevano, Italy

Background: Renal impairment (RI), defined as serum creatinine above upper normal limit or >2 mg/dl or a estimated glomerular filtration rate (eGFR) <60 ml/min/1.73mq, is one of the most common complications of MM, and it is associated with an increased risk of early death. The incidence of RI at MM diagnosis ranges from 20% to 50%, while its comparison occurred in 60% MM patients (pts). In this scenario tempestive diagnosis of RI in MM pts and exclusion of possible alternative causes of RI (like amyloidosis, diabetes or MIDD) are essential.

Aims: We applied a diagnostic algorithm obtained from the International Myeloma Working Group Recommendation in pts admitted to our department for RI (with known and unknown MM, or suspected cast nephropathy, CN), in order to investigate if this diagnostic workflow could positively impact on MM pt management.

Methods: We enrolled adult pts, known or unknown MM, admitted to our hospital for RI or suspected CN, with or without monoclonal component. Preliminary, we performed complete blood analysis, with eGFR (CKD-EPI and MDRD methods), serum and urine electrolytes, bicarbonatemia, serum and urine immuno fixation, fraction 3 and 4 of complement, cirrhoalbumin, HbA1c, arterial gas analysis, evaluation of urine rate every 6 hours, daily urine collection, urine sediment analysis. We also collected anamnesis on eventual nephrotoxic concomitant therapies like ASA, FANS, clinical parameters and objectives signs of RI (edema, symptomatic disionia). On the second day of hospitalization we requested protein electrophoresis on serum and urine, chest X-ray, ultrasonography of abdomen, ecocardography and electrocardiography. On the day three we evaluated the impact of previous exams and we decided. If nephroscopy was necessary, we performed a biopsy (bone marrow in suspected unknown MM pts, renal in suspected CN pts, umbilical fat for amyloidosis). All analyses were daily and coligially discussed between Internists and Nephrologists.

Table 1.

[Table content]

* *

22nd Congress of the European Hematology Association
Results: From March to December 2016 we admitted 57 pts with RI and monoclonal component (29 F, 28 M, 41-83 yrs range), 20 are known MM pts and 37 de novo pts. We diagnosed 11 de novo MM, 13 known MM with a de novo RI, 12 diabetes related RI, 3 amyloidosis, 16 other causes.

Summary/Conclusions: The implementation of the International Myeloma Working Group Recommendations in a routine clinical practice confirmed its feasibility and utility in his optimal work of MM pts. We obtained diagnosis of RI within 4 days, both in known and in de novo MM pts, with a positive impact on reduced hospitalization, unnecessary dylaisis and steroids overtreatment.

PB2013

NOCARDIOSIS PROVOKED BY NOVEL AGENTS AT RELAPSED MULTIPLE MYELOMA: CASE SERIES

Z. Bolaman1, A. Turgutkaya1, E. Ceylan2, B. Gültekin Korkmazgil3, M. Telli3, C. Karaman4, I. Yavasoglu1

1Adult Hematology, 2Pulmonology, 3Microbiology, 4Radiology, Adnan Menderes University Medical Faculty, Aydin, Turkey

Background: The proteosome inhibitors and immunomodulatory drugs which are used in MM treatment enhance the risk of infection by several mechanisms. Nocardial infections are rare in Turkey.

Aims: Here, we present three relapsed myeloma cases which developed nocardia pneumonia.

Methods: Case-1: 66 year old man, who has a history of autologous SCT 4 years ago and lenalidomide usage because of IgG kappa type myeloma, has been prescribed bortezomib for the relapse of the disease. He was immunocompromised not only because of the myeloma, and also because of the diabetes and renal failure without dialysis. He was admitted to the hospital because of the productive cough with dense sputum. His lymphocyte count was 120/mm3 and flow-cytometric analysis couldn't be performed. His lymphocyte count was 2300/mm3 and flow-cytometric analysis showed CD5:%88 and CD 20:%1. Thorax CT showed a 7x6x6 cm sized mass like lesion. Broncoscopic lavage examination showed branched bacillus via modified acid-fast and Gram stain. This typical morphological appearence was defined as Nocardia spp. Imipenem-cilastatin treatment started and control CT was performed after 10 days and it showed regression of the infiltration. He was discharged with oral TMP/SMX antibiotic therapy. Case-2: 71 year old woman, who has a history of two autologous SCT 12 and 5 years ago because of IgG kappa type myeloma; admitted to the hospital with productive cough during pomalidomide treatment. Her lymphocyte count was 520/mm3. Flow-cytometric analysis couldn't be performed, relapsed 5 months ago. He has been admitted to the hospital with non-productive cough complaint under the treatment of lenalidomide and dexamethasone. His lymphocyte count was 520/mm3. Flow-cytometric analysis couldn't be performed. Thorax CT showed 4 cm sized cavity and sputum microscopy showed acid resistant branched bacillus thought to be consistent with nocardiosis. The imipenem/cilastatin and TMP/SMX treatment have begun and 12 days later, a control CT was performed and showed regression. He was discharged with oral TMP/SMX antibiotic therapy.

Results: See Table 1 and Figure 1.

Summary/Conclusions: The proteosome inhibitors and immunomodulatory drugs which are used for the treatment of MM make T cell dysfunction and considering B cell dysfunction is also present because of the nature of the disease; this situation tends to provoke rare opportunistic infections such as nocardiosis. Thus, in these patients, it is significant to follow the lymphocyte count closely and to keep in mind that kind of rare microorganisms.

PB2014

LENALIDOMIDE IN PATIENTS WITH DIALYSIS-DEPENDENT END STAGE RENAL FAILURE (ESRF) AND MULTIPLE MYELOMA

P. Di Ciaccio1,*, S. Ling1

1Department of Haematology, Liverpool Hospital, Sydney, Australia

Background: Lenalidomide is an oral immunomodulatory medication with clinical efficacy in relapsed/refractory and treatment naive multiple myeloma (MM), Sq- myelodysplasia and lymphoma. Lenalidomide is eliminated predominantly unchanged by urinary excretion. Renal impairment is common in MM (15-40%) and approximately 10% of MM requires dialysis. However, there is a paucity of clinical safety data of Lenalidomide in ESRF. There is evidence that Lenalidomide can be safely used in patients with moderate and severe renal dysfunction with dose adjustment. However, published data in hemodialysis-dependent patients is limited to a handful of patients across small retrospective analyses and case reports. Patients with ESRF have generally been excluded from clinical trials investigating Lenalidomide. Phase III trials in the relapsed setting (MM-009, MM-010) excluded patients with a serum creatinine >221μmol/L. The FIRST trial (MM-020), investigating upfront use, excluded patients dependent on dialysis. There is no accepted clinical standard on the most appropriate dosing of Lenalidomide in dialysis. The manufacturer has provided guidelines, being 5mg daily, day 1-21, every 28 days (equivalent to 105mg per cycle). There is alternate well-cited pharmacological dosing that the more appropriate starting dose is likely 15 mg, three times per week, given post-dialysis (equivalent to 135mg per cycle).

Aims: To provide real-world evidence of an institutional experience of the use of Lenalidomide in dialysis-dependent MM.

Methods: We performed a retrospective audit of our in-centre experience with treating dialysis-dependent MM with Lenalidomide and included patients who completed at least one cycle of therapy. Patients were assessed for haematological toxicity, significant infective complications, thrombosis, disease response and progression-free survival. Best response was stratified by IMWG criteria. Patients' baseline characteristics, prior therapies, cytogentic and FISH data were collected.

Results: We identified 5 patients treated between 2010 and 2017, aged between 54 to 73 years old. All patients had relapsed/refractory MM and dialysis dependent ESRF. The median number of prior therapies was two. One patient had (11,14) on FISH and died from progressive disease. Dose schedules are shown in the Table 1. Almost all patients experienced grade III-IV haematological toxicity and 60% had grade III-IV infection. There was a positive correlation between dose and toxicity, and furthermore there appeared to be an inverse relationship between age and tolerated dose. Haematological toxicities and infection were ameliorated by dose adjustment in most instances. There was no drug related mortality, however one patient died of progressive disease. Four of the five patients were prescribed aspirin thromboprophylaxis, with no proven thrombotic complications seen. Where possible to assess, the ORR was 75% (3/4), with 2 patients achieving a very good partial response (VGPR), 1 partial response and 1 progressive disease. The lowest starting dose in this cohort was 10mg twice/week and the maximum dose was 25 mg three times/week.

Table 1.
PB2015
STUDY USE OF 18-F FDG PET / CT SCANNING INTO THE FIRST FOLLOW UP OF PATIENTS WITH MULTIPLE MYELOMA AND ASSOCIATION WITH BIOCHEMICAL RESPONSE
K. Vallejo Luna1, M. Simó2, J. Montoro3, C. Palacio3, M. Junquera4, M. Gironella Mesa5,6,*
1Hematology, Vall d’Hebron Institute of Oncology, 2Department of Nuclear Medicine, 3Department of Clinical Diagnostic, 4Department of Hematology, Hospital Universitari de Vall d’ Hebron, Barcelona, Spain

Background: Positron computed tomography (PET / CT) with 18F fluoro- doxoglucose-labeled glucose (FDG) is a reliable technique with high sensitivity and specificity for assessing skeletal involvement and recent studies propose it as a method for predicting treatment response in multiple myeloma. Conventionally, the response is measurable by the monoclonal component in both serum and urine and Minimal residual disease (MRD) by flow cytometry has been established as a mandatory tool. The studies are aimed at combining the measurement of paraprotein with imaging tests that help to promptly define response or failure to the treatment.

Aims: The primary endpoint was the correlation of the biochemical response with the FDG PET/CT in a second evaluation after first line treatment. The secondary endpoint was the correlation between MRD and with second FDF PET/CT.

Methods: We included in this retrospective and observational study at University Hospital of Vall d’Hebron, all patients with newly MM and PET/CT before to start a first line treatment and a second PET/CT when completing treatment. PET/CT were analyzed by the department of Nuclear Medicine with experience to grade the lesions in MM, were evaluated and categorized into positive or negative according to the criteria proposed by Zamagni, et al. The biochemical response was defined according to the standard IMWG response criteria. Results: Eighteen patients (8 males and 10 females) with untreated MM entered, seven patients were classified with ISS III, fifteen had a good performance status, none presented renal lesion, only 16% had hypercalcemia and 66% showed immunoparesis. Ten patients were IgG isotype, six were classified as light chains myeloma and two patients were oligosecretors. Seventeen patients had bone marrow infiltration with a median of 42% plasmatic cells. Two patients had a extramedullary plasmacytoma and nine had an anor- mal ratio of light chains. Seventeen patients were treated with bortezomib-based regimens. After treatment, fourteen patients achieved complete response, two partial response and two had progressive disease. PET/CT was positive in all patients pretreatment, 15 focal lesions, 2 diffuse bone marrow involvement plus focal lesions and 1 involvement of bone marrow alone. Twelve patients had more than 3 focal lesions and two had extramedullary disease. At the end of first line treat- ment, PET/CT was negative in eight patients (44%) and fourteen had complete biochemical response (78%). 62% of the patients with negative PET/CT showed negative flow minimal residual disease (MRD) and biochemical complete response. Two patients had PET/CT with progression disease and corresponded to a biochemical progression.

Summary/Conclusions: The correlation between PET/CT and biochemical response obtained after treatment was positive in patients with complete response. We found discordant data in two patients with oligosecretory myeloma. No correlation was shown between PET/CT and flow MRD.

PB2016
MULTIPLE MYELOMA IN BORNEO SARAWAK: A DEVELOPING WORLD’S EXPERIENCE
T.S. Lim6, L.P. Chew6
1Hematology Unit, Medical Department, Sarawak General Hospital, Kuching, Malaysia

Background: Sarawak, is the largest state of Malaysia situated on the island of Borneo. Sarawak General Hospital is the tertiary referral center of Sarawak (serving a population about 1 million people). It is 980 km away from its main hematology/transplant referral center in Kuala Lumpur, Malaysia, which is accessible only by airplane. Hence, treatment of patients with multiple myeloma in this part of the state is a big challenge due to its geographical constraint.

Aims: To identify demographics and clinical characteristics of patients with multiple myeloma; To establish treatment and outcome of patients with multiple myeloma.

Methods: This is a retrospective study examining basic characteristics and clinical outcomes of patients diagnosed with multiple myeloma between 2010 and 2016 in Sarawak General Hospital. Patients’ case notes were traced and the relevant information was entered into a pre-designed data collection form. Data was analysed and interpreted via IBM SPSS Statistics version 24.0.

Results: There were a total of 63 patients with the male to female ratio of 3:2. The median age for patient was 61 years old (range 31 to 86 years old). Majority of them were local natives of Iban or Bidayuh descendants (n=32, 50.8%) followed by Chinese (n=20, 31.7%) and Malays (n=11, 17.5%). Most common type of multiple myeloma is of IgG variant (n=27, 42.9%). The most common myeloma related organ or tissue impairment (ROTI) are anaemia (n=54, 85.7%) followed by bone lesion (n=48, 77.8%), renal impairment (n=27, 42.9%) and hypercal- caemia (n=18, 28.6%). More than half presented late with Dure Salmon stage III disease (n=34, 54%). Majority of patients were treated with dexamethasone/thalidomide (n=25, 39.7%). Sixteen patients (25%) received bortezomib based treatment. Three patients (n=3, 4.8%) undergone bone marrow transplant. Thirty five patients died (n=35, 55.6%). Median survival time was 21 months (95% CI: 16.26). One year, two years and five years survival rate was 67.4%, 43.6%, 31.6%. Patients who were 60 years old and above have lower median overall survival (20 months) compare to patients who were 60 years and below (36 months) even though they are not statistically significant (p=0.565).

Summary/Conclusions: Baseline characteristics of patients with multiple myeloma in Sarawak are similar to the rest of Asia. However, our medi- an overall survival was comparatively lower to our counterparts. Limitation wise, due to logistic and economic reasons, we do not have good access to cytogenetic and genetic profiling that enables us to prognosticate patients accordingly.

PB2017
A RETROSPECTIVE AND PROSPECTIVE AUDIT OF RADIOLOGICAL INVESTIGATIONS FOR SUSPECTED CASES OF PLASMA CELL DYSCRASIAS/MYELOMA IN THE ALTNAGELVIN AREA HOSPITAL
G. Baker1, N. Cunninghnam1
1Haematology, Western trust, Londonderry, United Kingdom

Background: The updated NICE guidelines for diagnosis and management of myeloma (2016) suggests whole-body MRI as first-line imaging for people with suspected myeloma and consideration of MRI/CT/PET in newly diagnosed myeloma to assess for bone disease or EM plasmacytoma.

Aims: Our aims were to ascertain: 1) Our current practice regarding radiological investigation for myeloma (2) Whether additional diagnostic information was gained using CT/MRI imaging (3) Since its release, is the trust compliant with the NICE guidance (4) The estimated cost of meeting the current NICE guidance

Methods: This retrospective and prospective audit included all patients having a skeletal survey performed for suspected multiple myeloma within the Alt- nagelvin Area Hospital (AAH). Retrospectively from 10/2/15 until 9/2/16 data was collected using the advanced search feature of the Sectra IDST PACS system. The ‘Reason for examination’ for each study was then analysed and those ordered for reasons other than suspected myeloma were excluded. Each case was analysed individually and any follow up MRI/CT/NMB imaging performed in the 6 month period following the skeletal survey were included in the data collection. The same information was gathered prospectively from 10/2/16-30/5/16 following the NICE guidance. 54 skeletal surveys where performed for suspected/myeloma pre guidance.

Results: The indications for requesting imaging is shown in Table 1A. No WB MRI/CT was performed in this period. 26% patients had new lytic lesions on skeletal survey. 23 patients had further imaging in the form of MRI or CT fol- lowing skeletal surveys. All the positive MRI findings offered additional diag- nostic information - including examples of missed multiple spinal deposits. The results of imaging are summarised in Table 1B. The false negative rate for skeletal surveys was 39% and the false positive rate was 22%. Following NICE guidance publication 23 patients had skeletal surveys performed for suspicion of myeloma between 10/2/16 and 30/5/16. The indications are summarised in Table 1C. No WB imaging was performed. 5 patients had positive skeletal sur- veys. 6 patients had subsequent CT/ MRI imaging. A skeletal survey was report- ed normal with a subsequent MRI showing multiple spinal deposits. The imaging results are summarised in Table 1D.

Table 1. The expected cost of implementing WB imaging for 60 patients per year in the AAH is £18,240. In comparison the cost of performing skeletal surveys would be £4200 per annum. NICE guidance 2016 offers an
economical model for imaging with WB MRI. In addition it reviews evidence which links time to diagnosis to survival and myeloma related complications. The NICE guidance offers clear evidence that WB-MRI should be the investigation modality of choice for suspected myelomatous disease. It offers a diagnostic and cost-effective strategy that will ensure health improvements for myeloma patients. This audit offers further evidence of the diagnostic accuracy of MRI imaging. At present failure to comply with NICE guidance will lead to delayed diagnosis of myeloma in certain patients and potential patient harm. Therefore I offer a business and health improvement case for the Western Trust to instigate WB-MRI imaging for all suspected myelomatous bony disease.

**PB2018**

**TONI DEBRE FANCONI SYNDROME DURING MYELOMA, ABOUT 8 CASES**

R. Cherifi1,*, B. Salah Edine1

1Hematology, Central Hospital Mohammed Seghir Nekkache, Algiers, Algeria, Algiers, Algeria

**Background:** The cast nephropathy with cylinders is the most frequent renal complication of the myeloma, which results from a catabolism of the light chains by the tubular cells and can lead a tubular chronic suffering showing itself by a syndrome of acquired Toni-Debré-Fanconi marked by a glycosuria, a phosphaturia, an aminoaciduria, a sometimes severe and sometimes revealing hypokalemia.

**Aims:** We reporting some observations informed by Multiple Myeloma complicated with a Fanconi syndrome.

**Methods:** From January 2000 till December 2010: 78 cases of Multiple Myeloma were brought together, whose circumstance of discovery 22 cases with renal failure, it’s was a evolutes complications in 12 cases; and in 10 cases it’s discovered at diagnosis. The renal achievement is dominated by Tubule disease in 11 cases, Randall syndrome 8 cases, and Nephrotic syndrome in 3 cases. The tubule disease of Fanconi is suspected at only 8 patients: in front of the presence of a glycosuria (without associated diabetes) and a frank proteinuria in the majority of the cases, with a hypophosphatemia and a sickle hypokalemia.

**Results:** The clinico-epidemiological and immuno-biological characters of these 8 patients are the following ones: - The median age is of 64 years (39-76), sex ratio 3. - The osseous pains and the muscular cramps dominate the clinical presentation with constant diffuse demineralization in the radiology. - The patients were classified (according to the Salmon-Durie classification): IIIB (3 cases) and IIIB (5 cases). ISS 3 in majority of the cases. - The monoclonal immunoglobulin observed: IgG kappa: 4cases, IgA kappa: 2cases, light chain kappa: 2cases. With a Bence Jones proteinuria isotype kappa and a glycosuria in the majority of the cases. - The gravity of the renal failure, based on the clearance of the creatinine: with an average clearance of 16,19 ml/m² (437); several in 3cases, terminal in 3cases. - We note more of hypocalcaemia while the hypercalcaemia is noted in a single case, the hypophosphatemia is found in half of the cases. The therapeutic approach is double: - Symptomatic: alkaline hydration, correction of the metabolic disorders and sometimes the renal extra purge (indicated in 3cases). - Specific: chemotherapies VAD cases, a patient died by cardio-vascular complication. Under treatment the recovery of the renal function is obtained in 3 cases, to the rest of the patients persists a stable renal failure.

**Summary/Conclusions:** The Syndrome of Fanconi is a frequent and often formidable complication during Myeloma, observed to 30-40% of the patients in an autopsique series. It is necessary to think to it in front of any renal achievement of myeloma of kappa light chain with renal glycosuria, a generalized aminoaciduria and a hypophosphatemia resulting respectively from a defect of the transport of the glucose, from amino acids and from phosphates by the renal proximal tubule. To improve the osseous and renal appearances, it is necessary to realize a calcic supplementation, phosphorous and by the vitamin D active, as well as the correction of the acidose and a specific treatment reducing the excretion renal of the light chains.

**DEPP RESPONSES WITH CARFILZOMIB-LENALIDOMIDE-DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS: A REAL LIFE EXPERIENCE**

V. Pedrazzi1, G. Rossini1, D. Cartino1, A. Mele1, P. Curci2, A. Giordano2, S. Citiso1, G. Specchia2, V. Pavone1,*,

1Hematology and TMO, Hospital Card. G. Panico, Tricase (LE), 2Hematology and TMO, Policlinico di Bari, Bari, Italy

**Background:** Carfilzomib is a new proteasome inhibitor with in contrast to the reversible binding of bortezomib, binds irreversibly and selectively to its target: the chymotrypsin-like activity of the 20S proteasome. The phase IB/II PX-171-006 study was the first study in which carfilzomib was combined with lenalidomide and dexamethasone. In the phase I dose-escalation part the maximum plateau of dose was established as well tolerated and in the phase II part the study focused the efficacy and toxicity in the subgroup treated with maximum planned dose. The ASPIRE trial showed superior response rates and progression free survival for carfilzomib-lenalidomide-dexamethasone compared with lenalidomide-dexamethasone in relapsed/refractory Multiple Myeloma patients.

**Aims:** The aims is explore the efficacy and tolerability of carfilzomib-lenalidomide-dexamethasone in relapsed/refractory Multiple Myeloma patients in real life.

**Methods:** All patients received carfilzomib 20/27 mg/m² days 1,2,8,9,15 and 16; lenalidomide 25 mg days 1-21 and dexamethasone 20 mg days 1,2,8,9,15,16, 22 and 23, according to post approval access protocol. After 2, 4, 6 and 8 cycles the responses, disease progression and toxicity were assessed using the International Myeloma Working Group Uniform Response Criteria and WHO score respectively.

**Results:** From January 2016 to February 2017 in hematology “Cardinale G.Panico Hospital” and “Bari Policlinico”, treated 15 relapsed/refractory Multiple Myeloma patients with carfilzomib-lenalidomide-dexamethasone. Six patients male (40%), 9 female (90%), mean of age 62 years (range 38-79); 10 (66%) and 5 (34%) relapsed/refractory multiple myeloma respectively. Median time from diagnosis to carfilzomib-lenalidomide-dexamethasone was 46 months (range 12-82); median of prior therapy was 3 (range 1-6); 9 (60%) received autologous transplantation while 1 (6%) prior therapy with lenalidomide; 15 (100%) prior therapy with bortezomib; 2 (14%) prior therapy with pomalidomide (Table 1). Eleven (73%) patients achieved after 2 cycles a response rate ≥PR, of these 3 VGPR. After 4 cycles, 5 (33%) and 1 (7%) have obtained at least a VGPR and CR respectively (Figure 1). Three patients were not evaluated for treatment discontinuation because of rapid progression disease and died during first cycle with a median of 5 prior lines therapy. Most grade 3-4 adverse events were haematological and well manageable, 10 (80%) trombocitopenia and 5 (35%) neutropenia grade 3-4. Dyspnea, fatigue and pyrexia were higher but were mostly grades 1 and 2. Only 2 patients developed respiratory failure and pneumonia while cardiac failure, ischemic heart disease and hypertension not were detected.

**Table 1:** Baseline patient characteristics.

**Figure 1.**

**Summary/Conclusions:** Carfilzomib-lenalidomide-dexamethasone is a powerful and efficacy association in relapsed/refractory Multiple Myeloma patients, which allows the achievement of deep responses from the first cycle of therapy. Non haematological adverse events of grade 3 or higher were reported in only 2 patients.
PB2020
CARFILOZIMB-LENALIDOMIDE-DEXAMETHASONE IN THE MANAGEMENT OF RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A REAL-LIFE EXPERIENCE
C. Cerchione1,*, K. Ferrara1, I. Peluso1, D. Nappi1, M. Di Perna1, I. Zacheo1, A. E. Pareto1, F. Pane1, L. Catalano1
1Hematologia, Ematologia e Trapianto/au federico ii, Napoli, Italy

Background: Carfilzomib is an epoxyketone proteasome inhibitor of second generation, proved to be effective in relapsed and refractory Multiple Myeloma (rrMM).

Aims: In this retrospective observational trial, it has been evaluated efficacy and tolerance of Carfilzomib, in combination with lenalidomide-dexamethasone (KRD) as salvage regimen in patients with relapsed and refractory MM (rrMM), whose prognosis is particularly severe.

Methods: 21 patients (12 M/9 F, Table 1), with rrMM, median age at diagnosis 62 years (r. 47-75), median age at start of treatment 65 years (r. 53-81) treated with several lines of treatments (median 3, r. 2-10), included 2 patients refractory to Bortezomib, underwent to KRD regimen (ASPIRE trial schedule: Carfilzomib starting dose 20 mg/m² on days 1,2 of cycle 1, target dose 27 mg/m² thereafter; Lenalidomide 25 mg on days 1 through 21; Dexamethasone 40 mg on days 1,8,15 and 22, every 28 days) for a median treatment cycles of 2 (r 1-8). ISS was equally distributed, and cytogenetic was evaluable in 8 patients, and in particular one del13q14 1qgain, one del 13q14 and one t(11;14). 86% of patients had previously been treated with schedule containing bortezomib starting dose 20 mg/m² on days 1,2 of cycle 1, target dose 27 mg/m² thereafter; Lenalidomide 25 mg on days 1 through 21; Dexamethasone 40 mg on days 1,8,15 and 22, every 28 days) for a median treatment cycles of 2 (r 1-8).

Results: Carfilzomib was well tolerated, with grade 2 anemia in 28% of patients, without necessity blood transfusions; 5% grade 1 and 9.5% grade 3 neutropenia (no ospedalization was required), no septic shocks were observed; 33% grade 2, 19% grade 3 and 5% grade 4 thrombocytopenia, without hemorrhagic events and necessity of transfusions. Concerning severe extrahematologic toxicity, it was observed grade 1 pneumonia in 47% of patients, treated by common antibiotic drugs; grade 2 Hypertension in 24% of patients; grade 3 arrhythmias in 5% of patients; grade 2 dyspnea in 5% of patients; grade 1 fatigue in 9.5% of patients. According to IMWG criteria, after a median follow-up of 3 months (r.1-13), ORR was 66,7% (14/21 : 8 VGPR, 6 PR) with 3 progressive diseases and 2 patients in stable disease, which can be considered as an impressive result in this subset of rrMM patients. In particular, for 1 patient, KRD was, after having achieved at least a PR, a bridge to second auSCT. Median time to response was 2 months (r.1-4), median OS from diagnosis was 47 months (9-170 range), median OS from start of Carfilzomib was 3 months (range 1-13).

Table 1.

Summary/Conclusions: KRD has shown significant efficacy in a particularly severe setting of patients, relapsed and refractory to all available therapeutic resources, and, in particular cases, it could be considered as a bridge to a second autologous or allogenic SCT.

PB2021
IMWG 14 DIAGNOSTIC CRITERIA TO INITIATE TREATMENT IN NEW DIAGNOSED MULTIPLE MYELOMA: REAL-WORLD STATISTICS
P. Gonzalez2,*, B. Ballina1, S. Gera1, M. Fuertes1, L. Villalobos1, V. Martínez-Robles1, J.A. Rodríguez-García1, F. Escalante1
1Hematología, Complejo Asistencial Universitario de León, LEÓN, Spain

Background: Diagnostic criteria for Symptomatic Multiple Myeloma (MM) Published in 2003 by the International Myeloma Working Group(IMWG'03) established for the presence of a bone Marrow infiltration by plasma cells (BMPC) in any percentage And / or the presence of a monoclonal component of any amount Along with the presence of signs or symptoms of organ damage (CRAB) attributable to the proliferation of plasma cells. These criteria have not changed in the last decade until the Recent revision of diagnostic criteria and treatment that IMWG Published by the end of 2014, which proposes an initial Pathologic condition (>10% BMPC or demonstration of a Plasmacytoma) as a preliminary condition before starting treatment. Due to “CRAB redefined” and / or the presence of markers of Rapid progression to “classical-symptomatic” MM criteria.

Aims: There are few information about real-life statistics in NDMM according to new criteria to initiate treatment. This 2year analysis shows a percentage of patients (22%) who have initiated new treatments superior to those described in the literature

Methods: We have performed a retrospective analysis with all new MM cases diagnosed from Dec-2014 (after new criteria were published) to Feb-2017 (28 months). 55 patients were diagnosed of MM. 26 were male and 29 female. The median age at diagnosis was 74 years (52-87), 11 were under 65 (U65) and 44 were over 65 (O65).

Results: 3 were diagnosed after biopsy of plasmacytommas. None of them have Bone Marrow (BM) infiltration but with criteria of MM after PET-CT multipotopic involvement. 7 of these NDMM were smoldering MM (sMM). All of them then completed initial staging with more sensitive imaging tests than conventional radiology (MRI and / or PET-CT) 2 of these sMM were under 65 years old and were included in a clinical trial. The other 5 were older than 65 and after a median of 16 months of follow-up did not meet criteria in initiate treatment. Of the 41 patients who started treatment, 10 of them were new criteria, the rest met criteria for classic organic disease (CRAB) Figure 1. 6 patients were diagnosed after performance of PET-CT (3 of them after plasmacytoma biopsy; initial diagnosis: solitary plasmacytoma, 1 after PET-CT negative but MRI positive, 2 with FLC ratio criterium and the last one with BM Plasmatic Cell (BMPC) >60%, MRI image and FLC criteria. Although these data are quite different from those reported previously, accurate diagnosis in initial stages may increment the proportion of real-active MM. We don’t observe increments in incidence rate in these period vs pre-2014 (reported to 22nd EHA abstract).

We observe that the early mortality is decreasing in the last 5 years (from 2013). The effect of early diagnostic may contribute to get these improvement of survival.

Figure 1.

Summary/Conclusions: One of the hypotheses for introducing new criteria for initiating treatment was that the initiation of adequate early treatment may improve the prognosis of patients with symptomatic NDMM. In an aging population such as the one we present, we believe that these new criteria to initiate treatment can improve the medium- and long-term prognosis of this group of people with few chance to start intensive or a lot of lines of treatment because of increasingly comorbidities by age. Further follow-up and evaluation of survival comparing the “classical” group vs new-criteria group are guaranteed to assess if these early treatment will improve survival.

PB2022
POMALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE: A CHANCE FOR REMISSION IN REFRACTORY AND/OR PROGRESSIVE MULTIPLE MYELOMA: A REVIEW OF A CASE SERIES DIAGNOSED IN A SINGLE CENTER
A. Gil Pérez1,*, D. de Miguel 1, D. Subirá1, H. Guillén1, A. Vázquez1, M. Díaz1, N. Goblan1, D. Morales1, S. Herrero1, J. Arbeteta1, B. Pinedo1
1Hospital General Universitario de Guadalajara, Guadalajara, Spain

Summary/Conclusions: One of the hypotheses for introducing new criteria for initiating treatment was that the initiation of adequate early treatment may improve the prognosis of patients with symptomatic NDMM. In an aging population such as the one we present, we believe that these new criteria to initiate treatment can improve the medium- and long-term prognosis of this group of people with few chance to start intensive or a lot of lines of treatment because of increasingly comorbidities by age. Further follow-up and evaluation of survival comparing the “classical” group vs new-criteria group are guaranteed to assess if these early treatment will improve survival.

Figure 1.
Background: The treatment of patients with multiple myeloma (MM) has dramatically changed over the past decade due in part to the development of new agents and myeloma-specific targets. Nowadays, new effective treatments exist for patients with RRMM not responding to bortezomib and lenalidomide. Pomalidomide alone has shown limited efficacy in patients with RRMM, but synergistic effects have been noted when combined with dexamethasone.

Aims: To show our experience with the use of 28-day cycles of pomalidomide (4 mg/day on days 1–21, orally) plus low-dose dexamethasone (40 mg/day weekly, orally) (Pom/dex) in RRMM.

Methods: This is a retrospective study performed between May 2014 and January 2017 in the Hospital of Guadalajara (Spain). Eight patients (3M, 5F), with a median age of 67 years (range, 40-81), diagnosed with MM and WM were included. Four were classified as high-risk myeloma (Patients 1–4). Patient 1 (P1) had plasma cell leukemia and received Pom/dex plus bortezomib; Patient 2 (P2) presented complex karyotype and received Pom/dex after three previous regimens and an autologous transplantation; Patient 3 and Patient 4 (P3 and P4) had extramedullary plasmacytoma and received Pom/dex/local radiotherapy.

The eight patients of this study had failed to bortezomib and lenalidomide-based therapy, and received Pom/dex until disease progression or unacceptable toxicity. Pom/dex was associated with ciclophosphamide in two patients, and with bortezomib in another two patients. The primary endpoint was progression-free survival (PFS).

Results: The median number of prior regimens was 2 (range, 1-4) and five of eight patients (62.5%) had previously received autologous transplantation. Median time from diagnosis to Pom/dex was 51.5 months (range, 28-155). Patients received a median of 6 cycles of Pom/dex (range, 2-16). In the whole series, the median follow-up was 60.5 months (IQR: 56.0-80.25), and median PFS was 11 months; 75% of patients had not progressed after 5 months, and 50% of patients after 11 months. The overall response rate was 85.7% (only one patient discontinued therapy for non-response). In standard-risk MM patients, median follow-up was 61 months (IQR: 46.25-140.25), and median PFS was 13 months; 75% of patients had not progressed after 2 months, and 50% of patients after 13 months. Regarding the high-risk group of patients, P1 achieved complete response after 6 cycles of Pom/dex/bortezomib; P2 achieved PFS of 11 months; P3 achieved plasmacytoma resolution after 6 cycles of Pom/dex plus local radiotherapy; P4 abandoned Pom/dex after 3 cycles because of severe neutropenia and sepsis. In this group median follow-up was 60.5 months (IQR: 56.3-79.8), and median PFS was 6 months; 75% of patients had not progressed after 5 months, 50% of patients after 6 months, and 25% of patients after 11 months. Regarding adverse events, they were present in two patients: one had neutropenia, and the second one pneumonia plus pulmonary venous thromboembolism. Both of them died (Figure 1).

Summary/Conclusions: In our experience, Pom/dex regimen has prolonged PFS of patients with RRMM, with an improvement of health-related quality of life. This regimen has been even valuable in high-risk patients who received Pom/dex after ≥2 treatment regimens. Pomalidomide plus low-dose dexamethasone, an oral regimen, could be considered a new treatment option as a standard of care for patients with RRMM who have poor prognosis and a high need for effective treatments.

ROUTINE SCREENING FOR KIT M541L IS NOT WARRANTED IN THE DIAGNOSTIC WORK UP OF PATIENTS WITH HYPEREOSINOPHILIA

N. Cross1, Y. Hoode1, G. Metzgeroth2, J. Schwaab2, A. Reiter2

1University of Southampton, Southampton, United Kingdom, 2Universitätsmedizin Mannheim, Mannheim, Germany

Background: The role of the KIT M541L variant in patients with hypereosinophilic (HE) is controversial. On the one hand, this variant is a recognised somatic single nucleotide polymorphism (c.1621A>C; rs3822214) with a minor allele frequency of 0.08 in the ExAC database and classified as benign/likely benign on ClinVar. On the other hand, it has been suggested that KIT M541L increases the sensitivity of the KIT receptor to stem cell factor (Foster R et al., Br J Dermatol. 2008;159:1160-90) and may be somatically acquired in idiopathic eosinophilia (EHA20). Consequently it has been suggested that HES patients should be screened for KIT M541L, as positive cases may benefit from imatinib treatment.

Aims: We aimed to (i) compare the KIT M541L allele frequency between patients referred for investigation of HE and normal healthy controls (ii) investigate the variant allele frequency (vaf) to determine if KIT M541L mutations may be acquired somatically and (iii) investigate the KIT M541L status in cases negative for PDGFRAβ abnormalities who responded to imatinib.

Methods: We screened healthy controls (n=214) and patients referred for investigation of FIP1L1-PDGFRA negative HE (n=220) for KIT M541L using an amplification refractory mutation system (ARMS) PCR designed to amplify allele specific products of different sizes, and able to detect KIT M541L down to 5% vaf. Fishers exact two tailed test was used to compare the allele frequency between HE and control and HE groups. Digital droplet PCR (ddPCR) was used for patients heterozygous for KIT M541L by the ARMS assay to determine whether the KIT M541L mutation burden was close to 50% (consistent with a constitutional polymorphism) or <50% (suggestive of a somatic mutation). We also studied pre-treatment DNA from 3 patients with hypereosinophilic syndrome who were treated with imatinib (400 mg/day) and showed normalization of eosinophil counts at a median of 0.8 months (0.4-5.0) after treatment for a duration of 13.6 months (range, 3.7-44.8).

Results: Forty two (19%) of HE cases tested positive for KIT M541 compared to 38 (18%) of healthy controls. The KIT M541L allele frequency was no different between cases and controls (0.095 versus 0.098; P=0.91). Of the 42 KIT M541L heterozygous HE cases, 40 had sufficient DNA for analysis by ddPCR. The mean allele burden was 50.4% (range 48.3%-56.0%, consistent with all instances being constitutional. None of the three imatinib responders tested positive for KIT M541L prior to treatment.

Summary/Conclusions: Whilst we cannot exclude the possibility that KIT M541L may be acquired somatically in very rare cases, we conclude that there is no clinical value in screening for this variant on a routine basis for patients with HE or HES.

PB2024

MUTATIONS OF THE JAK2 GENE AND CYTOGENETIC ABNORMALITIES ARE PREDICTIVE OF PROGRESSION TO HEMATOLOGICAL NEOPLASMS IN PATIENTS WITH IDIOPATHIC LEUKOCYTOSIS

N. Mori1,2,*, K. Yoshina3, M. Ohwashi-Miyazaki3, M. Shiseki3, H. Sakura4, M. Shikata5, H. Sakurai3

1Hematology, Tokyo Women’s Medical University, 2Internal Medicine, Tokyo Women's Medical University Medical Center East, 3Hematology, Tokyo Women’s Medical University, 4Internal Medicine, Tokyo Women’s Medical University Medical Center East, 5Internal Medicine, Tokyo Women’s Medical University Medical Center East, Tokyo, Japan

Background: Idiopathic leukocytosis and erythrophagocytosis are hematological disorders without specific causes. Frequent V617F mutations on the JAK2 gene have been reported in patients with polycythemia vera (PV), essential thrombocytosis, and primary myelofibrosis. We also found JAK2 V617F mutations in one of 11 patients with idiopathic erythrophagocytosis. Mutations of the CSF3R, JAK2, SETBP1 and ETNK1 genes have been found in chronic neutrophilic leukemia and atypical chronic myeloid leukemia (CML). Furthermore an autosomal mutation was found in the CSF3R gene in a family with chronic neutrophilia. However, little is known about mutations associated with idiopathic leukocytosis.

Aims: We previously analyzed the JAK2, CSF3R, CALR, SETBP1, and ETNK1 genes in 10 patients with idiopathic leukocytosis (EHA20). To elucidate the relevance of genetic alterations, we extended the analysis with 17 genes known to be involved in hematological neoplasms in 16 patients with idiopathic leukocytosis.

Methods: Leukocytosis is defined as a total white blood cell count more than two standard deviations above the mean, or a value greater than 11,000/μL. Those patients who satisfied the following criteria were included in the study: leukocytosis (predominantly neutrophils); the absence of apparent causes of leukocytosis; and documentation of the leukocytosis over a prolonged period.
of time. The period of observation was 1 year or longer in most patients. Sixteen patients with idiopathic leukocytosis were analyzed in the study. Neutrophils or mononuclear cells were collected after obtaining written informed consent from the 16 patients. Neutrophils from peripheral blood were purified by dextran sedimentation followed by hypotonic lysis and centrifugation with Ficoll-Conray. Mononuclear cells were isolated from bone marrow by Ficoll-Conray gradient centrifugation. DNA was extracted using the QIAamp DNA Blood Mini kit (Qiagen, Valencia, CA, USA). Mutations within hot spots of the CSF3R, JAK2, CALR, SETBP1, ETNK1, CBL, TET2, ASXL1, EZH2, IDH1/IDH2, DNM3TA, U2AF1, and CEGBP genes were analyzed by direct sequencing in both directions using a 3730XL DNA Analyzer (Life technologies, Carlsbad, CA, USA) and/or allele-specific polymerase chain reaction. Total RNA extraction and reverse transcription polymerase chain reaction (RT-PCR) were performed between the ETF6 and ABL1 genes in 10 patients. BCR/ABL1 gene was analyzed by RT-PCR or fluorescence in situ hybridization in 8 patients. The current study was conducted within the guidelines and with the approval of an ethics committee.

Results: JAK2 V617F mutations were found in one of the 16 patients with idiopathic leukocytosis. No mutations were found in the other genes in the 16 idiopathic leukocytosis patients. ETF6-ABL1 fusion gene was detected in one of the 10 patients. No BCR/ABL1 fusion gene was detected in the 8 patients.

Aims: The aim of our work was to investigate BCR/ABL expression in therapy resistant MPD patients with disease progression.

Methods: Peripheral blood samples 175 patients with progressive MPD and 67 patients with primary MPD was used as a biological material for experiments. Qualitative and quantitative analysis of BCR/ABL gene (p190, p210, p230) was performed by two-step PCR and real-time PCR. Jak2, Jak2-e12, MPL, CALR mutations were determined by direct sequencing and allele-specific PCR. RAG1 and RAG2 expression was analyzed by real-time PCR.

Results: 175 patients with progressive MPD were analysed: 50 (29%)- PV, 38 (22%)- ET, 22 (12%)- PMF, contained 55/67 (82%) JAK2V617F mutation. Jak2V617F mutation was identified in 139 patients, deletion in 12 exon of JAK2 gene, MPL W515L/K mutation in calreticulin gene (CALR) contributed a lot to understanding of molecular pathogenesis of MPD. However, detailed molecular mechanism underlying the progression of MPD remains unclear. Several cases of MPD with detected BCR/ABL expression were described repeatedly in previous publications. The phenomenon of simultaneous coincidence of mentioned molecular markers in each clinical case requires comprehensive study.

Summary/Conclusions: Our results are in line with previous reports and our data seems to indicate that breakthroughs in understanding of pathogenesis of JAK2V617F mutation will be obtained in near future and also advances in treatment of MPD will be possible in near future.

PB2026

Aims: The aim of our study was to identify the mechanism of regulation of Megacaryopoiese by miR-155. We used the miRNAs described in the literature as influential in the process of hematological disorders. They are: mir146b, mir 150, mir 29a and 155. After analysis of miRNA differential expression, mir-29a and mir-155 were less expressed in MF patients compared to healthy donors (P < 0.02 and P < 0.03), and mir-223 did not Present a statistically significant difference. Data on miR-29a correlate in part with the literature, since the data presented here relate to miRNA carried by VES rather than serum / plasma. However, low levels of miR-29a expression are related to aberrant auto-renewal of hematopoietic progenitor cells, thus indicating that VES may contribute to this mechanism. As for mir-155, the data obtained do not corroborate with the literature and, possibly, the VES do not participate in the mechanism of regulation of Megacariopoiese by mir-155. We used the miRNAs described in the literature as influential in the process of hematological disorders. They are: mir146b, mir 150, mir 29a and 155. Summary/Conclusions: MiRNAs present in the microvesicle content may col-
**Background:** Myeloproliferative neoplasms (MPNs) are a group of chronic myeloid cancer characterized by overproduction of mature hematopoietic cells. Mutations in one of three genes, Janus kinase 2 (JAK 2), myeloproliferative leukaemia proto-oncogene (MPL) and calreticulin (CALR), have been found in most patients with BCR-Ab1 negative MPNs. JAK2 mutations are present virtually all cases of Polycythemia Vera and 50-60% of prMF and Essential Thrombocythemia (ET). Recently, mutations in CALR gene were found in 50-80% of JAK2 and MPL mutation negative ET and prMF patients.

**Aims:** To evaluate immunohistochemical results of CALR gene mutation in the bone marrow samples of the JAK2V617F mutated and JAK2V617F wild type Primary Myelofibrosis (prMF) patients.

**Methods:** Bone marrow biopsy samples from 32 patients previously diagnosed as primary myelofibrosis with known JAK V617F mutation status were used. Bone marrow aspirates were collected from archives of Marmara University Pathology Laboratory. Bone marrow samples of two patients were already known as CALR mutated by PCR analysis. Bone marrow samples of three JAK2 wild type and CALR mutated ET, two JAK2 wild type, CALR mutated prMF patients and two CALR wild type ET patients were used as positive and negative control tissues for CALR immunohistochemistry. Immunohistochemistry: 4-µm unstained sections of each bone marrow biopsy specimens were cut onto electrostatically charged glass slides. Immunohistochemistry was performed on an automated immunostainer (Ventana Benchmark Ultra). CALR antibody (clone CAL2, Dianova, Germany) staining used a 1:100 dilution. Any cytoplasmic staining of the cells with CAL2 antibody was considered positive immunostaining.

**Results:** We studied 32 bone marrow specimens of primary myelofibrosis with 15 (47%) of them having JAK2 V617F mutation and 17 (53%) of them lacking JAK2 V617F mutation. CALR immunoreactivity was seen in 8 (25%) of all pr MF patients. CALR (MPL) and cal was seen in 8 (47%) of patients with PMF myelofibrosis who are negative for JAK2V617F mutation. CALR immunoreactivity was not seen in patients with PMF myelofibrosis who are positive for JAK2V617F mutation. CALR immunoreactivity was seen in 3 (100%) of patients with ET and 2 (100%) of patients with known CALR mutation. CALR immunoreactivity was seen in 21% of patients with CALR wild type ET patients. We observed that CAL2 immunostaining was seen mainly in the cytoplasm of the small and large megakaryocytes, and atypical megakaryocytes as found in fibrotic PrMF. Pale immunostaining was seen in myeloid and erytoid cell precursors. This immunostain also stained some small cells appearing as micromegakaryocytes.

**Summary/Conclusions:** An immunohistochemical stain easily detects the CALR mutation by staining of megakaryocytes in formalin-fixed bone marrow biopsy specimens. This method would be a easy, rapid, and cost effective way to detect CALR mutations in daily routine hematopathology biopsy evaluation of the myeloproliferative patients.

**Background:** Various groups have reported that isoforms of hypoxia-inducible transcription factor 1a (HIF-1a) and 2a (HIF-2a) can regulate both overlapping and distinct target genes. HIF-1a and HIF-2a have been shown to play opposite roles in the regulation of macrophage function [Takeda N. et al., 2010]. HIF-index incorporated as a strong prognostic biomarker of renal cell cancer [Szendrői A. e.a., 2016]. Only HIF1a was known as regulator expression of multidrug resistance gene (MDR1) and response to chemotherapy [Comerford K.M. e.a., 2002]. New data have shown exclusive role of HIF-2α in regulates the proliferation and glucocorticoid sensitivity in erythroleukemia cells [Khalili, e.a., 2016]. New data have shown a correlation between index of HIF and mRNA gene expression level of each bone marrow biopsy specimens were cut onto electrostatically charged glass slides. Immunohistochemistry was performed on an automated immunostainer (Ventana Benchmark Ultra). CALR antibody (clone CAL2, Dianova, Germany) staining used a 1:100 dilution. Any cytoplasmic staining of the cells with CAL2 antibody was considered positive immunostaining.

**Results:** We studied 32 bone marrow specimens of primary myelofibrosis with 15 (47%) of them having JAK2 V617F mutation and 17 (53%) of them lacking JAK2 V617F mutation. CALR immunoreactivity was seen in 8 (25%) of all pr MF patients. CALR (MPL) and cal was seen in 8 (47%) of patients with PMF myelofibrosis who are negative for JAK2V617F mutation. CALR immunoreactivity was not seen in patients with PMF myelofibrosis who are positive for JAK2V617F mutation. **CD177 EXPRESSION IN PERIPHERAL BLOOD NEUTROPHILS IN HEALTH AND DISEASE STATES**

A. Arafat1, 2, S. Rizk1, R. Samy1, N. Al-Hussein2, R. El-Hawary1

1Clinical and chemical pathology, 2Internal medicine, Cairo university, Cairo, Egypt

**Background:** Objective and specific assays are required in the identification of both chronic myeloproliferative disorders and myelodysplastic syndromes.

**Aims:** Exploration of the possibility of using the CD177 expression in the peripheral blood neutrophils for the diagnosis of either entity.

**Methods:** The 213 subjects were organized into 4 main groups; benign neutrophil leukocytosis group, secondary erythrocytosis group and clonal myeloid neoplasms group together with a haematologically normal group as controls. All cases were subjected to clinical assessment as well as the flow cytometry determination of the percentage (%) and mean fluorescent intensity (MFI) of peripheral blood neutrophils expressing CD177.

**Results:** Skewed high peripheral blood neutrophil CD177 MFI was significantly associated with Philadelphia-negative cMPDs patients (2.9-37.4; median 14.1) compared to controls (0.8-20.5; median 8.8). The MDS patients did not show a significant difference in either CD177% or MFI compared to the controls. Polycythaemia Vera (PV) patients had similar results of CD177 expression (% and MFI) compared to Essential Thrombocytosis (ET) patients. However, they had higher CD177 MFI levels compared to the secondary erythrocytosis patients and controls (4.8-37.4; median 16.5, 1.58-25.7; median 5.81, 0.85-20.5; median 8.8 respectively). CD177 MFI showed statistically significant higher values in ET patients compared to the haematologically normal control group (2.9-34.5; median 13.4 versus 0.85-20.5; median 8.8 respectively). No correlation between CD177 expression and JAK2 V617F allele burden could be detected in either PV or MDS patients. With a 20 p.d.u cutoff, the specificity of neutrophil CD177 MFI in Philadelphia-negative cMPDs patients’ diagnosis and differentiation of PV from secondary erythrocytosis was 93% and 85% respectively. The CD177 had a low accuracy of in the diagnosis of MDS patients. The CD177 patterns observed were one positive peak and bimodal pattern (Figure 1).

**Summary/Conclusions:** The CD177 expression is highly associated with Philadelphia-negative cMPDs. It could reliably represent a useful potential marker in detecting those disorders and differentiating them from reactive cases.
DETECTION OF THE MUTATIONS IN GENES JAK2 AND MPL IN THE DIAGNOSIS OF CHRONIC MYELOPROLIFERATIVE DISORDERS

K. Boboev1,*, K. Karimov1, A. Mohammad1

1Institute of hematology and blood transfusion, tashkent, Uzbekistan

Background: Chronic myeloproliferative diseases is a group of clonal Ph-negative hematological diseases, which include erythremia (polycythemia Vera, PV), chronic megakaryocytic leukemia (essential thrombocythemia, ET) and subleukemic myelosclerosis (primary myelofibrosis, PMF), chronic idiopathic myelofibrosis. The origin of these diseases is linked to transformation of hematopoietic stem cells, the result is the excessive production of mature cells of erythroid, granulocytic and megakaryocyte shoots with relatively long course of the disease. The frequency of occurrence of mutation V617F gene of JAK2 exon 12 and MPL gene varies in different literature.

Aims: Determination of the frequency of occurrence of mutations in genes JAK2 and MPL and identifying the importance of the verification of these diseases.

Methods: The study included 350 patients with chronic myeloproliferative diseases — with polycythemia Vera 150 patients, with essential thrombocythemia 78, with chronic idiopathic myelofibrosis 55 and 67 patients were examined with the purpose of differential diagnosis with Ph(-) Chronic myeloproliferative diseases. The age of patients ranged from 20 to 70 years, median age was 54 years. Isolation DNA of patients was carried out using a set of reagents “AmpliPrep RIBO-prep” (OOO Interlabservice, Russia). The concentration and purity of isolated DNA was determined by Nano Drop 2000 instrument (USA). Detection of gene mutation JAK2V617F and MPL gene was carried out by standard polymerase chain reaction on a thermal cycler 2720 “Applied Biosystems” (USA), using a set of primers “Litech” (Moscow).

Results: The result of the research showed that the incidence of the V617F mutation in JAK2 was varying in patients depending on the type of disease. In polycythemia Vera the mutation V617F in the JAK2 gene was identified in 147 patients (98,3%), with essential thrombocythemia in 42 patients of 78 (54,2%), with chronic idiopathic myelofibrosis in 55 patients of 67 (82,8%). In 7 patients with no hematological profile, wich examined with the purpose of differential diagnosis with Ph(-) Chronic myeloproliferative diseases, V617F in JAK2 was detected in 6 (8,6%), which allowed to confirm Ph(-) Chronic myeloproliferative diseases. A mutation in exon 12 of the JAK2 gene was detected in 2 of 33 (2,9%) of those surveyed V617FJAK2-negative patients exclusively diagnosed with polycythemia Vera. The MPLW515L mutation gene was detected in polycythemia Vera and chronic idiopathic myelofibrosis 2.2% (1 of 41) and 2% (1 of 52) of patients.

Summary/Conclusions: Thus established, our data confirm that mutations in the genes JAK2 and MPL are highly specific diagnostic markers in patients with Ph-negative chronic myeloproliferative diseases.

ASSOCIATION OF MYELOPROLIFERATIVE NEOPLASM AND LYMPHOPROLIFERATIVE DISORDER IN 3 PATIENTS

B. Foucher1,*, M. Dudez2, M. Daniel3, S. Girard2, C. Froelich2, F. Mestrallet2, L. Vila6,7

1Laboratoire, Hôpital d’instruction des armées Desgenettes, 2Laboratoire, Groupement Hospitalier EST, 3Laboratoire, Groupement Hospitalier Sud, 4department of cytogenetics and molecular biology, Groupement Hospitalier EST, 5department of oncology and hematology, Centre Leon Barad, 6Laboratoire, Groupement Hospitalier EST, 7Laboratoire, Centre Léon Bérard, Lyon, France

Background: Lymphoproliferative disorders (LPD) and myeloproliferative neoplasms (MPN) are two very different sets of hematological pathologies. However, several studies have shown that the risk for LPD onset in patients with MPN is higher than in the general population (1)(2). No single LPD seems to be more at cause and all MPN are likely to present the onset of an associated LPD.

Aims: We present 3 cases diagnosed in the Department of Hematology, « Groupement Hospitalier Est », Lyon, France, of patients bearing an association of MPN and LPD: an essential thrombocythemia (ET) with myeloma, ET with marginal zone lymphoma and a chronic myeloid leukemia with chronic lymphoid leukemia.

Methods: Diagnosis have been made thanks to cytology of peripheral blood, bone marrow aspirate and biopsy and confirmed by cytogenetic and molecular biology techniques.

Results: Case number 1. A 68 year old woman known to have essential thrombocythemia as a MPN, with V617F mutation of the JAK2 protein kinase. After 19 years of treatment by Hydrea, she developed a splenomegaly, anemia and slight lymphocytosis of 4.77 G/L. The blood smear, the bone marrow aspirate and biopsy examination revealed myelofibrosis evolution and an infiltration by 30% of a small sized clonal lymphoid population CD20+, CD5- Medullar karyotype was normal: 46, XX[10].In conclusion the ET has evolved into myelofibrosis and is associated with a lymphoproliferative syndrome, possibly marginal zone lymphoma. No additional treatment has been implemented. Case number 2. A 64 year old woman know to have ET with V617F mutation of the JAK2 protein kinase treated by acetic salicylic acid. 5 years after, she presented with IgG kappa type monoclonal gammapathy up to 28 g/L, without any associated clinical manifestations nor cytopenia. Medullar blood was diluted but showed slightly atypical plasocytes remaining under 10%.Myeloma was diagnosed anyway and the patient received 5 cures of Velcade-Melphalan-Prednisone which resulted in complete remission. The MPN remains stable to this day. Case number 3. A 62 year old man with chronic lymphoid leukemia, treated by six cycles of R-FC. While in remission since 2 years, hemogram shows hyperleucocytosis (WBC: 18.3 G/L) with thrombocyctemia (platelets: 1986 G/L) without anemia (Hb: 13.7 g/dL). Blood smear examination reveals 3% of myelemia and basophilia (3.66 G/L). BCR-ABL transcript is positive in 43% and karyotype points out a 9;22 translocation. (46, XY, t (9;22) (q34 ;q11)][1] nuc ish (BLX3, BCRX3,ABL.con BCRX2)[48/100]. Before starting Nilotinib, cytoreductive treatment by Hydrea was decided. Treatment is under way.

Summary/Conclusions: The three cases described highlight the diverse situations observed in cases of combined MPN/LPD pathologies. MPN with secondary onset of LPD are most frequently encountered, as was the case with patients 1 and 2. Cases of preexisting LPD and late onset MPN are rare (1), and cases of simultaneous discovery of both pathologies even more so (3). Several hypotheses have been formulated to explain the frequency of onset of these pathological associations: genomic instability due to JAK2 protein kinase activation, or due to BCR-ABL mutation, or exposure to cytotoxic chemotherapy or radiations (3).
Myeloproliferative neoplasms - Clinical

CLINICAL AND ANALYTICAL DIFFERENCES BETWEEN CALR TYPE-1 AND CALR TYPE-2 MUTATION IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS: A SINGLE CENTER STUDY

M. Sobas 1, M. Olejniczak 1, J. Andrasiak 2, M. Kuszewska 2, B. Jazwiec 1, J. Rybka 1, T. Wrobel 1, K. Kulczykowska 1
1Department of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Wroclaw Medical University, 2WroMedica Research Center, 3Wroclaw Medical University, Wroclaw, Poland.

Background: The JAK2V617F is a main molecular marker in myeloproliferative neoplasms (MPN) and is harbored in about 50-60% of essential thrombocythemia (ET) and primary myelofibrosis (PMF). Recently, CALR mutation was described in ET and PMF. JAK2V617F negative patients. There are two main variants of CALR mutation: type 1 (a 52-bp deletion) and type 2 (a 5-bp insertion).

Aims: To compare clinical and analytical data of ET and PMF patients with CALR type-1 vs CALR type-2 mutation.

Methods: We performed a single center study on 471 patients: 87 PMF and 384 ET. The JAK2V617F mutation was analyzed in DNA from peripheral blood leukocytes by PCR ARMS method. In all JAK2V617F negative patients detection of CALR mutation was performed by fragment length analysis and the results were confirmed by sequencing. Statistical data analysis was performed using a Statistica 12.5 software for Windows.

Results: From 384 ET patients 254 were JAK2V617F positive (66%), 80 were CALR positive (21%) and 51 were JAK2V617F and CALR negative (13%). From CALR positive patients: 36 (51%) had type-1, 34 (45%) type-2 mutation, and 10 (12%) type-3 mutation. From 87 PMF patients 56 were JAK2V617F positive (61%), 18 were CALR positive (21%) and 13 (15%) were JAK2V617F and CALR negative. From CALR positive groups: 13 (72%) had type-1 and 5 (28%) had type-2 mutation. Compared with ET carrying JAK2V617F mutation, patients ET CALR type-1 (type-1 plus type-2) had lower hemoglobin (13.3 vs 14.5 g/dl, p<0.001) and leukocyte (8.2 vs 9.7 G/L, p<0.001), higher platelet counts (1070 vs 800 G/L, p=0.001) but with no significant differences in frequency of thrombosis. In ET, CALR mutation was associated with increased odds of myelofibrotic transformation (odds ratio [OR]=2.61; 95% CI: 1.28 - 5.34; p=0.009) comparing with JAK2V617F positive patients. Patients ET CALR type-1 had higher leukocyte counts than ET CALR type-2 mutation (9.6 vs 7.3 G/L, p=0.008), but we did not find significant differences in hemoglobin, platelet counts, frequency of thrombosis or myelofibrotic transformation. Within PMF, no significant differences were observed. Moreover in PMF, there was no significant differences between the JAK2V617F, CALR type-1 and type-2 mutation status respect to the International Prognostic Score System (IPSS).

Summary/Conclusions: This study highlights that, although ET has a very good prognosis, there is a significant percentage of patients that will need a change of treatment, either because of resistance or intolerance.

THROMBOTIC AND BLEEDING RISK FACTORS IN ESSENTIAL THROMBOCYTHEMIA

A. Zherniakov 1, I. Martynkevich 1, V. Shuvavets 1, L. Polushkina 1, M. Fominik 1, V. Udal’eva 1, I. Zolotva 1, D. Shichabaeva 1, S. Voloshin 1, S. Bessmeltsev 1, A. Chechelkin 1, K. Abdulkadyrov 1
1Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Thrombosis and hemorrhage are the main category of complications, that affects the overall survival (OS), quality of life and therapy option choice in essential thrombocythemia (ET). Molecular marker presence (JAK2V617F, MPL, CALR) or its absence (triple-negative status (TN)) in ET supposed to impact on the clinical course, thrombosis rate and ET prognosis.

Aims: The aim of this study was to investigate interactions between the presence of molecular marker, thrombosis/bleeding rates and the OS in ET. Methods: Outpatient’s charts of 240 ET patients, who had been diagnosed with ET at our institution according to WHO 2008 criteria. The following data were assessed: complete blood count, bone marrow biopsy results, bone marrow cytogenetic, the restriction fragment length polymorphism (RFLP) results used for JAK2V617F detection, in case of JAK2V617F-negative status the PCR-RFLP (MPL detection) and the direct sequencing (CALR detection) results. Different thrombotic/bleeding complications rates were analyzed. The OS in ET patients was compared according to molecular markers revealed.

Results: According to their mutational status 182/240 (75.9%) patients (pts) were JAK2V617F-positive (JAK2+), 30/240 (12.5%) – CALR-positive (CALR+); type 1 (CALR1+) – 13/30 pts (43.3%), type 2 (CALR2+) – 17/30 pts (56.7%). Only two pts were MPL-positive (MPL+). (0.8%), TN were 26/240 pts (10.8%). Among 240 pts 183 (76.3%) hadn’t any thrombotic complication or bleeding event (no complications/NC), 57/240 (23.7%) had complications: 49/57 (85.9%) had thrombosis+ and 8/57 (14.1%) had bleeding events (hemorrhage+). Thrombotic complications in JAK2+ had 27.4% (50/182) pts, in TN – 30.7% (8/26) pts, in CALR+ – 18.2% (2/11) pts and no cases of thrombosis were detected in CALR2+ and MPL+ subgroups (p=0.001). There were significant statistical differences in

ESSENTIAL THROMBOCYTHEMIA: STUDY OF TREATMENT LINES REQUIRED. EXPERIENCE OF A SINGLE CENTER

M. Berenguer 1, 2, R. Pérez López 2, V. Cabanas-Perianes 2, M. Moya-Arnao 2, N. Ortega-López 3, E. Salido-Fríñez 2, A. Martínez-Marin 2, E. Fernández-Poveda 2, J. M. Morales-Jiménez 2
1Hematology, 2Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain, 3Internal Medicine, Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain

Background: Essential thrombocythemia (ET) is a chronic myeloproliferative neoplasm that shows similar survival prognosis as general population, with a very low rate of transformation to myelofibrosis and acute leukemia. There are different treatments for these patients with optimal responses at first. For the first line, it is usually treated with hydroxyurea, although in young patients it is usually replaced by anagrelide/ interferon. There are publications of hydroxyurea side effects, especially cutaneous, but there are not many studies about how many lines of treatment are needed to control the disease.

Aims: Study type and lines of treatment needed in patients with ET in a cohort of patients from January 1997 to January 2017.

Methods: We studied patients diagnosed of essential thrombocythemia in one area of the region of Murcia from January, 1997 to January, 2017. Those who started treatment and those who needed change were analyzed, either by resistance or by intolerance.

Results: In our area we have registered a total of 152 patients diagnosed with ET. Of these, 71% (108 patients) have required at least one treatment line. Table 1 shows the number of treatment lines required for the control of the disease. As it is shown in the Table, more than 20% of treated patients needed a second line and 6.5% required more than 2 lines. At last, Table 3 shows current treatment of ET patients.

median platelet count as follows: 742x10^9/l (thrombosis+) and 937x10^9/l (hemorrhage+) (p=0.003). No significant statistical differences in median hemoglobin and leukocyte count (p=0.75 and p=0.47) were detected. There were more than a half pts older than 60 years in groups NC (51%) and thrombosis+ (59%) and in group hemorrhage+ only 36% (p<0.001). Cardiovascular risk factors were reported in 24% pts (NC), 69% pts (thrombosis+) and 36% pts (hemorrhage+) (p=0.001). There were no significant statistical differences in follows risk factors as thrombosis >1000x10^9/l and leukocytosis >11x10^9/l (p=0.85 and p=0.72). No significant differences in OS among groups NC, thrombosis+ and hemorrhage+ (p=0.12) were found (Figure 1).

Figure 1. Summary/Conclusions: Leukocytosis >11x10^9/l and thrombocytosis >1000x10^9/l cannot be assessed as independent thrombosis risk factors in ET. JAK2V617F mutation was associated with increased risk of thrombotic complications in ET. CALR mutations were correlated with lower thrombosis risk and better OS rate, comparing to JAK2+ and TN status despite the fact of CALR+ patients had higher platelets level. Along with common thrombosis risk factors (age >60 and cardiovascular risk factors) mutational status may help to identify ET course and to optimize individual therapy option choice.

DETECTION OF JAK2 EXON 12 MUTATIONS BY HETERODUPEX ANALYSIS AND PYROSEQUENCING

T. Subbotina1,2, E. Dunaeva3, K. Mironov3, A. Kharseskin1, E. Vasilyiev3,4, M. Mikhailiev3,5, M. Osadchaya6, M. Smelyanskaya4, V. Khorzhevskyi2,7, I. Olkhovskiy2,8, G. Shipulin9
1Department of Medical Biology, Siberian Federal University, 2Krasnoyarsk branch of the Federal State budgetary institution «Hematology Research Center» Department of Health, Krasnoyarsk, 3Federal Budget Institute of Science «Central Research Institute for Epidemiology», Moscow, 4Krasnoyarsk regional hospital, 5Municipal Budget Health Service Institution «City Clinical Hospital № 7», 6Krasnoyarsk Territory Department of Health Regional state budget health facility «Krasnoyarsk interdistrict clinic №1», 7Krasnoyarsk State Regional Bureau of Pathology, 8Krasnoyask Scientific Center of the Siberian Branch of the Russian Academy of Sciences, Krasnoyarsk, Russian Federation

Background: Somatic mutations in codons 533-547 of JAK2 exon 12 are highly specific to confirm the diagnosis of polycythemia vera (PV). We have previously proposed techniques for the detection and quantification of JAK2 exon 12 allelic burden using a pyrosequencing method (Subbotina T et al, Haematologica 2014). However, due to the high cost of sequencing, developing a two-stage algorithm for detection mutations in JAK2 exon 12 using inexpensive screening of is of immediate practically necessity.

Aims: The aim of this study was to demonstrate the feasibility of using heteroduplex analysis with subsequent confirmation of the index product by electrophoresis on non-denaturing PAGE as the preliminary screening test for detection of JAK2 exon 12 mutations.

Methods: 274 patients with PV or unclear erythrocytosis and with a low JAK2V617F allele burden or unmutated JAK2V617 (51 women, mean age 52.2±15.7 years and 223 men, mean age 43.6±15.6 years) were included in this study. The informed consents from these patients were obtained. The PCR with the additional stage of formation heteroduplexes was performed using the Real-time PCR kit (Syntol, Russia) and CFX 96 Real Time System (Biorad, USA). PCR products were analyzed by electrophoresis in 8% PAGE. The presence of the mutations was identified and confirmed by pyrosequencing method with PyroMark Q24 (Qiagen, Germany). To verify the presence of mutations, the DNA sequences extracted from the clinical samples were cloned into pGem-T vector using standard protocol («Promega», USA), and obtained clones were sequenced using reagents and equipment of the «Applied Biosystems» (USA). JAK2 exon 12 allele burden was calculated as a measure of relative changes in allele burden between the baseline and follow-up sample (Theocharides A et al, Haematologica, 2008).

Results: We detected JAK2 exon 12 mutation in five out 274 patients. The results of electrophoresis on non-denaturing PAGE are reported in Figure 1. The type of №1-5 patient mutations were determined by pyrosequencing: N542-E543del (c.1624_1629delAATGAA); I540-E543delinsKK (c.1619_1627 TCA-gAAATGK) (c.1622_1627delGAAATG) and p.H538_K539L (c.1612_1616CACAATTT). These mutations have been already described. Main characteristics of 5 patients with JAK2 exon 12-mutated PV are reported in Table 1. The PV diagnosis of №1, 2, 3 and 5 patients was confirmed by bone marrow trephine biopsies histological examination. All five patients with JAK2 exon 12-mutated PV have an increased number of red blood cells, along with an accompanying increase in the concentration of hemoglobin and hematocrit level in the peripheral blood. Some of them had increase number of leukocytes and platelets in the disease dynamics. №1-4 patients was treated phlebotomy only and did not received any cytoreductive treatment to date. Patient №5 received hydroxyurea (HU). Importantly, two out five patients with JAK2 exon 12-mutated PV also have a mutation JAK2V617F (<1%). JAK2 exon 12 allele burden in sample from №1 patient is significantly increased in the disease dynamics.

Figure 1.

Summary/Conclusions: The proposed variant of the heteroduplex analysis with separation of the PCR product by electrophoresis on non-denaturing PAGE can be recommended for use as the preliminary screening test which is carried out before the confirming pyrosequencing. The two-stage approach allows to optimize the algorithm of the JAK2 exon 12 mutation detection and to improve the efficiency of testing for patients suspected of having PV in whom a JAK2V617F mutation is not detected or detected in a low allele burden. In five out 274 patients we detected JAK2 exon 12 mutation and confirmed the diagnosis of PV.

INTRODUCTION OF AN NGS GENE PANEL INTO CLINICAL SERVICE FOR MYELOPROLIFERATIVE NEOPALMS

A. Skowronska1,2, J. Bryon1, S. Clokie1, Y. Wallis1, J. Mason1, K. Reay1, M. Griffiths1
1West Midlands Regional Genetics Laboratory, Birmingham Women’s and Children’s NHS Foundation Trust, Birmingham, United Kingdom

Background: In the West Midlands region of the UK, all patients with a suspected myeloproliferative neoplasm (MPN) have access to quantitative analysis...
of JAK2 V617F by droplet digital PCR as standard of care. The British Committee for Standards in Haematology recommends that suspected MPN cases have investigation of JAK2 exon 12, CALR and MPL genes if JAK2 V617F is negative.

Aims: The aim of the project was to improve the MPN service by substituting sequential analysis of individual target regions within the JAK2, CALR and MPL gene with a single assay, and to increase the number of genes available for analysis.

Methods: A commercial next generation sequencing (NGS) gene panel (Oxford Gene Technology, SureSeq Myeloid Panel), coupled with the Illumina MiSeq platform was validated and implemented. The gene panel utilises hybridisation based enrichment technology and consists of 25 MPN-related genes. During the validation stage the following were enriched and analysed: 29 positive control samples with 30 known pathogenic variants, 30 negative control samples without known pathogenic variants in the JAK2, CALR and MPL genes, and 24 MPN samples of unknown mutational status. Thus so far over 200 clinical samples have been analysed and reported since the service was introduced in October 2016.

Results: The panel has successfully identified: a large range of known pathogenic variants at high sensitivity (JAK2 V617F variant allele frequency 1%, CALR Type 1 frameshift variant allele frequency 3%), a potential alternative driver mutation in a known low level JAK2 V617F positive patient, a rare MPL exon 4 pathogenic variant and also the detection of low level CALR pathogenic variants, which would not have been detected by Sanger sequencing analysis.

In one patient the panel identified the presence of two different JAK2 exon 14 pathogenic variants in cis (JAK2 V617F and JAK2 C618R). The JAK2 C618R presented in the hybridization of the probe binding site of the JAK2 V617F ddPCR assay which had led to a false negative result by ddPCR. The validation procedure also explored coverage and limits of sensitivity, potential chemistry specific artefacts and identified common polymorphisms for all 25 genes.

Summary/Conclusions: The panel has replaced the current sequential analysis of CALR, MPL and JAK2 exon 12 in JAK2 V617F negative patients and reduced turn-around-times with increased accuracy and sensitivity compared to Sanger sequencing and fragment analysis. Our current clinical service operates on a two tier system whereby clinicians can request analysis of the full 25 gene panel or a 4 gene subset (JAK2, CALR, MPL, CBL as an on silico analysis).

IN JAK2V617F POSITIVE MYELOPROLIFERATIVE NEOPLASMS, BLEEDING RISK CORRELATES WITH ALLELE BURDEN
I. Bertozzi1,*, E. Cosi1, C. Santarossa1, G. Bogoni1, F. Fabris1, M.L. Randi1
1Dep. Internal Medicine - DIMED, University of Padova, Padova, Italy

Background: Myeloproliferative neoplasms (MPN) are characterized by the presence of JAK2V617F mutation that is almost invariably associated with polycythemia vera (PV), but also occurs in the majority of patients with essential thrombocythemia (ET) or primary myelofibrosis (PMF). JAK2V617F-positive patients display different laboratory and clinically features from JAK2-wild type, but no clear correlation was found between the JAK2V617F allele burden and natural history of the disease. The most common causes of morbidity and mortality in MPN are thrombotic and hemorrhagic complications, albeit bleedings are less frequent than thrombosis and mostly represented by minor hemorrhagic events. Our objective was to investigate the impact of different allele burden on bleeding risk in MPN.

Aims: Aim of our study is to explore whether there is an association between JAK2V617F allele burden and hemorrhagic complications in a large cohort of MPN diagnosed and followed in a single center.

Methods: We selected 253 MPN (121 ET: 47.8%, 124 PV:49% and 8 PMF=3.2%) carrying JAK2V617F mutation. The median follow-up of patients was 8.8 years (0.1 – 37.3 y). Complete medical history and anti-thrombotic drug use were recorded. Hemorrhagic complications were classified as “major” or “minor” in agreement with ISTH criteria. The patients were categorized into four quartiles according to the amount of JAK2 mutant allele, (1st quartile 1-25%, 2nd quartile 25-50%, 3rd quartile 51-75% and 4th quartile 76-100%). Nominal variables were compared with X2test or Fisher’s exact where indicated. Survival has been evaluated only for groups with different prevalence of events during follow-up and were calculated with the Kaplan Meier method and compared with the Log Rank test.

Results: Three patients (1.2%) bleed at diagnosis (1 major and 2 minor hemorrhages) while 27 (11.8%) suffered for hemorrhages during follow-up (10 major and 17 minor). Prevalence of hemorrhages results higher in 4th quartile compared both to 2nd (p=0.003) and to 1st (p<0.001) quartiles. Hemorrhages-free survival was also lower in 4th quartile compared both to 2nd (p=0.004) and to 1st (p<0.001). The incidence rate of hemorrhages are respectively 0.7/100 pats /y for 1st quartile, 0.65/100 pats /y for 2nd quartile, 1.26/100 pats /y for 3rd quartile and 3.23/100 pats /y for 4th quartile with a IRR of 5 and of 4.6 for the 3rd quartile respectively versus 2nd and 1st one. No statistically significant difference have been observed in the use of anti-thrombotic drugs among patients of the different quartiles.

Summary/Conclusions: Risk factors for hemorrhage in MPN are not well defined, and there is no risk estimation model for this outcome. Acquired von Willebrand disease, entity of platelet increased count and aspirin use have been implicated in bleeding occurrence. Previous reports fail to demonstrate a correlation between JAK2 mutation and bleeding risk. In contrast, in our cohort we found a significantly higher incidence of bleeding manifestations during follow-up in patients with higher allele burden. Interestingly no differences were seen in administration of anti-thrombotic drugs among quartiles, suggesting an independent role of JAK2 allele burden in the different distribution of hemorrhagic events.

PB2038
JAK2 ALLELE BURDEN IN PATIENTS WITH PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS
M. Napolitano1,*, S. Siragusa1, M. Santoro1, M.R. Lanza Caricchio1, M. Bonò1, F. Di Piazza2, A. Russo2, V. Accurso1
1UO Ematologia, 2Laboratorio di genetica e oncologia molecolare, 3UO Oncologia, University Of Palermo, Palermo, Italy

Background: The JAK2V617F allele burden (JAK-AB) plays a central role in chronic myeloproliferative neoplasms (cMPNs); its presence has also been advocated in the differential diagnosis of cMPNs and as independent risk factor for venous thromboembolic complications. New treatment with Ruxolitinib may decrease JAK-AB but at the present, it is not clear the clinical advantage of JAK2V617F allele burden.

Aims: Primary aim of the current study was to evaluate at diagnosis the JAK-AB in patients with Philadelphia negative cMPNs, in order to evaluate any association with standard demographic, clinical and laboratory parameters with particular reference to thrombotic risk.

Methods: Peripheral blood samples from patients with Ph-negative cMPNs were collected, DNA from leucocytes were analysed for JAK-2 (V617F) gene mutation with amplification-refractory mutation system (ARMS) PCR, subsequently a real-time quantitative polymerase chain reaction (qRT-PCR) for JAK2V617F allele burden measurement was applied. A multivariate analysis was then performed to evaluate any association of AB with demographic and clinical data.

Results: One hundred and twelve patients with Philadelphia negative cMPNs were investigated: 52 females with a median age at diagnosis of 69 years (age range: 18-85 years), 60 males with a median age of 65 years (age range: 18-82 years). Thirty-four patients had Essential Thrombocythemia (ET), fifty-two had Polycythemia Vera (PV) and twenty-six had primary myelofibrosis (PMF). Three patients (1.2%) bleed at diagnosis (1 major and 2 minor hemorrhages), while 27 (11.8%) suffered for hemorrhages during follow-up (10 major and 17 minor). Prevalence of hemorrhages results higher in 4th quartile compared both to 2nd (p=0.003) and to 1st (p<0.001) quartiles. Hemorrhages-free survival was also lower in 4th quartile compared both to 2nd (p=0.004) and to 1st (p<0.001). The incidence rate of hemorrhages are respectively 0.7/100 pats /y for 1st quartile, 0.65/100 pats /y for 2nd quartile, 1.26/100 pats /y for 3rd quartile and 3.23/100 pats /y for 4th quartile with a IRR of 5 and of 4.6 for the 3rd quartile respectively versus 2nd and 1st one. No statistically significant difference have been observed in the use of anti-thrombotic drugs among patients of the different quartiles.

Summary/Conclusions: Our report cannot confirm any correlation between allele burden and thrombotic risk, according to currently adopted scoring systems.

COMPARISON OF CLINICAL AND LABORATORY DATA, INCLUDING JAK2-46/1 HAPLOTYPE, BETWEEN PATIENTS WITH IDIOPATHIC ERYTHROCYTOSIS AND POLYCYTHEMIA VERA
M. Napolitano1,*, S. Siragusa1, M. Santoro1, F. Di Piazza2, M. Bonò1, S. Mancuso1, A. Russo2, V. Accurso1
1UO Ematologia, 2Laboratorio di genetica e oncologia molecolare, 3UO Oncologia, University Of Palermo, Palermo, Italy

Background: Idiopathic erythrocytosis (IE) is a relatively rare finding characterized by an increased red blood cell mass without an identifiable cause. Diagnosis of IE is based on the exclusion of primary and secondary erythrocytosis including JAK2-wild-type polycythemia Vera (PV).

Aims: In the current study, we report clinical features and laboratory data able to discriminate IE from PV, at diagnosis.

Methods: We have here analyzed clinical and laboratory parameters, including JAK-2 46/1 haplotype, from patients with a confirmed diagnosis of IE and PV, followed from January 2010 to December 2016. Data were statistically analyzed, nominal variables were compared with X2-test and continuous variables with the Mann-Whitney test.

Results: Overall, 40 patients with IE and 93 patients with PV were included in the current analysis (Table 1). Splenomegaly and itch were reported only in patients with IE, while Jak-2 (V617F) and exon 12 mutations were negative in all patients with IE, while JAK-2 46/1 haplotype was found at heterozygous state in 18 patients and at homozygous state in 2 patients with IE.

Summary/Conclusions: In the current study, we highlight peculiar clinical and laboratory findings of IE, in comparison with Polycthemia Vera. As shown by available studies, Hb and HCT level do not easily discriminate between the two categories of patients while gene panels may be useful to improve diagnostic accuracy of IE. We have here first observed the presence of Jak-2 461/6 haplotype in approximately half patients with IE, even in absence of Jak-2 mutations; the homozygous status was statistically different among PV and IE patients. The role of such association deserves further specific studies.

PB2119

PLATELET AGGREGATION STUDY OF ESSENTIAL THROMBOCYTHEMIA TREATED WITH ANAGRELIDE

1Department of Hematology and Oncology, 2Department of Pathology and Clinical Laboratory, Japanese Red Cross Society Himeji Hospital, Himeji, 3Hemostasis Product Engineering, Sysmex Corporation, Kobe, Japan

Background: Essential thrombocythemia (ET) is a myeloproliferative neoplasm characterized by thrombocythemia and abnormal megakaryocyte proliferation. Patients with elevated platelet count are considered to be a high-risk group for thromboembolic and/or hemorrhagic complications. In Japan, anagrelide treatment was recently approved for the 1st line as a cell reduction therapy on ET. Even now, there are few study whether the risk of thrombosis has decreased after anagrelide treatment. Moreover, the platelet count problem uncertainty remains what is the best practice to follow when the platelet count in platelet-rich plasma (PRP) exceeds about 600 x10^9/L, in the recent recommendation for the standardization of light transmission aggregometry by the platelet physiology subcommittee of Scientific and Standardization Committee /International Society of Thrombosis and Hemostasis.

Aims: The aim of this study was to characterize the platelet aggregation (PA) in patients with ET. We would also clarify whether there were any changes of hemostatic side effect and platelet aggregability before and after treatment with anagrelide.

Methods: This study has been conducted with blood sample obtained from six healthy subjects, compared to 18 consecutive patients with ET. None of the patients was taking anticoagulants or cytoreductive agents. We also studied six healthy subjects as control group. Platelet aggregation (WBA) and LTA using PRP were performed; ADP-induced PA or collagen-induced PA used natural count PRP and platelet count adjusted PRP with platelet-poor plasma. Data were compared in the groups using the Tukey-Kramer test. This study was approved by the Ethical committee of our hospital. All study procedures were performed in accordance with the Declaration of Helsinki.

Results: The result of WBA was not obtained, because the filter was obstructed by giant platelets. In the natural PRP, even over 900 x10^9/L, the platelet aggregability was markedly increased compared with the control (ADP-induced PA: p=0.023, collagen-induced PA: p=0.001), but, was not significantly different (ADP-induced PA: p=0.703, collagen-induced PA: p=0.986) in the count adjusted PRP. These results were not confirmed in cases with platelet counts of less than 600x10^9/L. There was no decrease in platelet aggregation before and after treatment with anagrelide (ADP-induced PA: p=0.3403, collagen-induced PA: p=0.514).

Summary/Conclusions: In the ET patients with platelet counts more than 900x10^9/L, the platelet aggregation by LTA with natural count PRP was remarkably accelerated and this data seemed to reflect the disease state. Although treatment with anagrelide showed cyto-reductive effect without any hemorrhagic complication in patients with ET, it did not fully reduce platelet aggregability.

PB2043

A SINGLE CENTRE EXPERIENCE OF MASTOCYTOSIS

G. Özkan1, Ò. Tepes1, N. Demir1, Ò. Arslan1, S. Erdem1, Ò. Doğan1, N. Büyükbabani2, C. Baykal1, R. Tanakol3, M. Naśliçalı1, A.S. Yavuz1

1Hematology, 2Pathology, 3Dermatology, 4Endocrinology and Metabolism, Istanbul Medical Faculty, Istanbul, Turkey

Background: Mastocytosis considered as a subcategory of myeloid neoplasms based on World Health Organization (WHO) 2016 classification, is characterized by expansion and accumulation of abnormal clonal mast cells in...
one or more organs. KITD816V mutation and other KIT mutations play as driver of systemic mastocytosis patients. Recent studies show that high allele burden of KITD816V and high serum tryptase levels correlate with aggressive disease. Recently the importance of CD30 expression on neoplastic mast cells has been confirmed. CD30 is expressed aberrantly on neoplastic mast cells in patients with advanced systemic mastocytosis.

Aims: In this study we aimed to present demographic data, clinical follow-up and treatment of patients with mastocytosis and identify the impact of KIT D816V allele burden and expression of CD30 by mast cells in systemic mastocytosis.

Methods: We performed a retrospective study on 54 adult patients with mastocytosis (24 female, 30 male; mean age 44±13) who fulfilled WHO criteria between 2006 and 2016. These patients comprise cutaneous mastocytosis (CM) (n=10), indolent systemic mastocytosis (ISM) (n=30), smoldering systemic mastocytosis (SSM) (n=2), aggressive systemic mastocytosis (ASM) (n=4), systemic mastocytosis with associated neoplasms (SMAN) (n=3), mast cell leukemia (MCL) (n=4) and mast cell activation syndrome (MCAS)n=1).

Results: At diagnosis, age of patients with advanced disease was higher than ISM and SSM group (p=0.001). Most frequent symptom of disease was skin lesion (urticaria pigmentosa) (%64). Skin lesions were significantly higher in patients with ISM and SSM than with advanced disease (p<0.009). But B symptoms were significantly higher in advanced disease variant (p=0.013). Anemia, trombocytopenia, elevation of ALP and GGT, hypalbuminemia were significantly advanced in disease variant than in ISM and in SSM. Osteoporosis was higher in patients with ISM and SSM than with advanced disease, %56 and %18 respectively. KITD816V mutation was detectable in peripheral blood in 33 of 40 mastocytosis patients (%82) with a median Ct value 36±4. Median Ct value was significantly lower in advanced SM (Ct: 32±5 ) than in SM and SSM (Ct: 36±4 ) (p=0.028) showing a significantly higher allele burden. Expression of CD30 on mast cells in bone marrow biopsies with immunohistochemistry in advanced SM was detectable in 20 of 32 systemic mastocytosis patients (%62). There was no significant difference expression of CD30 on mast cell between patients with ISM (%65) (13/20) and advanced SM (%87) (7/8) (p=0.371). There was no significant correlation between elevated serum tryptase level and CD30 expression (p=0.114).

Summary/Conclusions: The definition of disease subcategories in systemic mastocytosis is important for choosing the treatment modality (cytoreduction or allogeneic stem cell transplantation vs treatment of the mediator symptoms) for the individual patient. CD30 is a diagnostic marker and also a possible therapeutic target.

JAK2 PSEUDO-KINASE AND KINASE MUTATIONS IN THE ETIOLOGY OF THROMBOCYTOPAenia
M. Coucelo1,*, J. Azevedo1, A.L. Pinto1, A.T. Simões1, S. Marini1, T. Magalhães Maia1, J.C. Almeida1, A.I. Espadana1, L. Ribeiro1
1Serviço de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal
Background: Thrombocytosis is defined as an abnormally increased number of platelets (>450x10⁹/L) in the blood counts, whose cause can be primary or secondary, hereditary or acquired. Hereditary thrombocytosis is a rare congenital disorder characterized as essential thrombocytemia (ET) triple negative. The characterization of these rare forms of thrombocytosis and the follow up of these patients across generations, will improve the understanding of this entity.

Aims: To analyze differences in treatment strategies used by physicians and pts to manage their MPN between the UK and the Rest of Surveyed World (ROSW).

Methods: A cross-sectional survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK. The Internet-based survey was administered separately to MPN patients and treating physicians (the two samples were not linked). Observed differences between the UK and ROSW are described in terms of treatment patterns and patient physician communication.

Results: A total of 699 pts (UK, n=286; ROSW, n=413) and 219 physicians (UK, n=31; ROSW, n=188) completed the survey. UK physicians were more likely to report using treatments than ROSW. UK physicians reported using treatments than ROSW. UK physicians reported using treatments than ROSW. This difference was greater in PV and ET than MF. For MF the most commonly received treatments were ruxolitinib (UK 55%, ROSW 28%), hydroxyurea (UK 53%, ROSW 38%), aspirin (UK 83%, ROSW 58%), phlebotomy (UK 76%, ROSW 67%) and HU (UK 63%, ROSW 36%) and for ET they were aspirin (UK 94%, ROSW 52%), HU (UK 31%, ROSW 18%). Physician reported use of treatments prescribed demonstrated a similar pattern as a greater proportion of UK physicians reported using treatments than ROSW. UK physicians reported use of treatments prescribed demonstrated a similar pattern as a greater proportion of UK physicians reported using treatments than ROSW. UK physicians rated who they thought should be the main decision maker on a scale of 1 (the patient) to 10 (physician) for treatment recommendations. Most frequent symptom of disease was skin involvement myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), experience a substantial disease burden. The international MPN LANDMARK survey evaluated the patient-reported impact of MPNs in pts across 6 countries and identified current treatment strategies in these pts.

Aims: To analyze differences in treatment strategies used by physicians and pts to manage their MPN between the UK and the Rest of Surveyed World (ROSW).

Methods: A cross-sectional survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK. The Internet-based survey was administered separately to MPN patients and treating physicians (the two samples were not linked). Observations differences between the UK and ROSW are described in terms of treatment patterns and patient physician communication.

Results: A total of 699 pts (UK, n=286; ROSW, n=413) and 219 physicians (UK, n=31; ROSW, n=188) completed the survey. UK physicians were more likely to report using treatments than ROSW. UK physicians were more likely to report using treatments than ROSW. This difference was greater in PV and ET than MF. For MF the most commonly received treatments were ruxolitinib (UK 55%, ROSW 28%), hydroxyurea (UK 53%, ROSW 38%), aspirin (UK 83%, ROSW 58%), phlebotomy (UK 76%, ROSW 67%) and HU (UK 63%, ROSW 36%) and for ET they were aspirin (UK 94%, ROSW 52%), HU (UK 62%, 30% ROSW) and anagrelide (UK 14%, ROSW 18%). Physician reported use of treatments prescribed demonstrated a similar pattern as a greater proportion of UK physicians reported using treatments than ROSW. UK physicians rated who they thought should be the main decision maker on a scale of 1 (the patient) to 10 (physician). UK patients were slightly more inclined to want to be involved in treatment decisions (mean: UK, 6.25; ROSW, 7.01). UK physicians were more likely to disagree with their physician on primary treatment recommendation than ROSW (16% UK, 7% ROSW). But despite this UK physicians were more involved in treatment decisions (mean: UK, 6.25; ROSW, 7.01). UK physicians supported this more as ‘agreed strongly’ with the statement ‘I involve my MPN patient in treatment decisions’ (UK, 39%; ROSW 28%). Summary/Conclusions: In comparison with ROSW UK physicians were more likely to prescribe drug treatments for ET/PV. Interestingly, UK patients were also more likely to disagree with their physician on primary treat-
ANALYSIS OF EMERGING MOLECULAR SIGNATURES AND ASSOCIATED CLINICAL FEATURES IN MPN

S. H Al Shemakh1,*, R. Rajan2
1Department of Medicine, Kuwait University, 2Bone Marrow and Stem Cell Transplant Lab, Kuwait Cancer Center, Kuwait, Kuwait

Background: Myeloproliferative neoplasms (MPNs) are a group of clonal hematological disorders that arise from transformation of a multipotent hematopoietic stem cell which includes polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF). Driver mutation’s con- fer red advantage on the cancer cell and most is selected in the tissue microenvironment within which the neoplastic cells arise. Three-quarters of these patients carry the unique JAK2V617F mutation, JAK2 exon 12 mutations are found in 5% of patients with PV, MPL exon 10 mutations are present in about 5% ET/PMF and CALR mutations are found in 50-70% patients with ET/PMF.

Aims: In this study we investigated the prevalence of these so called driver mutations in patients with MPN’s from January 2007 – January 2017 reported in our center.

Methods: We analyzed 3000 samples with suspected MPN for JAK2V617F mutation by ARMS-PCR and their allele burdens were reported by RQ-PCR. We have screened a cohort of 500 patients for JAK2/MPL/CALR mutations by a sequential molecular analysis which includes PCR, RT-PCR and fragment analysis.

Results: JAK2V617F mutation is present in 50% of patients with MPN. Among 600 cases submitted for sequential molecular analysis identified 372 cases with JAK2V617F mutation, 70 cases with CALR mutation, and 6 cases with MPL mutations. Allele burden study on JAK2V617F positive patients revealed that patients with ET have the lowest allele burden, those with PV an interme- diate one and those with PMF showed the highest burden. Measurement of JAK2V617F allele burden by RQ-PCR for a PMF case after allogeneic trans- plantation (TPT) reported that allele burden of 2.9% 20 days of transplant and a negative result after 60 days of transplant vs 13% before ASCT. CALR mutation is found in ET and PMF cases that are mutually exclusive with JAK2V617F and MPL exon 10 mutations in ET whereas 2 cases with PMF found to be positive for JAK2V617F and CALR mutations. We found 40 cases with a 52-bp deletion, 14 cases with a 14bp deletion and 26 cases with a 5bp insertion. CALR variants reported in our cohort were 54% type 1 and 46% type 2 mutations. We found a tendency towards older age among type 2 carriers compared to type 1 carriers (median age at diagnosis: 57 years versus 52 years) or compared to non-type 2 carriers (median age at diagnosis: 57 years versus 58 years). Similary, platelet count at diagnosis tends to be higher in the subgroup of type 2 mutation carriers than in patients with the type 1 mutation while hemoglobin levels and white blood cell count were lower compared to those with non-type 2 mutation. The mutual allele burden of JAK2V617F/CALR exon indel mutations of two PMF patients found as 10%/85% and 15%/55% respectively. In our cohort, 10% of the patients with CALR mutation had anemia, 21% had splenomegaly, and 43% had megakaryocytes at time of diagnosis. Compared with JAK2 V617F-positive ET and PMF, CALR-mutant ET and PMF are clinically correlated with lower WBC, leukocyte and hemoglobin counts, higher platelet counts, and a reduced risk of thrombosis.

Summary/Conclusions: Despite multiple studies of CALR genes as molecular marker’s for MPN’s, the diagnosis of 95% of patients with MPN. As a novel mutation, CALR testing also has a prognostic significance and it was not mutually exclusive with JAK2V617F mutation. Measurement of JAK2 V617F allele burden early after transplantation is an important predictive parameter in monitoring ET patients following this treatment. The knowledge of driver mutations can provide valuable information for diagnosis and prognosis, which ultimately can be highly useful for clinical decision making for the management of patients with MPN.

IMPACT OF THE TYPE OF CALR MUTATIONS ON THE CLINICAL AND LABORATORY FEATURES OF ESSENTIAL THROMBOCYTHENIA AND PRIMARY MYELOFIBROSIS

E. Lisina1,*, P. Butyl1, N. Siordia1, A. Silyutina1, E. Lomaia1, A. Zaritskey1
1Federal Almazov North-West Medical Research Centre, St. Petersburg, Russian Federation

Background: In 2013, in the majority of JAK2V617F negative patients with essential thrombocytosis (ET) and primary myelofibrosis (PMF) have been identified mutations in the 9 exon of CALR gene. Described more than 30 different mutations, subdivided into two subtypes: deletions (type I) and insertions (type II). They are data on the phenotypic effects, depending on the version of CALR mutations. However, the prognostic significance of mutations CALR is still insufficiently clear.

Aims: To assess the impact of the type I and type II mutations of CALR on the clinical and laboratory features of ET and PMF.

Methods: A multicenter reanalysis of patients with MPF from January 1st, 2013 – December 31st, 2016, was carried out. Samples of peripheral venous blood were obtained from 149 patients with ET (n=76) and PMF (n=73). Patients that were negative for JAK2V617F and MPL515L/K mutations were studied for CALR mutations presence as described in original paper (T.Klampf, 2013). CALR Mutations were detected in 34 patients with ET (10 - men, 24 - women) and 25 patients with PMF (13 - men, 12 - women). Statistical data processing was carried out in the program STATISTICA for Windows 6.0.

Results: The frequency of mutations CALR was comparable in patients with ET and PMF (44.7% and 35.6%). Mutations of type II is 2 times more common in ET than with the TFM: 17.1% v 9.6% (p=0.178). Mutations of type I detected in ET, in 18 cases - in PMF, type II in 13 cases - in ET and 7 - in PMF. The median of follow-up period of patients with ET with type I mutation was 36 months (3-87), with type II - 22 months (2-90). In PMF, the median of follow-up in the group with type I mutation was 46 months (3-133), type II - 77 months (4-115). Hematological parameters in patients with ET showed higher levels of WBC in patients with type I mutation (p=0.043), the level of Hb in this variant was lower (p<0.009). In PMF levels of Hb were similar in the studied groups. Type of mutations had no significant effect on the number of WBC in patients with PMF. However, PLT was higher in PMF patients with type II mutations (p=0.014). Spleen size in ET patients on the time of the diagnosis date was slightly different: in type I - 106.5m, type II - 119.6m (p=0.076). The type of mutation in our study had no effect on the stratification according to the IPSS. Also there were no significant differences in assessing of the effect of therapy. Spleen size on the time of the diagnosis date in PMF patients with type I mutation were slightly larger (180,9mm vs 169,9mm). Revealed mutated induced fibrotic changes of the bone marrow (BM) in patients with type I CALR mutations (p<0.005). CALR mutation type had no influence on the distribution of patients with PMF, depending on the risk groups on the scale of IPSS and DIPSS.

Summary/Conclusions: The effect of type of CALR mutation on the clinical and laboratory features of the ET and PMF has found. Type of CALR mutations in our study had no effect on the number of PLT in ET, but have a value for this index in PMF. Type I mutations in ET accompanied higher WBC level and a lower level of Hb. The published studies have not shown the influence of the type of mutation in the Hb level and the number of WBC in ET. An important observation was the detection of different expression of type I mutation on development fibrotic changes of BM in PMF. Our data are consistent with previously published studies that showed no effect on the stratification of patients according to the scale on the IPSS.

THE UNIQUE CASE OF GERMLINE CEBPA MUTATION IN PATIENT WITH FIP1L1/PDGFRα ASSOCIATED MYELOID/LYMPHOID NEOPLASM WITH EOSINOPHILIA

N. Gabeeva1,*, E. Zvonkov1, E. Parovichnikova2, D. Koroleva1, O. Gavrilina1, S. Kusnetsova1, L. Grebenuk1, T. Obukhova1, A. Kovringa1, L. Kuzmina2, V. Savchenko3
1Scientific and clinical department of chemotherapy for lymphomas, 2Scientific and Clinical Department of Hematobiostasis Chemistry, Hematopoietic Depression and Bone Marrow Transplantation, 3National Research Center for Hematology, Moscow, Russian Federation, 4cytogenetics department, Departament of Clinical and Laboratory Analysis, 5Department of bone marrow transplantation, National Research Center for Hematology, Moscow, Russian Federation

Background: Myeloid/lymphoid neoplasms with eosinophilia (M/NE) associated with PDGFRA rearrangement are rare disorders. The most frequent FIP1L1/PDGFRα (F/P) fusion gene results from a cryptic interstitial deletion at 4q21 with constitutive activation of tyrosine kinase (TK) activity. Although known since 2003, many questions remain in understand- ing the biology, disease course and response to therapy. The F/P fusion gene may clinically present as chronic eosinophilic leukemia (CEL), T-cell lymphoblastic leukemia-lymphoma (T-LL/LBL), myeloproliferative neoplasm with eosinophilia (M/NEALM) or acute myeloid leukemia (AML) may also occur at presentation or during the course of the disease. While F/P is the driver mutation, to date there are few data about genetic vari- ants of the disease that may contribute to clinical outcome. CCAAT/enhancer binding protein alpha (CEBPA) gene functions as key regulator of granulocytic differentiation in CEBPA mutations. Mutations of CEBPA gene can cause the proliferation and blocking differentiation of myeloid lineage in AML. Germline CEBPA mutations is a very rare and account about 1% in AML only.

Aims: We present the first case of detection of familial germinal CEBPA muta-
tion in a patient with F/P MLNe who received related allogeneic transplantation from brother.

**Methods:** A 26-year-old male patient was presented with a 4-week history of fever, fatigue, difficulty in swallowing. Physical examination revealed generalized lymphadenopathy, splenomegaly, tonsils enlargement, leukocytosis (20x10^9/L), with marked eosinophilia (4x10^9/L). A bone marrow aspirate showed 2% blasts, 21% eosinophils. Histological examination of an cubital lymph node biopsy showed diffuse proliferation of medium-sized lymphocytes. Immunohistochemistry and flow cytometry showed that the lymphoblastic population expressed CD2, CD5, CD7, CD4, CD99, TdT and CD1a. Polymerase chain reaction (PCR) analysis from samples of the lymph node and bone marrow failed to detect translocation involving the BCR-ABL, FLT3-ITD and NPM1. A diagnosis of T-cell lymphoblastic lymphoma (T-LBL) associated with reactive eosinophilia was rendered. The patient began standard multiagent chemotherapy in accordance with ALL-2009 protocol (ClinicalTrials.gov Identifier: NCT0119933) and achieved complete clinical remission. As he was planned to conduct autologous hematopoietic stem cell transplantation (HSCT), bone marrow biopsies obtained from the patient were successfully harvested after stimulation of hematopoiesis. However, within 10 days after the discontinuation of G-CSF he developed leukocytosis (130x10^9/L) with 21% of eosinophils (absolute number 27,3x10^9/L) and cubital lymphadenopathy. Histological examination of lymph node showed T-LBL relapse. Bone marrow biopsy revealed the expansion of predominantly eosinophilic cells. The study was carried out to exclude second myeloproliferative disease. Molecular and cytogenetic examinations of bone marrow failed to reveal BCR-ABL, FLT3 and NPM1, but showed CEBPA (TAD2) mutation.

**Results:** FISH probe revealed deletion 4q12 (F/P rearrangement), confirmed by RT-PCR. BCR-ABL and FLT3 were also found in the bone node cell. Analysis at 2008 WHO classification, he was diagnosed as «PGDFRA-associated MLNe». The patient was subsequently treated with imatinib mesylate at the dose 100mg daily and showed a good clinical response. After 4 months minimal residual disease still persisted in bone marrow (RT-PCR positive for F/P and PCR for CEBPA mutation) and he received an autologous HSCT from his brother. Routine testing of chimism at 2 months after HSCT revealed the recipient DNA less than 5% and positive probe for F/P and CEBPA. We hypothesized the germlinal origin of CEBPA mutation.

**Results:** The same N-terminal (TAD2) CEBPA mutation was found in the patient's skin, bone and marrow, and in the patient's brother bone marrow samples. Unfortunately, no materials from parents was available for analysis at that time.

**Summary/Conclusions:** Germline CEBPA mutations is very rare event and have been identified as causative gene mutations in familial AML. For the first time to our knowledge this mutation was detected in patient with PGDFRA-associated MLNe. This observation is of particular interest because it will provide novel insight about the genetic basis and the additional events responsible for the course of the disease.

**DEVELOPMENT AND DESIGN OF A RANDOMIZED CONTROLLED TRIAL USING ONLINE YOGA FOR SYMPTOM MANAGEMENT IN MYELOPROLIFERATIVE NEOPLASM PATIENTS**

J. Huberty1,*, R. Eckert1, K. Gowin2, B. Ginos2, H. Kosiorek2, A. Dueck2, J. Hynan3, E. Silkova4, H. Kosiorek2, A. Dueck2, B. Taylor7

1School of Nutrition and Health Promotion, Arizona State University, 2Mayo Clinic, 3College of Nursing and Health Innovation, Arizona State University, Phoenix, United States

**Background:** Patients with myeloproliferative neoplasms (MPN), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), experience a substantial disease burden. The international MPN LANDMARK survey evaluated patient-reported impact of MPNs across 6 countries. **Aims:** To analyze differences in disease and symptom burden of MPN patients between the UK and the Rest of World (ROSW). **Methods:** A cross-sectional survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK. The internet-based survey was administered separately to MPN patients and treating physicians (the two samples were not linked). Observed differences between the UK and ROSW are described in terms of symptom burden. **Results:** A total of 699 pts (UK, n=286; ROSW, n=413) and 219 physicians (UK, n=109; ROSW, n=110) completed the survey. UK patients reported more symptoms than those in ROSW (9.02 vs 5.95 respectively). A higher proportion of UK patients reported experiencing symptoms compared with ROSW (e.g. fatigue and tiredness UK - 87% MF and PV, 86% ET; ROSW - 64% MF, 39% PV, 45% ET). This pattern was observed for 28 of the 31 symptoms recorded. A similar difference was seen when physicians were asked about frequency of patient-reported symptoms (e.g. fatigue and tiredness UK – 90% MF, 67% PV, 70%; ROSW – 71% MF, 55% PV, 48% ET). Patients rated symptom severity from 1 (not severe at all) to 10 (worst possible). The UK was higher than ROSW for the three most common symptoms; fatigue and tiredness (mean: UK 6.73, ROSW 5.38), joint pain (mean: UK 5.76, ROSW 4.63), and abdominal discomfort (mean: UK 3.18, ROSW 2.41). A trend towards higher self-report symptom burden compared to the wait-list control and to achieve the feasibility (i.e., implementation, practicality) of collecting biomarkers that are potentially related to MPN symptoms and disease (i.e. inflammatory cytokines and cortisol) in a national study. The implementation was conducted with early feasibility data reported herein; efficacy and safety was collected at conference (UK 81% satisfied vs ROSW 90%) and disease management (UK 87%, ROSW 90%). However, UK patients were more likely to disagree with the statement ‘My doctor understands how much my condition impacts my life’ (UK 39% vs 22% ROSW). UK physicians had more MPN patients under their care than ROSW (mean patients under care in last 12 months: UK 43.9, ROSW 25.0, 46 MV, 47 ET, ROSW -15 MF, 31 PV, 20 ET). UK and ROSW were also more likely to agree with the statement ‘There is not enough time during the appointment to discuss all of the symptoms a patient is experiencing’ (UK 74% vs ROSW 54%).
Summary/Conclusions: UK patients perceive a higher symptom burden than ROSW in terms of frequency and severity. While UK physicians agree with regards to frequency, they didn’t perceive a greater symptom severity in their patients compared to ROSW physicians. Patient/physician disconnect was unlikely to be the cause as satisfaction was high and similar to that in ROSW. However, UK physicians not only have more patients under their care than their ROSW counterparts, they are also more likely to feel they don’t have enough time to discuss all symptoms. This is likely to be impacting on the ability of patients and physicians to communicate fully on symptoms and to agree on the best disease management plan.

RESULTS FROM PEN-PV STUDY, A SINGLE-ARM PHASE 3 TRIAL ASSESSING THE EASE OF SELF-ADMINISTERING ROPEGINTERFERON ALFA-2B USING A PRE-FILLED PEN IN POLYCYTHEMIA VERA PATIENTS

1Hematology and Hemostaseology, Medical University Vienna, 2AOP Orphan Pharmaceuticals AG, Vienna, Austria, 3Clinic of Hematology, University Multi-profile Hospital for Active Treatment “Sveti Georgi”, Plovdiv, Bulgaria, 4Teaching Unit of Hematology Department, University Hospital in Krakow, Krakow, Poland, 5Clinical Hematology Clinic, Multiprofile Hospital for Active Treatment “Svetla Marina”, Varna, Bulgaria, 6Department of Internal Medicine II, Kaposi Mor County Teaching Hospital, Kaposvar, Hungary, 7Samara Kalinin Regional Clinical Hospital, Samara, Russian Federation, 8Department of Clinical Hematology, University Hospital Hradec Králové, Hradec Králové, Czech Republic, 9Medical and Health Science Center, University of Debrecen, Debrecen, Hungary, 10Department of Hematology, Cherkasy Regional Oncology Center, Regional Treatment and Diagnostics Hematology Center, Cherkasy, Ukraine, 11First Department of Internal Medicine, Multiprofile Hospital for Active Treatment - Hristo Botev, Vratsa, Bulgaria, 12Clinic of Internal Medicine - Hematology and Oncology, University Hospital Brno, Brno, Czech Republic, 13Department of Hematology, Roskilde Hospital, University of Copenhagen, Copenhagen, Denmark, 14Centre d’Investigations Cliniques, Hôpital Saint-Louis et Université Paris Diderot, Paris, France

Background: Interferon-alpha (IFNa) based therapies have been successfully used in myeloproliferative neoplasms for over thirty years. A known burden for long-term therapy applying IFNa in otherwise fit outpatients is the necessity of frequent hospital visits for product administration. Ropeginterferon alfa-2b (AOP2014) is a novel long-acting monopeptide IFNa allowing initially bi-weekly and, in long-term maintenance, monthly administration. To further improve on convenience and compliance, a pre-filled, dose-adjustable pen was developed for patient self-administration at home.

Methods: The study was performed in 18 sites in 8 European countries. Patients were eligible who completed the AOP2014-arm in the PROUD-PV study (12 months of treatment). A total of 7 visits was scheduled within 3 months (two supervised self-administration visits at site, followed by four self-administrations in the home-setting, and a final assessment visit at study site). A total of 36 patients were enrolled and received the AOP2014 pen for self-administration. The mean age was 58.5 years (range 37 to 77 years), 23/36 (63.9%) were male patients and a large proportion of patients (15/36 (41.7%)) had already received treatment before enrolling the study. At the first supervised visit prior using the pen correctly in a home-setting. All patients had no previous experience with self-injection, and no early withdrawal of the pen (before injection was complete), both observed by the investigator. At the second supervised visit full the success rate was 91.7% (33/36). The majority of observations resolved after the second supervised visit. Only 5 patients (13.9%) needed one additional supervised visit prior using the pen correctly in a home-setting. All patients had achieved full success, defined as no technical problems with the pen experienced by the patient during the injection, and no early withdrawal of the pen (before injection was complete). The patients responded favourably to the use of the pre-filled pen for the administration of AOP2014 and the accompanying instructions. Based on the Investigator’s assessment, no patients exhibited any visible pain or physical discomfort, appeared to be dissatisfied when using the pen or exhibited any frustrational reactions. No patients experienced a positive AE with the use of the pen. The majority of patients (32/36 patients) rated the instructions for the AOP2014 pen (i.e. scope and structure of the leaflet, clarity and comprehensibility of the text, clarity of the images and design of the leaflet), and the AOP2014 pen itself (i.e. setting the dose, user-friendliness, injection procedure) as “satisfactory” or “good.” The haematological parameters and spleen size remained stable throughout the study, and the rate of responders (haematological response with and without spleen size) was maintained during the entire study, suggesting that the use of the pen device did not affect drug activity. Of the 47 adverse events (AE) reported during the study, 19 were related. Most AE were of moderate to mild severity. A single serious AE (mild, unrelated), one pen-related AE (mild nervousness reported prior first administration in the home setting), and one Grade 3 TEAE (pain in extremity, related) were recorded, but none led to a dose reduction.

Figure 1.
Summary/Conclusions: The AOP2014 pen was well accepted and no major difficulties were reported. The study drug performed as expected and there were no safety concerns arising from the administration of AOP2014 using the pen device. The AOP2014 pen allows for individual dosing and a patient-convenient mode of self-administration of ropeginterferon alfa-2b at home and is expected to support adherence and compliance in the long-term treatment of PV patients.

PB2055

CLINICAL IMPLICATION OF QUANTITATIVE JAK2 V617F ANALYSIS WITH DROPLET DIGITAL PCR IN MYELOPROLIFERATIVE NEOPLASMS

Background: JAK2 V617F is the most common genetic mutation in myeloproliferative neoplasms (MPN) and included in the major diagnostic criteria. Beyond the description of existence, quantification of mutational load is proposed as a useful information to classify subgroups of MPN and to predict prognosis. Droplet digital PCR (ddPCR) is a novel assay which has an advantage in accurate and reproducible quantitative analysis.

Aims: This study was planned to verify the correlation of ddPCR with pyrosequencing in diagnosis of MPN and to investigate clinical implication of the mutation burden in disease course.

Methods: Between 2012 and 2016, peripheral blood or bone marrow samples were obtained from 56 patients at diagnosis and every 3 months after enrollment. Inclusion criteria were 1) older than 20 years, 2) who were newly diagnosed with MPN and 3) diagnosed with MPN before, not met the indication of JAK2 inhibitor treatment yet. JAK2 V617F mutation was detected by pyrosequencing as diagnostic work-up. The ddPCR was performed using the same samples with pyrosequencing to prove correlations between assays and to establish a detection sensitivity cutoff. Clinical aspects and hematologic profiles of enrolled patients were reviewed.

Results: The lowest value of measured JAK2 V617F allele by ddPCR except negative samples in our study was 0.01%, which was approximately 0.07 copies/µL of mutant allele. Some discrepancies were observed from 0.0001% to 0.01% concentration between the expected and measured values in ddPCR detection sensitivity assay. 0.1% was determined as the cutoff. Forty-two patients (75%) were positive for JAK2 V617F by pyrosequencing and 46 (82.1%) were positive by ddPCR. The mean mutated allele at diagnosis was 37.5±30.08%. With ddPCR, the mean was 40.7±33.2%. Pyrosequencing and ddPCR were highly correlated (r=0.9712, P<0.001). JAK2 V617F burden measured with ddPCR was significantly different by subgroups (P<0.001). In comparison of one disorder with another, polycythemia vera (PV) had more amount of mutant allele than essential thrombocytosis (ET) (P=0.001), however, differences between PV-mycelofibrosis (MF) and ET-MF were not statistically significant. Follow-up samples were available in 12 patients and 8 were JAK2 V617F positive. Among them, reduction of mutant burden after treatment was observed in 6 patients (75%). JAK2 V617F burden showed initial reduction in a MF patient treated with JAK2 inhibitor, however, after dose reduction for toxicities, the JAK2 V617F mutation increment with hematologic aggravation was discovered. Mutation burden decrease showed a tendency consistent with hematologic improvement. Hematologic characteristics and JAK2 V617F load at the initial diagnosis and follow-up after treatment (Table 1, Figure 1).

* Data from the first follow-up sample. † Data from the next follow-up sample in the same patient.

Figure 1.

Summary/Conclusions: In our study we can confirm that there are differences between clinical and laboratory finding according with mutational status, as shown in previous studies. The most consistent finding of this study was the presence of laxes groups of megacaryocytes significantly higher in those with CALR mutations. The major limitations of this study include a small number of patients and biopsies available to analysed, this might be the mayor causes for the lack of the data demonstrating clinical and histological relevance. But our results should not be underestimated because, to our knowledge, this is the second study thus has investigated this relation.

PB2054

JAK2, CALR AND MPL MUTATIONS: CORRELATION WITH PHENOTYPE DISEASE AND HISTOPATHOLOGICAL FEATURES OF BONE BIOPSY

Background: Drivers mutations JAK2, CALR and MPL are mutually exclusive in Essentials thrombocytopenia (ET) and these are included in the diagnostic criteria of mieloproliferative neoplasms (MPNs). Consistent with known literature, the molecular characterisation have implications in the phenopitope disease and it might be interesting to study if these are associated with the histopathological characteristics of bone marrow biopsy.

Aims: The purpose of this work is analyse the correlations between clinical-biological and histological characteristics of bone marrow biopsy and the mutational status (JAK2, CALR, MPL).

Methods: The study included 76 patients with ET diagnosed according to WHO criteria at the Haematology Department from Hospital de Jerez from January 2005 to December 2015. We examined the prevalence, and clinical and laboratory correlations of JAK2/CALR/MPL mutations. To evaluated the histology, one pathologist with expertise in haematopathology review the bone marrow biopsies corresponding to 44 patients with ET. We included only bone marrow biopsies of at least 10 mm in length and/or minimum 8 inter-trabecular areas. The pathologist only had access to age and gender data. Mutations JAK, CALR and MPL were analysed by PCR real time and sanger sequencing.

Results: There were 55 (72%) patients JAK2, 12 (15.5%) patients CALR, one patient MPL and 9 (11.8%) patients triple-negative (TN). The main clinical and laboratory features of the patients are show in Table 1A. As can be seen, one patient mpl and 9 (11.8%) patients triple-negative (TN). The pathologist only had access to age and gender data. Mutations JAK, CALR and MPL were analysed by PCR real time and sanger sequencing.

Summary/Conclusions: In our study we can confirm that there are differences between clinical and laboratory finding according with mutational status, as shown in previous studies. The most consistent finding of this study was the presence of laxes groups of megacaryocytes significantly higher in those with CALR mutations. The major limitations of this study include a small number of patients and biopsies available to analysed, this might be the mayor causes for the lack of the data demonstrating clinical and histological relevance. But our results should not be underestimated because, to our knowledge, this is the second study thus has investigated this relation.

CLINICAL IMPACT OF JAK2 AND CARLETICULIN GENE MUTATIONS ON PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

M. Napolitano,1, 2 S. Siragusa,1 S. Mancuso,1 M. Santoro1, V. Leone2, C. Marino2, D. Piazza1, A. Russo1, V. Acquaviva1
1UO Ematologia, University Of Palermo, Palermo, 2Oncoematologia, ASP Local Hospital, Trapani, 3Laboratorio di genetica e oncologia molecolare, 4UO Oncologia, University Of Palermo, Palermo, Italy

Background: JAK2 (V617F) gene mutation is found in approximately 60% of patients with Essential Thrombocytemia (ET), while 5-10% of JAK2 (V617F) negative ET patients carry MPL gene mutations including codon 515. Recently, mutations at the exon 9 of calreticulin (CALR) gene have been identified in approximately 50% of patients with ET, unmutated for Jak2 and MPL.

Aims: Primary aim of the current study was to analyze the prevalence of JAK2, MPL and CALR gene mutations in patients with ET; secondary aim was to evaluate the impact of gene mutations on clinical features of ET at diagnosis.

Methods: A cohort of consecutive patients with a diagnosis of ET followed between January 2013 and June 2016 were considered. JAK2 (V617F) gene mutation was detected by PCR testing; MPL and CALR mutations were analyzed by direct sequencing methods. Thrombotic risk score was calculated according to European Leukemia Net recommendations. Data were statistically analyzed.

Results: Overall, 148 patients were included: 107 (72.30%) had JAK2 (V617F) gene mutation (JAK2+), 12 (8.10%) carried a mutation at exon 9 of CALR gene (CALR+), 3 (2.02%) carried a mutation at codon 515 of MPL gene, 26 (17.58%) patients were not mutated for JAK2, CALR and MPL genes (triple negative). JAK2+ subjects, compared to JAK2- patients, had a younger age at diagnosis: median age 48 years (25-92) in CALR+ patients vs 72 years (18-93), respectively. Patients with MPL mutation had a median age of 82 years while triple negative patients had a median age of 59 years (23-89). The median score for thrombotic risk was 0 in CALR+ patients and 1 in JAK2+, MPL+ and triple negative patients. The distribution of International Prognostic Score for Essential Thrombocytemia (IPSET) categories was also statistically significantly different (p=0.003) for the three groups. The percentage of high-risk patients was 0% in the CALR+ group, 20% (2/10) in JAK2+ group, and 30% (5/16) in the triple negative group. The IPSET1 model also stratified patients with statistically significant difference (p=0.001) among the three groups: the percentage of high-risk patients was 16, 66 (2/12) in the CALR+ group, 82, 35% (88/107) in the JAK2+ group, and 33, 9(8/29) in triple negative group. CALR+ patients belonged more frequently to the low/intermediate risk group than JAK2+ patients (80% versus 17.5%, p=0.05). The incidence of thrombotic events at diagnosis of ET was 0 in the CALR+ group, 28, 30% (30/107) in the JAK2+ group and 23, 07% (6/26) in the triple negative group. The median overall survival was not reached in any group.

Summary/Conclusions: CALR+ patients with ET are phenotypically distinct from JAK2+ and triple negative patients. We can speculate a potential protective role of CALR mutation given the absence of thrombosis in IPSS and IPSET1 high-risk patients.

PB2057

RUXOLITINIB IN MYELOFIBROSIS: A MULTICENTRE EXPERIENCE FROM THE EAST OF ENGLAND

J. Russell1,2, D. Sparksman2, A. Ducu3, K. Maw2, M. Gomez2, M. Mangi2, I. Whalley2, A. Collins2, S. Sadullah2
1Department of Haematology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, 2James Paget University Hospital, Great Yarmouth, 3Norfolk and Norwich University Hospital, Norwich, Ipswich Hospital, Ipswich, United Kingdom

Background: Ruxolitinib, an oral Janus Kinase (JAK1/2) inhibitor, was approved in the EU in August 2012 for treating disease-related splenomegaly and constitutional symptoms in adults with primary myelofibrosis (PMF), post-polycythemia vera myelofibrosis (PPV-MF), and post-essential thrombocythaemia myelofibrosis (PET-MF).

Aims: We present a retrospective multicentre analysis of MF patients treated with ruxolitinib from August 2012 to December 2016 at 3 centres in the East of England to assess its efficacy, safety, and tolerability in a ‘real-world’ clinical setting.

Methods: Retrospective data collection using electronic medical records and cancer registry data identified 49 MF patients treated with ruxolitinib at the James Paget, Norfolk and Norwich, and Ipswich hospitals (28, 14 and 7, respectively) over a 52-month period. Five had less than 3 months’ follow-up and were excluded.

Results: The patient group was 61.4% male, with a median age of 71 years (41–91). There were 16 (36.4%) patients with PMF, 13 (29.5%) with PPV-MF, 9 (20.5%) with PET-MF, and 6 (13.6%) with post-myeloproliferative disorder (unclass.-MF). The indication for treatment was painful splenomegaly in 20 (45.5%) patients, constitutional symptoms in 23 (52.3%), and portal hypertension in 1 (2.3%). Ruxolitinib was first-line therapy in 10 (22.7%) patients, second-line in 24 (54.5%), and third-line or greater in 10 (22.7%). Starting doses ranged from 5mg BD in 2 (4.6%), 10mg BD in 14 (31.8%), 15mg BD in 11 (25%) and 20mg BD in 17 (36.4%). Common side effects included anemia, fatigue, and neutropenia. Twenty-nine patients (65.9%) remain on treatment.

Conclusion: In this East of England multicentre experience, response and safety profile was similar to trial data although we observed an increased incidence of minor haematologic AEs that were readily managed with supportive care. Weight gain was associated with a strong survival advantage and could prove a useful clinical marker of response. The majority of patients remain on active treatment.

PB2058

MONITORING OF TRANSIENT MYELOPROLIFERATIVE DISORDER AND LEUKEMIA IN DOWN’S SYNDROME: A SINGLE UNIVERSITY HOSPITAL STUDY

J. Park1*, I. Hwang1
1Pediatrics, AJOU University School of Medicine, Suwon, Korea, Republic Of

Background: Children with Down syndrome (DS) have a 10- to 20-fold increased risk of developing leukemia. But some patients don’t suffer leukemia and even have significant numbers of blast cell in their peripheral blood. These patients have a myeloproliferative disorder called Transient myeloproliferative disorder (TMD), and it is a disease entity unique to DS newborns and is defined as the morphologic detection of blasts in DS less than three months of age.

Aims: This study gathered DS patients to find some difference between leukemia and TMD, to determine prognosis and risk factors.

Methods: We collect 317 patient’s blood lab results in 433 DS patients. 102 patients have leukocytosis, and in 18 case found blast cells in their peripheral blood.

Results: 12 patients have found blast in three months of life, 11 of them finally diagnosed to TMD, and only 1 patient progress to Acute Myeloid Leukemia (AML) in 98 days of his life. Other 6 patients have blast in their blood after three months of life, and underwent chemotherapy due to hematologic malignancy. All patients with leukemia has anemia at diagnosis, which is not found in TMD patients (p=0.018). In 7 leukemia patients, 3 was acute lymphoblastic leukemia (LAM), 4 was acute myeloid leukemia (AML). All AML patients was 13 years old, and 6 of them was female. Moreover, we found a condition called trisomy 21 at their diagnostic point, which didn’t found in TMD and ALL patients, even it didn’t confirm former examination.

Conclusion: DS Patient who has blast in their peripheral blood before 3 months of life need closely follow up their Complete Blood Count and Chromosome analysis to find whether TMD progress to leukemia.

PB2059

INFECTIOUS EVENTS IN A COHORT OF PATIENTS WITH MYELOFIBROSIS UNDER TREATMENT COMPARING RUXOLITINIB WITH CONVENTIONAL THERAPY, A MONOCENTRIC EXPERIENCE OF 22 PATIENTS RETROSPECTIVELY ANALYZED

L. Torti1*, A. Morelli1, F. Schiavoni2, D. P. Bartolomei1
1Department of Hematology and Bone Marrow Unit, Pescara, 2Section of Hematopathology, Department of Hematology and Oncological Sciences, S. Orsola-Malpighi Hospital, Bologna, Italy
Background: Treatment with the Janus-activated kinase (JAK) 1 and 2 inhibitor ruxolitinib decreases constitutional symptoms and spleen size in myelofibrosis. However accumulating evidences suggest that the drug also exerts substantial immunosuppressive activity. The impressive clinical activity of ruxolitinib is predominantly mediated by its profound anti-inflammatory effects modulating dendritic cell (DC) function resulting in impaired CD4+ and CD8+ activity. Several studies have shown that Ruxolitinib affects different cytokines (IL1, IL6 and TNFaIla) and other immune processes and has been linked to increased incidence of opportunistic and no opportunistic infections. Herein we report our experience at our Centre.

Aims: In our retrospective study we analysed myelofibrosis patients treated with Ruxolitinib and cytoreductive treatment with Hydroxyurea and supportive therapy followed in our Department from 2012 to 2016 to evaluate rate of infections developed.

Methods: We reviewed 22 patients presenting myelofibrosis (median age 72, range 60-86) describing clinical and biological features (Table 1). Our aim was description of documented infections identified with conventional treatment and with Ruxolitinib. They were 11 treated with JAK inhibitors and 11 with Hydroxyurea taken orally, similar for age and clinical features.

Results: A total of 22 patients consecutively diagnosed were included in this analysis. There were 15 primary and 7 secondary myelofibrosis patients. According to the Dynamic International Prognostic Scoring System (DIPSS) 8 were low risk, 10 were intermediate risk and 4 were high. A total of 5 documented infections were identified throughout the evaluation period, 4 were grade 1 and one grade 2. They are various including oral herpes simplex reaction, pneumonia, recurrent viral flu syndromes, esophagitis fungal and urinary infections. All of them were present in the subgroup of patients undergoing therapy with Ruxolitinib (45%) after a medium time of 8 months from beginning of therapy (range 3-10). No patients received any anti-infective prophylaxis. Median total daily dose of ruxolitinib was 10 mg (range 5-20). All of this infections were resolved after anti-infectious treatment with antibiotics or antifungal therapy or in alternative by careful monitoring. None of patients were treated with concomitant immunosuppressive therapy. 3 of this patients presented renal impairment (median creatinine clearance of 46 ml/min).

Summary/Conclusions: These data in our small series of patients suggest a higher incidence of ruxolitinib associated infections observed in clinical practice compared to traditional treatment. Immunosuppressive effect of Ruxolitinib is reported and the use of this drug in the transplant setting with beneficial effects on alloreactivity and on graft versus host disease is becoming more common. These patients might benefit from receiving prophylactic therapy with antiviral drugs or antibiotics or antifungal therapy or in alternative by careful monitoring. Finally nowadays physicians and patients should be aware of potential risks of using ruxolitinib including the risk of infections.

In summary, infections can occur in patients treated with ruxolitinib but are generally mild. Generally infections were non-life threatening and managed with appropriate supportive care. Special care probably should be taken for patients older (more than 75 years old), treated with corticosteroid therapy and with renal impairment. However larger studies are needed to confirm these observations.

PB2060
THE JAK2V617F MUTATION AND LEUKOCYTOSIS AS RISK FACTORS FOR INCIDENCE OF THROMBOTIC COMPLICATIONS IN PATIENTS WITH POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA
E. Simonović1,*, V. Colić1
1Internal Medicine, General Hospital Leskovac, Leskovac, Serbia

Background: Polycythemia vera (PV) is a clonal, chronic, progressive myeloproliferative disease, caused by transformation of pluripotent hematopoietic stem cell. It is a malignant hematological disease that leads to excessive proliferation of erythroid, myeloid and megakaryocytic elements in the bone marrow. Essential thrombocythemia (ET) is a clonal disorder of unknown etiology characterized by a hyperplastic and reactive megakaryocytic stem cell, and it is characterized by enhanced formation of megakaryocytes in the bone marrow and for no apparent cause, by markedly increased platelet counts in peripheral blood. PV and ET belong to a group of Philadelphia chromosome negative myeloproliferative neoplasms. Thrombotic and hemorrhagic complications are the most common cause of morbidity and mortality in patients with PV and ET. It is thought that the mechanisms that lead to thrombosis in MPN are the following: increased blood cell mass, abnormal platelet function and the phenomenon of spontaneous aggregation. The contribution to the incidence of thrombosis: increased level of products that are formed in the activation of platelets (thromboxane, p-selectin); increased production of microparticles that are parts of various cell membrane structures of platelet origin; JAK2V617F mutation. In patients with MPN there is increased activity of the coagulation system due to the resistance to the anticoagulant function of thrombomodulin.

Aims: The aim of this study is to monitor JAK2V617F mutations and leukocytoses as potential risk factors for the development of thrombotic complications in patients with polycythemia vera and essential thrombocythemia.

Methods: During the five-year period we monitored the occurrence of thrombotic complications in 56 patients (of both sexes, aged between 30 and 78 years), being diagnosed with PV and 22 patients (of both sexes, aged between 38 and 79 years) being diagnosed with ET. We used methods of clinical, laboratory, ultrasound and CT scans. With regard to the risk factors we followed the presence of JAK2V617F mutations and leukocytoses.

Results: Leucocyte count ranged from 5.2-27,1 x 10⁹/L. The highest leucocyte count was recorded in the group with PV (p<0.01). JAK2V617F mutation was also statistically more significantly present in patients with PV. The highest percentage of thrombotic complications (arterial and venous) was found in the group of patients with ET, which was statistically more significant relative to PV. Thrombotic complications in those groups were more frequent in patients with PV diagnosed with leukocytosis, but statistical significance was present only in the group with PV. Thrombotic complications were more frequent in both groups compared to patients with JAK2V617F positive patients, but without statistical significance. It is believed that activated neutrophils bind to platelets by influencing the increased expression of tissue factor activity, as well as the activation and damage of the endothelial cells, especially with JAK2V617F positive patients.

Summary/Conclusions: Leukocytosis and JAK2V617F mutation may be considered as potential risk factors for the incidence of thrombosis in patients with PV and ET. Further follow-up of those patients, as well as a larger number of subjects are needed.

PB2061
RISK FACTORS FOR INCIDENCE OF HEMORRHAGIC COMPLICATIONS IN PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS
E. Simonović1,*, L. Macanakovic-Golubovic2
1Internal Medicine, General Hospital Leskovac, Leskovac, Serbia, 2Internal Medicine, Clinic of Hematology, Niš, Serbia

Background: Myeloproliferative neoplasms (MPN) are the group of clonal, malignant hematopoietic stem cell disorders, characterized by the proliferation of one or more blood lines with normal or nearly normal maturing in the bone marrow and in extramedullar hematopoietic organs. Hemorrhagic syndrome is a complication that occurs in about a quarter of patients with PV and even 60% of patients with ET. Bleeding complications may complicate the clinical course of the IMF. It is manifested in the form of petechiae and ecchymoses, or may be life-threatening as uncontrolled esophageal bleeding. Bleeding occurs due to ineffective megakaryocytopoiesis, retention of platelets in the large spleen, qualitative
platelet disorders, acquired deficiency of factors V and VIII, disseminated intravascular coagulation (DIC).

Aims: The aim of this study is to monitor the count of erythrocytes, leukocytes and platelets, as well as hemoglobin and hematocrit values as potential risk factors for the incidence of hemorrhagic complications in patients with chronic myeloproliferative neoplasms.

Methods: During the three-year period we monitored the occurrence of hemorrhagic complications in 139 patients of both sexes, aged between 30 and 87 years, being diagnosed with Ph-myeloproliferative neoplasms. Patients were classified into the following groups: 1. Group with polycythemia vera (PV) (61); 2. Group with essential thrombocytosis (ET) (28); 3. Group with idiopathic myelofibrosis (IMF) (25); 4. Group with unclassified myeloproliferative neoplasms (MPNs) (25).

The following possible risk factors were monitored: counts of erythrocytes, leukocytes and platelets, as well as hemoglobin and hematocrit values. We used methods of clinical, laboratory, endoscopy, ultrasound and CT scans.

Results: The highest percentage of hemorrhagic complications were in the group of patients with ET and IMF (p<0.01), followed by the group with MPNs (p<0.001) and the lowest in the group of patients with PV (p<0.01). Among the groups of patients with PV and MPNs there was no statistically significant difference in those parameters. In the group of patients with PV and MPNs hemorrhagic complications were more frequent in percentage in patients with leukocytosis and erythrocytosis, but without statistical significance. The highest platelet count was found in the group of patients with ET and MPNs (p<0.001), and the lowest in the group of patients with IMF (p<0.01). Among the group of patients with PV and MPNs there was no statistically significant difference with regard to platelet count. Hemorrhagic complications were more frequent both in patients with platelet count below 10x10^9/L (p<0.05) and in patients with platelet count over 1000x10^9/L (p<0.01). The increase in platelet count influences the adsorption of larger von Willebrand multimers on the platelet membrane, thus having an effect on their elimination from circulation and degradation.

Summary/Conclusions: The platelet count can be considered a significant parameter for monitoring the risk of hemorrhagic complications in patients with myeloproliferative neoplasms, particularly with ET and IMF. Deviation from the count of leukocytes, erythrocytes, hemoglobin and hematocrit values may be considered as a potential risk factor for bleeding in patients with myeloproliferative neoplasms, but further follow-up and a larger number of subjects are needed. The age of the patient can also be considered as a risk factor for the incidence of hemorrhagic syndrome in those patients. The follow-up of patients with unclassified myeloproliferative neoplasms has been particularly important, which showed a high prevalence of hemorrhagic complications, and with the purpose of their further differentiation.

PB2063

CLINICAL RELEVANCE OF JAK2V617F MUTATIONAL LOAD IN PATIENTS WITH PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS FROM REPUBLIC OF MACEDONIA (SINGLE-CENTER EXPERIENCE)

M. Popova-Labacheska1,*, L. Cveceska1, A. Dimovski1, M. Ivanovski1, D. Dukovski1, B. Kocosi1, A. Eftimov1, S. Trajkova1, I. Panovska-Stavidis1

1Hematology, University Clinic of Hematology, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: Polycythemia vera (PV), essential thrombocytosis (ET), and primary myelofibrosis (PMF) are Philadelphia chromosome negative myeloproliferative neoplasms (MPN) characterized by the expression of an acquired activated JAK2V617F mutation. Up to date, it remains controversial how one mutation can lead to expression of three different clinical MPN phenotypes. However, several studies have shown that the JAK2V617F allele burden may correlate with specific MPN entity.

Aims: In order to further clarify these observations, we evaluated the JAK2V617F mutational status and its clinical implications in 233 JAK2V617F+ patients from the Republic of Macedonia.

Methods: We conducted a single center retrospective study which included 233 patients with JAK2V617F+MPN diagnosed according to WHO criteria, with median follow-up period of 4 years. Identification of the JAK2V617F allele burden was analyzed with the Real Time PCR method using the Larsen protocol. Based on the mutational load patients were divided in three groups: first with <10% mutational load, second with 10-50% load and third with >50% mutational load. The correlation of the allele burden with various clinical parameters was done by the independent’s tests using Statgraphics 4.3 software.

Results: Our study shows that median allele burden was lowest in patients with ET (22.8%), follow by PV patients (37.1%) and PMF pts (49.6%) (p<0.01). A higher mutation burden (>50% vs <10%) was associated with advanced age (67.5 vs 58.5 years and 65 vs 58 years in ET and PMF pts respectively), with higher leukocyte count (102.2 vs 81.7 vs 81.8 vs 12.4, and 9.8 vs 9.8 in ET, PV and PMF pts respectively), with elevated erythrocyte count (5.76 vs 4.85 and 5.59 vs 4.52 in ET and PMF pts respectively), and with higher hemoglobin level (g/dL) and platelet count 10^12/L (15.45 vs 14.35 and 1071.5 vs 860.5 in ET patients respectively) (p<0.05 for all comparisons).

Background: Chronic neutrophilic leukemia (CNL) is a rare BCR-ABL1--negative myeloproliferative neoplasm (MPN) with only 200 patients reported to date according to the WHO criteria. These cases are characterized by a high number of mature neutrophils in peripheral blood (PB), a hypercellular bone marrow due to neutrophilic granulocyte proliferation and hepatosplenomegaly. None standard of care exist for CNL; most patients are palliated with hydroxyurea, interferons, splenectomy or splenectomy.

Methods: On May 2015 a 76 aged male patient presented at our Institution with fatigue, night sweats, neutrophilic leukocytosis (neutrophils 42.080/mm, immature granulocytes <5%), and symptomatic splenomegaly (277x127x200 mm). Blood smear showed chronic myeloid leukemia (CML), atypical CML (aCML) or chronic myelomonocytic leukemia (CMML), however, this diagnosis has been more defined since the oncogenic mutations in the granulocyte colony-stimulating 3 factor receptor (CSF3R) gene were identified in 83% of WHO-defined CNL patients.

Results: Our patient was initially treated with hydroxyurea with a provisional diagnosis of prefrictic phase of primary myelofibrosis (PMF), but symptoms worsened and the therapy was interrupted after 9 months for progressive anemia (Hb 9.9 g/dL) and thrombocytopenia (82.000/mm); meanwhile polymerase chain reaction (PCR) studies revealed the presence of CSF3R T618I mutation, suggesting diagnosis of CNL. By taking into account the activity of ruxolitinib in overt PMF, we decided to start this drug. The initial dose was 5 mg twice daily with a gradual increase in the dose to 20 mg twice daily when platelet count became normal.

Results: On a follow-up of 6 months after initiation of ruxolitinib therapy, symptoms resolved, hemoglobin and platelet levels improved (PLT 186.000/mm), leukocytosis persisted (WBC 24.600/mm), and the patient achieved a dramatic reduction in spleen size (209x119x74 mm).

Background: Current data suggest that constitutively active JAK-STAT signaling plays a central role in the pathogenesis of BCR-ABL1--negative myeloproliferative neoplasms (MPNs); our experience suggests that ruxolitinib use in CNL patients can induce partial responses by improving marrow function (normalization of hemoglobin and platelet counts), splenomegaly and symptoms.
Non-Hodgkin & Hodgkin lymphoma - Biology

PB2064
PERIPHERAL BLOOD CELL STUDY FROM PATIENTS WITH FOLLICULAR LYMPHOMA AND DIFFUSE LARGE B-CELL LYMPHOMA: WHAT SHOULD WE EXPECT?
D. Subirá1, H. Guillén1, C. Fernández Maqueda2, A. Gil1, D. de Miguel1, N. Goibano1, F. Barriopedro1, M. Morales1, M. Diaz Morfa1, J. Arbeleta1, A. Vázquez1, S. Herrero1
1Haematology, Hospital Universitario de Guadalajara, Guadalajara, 2Haematology, Hospital Universitario Puerta de Hierro, Madrid, Spain

Background: Follicular lymphoma (FL) may evolve to diffuse large B-cell lymphoma (DLBCL) and interactions between neoplastic cells and immune tumour microenvironment have been involved in this process. However, the potential value of the peripheral blood study to identify FL patients at high risk of progression is less known.

Aims: To describe the peripheral blood findings of patients with FL and DLBCL at diagnosis, and to investigate whether a particular lymphoid distribution could be associated with aggressive disease.

Methods: The study (performed between September 2012 and January 2017) included 52 patients (50 female) with a median age of 70.5 years (71% >60 years). Patients were newly diagnosed with in situ FL (n=1), Grade 1 FL (n=12), Grade 3 FL (n=11), and DLBCL not otherwise specified (n=28). In situ FL and Grade 1,2 FL were grouped as low-grade FL. Most patients with FL (11/13 low grade and DLBCL 8/11, Grade 3 FL) had clinical stages III/IV. Patients with primary or secondary immunodeficiency and those who had already received corticosteroids or chemotherapy were excluded from this study. A whole blood sample was studied at diagnosis of lymphoma and prior to the start of therapy, using multicolour flow cytometry immunophenotyping and a standardised monoclonal panel. A single monoclonal antibody panel including reagents against CD19, CD20, CD22, kappa, lambda, CD3, CD4, CD8, CD56 and CD45 was used, and a minimum of 300,000 events were acquired on the flow cytometer. Results were expressed as the absolute number/10⁶ of monocytes, lymphocytes, T cells, CD4, CD8 and NK cells. Polyclonal and monoclonal B lymphocytes were also identified.

Results: No difference in the distribution by sex or age was found between patients with FL and DLBCL. A low cell count in at least one lymphocyte population was detected in 35/52 patients (67.3%). 100% of cases had a low number of polyclonal B cells (<100/ml). Comparing low-grade FL, grade 3 FL and DLBCL, no statistically significant difference regarding monocytosis, CD4, CD8 and total T cells. Low-grade FL and DLBCL showed the highest number of differences, involving lymphocytes (257±2439 versus 1495±671, p=0.001), NK cells (381±312 versus 204±167, p=0.03), the CD4/CD8 ratio (1.5±0.49 versus 2.06±1.44, p=0.002), and circulating monoclonal B cells, for both percentage (15.2±23.23 versus 9.2±5.25, p=0.001) and absolute number (869±1758 versus 18.75±64.47, p<0.001). Grade 3 FL and DLBCL also showed a different CD4/CD8 ratio (1.16±0.45 versus 2.06±1.44, p=0.001), with a trend toward significance regarding CD4 T cells (413±184 versus 685±457, p=0.077). Grade 3 FL had a lower number of polyclonal B cells as compared to DLBCLs (66±41 versus 105±102, p=0.048). The peripheral expression of monoclonal B cells was higher in low-grade FL than in grade 3 FL, in both percentage (15.2±23.23 versus 4.58±2.48, p=0.008) and number (869±1758 versus 43.36±69.91, p=0.002) of monoclonal B cells. The number of lymphocyte subpopulations (CD3+versusCD4+withlow-cellcountswashigheringrade3FLthangoinggrade3FL(p=0.03).

Summary/Conclusions: The peripheral lymphocyte profile in patients with FL and DLBCL is heterogeneous, but B-lymphopenia and CD4/CD8 ratio deviations are frequent findings. Regardless of clinical stage, low-grade FL had more circulating lymphoma cells and preserved lymphocyte populations than grade 3 FL. Further studies are warranted to confirm these exploratory findings and determine their clinical implications.

PB2065
POTENTIALITY OF PDPK1 AS A THERAPEUTIC TARGET MOLECULE IN MANTLE CELL LYMPHOMA
Y. Chinen1, Y. Shimura1, M. Yamamoto-Sugitani1, T. Kobayashi1, T. Taki1, S. Horiike1, M. Taniwaki1, J. Kuroda1
1Kyoto prefectural university of medicine, kyoto, Japan

Background: Mantle cell lymphoma (MCL) is cytogenetically and molecularly characterized by chromosomal translocation t(11;14)q(13;q32) for deregulated cyclin D1 (CCND1) overexpression, and has remained as one of hard-to-treat subtypes of non-Hodgkin lymphomas (NHLs).

Aims: The development of novel therapeutics for MCL has been urgently needed, therefore, this study investigated the potency of PD901 as a therapeutic target molecule in MCL cell lines.

Methods: Four MCL-derived cell lines (Mino, Jeko-1, JVM-2 and Z138 cells), three diffuse large B-cell lymphoma (DLBCL)-derived cell lines (KUPM-MS3, KUPM-UH1 and A3/KAW cells) and a Burkitt lymphoma (BL)-derived cell line (Namalwa) were utilized in this study. Patient-derived biopsied specimens were obtained with informed consent and subjected to the immunohistochemical (IHC) staining of phospho (p-) PDPK1 on serial 5μm-thick sections. Cell proliferation was assessed by a modified MTT assay. Antibodies utilized for Western blotting was performed for evaluating protein expression levels of PD901, p-PDPK1Ser241, p-RSK2Ser292, and RSK2. BX-912, a specific inhibitor for PD901, was purchased from Selleckchem (USA). RNA interference of PD901 was performed by transfecting small hairpin RNA plasmids into MCL cell lines by means of nucleofection (Lonza, Switzerland). This study was approved by the institutional review board of our institute.

Results: By means of IHC examination, our study revealed that PD901 was activated through phosphorylation in tumor cells of all 7 MCL patient-derived specimens examined, and this was also the case in all 5 follicular lymphomas examined. These indicated that PD901 is generally active in various types of B-cell lymphoid neoplasms. The in vitro treatment with BX-912 for 48 hours resulted in the dose-dependent inhibition of cell proliferation in all four MCL cell lines (IC50 0.9-2.5 mM), and this inhibitory effect of BX-912 was more profound in MCL cell lines compared with three DLBCL cell lines (IC50 3.7-17.0 mM) and a BL cell line (IC50 2.9 mM). In addition, the flow cytometric analysis revealed that the growth inhibition of MCL cells by PD901 blockade with BX-912 was at least partly mediated through the induction of apoptosis. As the molecular sequelae, PD901 blockade by BX-912 resulted in dephosphorylation of RSK2 and AKT activity or CCND1 expression was unaltered by BX-912 treatment in MCL cells. By gene knockdown of PD901 by RNA interference using three different short hairpin RNAs, we further validated that the reduction of PD901 protein caused the inactivation of RSK2 and the growth inhibition in MCL cell lines. Finally, when combined with various agents that affect the peripheral expression of monoclonal B cell such as doxorubicin, etoposide, fludarabine, bortezomib, or ABT263, BX-912 showed additive/synergistic growth inhibitory effects in MCL cell lines.

Summary/Conclusions: Collectively, our study suggested that PD901/RSK2 signaling axis is the potential therapeutic target in MCL.

THE ACQUISITION OF RESISTANCE TO BENDAMUSTINE HYDROCHLORIDE INDUCES MULTIDRUG RESISTANCE IN A NOVEL MANTLE CELL LYMPHOMA-DERIVED CELL LINE KUPM-KYU1
T. Takimoto1,1, H. Nagoshi1, S. Maegawa1, T. Tatekawa1, T. Tsukamoto1, T. Kobayashi1, Y. Shimura1, Y. Chinen1, Y. Mizuno1, Y. Shimura1, T. Kobayashi1, T. Taki1, S. Horiike1, M. Taniwaki1, J. Kuroda1
1Haematology, Hospital Universitario de Guadalajara, Guadalajara, 2Haematology, Hospital Universitario Puerta de Hierro, Madrid, Spain

Background: Bendamustine hydrochloride (BH) has been one of the most cytotoxic moieties in mantle cell lymphoma (MCL), however, its mechanisms of action and the mechanisms for the acquisition of resistance to BH have not been fully clarified.

Aims: We tried to identify the underlying mechanisms for BH resistance to develop the strategy to overcome BH resistance.

Methods: This study was conducted in accordance with the Declaration of Helsinki and with the approval of the Institutional Review Board. Patient’s sample was obtained along with the written informed consent. We firstly established a novel MCL-derived cell line, KUPM-KYU1, from circulating lymphoma cells of a 77-year-old male patient with MCL. A BH-resistant subline of KUPM-KYU1 (KUPM-KYU1R) was established by continuous exposure to BH with gradual escalation of its concentration from 5 μM up to 50 μM for about 8 months. Cyto-genetic analysis was performed by double color-fluorescence in situ hybridization and spectral karyotyping (SKY). The comparative gene expression profile (GEP) and the ingenuity canonical signal pathway analyses between of KUPM-KYU1 and KUPM-KYU1R was performed to identify the differential gene expression pattern along with the acquisition of BH resistance. Cell viability was evaluated by a modified MTT assay.

Results: SKY analysis revealed that both primary tumor cells and KUPM-KYU1 had complex karyotype including three-way translocation (8;14;11) (q24;q32;q23) (involving of cyclin D1), and the t(11;14) involving of cyclin D1 and CCND1 to BH was 20 μM in KUPM-KYU1 cells, while the cell proliferation was not inhibited by up to 60 μM of BH in KUPM-KYU1R cells. When compared with the parental KUPM-KYU1 cells, KUPM-KYU1R cells showed the partial cross-resistance against doxorubicin, mafosfamide, melphalan, and vincristine. By GEP analysis, total of 472 upregulated and 412 downregulated genes were differentially expressed in KUPM-KYU1R compared with KUPM-KYU1 cells, including 312 upregulated more than 1.5-folds and 160 downregulated less than 0.67-folds in KUPM-KYU1R cells. The ingenuity canonical signal pathway analysis based on the GEP results sug-
gested that KPUM-YY1R cells harbored the distinct gene expression patterns in MDRI, a gene for P-glycoprotein (P-gp) of drug transporter in multicentric MGST1, a member of glutathione S-transferase (GST) families, and argininosuccinate synthetase 1 (ASS1), a rate-limiting enzyme for arginine biosynthesis. The upregulation of MDRI (P-gp) and MGST1 were confirmed by Western blot or RT-PCR analysis in KPUM-YY1R compared with KPUM-YY1. Importantly, the addition of P-gp inhibitor or GST inhibitors, such as ethacrynic acid, at least partly restored the sensitivity to BH in KPUM-YY1R cells, indicating the functional significance of the upregulation of MDRI and MGST1 in the development of BH resistance in MCL. In addition, BH resistance cells were also found to express decreased mRNA level of ASS1 whose roles to play tumor suppressor roles and its loss has been associated with clinical aggressiveness in various cancers.

Summary/Conclusions: This study revealed that the multiple molecular mechanisms overlappingly underlie the development of BH resistance, therefore, the acquisition of BH resistance potentially leads multidrug resistance in MCL cells. This study demonstrated that developed KPUM-YY1R cells and KPUM-YY1R cells derive the identification of multiplex mechanisms underlying BH activity/resistance and the future development of strategy which overcomes the treatment refractoriness in MCL.

Methods: We performed a retrospective analysis of BM involvement in patients with newly diagnosed NHL in the Korea University Hospital from January 1991 to December 2016. OS was compared according to the BM groups, which were divided into three groups: the group without BM involvement in both BM aspiration and biopsy, the group with atypical lymphocytes only in BM aspiration, and the group with BM involvement in biopsy regardless of BM aspiration results. Atypical lymphocytes were identified as positive in BM aspiration if they displayed cleaved nuclei, vacuolation, and granulation including lymphoid aggregates, and the presence of mature B-cell neoplasm, and lymphoma associated hemophagocytic lymphohistiocytosis. Reactive changes, or relative lymphocytosis were excluded. OS was assessed using the Kaplan-Meier method, and the log-rank test was used for comparison between the groups. Multivariate analysis were performed using a Cox proportional hazards model.

Results: In total, the data of 1,773 patients, of which 391 patients had indolent NHL and 1,382 patients had aggressive NHL, were reviewed. Of the 1,773 patients, 1,148 (64.7%) yielded negative results on both BM aspiration and biopsy, 30 (1.7%) yielded positive results with atypical lymphocytes only in BM aspiration, and 190 (10.7%) yielded positive results on biopsy. Remaining 405 patients were excluded owing to inadequate results in BM aspiration and/or biopsy. Median follow-up duration was 37.62 months (range, 0-288).

At the time of Kaplan-Meier survival analysis, OS was significantly worse for patients with BM involvement in biopsy compared with those with no BM involvement in both BM aspiration and biopsy. Atypical lymphocytes only in BM aspiration and biopsy (2-year OS, 42.8% vs 60.6%; log-rank P=0.184). Patients with atypical lymphocytes only in BM aspiration also had no significant difference compared with those with BM involvement in biopsy (log-rank P=0.291; Figure 1).

Multivariate analysis was performed by adjusting survival related variables such as sex, age, lactate dehydrogenase, Ann Arbor stage, Eastern Cooperative Oncology Group performance status, number of extranodal sites, lymph node characteristics (indolent vs aggressive), and transplantations. The calibration according to BM involvement remained a significant prognostic factor for OS (P<0.001). However, in the subgroup analysis, the group with atypical lymphocytes only in BM aspiration showed no significant difference compared to the group without the BM involvement in both BM aspiration and biopsy (OS 2-year OS, 42.8% vs 60.6%; log-rank P=0.074). Therefore, the detection of atypical lymphocytes only in BM aspiration had no significant difference in the OS even when the relevant factors were corrected.

Summary/Conclusions: This study suggests that the detection of morphologically atypical lymphocytes only in BM aspiration, but not in biopsy, is not significant predictor in untreated tumors, ii) tumors realpsing from R-CHOP treatment. In vivo imaging approach allows us to precisely quantify tumoral development and response to therapy, as well as to screen therapeutic candidates with in vivo imaging approach. The in vivo imaging approach may be used as an in vivo screen to predict treatment response and to identify targets for therapy.

Methods: 10 millions cells of a U2932 lymphoma cell line were xenografted into 60 athymic nude immuno-deficient mice. Tumoral growth was repeatedly quantified in vivo using mass spectrometry imaging (MSI) analysis to study the tumors characteristics during R-CHOP treatment and relapse. The in vivo imaging approach allows us to precisely quantify tumoral development and response to therapy, as well as to screen therapeutic candidates based on selected molecular targets. In vivo imaging allows us to precisely assess primary tumor.
PB2069
THE PROGNOSTIC ROLE OF INDOLEAMINE 2,3-DIOXYGENASE EXPRESSION IN HODGKIN’S LYMPHOMA.

T. Skrypets1,*, O. Novosad1, N. Svergun2, O. Skachkova2, O. Gorbach2, V. Solovev1, N. Khranovska2, I. Kryachok1
1Onchemotherapy, 2Experimental Oncology, National Cancer Institute, Thracic surgery, Clinical Hospital №18, Kiev, Ukraine

Background: Indoleamine 2,3-dioxygenase (IDO) is an inducible enzyme that catalyzes the initial and rate-limiting step in tryptophan along the kynurenine pathway. IDO is a key factor maintaining immune tolerance and expression and it correlates with poor clinical outcome in different types of cancer and hematological malignancies. It also plays a role in a lot of pathophysiological processes, such as antitumor and antimicrobial defense. IDO causes immune-suppression in the tumor microenvironment by tryptophan breakdown. Although, only several reviews have been made to evaluate IDO prognostic value and its expression value in hematological malignancies.

Aims: The aim of the study was to assess the impact of the IDO expression on clinical outcome in patients with Hodgkin’s lymphoma (HL).

Methods: A total number of 35 patients with HL were included in the group (10 males and 25 females; median age: 17-60 years, range: 38.5 years). Early stages (I-II) and advanced stages (III-IV) were diagnosed in 48.5% (17/35) and 51.4% (18/35) of patients, respectively. B-symptoms had 37.1% (13/35) of patients at the time of diagnosis. Patients were treated with ABVD or BEACOPP (14/esc) and radiation therapy. The mRNA expression level of IDO was measured in pre-treatment tumor tissue specimens from HL patients using real-time qPCR analysis.

Results: For 35 patients with HL, the overall response rate after the first-line therapy was 88.6% (31/35). Progression of the disease during the therapy was observed in 11.4% of patients (4/35). Among the patients, who achieved a remission, 9 had relapses. In our study, only 20% (7/35) of HL patients were IDO-positive (IDO+), while the majority of cases in the group (80%, 28/35) were IDO-negative (IDO-). There were no significant differences in IDO expression between histological subtypes of HL. We also did not find any association between stage of disease and IDO expression in our study. Patients with the absence of IDO expression tended to have a better response to the 1st line chemotherapy compared to patients with positive IDO expression. The overall response rate was achieved in 71.4% (57/80) of IDO+ cases and 92.9% (28/30) of IDO- cases. The relapse rate in IDO+ patients was more frequently found in HL cases with IDO+ compared IDO-expression (28.5% (2/7) versus 7.1% (2/28), respectively, p=0.05). We did not register any death of patients in IDO+, while one patient in IDO+ group died during the follow-up period (median duration – 37 months; range: 12-60 months). Patients achieved in 71.4% (5/7) of IDO+ cases and in 92.9% (26/28) of IDO- cases. The prognostic significance of IDO+ expression in clinical outcome of HL patients was 57.7%, while 5 year EFS was 51.6%. When comparing incidence of relapse in relation to non-complex karyotype, we found that nine out of 16 (56.2%) patients had complex karyotype experienced relapse whereas relapse occurred in only 6 (12.5%) patients having non-complex karyotype (p-value= 0.005)

Summary/Conclusions: The frequency of secondary chromosomal abnor- malities in our series is in concordance with other publications with duplication 1q being the most common, followed by deletion 6q, 13q, and 17p. Complex karyotype was significantly associated with higher incidence of relapse and poor outcome.

IGVH SOMATIC MUTATION PROFILE AS PATHOGENETIC SIGNATURE IN SPLENIC MARGINAL ZONE LYMPHOMA AND SPLENIC DIFFUSE RED PULP LYMPHOMA

H.L. Julhakyan1,*, B. Biderman1, L. Al-Radi1, I. Yakutik1, S. Korzhova1, A. Krovigina1, A. Sudarikov1, V. Savchenko1
1National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Splenic lymphomas (SLs) are rare chronic lymphoproliferative neoplasms with a very indolent clinical course and a non-characteristic phenotype and karyotypic pattern. The main criteria for SMZL and other SLs is the localization of the lymphoma in the red pulp of the spleen and characterized by a peculiar morphology with micronodular pattern of infiltration, biphasic cytology, and the almost constant presence of marginal zone differentiation. Splenic diffuse red pulp lymphoma been introduced as a provisional entity but differential diagnosis with other SLs is needed to be done. Currently, the therapeutical approach is based on the histopathological diagnosis.

Aims: The aim of our study to determine the immunoglobulin variable heavy chain (IgVH) gene usage and somatic mutation patterns in a series of SMZL and SDRP patients.

Methods: We studied 24 patients with SMZL, 40 patients with HCL and 10 patients with SDRPL. Diagnosis was based on standard WHO criteria. In all patients, the diagnosis was based on peripheral blood and BM findings. The baseline clinical and laboratory features as well as follow-up and outcome were recorded for each patient. Rearranged IgVH genes were amplified essentially in reactions that contained only one of the 5‘ leader region primers for the indicated IgVH gene (VH4-34) and 1 or 2 other primer set, depending on the rearranged VH region. PCR products were subjected to sequencing using appropriate positive and negative controls. The rearranged VH genes identified for each case seemed to represent functional rearrangements because no stop codons or crippling mutations were identified.

Results: A comparison of the VH genes to reported germline sequences in SMZL revealed that 3 cases used VH3 segments, while 8 cases used VH1 segments. In 6 cases VH1 was used alone. In one case, a single VH4 was found. A comparison of the VH genes to reported germline sequences in SDRP revealed that 5 cases used VH3 family VH gene segments and five the VH4 family, one of case with unmutaited IgVH genes.

Summary/Conclusions: Our analysis also showed the selective use of VH1 gene segments in SMZL cases. A 31% of VH1 and VH2 cases were characterized by mutations in VH4 family genes. A VH2 was found in VH1 family segments. The VH3 family genes were represented at a lower frequency (8.33% and 25%, respectively). The present study may revealed that SMZL and SDRPL derive from different cellular origin and may use in differential diagnosis.

CELL OF ORIGIN ASSIGNMENT USING IMMUNOHISTOCHEMISTRY IS INFLUENCED BY BCL-2 EXPRESSION IN DLBCL PATIENTS TREATED WITH CHEMOTHERAPY

R. Yassin1, S. Shieban2, T. Pasha1, G. Gmati1, H. Salama3, K. Abuelgasim3, R. Yassin1, S. Shieban2, T. Pasha1, G. Gmati1, H. Salama3, K. Abuelgasim3, M. Al-Zahrani1, A. Hejazi3, A. Ahmed3,4, M. Damlaj1,4,*

Summary/Conclusions:

COO assignment using IHC demonstrated superior

Figure 1.

R. Yassin1, S. Shieban2, T. Pasha1, G. Gmati1, H. Salama3, K. Abuelgasim3, M. Al-Zahrani1, A. Hejazi3, A. Ahmed3,4, M. Damlaj1,4,*

Background: Diffuse Large B-cell Lymphoma (DLBCL) is a heterogenous disease with variable clinical and pathologic presentations. Using gene expression profiling or Lymph2Cx assay, DLBCL can be assigned as germinal center (GCB) or non-germinal center (Non-GCB) subtype. However such assays remain cumbersome or unavailable for routine clinical care. Immunohistochemical (IHC) algorithms, such as the one proposed by Hans et al., are easy to use but demonstrated variable concordance to gene expression profiling. Importantly, cell of origin (COO) assignment appears to influence overall survival (OS) but not progression free survival (PFS). Furthermore, antiapoptotic BCL-2 oncogene expression confers prognostic significance in GCB DLBCL but its significance in Non-GCB is unknown.

Aims: To examine the prognostic impact of cell of origin (COO) assignment in conjunction with BCL-2 expression in a cohort of DLBCL patients.

Methods: After due IRB approval, adult patients diagnosed with DLBCL and treated at our institution between 2010 – 2015 were identified. Clinical and pathologic variables were retrospectively abstracted. IHC expression was deemed positive if >30% of staining was observed. Cell of origin analysis was determined by the Hans criteria. All patients were treated with combinational chemotherapy by containing rituximab. Patients who died prior to receiving therapy were excluded. Categorical and continuous variables were compared using Chi-squared and Wilcoxon tests, respectively. Time to end point analysis was computed using the method of Kaplan and Meier with log ranks. Relapse, progression or death was considered an event for PFS estimation. Analysis was computed using JMP software, version 11.

Results: A total of 122 patients were identified and analyzed. Median follow up of the cohort was 21.8 (1.47 - 107) months, during which OS was 73.5% and PFS was 59.9%. Stratified by IPI, 2-year OS was 85%, 76.3%, 72% and 49.5% for low, low-intermediate, high-intermediate and high risk patients, respectively (p=0.006). After stratifying patients to GCB and Non-GCB, base-line characteristics between the strata with regards to gender, age, stage, extranodal disease, lactate dehydrogenase (LDH), International Prognostic Index (IPI) and BCL-2 expression were not significantly different.

At 2-years, PFS was significantly higher for GCB vs Non-GCB at 72.5% vs 48.6%, respectively (p=0.008) but OS was similar at 77.6% vs 69.9% (p=0.2) (Figure 1). Interestingly, BCL-2 expression predicted OS irrespective of COO assignment. Patients with BCL-2 expression had a 2-year OS of 55.6% vs 56.2% for GCB and Non-GCB, respectively. Whereas, patients without BCL-2 expression has a superior 2-year OS at 79.9% vs 78.3% for GCB and non-GCB, respectively (p=0.02).

Summary/Conclusions: COO assignment using IHC demonstrated superior PFS for GCB over non-GCB however this was mitigated by BCL-2 expression. This raises questions regarding the currently presumed pathogenesis of the different subtypes and how to utilize the currently available targeted therapies including BCL-2 inhibitors. These observations warrant further study.

PB2073

ARE DIFFERENCES BETWEEN PEDIATRIC EBV-ASSOCIATED LYMPHOMAS AND CARRIERS REGARDING LATENCY PROFILE AND MICROENVIRONMENT COMPOSITION INVOLVED IN LYMPHOMAGENESIS?

A. Vistropol1, M. Cohen1, O. Jimenez1, F. Huaman1, E. De Matteo2, M.V. Preciado1, P. Chabany1,2,*

1Oncology, 2Pathology & Laboratory Medicine, 3King Abdulaziz Medical City, 4King Abdullah International Medical Research Center (KAIMRC), Riyadh, Saudi Arabia

Background: Epstein–Barr virus (EBV) infects more than 90% of the population worldwide. The virus has evolved to persist long in B-lymphocytes of infected individuals, but disruption of this tightly regulated B-cell infection could result in EBV-associated B cell lymphomas. In Argentina, primary infection is mostly subclinical and 90% of patients are seropositive by 3 years old. However, EBV presence is statistically associated with Hodgkin lymphoma (HL) and Diffuse Large B cell lymphoma (DLBCL) in patients younger than 10 years, suggesting a relationship between low age of EBV infection and B-cell lymphoma development in children from Argentina.

Aims: Given that viral latent proteins and microenvironment composition play a key role in tumorogenesis or control of viral infection, our aim was to compare this scenario in pediatric EBV-associated lymphomas derived from lymphoma germinal center (GCB) and post-GCB compartments, in EBV carriers, to investigate whether an alteration of microenvironment could be related to lymphomagenesis

Methods: Formalin fixed paraffin embedded (FFPE) pediatric biopsy samples from 26 DLBCL, 55 HL and 41 tonsils from EBV carriers were analyzed. Immunohistochemistry for LMP1, EBNA2, CD4, CD8, Foxp3 and GrB was performed, together with EBERs in situ hybridization, and positive cells were counted in the EBV+ milieu.

Results: Latency II pattern (LMP1+ EBNA2-) was predominant in HL (100%), DLBCL (55%), as well as in EBV+ CG in pediatric carriers (90%). CD4+ cell count displayed no differences between EBV+ and EBV- HL or DLBCL (p>0.05, Mann Whitney test), whereas statistically higher CD4+ cells were counted at the EBV+ GC in pediatric carriers (p=0.014, Mann Whitney test). On the other hand, CD8+ cells did not exhibit statistical differences neither in EBV-associated lymphomas nor in benign conditions at the GC, and the same was observed in the post-GCB compartments (p>0.05, Mann Whitney test). In contrast, CD8+ cell count were statistically higher exclusively at EBV+ subepithelial region in tonsils, compared to EBV- counterparts (p=0.0039, Mann Whitney test). Finally, cytotoxic activity evaluated by GrB expression displayed a trend to higher mean in EBV+ DLBCL (p=0.057, Mann Whitney test) but not in HL. Concerning EBV, pediatric carriers did not shown differences in cytotoxic activity according to EBV presence at the GC (p>0.05, Mann Whitney test). In fact, GrB cytotoxic activity was prevalent only at the EBV+ subepithelial region (p=0.0420, Mann Whitney test).

Summary/Conclusions: Latency II pattern prevails in both pediatric EBV-associated lymphomas and in EBV+ GC from carriers, indicating that LMP1expression may collaborate in the lymphomagenesis process at the GC in pediatric patients from our country. Cytotoxic activity against EBV infection may be only relevant in pediatric DLBCL, and in EBV+ subepithelial regions in pediatric carriers, whereas in EBV+ HL is not increased, in contrast to previously described. CD4+ T helper cell response plays a key role at the GC region in EBV carriers, by participating directly as effectors cells, by helping to the overall immune response in the control of viral infection and restrict latency expression to type II pattern, and, ultimately, by limiting the cell outgrowth. Failure in this process may trigger malignant transformation in EBV-associated lymphomas.

PB2074

MICRORAY EXPRESSION PROFILE OF LONG NONCODING RNAS IN GERMINAL CENTER-LIKE DIFFUSE LARGE B-CELL LYMPHOMA

H. Gao1*, Z. Gong1,2, W. Yang1

1Hematology, Shengjing hospital of China Medical University, Shenyang, China, 2Hematology, Weill Cornell Medicine, New York, United States

Background: Long noncoding RNAs (lncRNAs) are constantly transcribed and involved in a variety of biological activities. The contributions of lncRNAs to the development of germinatal center (GCB)-like diffuse large B-cell lymphoma (DLBCL) remain largely unknown.

Aims: The aim of this study was to investigate the expression profile of IncRNAs in human GCB DLBCL cell lines (OCI-ly1 and OCI-ly19) and normal B lymphocytes by microarray

Methods: We used Arraystar Human LncRNA Microarray V3.0 for profiling of IncRNAs in our specimens. Sample labeling and array hybridization were performed according to the Agilent One-Color Microarray-Based Gene Expression Analysis protocol (Agilent Technology) with minor modifications. Quantitative analysis protocol (Agilent Technology) with minor modifications.

Summary/Conclusions: lncRNA expression profiles were compared between the two GCB DLBCL cell lines. The overall patterns of lncRNA expression were similar between the two cell lines, indicating that lncRNA expression is not significantly affected by the cell line. However, some lncRNAs were differentially expressed between the two cell lines, indicating that lncRNA expression may be involved in the development of GCB DLBCL.

MICRORAY EXPRESSION PROFILE OF LONG NONCODING RNAS IN GERMINAL CENTER-LIKE DIFFUSE LARGE B-CELL LYMPHOMA

H. Gao1*, Z. Gong1,2, W. Yang1

1Hematology, Shengjing hospital of China Medical University, Shenyang, China, 2Hematology, Weill Cornell Medicine, New York, United States

Background: Long noncoding RNAs (lncRNAs) are constantly transcribed and involved in a variety of biological activities. The contributions of lncRNAs to the development of germinatal center (GCB)-like diffuse large B-cell lymphoma (DLBCL) remain largely unknown.

Aims: The aim of this study was to investigate the expression profile of IncRNAs in human GCB DLBCL cell lines (OCI-ly1 and OCI-ly19) and normal B lymphocytes by microarray

Methods: We used Arraystar Human LncRNA Microarray V3.0 for profiling of IncRNAs in our specimens. Sample labeling and array hybridization were performed according to the Agilent One-Color Microarray-Based Gene Expression Analysis protocol (Agilent Technology) with minor modifications. Quantitative
FLOW CYTOMETRY IN EVALUATION OF EXTRANODAL LYMPHOMA PRESENTING AT UNUSUAL LOCATIONS COMPARED TO NODAL LYMPHOMAS

P. Prakash1, M. Choudhury2, S. Sharma2
1Medical Oncology, Amrita Institute of Medical Sciences, Kochi, Kerala
2Pathology, Amrita Institute of Medical Sciences, Kochi, Kerala

Background: Immunophenotyping is a fundamental step in the diagnosis of hematological lymphomas arising at extranodal sites. We present here an evaluation of the possible diagnostic challenges due to its morphological diversity. In recent years flow cytometry (FCM) has proven useful in the evaluation of nodal and extranodal lymphoproliferative disorders on samples obtained by surgical specimens or fine needle aspiration cytology (FNAC). Flow cytometry can additionally help in identifying B or T cell nature of neoplastic cells, clonality in case of B-cell neoplasms and any aberrant phenotype. The possibility of detecting CD20 status can help in initiating targeted therapy without undergoing tissue biopsy to do so. FNA cytology with Flow cytometry can serve as a replacement for open biopsy and may help in eliminating the need for more invasive procedures. In this study FCM analysis on cytological specimens, including nodal and extranodal mass from GIT, Thyroid, Kidney, Breast, Tonsil, cerebrospinal fluid and ascitic fluid, was performed.

Aims: The aim of our study was to evaluate the efficacy of flow cytometer for the evaluation of extranodal and nodal lymphomas on 40 patients.

Methods: The current study was prospectively conducted on 40 patients with a clinical suspicion of hematolymphoid neoplasms. Samples for flowcytometric immunophenotyping (FCI) were obtained by fine needle aspiration (FNA) or by tissue scraping along with samples for cytomorphological, histological and immunohistochemical evaluation. Samples collected in isotope were submitted for FCI on 5-color Beckman Coulter FC-500, using a set of mature and immature B cells panels, and extranodal lymphomas on samples obtained by surgical specimens or fine needle aspiration cytology (FNAC). Flow cytometry can additionally help in identifying B or T cell nature of neoplastic cells, clonality in case of B-cell neoplasms and any aberrant phenotype. The possibility of detecting CD20 status can help in initiating targeted therapy without undergoing tissue biopsy to do so. FNA cytology with Flow cytometry can serve as a replacement for open biopsy and may help in eliminating the need for more invasive procedures. In this study FCM analysis on cytological specimens, including nodal and extranodal mass from GIT, Thyroid, Kidney, Breast, Tonsil, cerebrospinal fluid and ascitic fluid, was performed.

Results: Flowcytometric immunophenotyping conducted on extranodal sites included total 10/40 (25%) cases out of which most common site was GIT (4 cases) followed by CNS (3 cases), Kidney (1 case), Thyroid (1 case), Breast (1 case), and Tonsil (1 case). Definite diagnosis using only FCI could be obtained in 25/40 (62.5%) cases in which 6/10 (60%) cases was conducted on extranodal and 19/30 (63%) cases on nodal tissue samples. The remaining 15 cases which could not be categorized by FCI included Hodgkin lymphoma (6 cases), inadequate cellularity (5 cases), Tuberculosis (2 cases), ALCCL (1 case), Mantle cell lymphoma (1 case) and Ewing’s/PEMT (1 case). Combining FCI with cytological findings definite diagnosis could be found in 33/40 (82.5%) cases compared to 30/40 (75%) cases. Immunohistochemical (IHC) analysis of CD26 (DPP4) added to the presence of CD39 in CD26-CD38+ (50% vs 65; p=0.04, CD26-CD39+ (50 vs 65; p=0.06, CD39 (49 vs 59; p=0.15).

While HL and FL cells are significantly different: CD38 (64 vs 23; p<0.05), CD26-CD38+ (50 vs 18; p<0.05), CD39 (44 vs 23; p<0.05). The other three types of NHL, few in number, show a tendency to a significant difference compared with HL.

Summary/Conclusions: The our data show the phenotypic variations in the microenvironements of different types of lymphoma emphasizing of DBCL the similarity with HL and the difference with FL and other NHL. They also suggest a link between a activated environment (CD38+) and a high CD39, which, in addition to a low CD26, could enhance the generation of adenosine and, therefore, an increased immune suppressive activity. The profile by FC of CD4 T infiltrating can characterize lymphomas in its environment indicating also signals and biological mechanisms representative of possible therapeutic target

PB2075

POSSIBLE ROLE OF FLOW CYTOMETRY TO CHARACTERIZE INFILTRATING CD4 CELLS IN THE MICRO ENVIRONMENT OF LYMPHOMA TISSUE SAMPLES

R. Di Gaetano1, D. Belvini1, B. Callegari1, M.A. De Benedetto1, E. Pilotto1, R. Sarto1, G. Tagariello1
1Haematology Castelfranco Veneto, Azienda ULSS 2 Marco Trevisiana, Castelfranco Veneto (TV), Italy

Background: In our previous work (Di Gaetano et al, Ann Haematol, 2014) we analyzed by flow cytometry (FC) the rich infiltrating characterizing the microenvironment of Hodgkin lymphoma (HL), mainly comprised of CD4 T lymphocytes. We confirmed that the majority of these CD4 T expressing the activation (CD38+) and the inhibitory (CD26) phenotype were found in the subset CD4+CD26-CD38+ to identify the non-neoplastic cellular pattern in HL. A subset connectable to regulatory T (Treg) cells, because the low expression of CD26 (DPP4) added to the presence of CD39 (NTPDase) may be responsible for the generation of adenosine, which plays a major role in T-regulated immunosuppression.

Aims: We wanted to test if this subset may also characterize T infiltrating lymphocytes the lymph nodes of Non-Hodgkin’s lymphomas (NHL) and to verify the expressions of the two enzymatic markers (CD26 and CD39) in microenvironements of HL and NHL analyzed by FC

Methods: In 2016 we analyze by FC in lymph nodes of 6 HL and in 32 NHL (12 DLBCL, 10 FL, 5 SLL, 3 MZL, 2 MCL ) the CD4 T subset testing the expres-}

TREG CD4 PHENOTYPE IN THE PERIPHERAL BLOOD OF LYMPHOMAS

R. Di Gaetano1, D. Belvini1, E. Pilotto1, B. Callegari1, M.A. De Benedetto1, R. Sarto1, G. Tagariello1
1Haematology Castelfranco Veneto, Azienda ULSS 2 Marco Trevisiana, Castelfranco Veneto (TV), Italy

Background: The T regulatory (Treg) cells down-regulate antitumor responses by several distinct mechanisms. One is the adenosinergic pathway which, through ectonucleotidases, sequentially converts ATP to adenosine, which plays a major role in Treg-mediated immunosuppression.

Aims: By using the same FC technique we wanted to explore if, as in the lymph nodes, CD4 T regulatory T cells in the peripheral blood were characterized by the expression of CD26 and CD39.

Results: In CD4 T HL, CD39 is expressed in 44% of the subset and the increased presence (50%) of CD4+CD26-CD39+ cells is confirmed. Compared with HL, the cells of DBCL are not statistically different: CD38 (64 vs 55; p=0.39, CD26-CD38+ (50 vs 46; p=0.66, CD39 (44 vs 59; p=0.15).

While HL and FL cell are significantly different: CD38 (64 vs 23; p<0.05), CD26-CD38+ (50 vs 18; p<0.05), CD39 (44 vs 23; p<0.05). The other three types of NHL, few in number, show a tendency to a significant difference compared with HL.

Summary/Conclusions: The our data show the phenotypic variations in the microenvironements of different types of lymphoma emphasizing of DBCL the similarity with HL and the difference with FL and other NHL. They also suggest a link between a activated environment (CD38+) and a high CD39, which, in addition to a low CD26, could enhance the generation of adenosine and, therefore, an increased immune suppressive activity. The profile by FC of CD4 T infiltrating can characterize lymphomas in its environment indicating also signals and biological mechanisms representative of possible therapeutic target

Keywords: Flow cytometry, extranodal lymphoma
the clone of B lymphocytes involved in cancer. This may support that leukemic cells may contribute to create and to characterize an immune-subversive environment and to facilitate immune escape mechanisms. FC analysis of CD26 and CD39, markers likely connected with the adenosinergic pathway, in PB can represent effective parameters to determine and characterize the Treg CD4 in different types of lymphoma and could serve as targets in the follow-up of HL and B-NHL.

BCL-2 AND Ki-67 AS INDEPENDENT PREDICTORS OF POOR-RISK IPI GROUP OF PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

E. Suljovic Hadzimesic1,*, S. Radovic2, A. Soto-Hatzifici1, N. Obralic3, N. Bilalovic4, A. Kozaric5, A. Dizaedere2, S. Kurtovic6, V. Bijedic3, M. Skuric-Tomic1

1High Dose Therapy Department, Clinical Center University of Sarajevo, Hematology Clinic, 2Institute of Pathology, Medical Faculty University of Sarajevo, 3Clinical Center University of Sarajevo, Hematology Clinic, 4Clinical Center University of Sarajevo, Pathology, Cytology and Human Genetics Department, Sarajevo, Bosnia and Herzegovina

Background: Diffuse large B cell lymphoma (DLBCL) is heterogeneous disease in terms of clinical behaviour, morphology, phenotype and genetics. Gene expression profiling has made a distinction between two entities germinal center B-phenotype (GC), activated B-center phenotype (ABC). Use of immunohistochemical algorithms for identification of these phenotypes has been translated into clinically feasible approach defining groups as GCB, non-GCB. These algorithms do not provide completely accurate prognostic information so the International Prognostic Index (IPI) which identifies poor- and good-risk patients, diffuse large B cell lymphoma (DLBCL) is still part of all current diagnostic guidelines; however, the majority of patients have an intermediate IPI, with an uncertain prognosis.

Aims: In this study, we investigated the impact of bcl-2, bcl-6, CD10, MUM1 and Ki-67 on IPI as well as impact of GCB and non-GCB subclassification according to Hans and Muris algorithm on IPI risk stratification.

Methods: We have analyzed 50 patients with DLBCL for the expression of bcl-2, bcl-6, CD10, MUM1 and Ki-67. Patients were divided into two groups, the non-GCB, GCB group or favorable group 1 and unfavorable group 2, according to Hans’s algorithm and Muris’s algorithm. Clinical-pathological, biochemical, and molecular parameters have been studied with special emphasis on the expression of CL and biomarkers individually. The impact of the expression of bcl-2, bcl-6, CD10, MUM1 and Ki67 on IPI-highest score in multiple regression analysis, afterwards in regression equation and variance analysis.

Results: Group with GCB phenotype (defined by expression of bcl-2, bcl-6, CD10 and MUM1) according to Hans’s and Muris’s algorithm showed positive correlation with good-risk patients identified by IPI. Multiple regression analysis proved impact of biomarkers on IPI. Following this analysis, bcl2 and Ki-67 are independent predictors of poor-risk IPI group afterwards in regression equation and variance analysis.

Summary/Conclusions: Multiple regression analysis proved impact of biomarkers on IPI. Following this analysis, bcl2 and Ki-67 are independent predictors of poor-risk IPI group afterwards in regression equation and variance analysis.

PB2079

COMPARATIVE PATHOLOGIC ANALYSIS OF MEDIASTINAL B-CELL LYMPHOMAS: EXPRESSION OF P63 BEST DIFFERENTIATES PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA FROM CLASSICAL HODGKIN LYMPHOMA

1Pathology, Sanggye Paik Hospital, Inje University college of medicine, 2Pathology, Seoul St. Mary’s Hospital, The Catholic University, Seoul, 3Pathology, Hal- lym University Sacred Heart Hospital, Anyang, 4Pathology, Soonchunhyang University Hospital, Pucheon, 5Pathology, Ajou University School of Medicine, Suwon, 6Pathology, Ulsan University Hospital, Ulsan, 7Pathology, Eulji University Hospital, Seoul, 8Pathology, Inha University Hospital, Ichon, 9Pathology, Seoul National University Boramae Hospital, Seoul, Korea, Republic Of

Background: Mature B-cell lymphomas of the mediastinum include primary mediastinal large B-cell lymphoma (PMLBCL), classic Hodgkin Lymphoma (CHL), B-cell lymphoma unclassifiable, with features intermediate between diffuse large B-cell lymphoma (DLBCL) and Hodgkin lymphoma (HL). PMLBCL, CHL and mediastinal CHL, mostly nodular sclerosis (NS) share many clinicopathologic characteristics, however, therapeutic options and responses are quite different.

Aims: We aimed to find distinctive histologic or immunohistochemical findings to better differentiate PMLBCL and CHL of the mediastinum.

Methods: A total of 32 cases of mediastinal B-cell lymphomas consisting of 16 PMLBCL (N=16), 13 CHL (N=13), and 3 gray zone lymphoma (N=3) were collected from 6 university hospitals from Korea. Immunohistochemistry (IHC) for various cell lineage markers and EBV in situ hybridization were performed to confirm the diagnosis, and additionally, expression of P63, GATA3 and cyclinE was investigated.

Results: Most clinical features were overlapped between PMLBCL and CHL except more frequent disease progression and mortality in PMLBCL (p<0.05). In pathologic review, presence of epithelioid granuloma favored CHL (p=0.078), whereas fine reticulated fibrosis was unique for PMLBCL (p=0.001). By IHC, P63 was predominantly positive in PMLBCL (15/16) than CHL (2/11) with the highest diagnostic power (p<0.001). GATA3 was expressed in the majority of CHL (9/12) compared with PMLBCL (0/16) (p<0.001). Expression of cyclinE was rarely found in a minor population of PMLBCL.

Summary/Conclusions: Expression of P63 in the tumor cells, even focal, is the most helpful feature to distinguish PMLBCL from mediastinal CHL. Additional diagnostic markers include GATA3 in CHL and reticul fibrosis in PMLBCL.

PB2080

CASTLEMAN’S DISEASE: HISTOLOGICAL SUBTYPES AND MICROVESSEL DENSITY

A. Mikhailov1,*, V. Baykov2, S. S. Bessmeltsev3, G. Raskin4, V. Rugal5, N.Y. Semenova3

1Department of hospital therapy and cardiology, North-Western state medical university n.a. I.I.Menchikov, 2Department of pathology, First St.-Petersburg state medical university n.a. I.P.Pavlov, 3Russian research institute hematology and transfusiology, 4Department of pathology, Russian national scientific centre of Radiology and surgical technologies, 5Department of pathology, Russian research institute hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: Castleman’s disease (CD) is a rare non-clonal lymphoproliferative disorder. Most of the cases are characterized by increased vascularity in the affected tissue. The disease falls into two major histological variants: plasma cell type and hyaline vascular type. However, the correlation between microves sel density and the subtype of the disease has not been established yet. We aimed to investigate the association between microvessel density and histological type of CD.

Methods: Twenty-eight lymph nodes from patients diagnosed with CD were used for the study. The age of the patients ranged from 24 to 65 years, 14 were male and 14 were female. Three nodes without evidence of metastasis removed for breast cancer were used as controls. The diagnosis of hyaline vascular CD was based on overall preserved immunoarchitecture with typical angio-follicular hyperplasia, circular arrangement of mantle cells around hyalinized germinal centers ("onion skin" pattern). The plasma cell type of CD was confirmed by presence of perifollicular sheets of CD138+ plasma cells. Vessels were counted in CD with CD34 immunostaining. Slides were scanned by whole slide digital Panoramic scanner. Percentage of blood vessel area (vessel density index) was calculated using Panoramic Viewer software, statistical analysis was conducted with Student’s-t test.

Results: The plasma cell variant of CD was diagnosed in 8 patients, the hyaline vascular variant – in 20 patients. In control group vessels occupied 10±1.0% of the area. In patients with plasma cell variant percentage of blood vessel area was increased to 15±1.4% (p<0.05). Patients with hyaline vascular CD were divided into 2 groups depending on the vessel density index. In 15 patients (75%) percentage of vessel area was 6.8±2.3%, which was somewhat lower than in patients with plasma cell variant (not statistically significant). In 5 patients (25%) with hyaline vascular CD, the percentage of vessel area was higher - 12±3.5% (p<0.05) and did not differ from levels in patients with plasma cell variant.

Summary/Conclusions: The highest index of vessel density in the lymph node variant with plasma cell was observed in 5 patients with plasma cell variant. In hyaline vascular variant, the index was characterized by significant variability, which could reflect the heterogeneity of this type of the disease. Increased density of blood vessels in the lymphoid tissue may be considered as a possible target for angiogenesis inhibitors, especially in patients with progressive disease.

PB2081

PROGNOSTIC SIGNIFICANCE OF IMMUNOHISTOCHEMICAL MARKERS IN R-CHOP TREATED DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS

A.-M. Picleanu1,*, S. Patrascu2, L. Mogoanta3

1Hematology, Filantropia Hospital Craiova, 2Surgery, Emergency Hospital Craiova, 3Histology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background: Despite its clinical, morphological and molecular heterogeneity, diffuse large B-cell lymphoma (DLBCL) is the most frequent lymphoid malig-
nancy in adults. The role of immunophenotype variability for the therapeutic outcome has long been the cornerstone for DLBCL management strategy.

**Aims:** To evaluate the immunophenotypic characteristics of DLBCL and the prognostic significance of specific biomarkers such as bcl2, bcl6, CD 10 and MUM1, in a population-based cohort of patients treated with R-CHOP.

**Methods:** We performed a retrospective assessment of all cases of DLBCL diagnosed at our institution between 2005-2013. The immunohistochemical expression patterns of all DLBCL patients were analyzed and correlated with the therapeutic response to R-CHOP regimen.

**Results:** The study included 101 patients diagnosed with DLBCL, with a median age at diagnosis of 57.1 years (19-90 years) and male/female ratio of 1.3/1. Ninety-one patients were eligible for R-CHOP treatment. The median follow-up was 41 months. Out of the 90 cases analyzed by immunohistochemistry CD10, BCL2, BCL6 and MUM1 expression was found in 17.6%, 50.5%, 72.7% and 81.8% of cases, respectively. Negative expression for CD10, as well as positive expression for BCL2, as adverse prognostic factors for 3-years overall survival (OS) and disease free survival (DFS) (OS for bcl2: 72.3 vs 89.7, p<0.05, OS for CD10: 84.1 vs 75.1, p<0.05). BCL6 and MUM1 expressions, however, did influence neither OS nor DFS.

**Summary/Conclusions:** This study confirms the prognostic value of a multi-marker assessment which includes bcl2, bcl6, CD 10 and MUM1 expression for patients R-CHOP therapy.

**LYMPHOID NEOPLASMS: A REALLY IMPORTANT TRIGGER IN HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS**

V. Martínez Robles,1,2 S. Calleja,2 B. Balima, S. Cerdà,1 S. Fernández-Ferrero,1 F. Escalante,1 F. Ramos,1 J.A. Rodríguez-García1

1Hematology and Hemotherapy, 2Immunology, Complejo Asistencial Universitario de León (CAULE), León, Spain

**Background:** Triggered by several conditions Hemophagocytic lymphohistiocytosis (HLH) is an unusual, aggressive and life-threatening dysfunction caused by an excessive immune activation. It has become more recognized over the past decade. HLH was first described in 1939 by Scott and Robb-Smith, next case was reported in 1952 by Farquhar and Claireaux describing two infant siblings with progressive and lethal cytopenias, hepatosplenomegaly, and fevers with autopsy showing hemophagocytosis. A lengthy and unstoppable activation of antigen-presenting cells (macrophages, histiocytes) and CD8+ T and NK cells is characteristic. This condition leads to an important hyperinflammatory situation and organ damage including splenomegaly, fever, cytopenia, hypertrigliceridemia and/or coagulopathy. Histiocyte Society (HS) criteria have been applied for diagnosing HLH, however not all of them are usually showed at the presentation. This disease can be described in two different scenarios: primary (usually in children, genetic, and known as familial form) and secondary (acquired). It can be triggered by a large variety of events that disrupt immune homeostasis. When we talk about triggers, we can divide them in two broad categories, those that cause immune activation and those that lead to immune deficiency. Lymphoid neoplasms can be both.

**Aims:** Due to the lack of publications about HLH secondary to Lymphoid Neoplasms (LN), we would like to analyze the casuistry of our hospital and making a comparison with the current literature.

**Methods:** We conducted a retrospective analysis through medical files of all patients with suspected diagnosis of HLH between 1994 and 2017 in our inpatient ward. Clinical features, age, diagnostic criteria proposed by the HS, etiology, treatment and evolution were analyzed. In our study 18 out of 50 patients met the requested criteria for HLH diagnosis.

**Results:** We report 10 LN secondary cases (4 males, 6 females). The median age at diagnosis was 60.5 years, ranged between 46 and 80 years. In all of them, but in one, who presented long-term pancytopenia, symptoms were developed very fast. The most frequent causes of consultation were cytopenia and general syndrome. In two of them HLH was diagnosed with LN relapse, in one patient during a transformation from a low-grade B-cell lymphoma to DLBCL (Diffuse large B-cell lymphoma), in 6 of them we diagnosed LN and HLH concomitantly, and in the last one coinciding with a Richter Syndrome. Four of 10 were secondary to T-cell neoplasm. All patients met 5 or more HS diagnostic criteria. In only 3 of them HLH was healed. One patient is still in remission. Nine died, 7 of them due to HLH complications. Treatment was chemotherapy (depending on their LN) in almost all of them. Fluctuations were detected among activity HLH parameters due to LN response. Detailed characteristics of patients are shown in Table 1.

**Table 1.**
Summary/Conclusions: HLH triggered by LN is diagnosed in older patients than other causes secondary HLH (46-80 vs 4-8 y/o in our center), we think this is because in our experience there are not children or Young adult in HLH due to LN group. We would like to highlight that although LN is a very common HLH trigger there are a few works describing them in the literature, that is why we would like to spread our experience. We would like to emphasize in the importance of an early diagnosis. Despite being a serious disease, it is still underdiagnosed, reaching the diagnosis most of the times after seeing hemophagocytic phenomena in bone marrow biopsy. Agreeing with literature, main consulting reasons are similar to our series. Correlation between neoplastic activity and immune activation, as well as test and facts which could predict evolution should be more studied. Finally we would like to address the necessity of considering this possibility in the face of a patient with fever which does not respond to antibiotics and has not clarified citopenia, as well as the importance of conducting cheap and very profitable test such as ferritin or tryglycerides level when symptoms or clinical features of lymphoid neoplasms are not concordant with the expected evolution.

Background: Health networks focused on rare diseases were created following a call for proposals from the French Ministry of Health in the summer of 2013. The main missions of this network is to facilitate and to coordinate the actions being implemented by all actors involved in treating rare diseases. Of the 23 national networks identified in 2014 in France, the network for rare immunohematological rare diseases “MaRIH” brings together national reference centres and recognized centres of expertise as well as patients’ associations involved in treating those pathologies, on behalf of scientific medical societies.

Aims: Improving care, communication and training, pushing forward research development and epidemiological surveillance.

Methods: MaRIH brings together people involved in those medical pathologies: 8 national reference centres, 5 centres of expertise, more than 50 diagnosis and/or research laboratories, 9 patients’ associations on behalf of 7 scientific societies.

Results: The main missions of this network are to improve the care, the research and to educate professionals, patients as well to disseminate more information and knowledge to the general public on these rare diseases. Improving care: Thanks to its visibility (events, leaflets, website), MaRIH should help primary care doctors to more quickly diagnose and therefore provide faster and appropriate treatment based on best practice recommendations at the national level (PND5) as well as international guidelines. The network will also be setting up new initiatives to take care of each national and hematological rare disorders through MaRIH centres so physicians in France or in other countries can have easily an expert opinion for their patients. At the same time, improving the child-adult transition was identified by the steering committee as a top priority. Communication and training: MaRIH is involved in organizing many events in France to improve the visibility of the centres and to provide education on these rare diseases. The 1st annual conference of the network took place on June 25th 2015 and the third one is planned on June 1st 2017 in Paris. Moreover, a patient’s day meeting was organised on January 30th 2016 in Paris to inform on the update status of research on their disease as well as to help patients in daily common problems (sport, psychology, transusion…). Pushing forward research development and epidemiological surveillance: the network has appointed a research project manager for its scientific and strategic committee to support, provide stability for and add value to research centre activities. The research project manager watch out for calls for tender, set-up of new registers and continually monitor the regulations for retrospective and prospective studies, both in France and at the international level. Furthermore, MaRIH supported successfully the application of several of its members for European reference networks (Figure 1).

Figure 1.

Summary/Conclusions: The creation of these new networks allows strengthening the links between the various actors involved in the field to improve care and answer transversal questions. In this way, MaRIH pilot concerted actions to all its members around immunohematological rare diseases by: 1- increasing the visibility of the actors on the web or during events. The MaRIH website includes all the informations of the members as well as recommendations and events (www.marih.fr). 2- communication and training. MaRIH organizes two annual events, one for patients and another one for professionals. Moreover, MaRIH sends clinical cases by email to professionals and produce an annual webcast. 3- pushing forward research development and epidemiological surveillance. Thanks to his research project manager, MaRIH facilitates the submission and the set-up of new registries or clinical studies. In the future, MaRIH will continue and futher develop all these actions, in close collaboration with the French Ministry of health.

PB2084
CLINICAL FEATURES AND PATHOLOGY OF PATIENTS WITH THROMBIC MICROANGIOPATHIES
Ü. Ergene1,2, Ö. Özlü1
1hematology, salud bilimleri university, izmir, Turkey

Background: Thrombotic microangiopathy (TMA) is a heterogeneous group of disease that has a fatal pattern of endothelial damage. TMA can be found in association with diverse clinical conditions such as carcinoma metastasis, malignant hypertension, infections, and TTP (thrombotic thrombocytopenic purpura). TTP is a rare, life-threatening multisystem disease, characterized by microangiopathic hemolytic anemia, thrombocytopenia, fever, renal dysfunction, and neurological disorders.

Aims: The purpose of this study is to evaluate the etiology associated with TMA.

Methods: All of the six TMA patients who were newly admitted to our clinic in two months period were enrolled in this study. Effectiveness, response, adverse effects and safety of plasmapheresis were evaluated using laboratory and clinical findings. (See Table 1).

Results: First patient presented with cachexia, thrombocytopenia, and TMA. He did not respond to plasmapheresis and corticosteroid treatment. We diagnosed carcinoma metastasis and liver metastasis, respectively, through bone marrow biopsy and PET (positron emission tomography). We thus ascertained that TMA was due to carcinoma unknown primary. The second patient presented with general neurological findings like Guillain-Barre Syndrome and paraplegia with renal failure, thrombocytopenia, and TMA. After PLEX and corticosteroid treatment, laboratory and neurological clinical recovery were observed after one month. The third patient had chronic obstructive pulmonary disease and pneumonia in anamn思维方式 who presented with anemia, thrombocytopenia, fever and pneumonia findings. We conducted PLEX therapy. On the 8th day of PLEX, the patient had anaphylaxis, we performed cardio pulmonary resuscitation. The fourth patient
presented with acute renal failure with malignant hypertension. We performed hemodialysis together with PLEX treatment. Because his diagnosis was acute renal failure, malignant hypertension, and TMA. The fifth patient presented with epistaxis and sepsis. He had chronic TTP diagnosis for two years ago. We diagnosed the patient as relapse TTP. Early treatment against infection and PLEX increased his platelet counts as early as the second day of treatment. The sixth patient presented with a fever that had been going on for five days. We treated the patient with PLEX together with the corticosteroid. Because his ADAMTS13 level was very low and he had 35% schistocytes.

Table 1.

| Summary/Conclusions: | We diagnosed our first patient with carcinoma unknown primary, who did not respond to PLEX and corticosteroid treatment. The results we received for that patient indicate that PLEX with corticosteroid treatment alone, remain ineffective in cancer-related TMA patients. Etiology of our second patients TMA was idiopathic. His clinical and laboratory findings improved rapidly in response to PLEX and pulse corticosteroid treatment. One viral infection induced TMA patient had anaphylactic reaction receiving his 8th PLEX. Allergic reactions should always be kept in mind when administering PLEX. One patient with TMA and malignant hypertension-induced renal failure was successfully treated with PLEX, hemodialysis and anti-hypertensive treatment. We successfully treated our bacterial infection and sepsis-induced TMA patients with PLEX and antibiotic administration. In second TMA group, we coupled PLEX with high dosage corticosteroid treatment even though he had an infection. For he had high schistocyte count and atypical neurological findings. ADAMTS 13 activity may only be a guide for diagnosis of TTP, but it is unreliable for a definitive one. In conclusion, diagnosis of TTP and other TMA is difficult. Etiology, clinical features, laboratory findings should all be taken into account when diagnosing TMA. While it is established that ADAM TS13 deficiency is the major cause in acquired TTP, finding the etiology of other TMA entities is the major challenge for a successful treatment of the latter. |

HEMOALYSIS AS SCREENING TEST IN LYSONOSMAL STORAGE DISEASES
L. López De Frutos1,2, J.J. Cebolla1,3, P. Irún1,2, P. Giraldo1,2,3
1Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Fundación Española para el Estudio y Terapéutica de la Enfermedad de Gaucher y Otras Lisosomas (FEETEG), 3Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Centro de Investigación Biomédica en Red en Enfermedades Raras (CIBERER), Departamento de Bioquímica, Biología Molecular y Celular, Universidad de Zaragoza, Zaragoza, Spain

Background: Lysosomal storage disorders (LSDs) are a group of rare inherited metabolic diseases, whose clinical hallmark is organomegaly among others, due to progressive accumulation of several non-catalyzed products inside the lysosomes. This storage leads to intracellular oxidative stress status triggering oxidized metabolites production as oxysterols, which are related to apoptosis and cellular eriptosis, as well as haemolysis dysregulation.

Aims: To evaluate the link between LSDs and haemolysis and if it could be used as a screening test in LSDs.

Methods: The osmotic resistance test (ORT) was evaluated in 150 samples including controls, LSDs carriers (LSDs-C) and LSDs patients (LSDs-P). Briefly, the blood was mixed with different concentrations of sodium chloride solution (NaCl) and the haemoglobin released was quantified by spectrophotometry. The raw data was normalized using isotonic solution (0.9% NaCl). The statistical analysis (non-parametric tests and ROC curves), was computed by IBM SPSS statistics v22 software and all statistical tests will be considered and taken as bilateral significance level α=0.05.

Results: The analysis showed that haemolysis at 0.48% of NaCl allow us to sort out controls vs LSDs-C/LSDs-P (AUC=0.725) whereas no significant differences were observed between LSDs-C and LSDs-P (p-value>0.05).

Summary/Conclusions: According to our results the ORT test is an useful screening test in LSDs.

PB2086

CLINICAL SIGNIFICANCE OF ELEVATED SERUM COBALAMIN (VITAMIN B12) LEVELS
I. Yaman Bajin*, E. Sabancı, S. Aykan, M. Çetin, F. Gürüm1
1Pediatric Hematology, 2Pediatrics, Hacettepe University, Ankara, Turkey

Background: Hypercobalaminemia is a frequent but underestimated abnor-mality. Elevated serum cobalamin levels may be a sign of a wide range of diseases like solid neoplasms, hematological disorders like myeloproliferative disorders, chronic myelogenous leukemia, promyelocytic leukemia, poly-cythemia vera, hyperesinosinophilic syndrome as well as liver and kidney diseases.

Aims: We aimed to evaluate the underlying disorders of the patients with high cobalaminemia levels (>1000 pmol/l) between 01.02.2016- 01.02.2017 in Hacettepe University Pediatric Hematology Department.

Methods: We investigated the patient records of the patients examined between 01.02.2016-01.02.2017 in our department and included the patients with serum cobalamin levels higher than 1000 pmol/l. We excluded the patients who are taking Vitamin B12 supplement.

Results: There were 46 patients with serum cobalamin levels higher than 1000 pmol/l out of 14367 patients seen between 01.02.2016- 01.02.2017 in our department. The reason to check the cobalamin levels were anemia, neutropenia and thrombocytopenia in most of the patients. Only 2 patients were referred to our department because of hypercobalaminemia. The underlying disorders were found to be leukemia in 3 patients (Acute lymphoblastic leukemia (ALL) n:1, acute myeloblastic leukemia (AML) n:1, large granular lymphocytic leukemia (LGLL) n:1), myelodysplastic syndrome (MDS) in 2 patients, isolated thrombocytopenia in 4 patients, isolated neutropenia in 7 patients, bicytopenia in 4 patients and aplastic anemia in 2 patients, cobalamin metabolism defects in 10 patients, hypereosinophilia in 2 patients, polisitemia in 1 patient, cystic fibrosis in 1 patient, HIV in 1 patient, FMD (familial mediterranean fever) in 1 patient, chronic kidney failure in 2 patients, sickle cell anemia in 1 patient, factor V Leiden in 1 patient, and hemophagocytosis in 1 patient.

Summary/Conclusions: An observed elevation of cobalamin merits the a full diagnostic work up to assess the presence of an early diagnostic marker of these diseases. When we look at the patients except hematological neoplasm and cytopenias, most of the underlying reasons is associated with inflammation and infection, cobalamin was found to be elevated as an acute fase reactant. A certain approach is needed whether to determine the potential indications to search for high serum cobalamin levels and to determine the practical clinical strategy when elevated cobalamin levels discovered.
Hematotoxic Effects of Generic Triazole Fungicides TEBUCONAZOLE on Wistar Hanover Rats

T. Userko1, V. Shulyak1, N. Nedopytanska1, M. Prodanchuk1

IL. I. Medved’s Research Center of Preventive Toxicology, Food and Chemical Safety, Ministry of Health, Kiev, Ukraine

Background: Pesticides are extensively used in agriculture today. Fungicides based on derivatives of triazole are the most widespread all over the world. Tebuconazole (TB) is one of the most frequently used substance of this group. Literature review confirms that triazole fungicides have the ability to cause different hematotoxic effects.

Aims: Since 2007-2016 years we have investigated 10 test-substances of generic tebuconazoles (purity up to 97%) from different manufacturers with purpose to assess their hematotoxic action on males Wistar Han rats peripheral blood in the subchronic 90-days oral toxicity study (according to SOP and OECD 408 recommendations in compliance with GLP).

Methods: The Wistar Han males were randomly allotted to four groups. The input controls of peripheral blood parameters were conducted after a period of animals acclimatization. The goal was to evaluate the physiological state of the Wistar Han rats and the blood picture in case of treatment. Donor animals received the test substance for 13 weeks: 1 group (control), 2 group (generic tebuconazole 100 mg/kg/day), 3 group (generic tebuconazole 200 mg/kg/day) and 4 group (generic tebuconazole 400 mg/kg/day).

Results: As a result, peripheral blood parameters of the control group were in the normal range and didn’t differ from the levels at the beginning of the experiment. The generic TB showed a significant decrease of HGB concentration, hematocrit (HCT), total amount of erythrocytes (RBC), hemoglobin (Hb) and platelets (PLT), mean corpuscular hemoglobin (MCH) were evaluated.

Summary/Conclusions: As a conclusion, due to the results the triazole fungicides generic tebuconazoles have hematotoxic action. They induce anemia in Wistar Han rats and quantitative white blood cells changes. Today it is very important to investigate the hazardous effects of pesticides on the blood system.
Summary/Conclusions: Immunosuppressive therapy including cyclosporine with or without steroid has been reported as the most effective treatment in primary acquired PRCA. Consistently, we had a dramatic response to immunosuppressive therapy in our patient.

PB2091
APLASTIC ANEMIA IN CHILDHOOD: A TEN YEARS’ SINGLE CENTER EXPERIENCE
A. Apsemidou1, 1-T.-S. Tzioila1, A. Tragianidou1, E. Chatzipanteles1, M. Papageorgiou1, L. Damianidou1, T. Papageorgiou1, T. Koltea2
A. Giannopulos3
1Pediatrics-Pediatric Hematology/Oncology, 2Pathology, 3Pediatrics-Pediatric Cardiology, AHEPA University Hospital, Thessaloniki, Greece

Background: Aplastic anemia in childhood is a rare, life-threatening disorder, characterized by peripheral blood pancytopenia and a hypocellular bone marrow without signs of dysplasia or fibrosis. Acquired aplastic anemia needs to be distinguished from inherited bone marrow failure syndromes or myelodysplastic syndromes.

Aims: The aim of this study is to assess the clinical and laboratory findings at the time of diagnosis, the treatment approach and the outcome of children with aplastic anemia treated in our department during the past decade.

Methods: This retrospective study evaluated 9 children with aplastic anemia, who were treated and followed up in the Pediatric Department of AHEPA, during the period 2006-2016.

Results: We identified 9 children with aplastic anemia. The patients’ population included 6 (66.7%) males and the mean age at admission was 9.7 years. At the time of diagnosis, the average neutrophil count was 750/mm3, the Hb count was 8.4mg/dl and platelets count was 8770/mm3. In all of our cases aplastic anemia was acquired, expect one case of Fanconi anemia. Predisposing risk factors (including drugs exposure, viral infections, chemicals) were identified in 4 patients. Among the 9 studied patients, 3 (33.3%) had severe anemia, 2 (22.2%) had severe and 4 (44.5%) had very severe aplastic anemia. All of the patients received immunosuppressive therapy (consisting of antithymocyte globulin, cyclosporine A and steroids), 2 remained transfusion independent, 4 underwent bone marrow transplantation -2 from a matched related donor and 2 from a matched unrelated donor. One patient with refractory disease received, as an alternative first line therapy, etrolomopag. Complete response was achieved in 22.2%, partial response was achieved in 22.2%, relapse occurred in 11.1% and 44.5% of the patients had refractory disease. The overall survival was 77.8%.

Summary/Conclusions: A remarkable progress has been made during the past decades in the understanding of pathogenesis and management of children with aplastic anemia. Bone marrow transplantation from a matched related donor is the recommended first line therapy resulting in an excellent survival rate that exceeds 90%. In the future the development of targeted strategies for patients that are not eligible for bone marrow transplantation will further improve outcome and diminish the disease’s late complications.

PB2092
CAUSES OF IRON DEFICIENCY ANEMIA IN THE HEMATOLOGY CLINIC – SINGLE CENTER EXPERIENCE
M. Ionita1, 1I. Ionita1, D. Calamar1, D. Oroș1, V. Todoroscu1, C. Ionita1, C. Sorica1, H. Ionita1
1Hematology, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania

Background: Iron deficiency anemia (IDA) is the common nutritional deficiency worldwide. The studies concerning various causes of IDA in adult men are rare, although it is assumed that chronic gastrointestinal blood accounts for the majority.

Aims: Of the study is to evaluate retrospectively adult men with IDA that were hospitalized in our Hematology Clinic.

Methods: Two hundred fifteen male with IDA were enlisted at this study from January 2005 to december 2015. Anemia was defined as Hg <13g/dL using the WHO criteria. IDA was considered present if serum ferritin was 15 ng/mL combined with serum iron concentration <30ug/dL with a transferrin saturation of <10%. Complete physical examination, the history of the disease and fecal occult blood test (FOBT) of three spontaneously passed stools was done in all patients. All patients had complete blood count, serum and total iron binding capacity, and a serum ferritin level. Most patients underwent esophagogastroduodenoscopy (EGD). Colonoscopy was performed if lesion that caused IDA was not found, and/or FOBT was positive. The abdominal CT scan were performed according to clinician’s recommandation together with other tests related with blood lost.

Results: The median age was 62 (range 32 to 86) years old. 168 of 215 (78.8%) men with IDA had symptoms such as fatigue, dizziness, or digestive complaints. The history of prior gastrectomy, hemorrhoid, that probably had caused IDA were reported in 32 (14.8%), 43 (20.0%), patients, respectively. FOBT was positive in only 65 (30.23%) subjects. 170 (79.06%) patients underwent EGD. The most common findings from EGD were gastritis (48 patients) and peptic ulcer (39 patients). Seventy eight (36.27%) patients were found to have upper gastrointestinal disorders (20 patients with erosive gastritis, 19 gastric ulcer, 16 duodenal ulcer, 23 gastric cancer. Eighty-nine (41.39%) patients underwent colonoscopy. That showed 44 clinically important lesions that probably caused IDA; colon cancer in 17 (7.90%) patients, colon polyp in 10 (4.65%) patients and hemorrhoid in 17 (7.90%) patients. Concerning malignant lesions which are responsible for IDA, the malignant lesions were found more frequent in patients older than 50 years accounting for 20.45% (27/132 patients) and patients younger than 50 years 17.80% (13/73 patients).

Summary/Conclusions: The hematological indices are influenced by a wide variety of factors, especially age, gender, and serum level of Apo B. As age,
Apo B, while cell count, and platelet count all impose risk of thromboembolism, further work exploring the interactions and impacts of these parameters on the development of cardiovascular diseases should be mandatory.

PB2094

UNUSUAL DISTRIBUTION OF INTERLEUKIN-10 C-592A GENE POLYMORPHISM IN PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA FROM NORTH-WESTERN RUSSIA

S. Bessmeltsev1, I. Zlotova3, S. Gritsaev2, J. Sidorova3, I. Pavlova3, A. Pavlova3, B. Sennestal2

1Laboratory of Biochemistry, 2Russian Research Institute Of Haematology And Transfusionology, Saint-Petersburg, Russian Federation, 3Laboratory of Immuno-hematology, Russian Research Institute Of Haematology And Transfusionology, Saint-Petersburg, Russian Federation

Background: Primary immune thrombocytopenia (ITP) is a rare hematological disease with unknown etiology. It is characterized by heterogeneity of the laboratory parameters as well as the features of clinical manifestation. DNA polymorphism of several cytokine genes has been suggested to modulate the risk of ITP development or/and treatment response in distinct population groups. There is no data on the prevalence of cytokine gene polymorphisms in ITP patients from the North-Western region of Russia (NWR).

Aims: To establish the features of genotypes distribution for several cytokine promoter gene polymorphisms in ITP patients from NWR.

Methods: A total of 68 patients (59 women and 9 men) with chronic primary ITP were involved in the study. The median age of the group was 57 years (range: 24-77). The mean duration of ITP was 7 years (2-48). In 19 (32.2%) women, ITP was diagnosed before 30 years old; 26 (38.2%) patients (5 men and 21 women) were diagnosed at age 30-50 years; 23 (33.8%) patients (9 men and 14 women) developed ITP after 50 years old. The control group consisted of 240 healthy persons originated from NWR. Nucleotide variations in the genes coding for interleukin (IL) -1b (IL1B) and -6 (IL6), -1b (IL1B), -592A and -592C of the IL-10 and tumor-necrosis factor alpha (TNFA-308 G/A) were discriminated by PCR and subsequent restriction analysis (PCR-RFLP). Intergroup differences in genotype frequencies were assessed by Fisher’s exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated by using the GraphPad Prism 5.0 software.

Results: The frequency of the IL-10 -592CC genotype was slightly increased in the ITP group when compared to controls (65.7% vs 54.0% respectively; OR=1.6, CI: 0.9-3.1, p=0.15). Interestingly, this variant of the IL-10 gene was more prevalent among women than men with ITP (71.2% vs 25.0% respectively; OR=7.4, CI: 1.4-40.5, p=0.016). When compared to controls, the IL-10 -592CC genotype was significantly overrepresented in the group of women with ITP (71.2% vs 54.0%; OR=2.1, CI: 1.1-4.2, p=0.044). On the contrary, in the group of affected men we observed the increase of persons who had IL-10 -592AA allele (75.0% vs 46.0% in control group; OR=3.5, CI: 0.7-18.3, p=0.15). Genotype frequencies for other studied genes were similar between the patients and control group as well as between women and men with ITP. We have also found almost 2-fold increase of the IL-1b -311C frequency in women diagnosed before 30 years old compared to other patients (15.8% vs 8.2% respectively; OR=2.1, CI: 0.4-10.5, p=0.39). The presence of the TNFA-308A allele was more often seen in patients diagnosed before 50 years old (26.7% vs 8.7% in other ITP patients; OR=3.8, CI: 0.8-18.8, p=0.12).

Summary/Conclusions: We suggest that the IL-10 -592CC genotype is associated with increased risk of ITP in women from NWR. On the other hand, the IL-10 -592AA allele could be involved in pathogenesis of ITP in men. Further studies are needed to clarify the significance of TNFA and IL-1b gene polymorphism in ITP development.

PB2095

COMBINED TREATMENT OF AZATHIOPRINE AND ROMIPLOSTIM IN PATIENTS ITP REFRACTORY TO STEROIDS OR THROMBOPOIETIN ANALOGS

M. E. Mingot-Castellano1,*, I. Sánchez-Bazán1, J. Díez-Pastor1

1Hematology, Regional University Hospital of Málaga, Málaga, Spain

Background: More than 70% of patients with Immune Primary Thrombocytopenia (ITP) respond to steroids, but 40 to 70% relapse in the first year follow-up. The use of romiplostim in this group is effective, although 9% failure has been described. In recent literature, there are clinical cases and series describing the potentiating effect of combined treatment with thrombopoietin analogues and immunosuppressive drugs such as steroids, cyclophosphamide and rituximab. We have not found references to the combined use of azathioprine (AZA) and romiplostim (ROM).

Aims: To describe our experience in the combined use of azathioprine and romiplostim as a rescue treatment in patients with acute or newly diagnosed ITP refractory to corticosteroids or corticosteroid-dependence and refractory to maximal doses of romiplostim monotherapy.

Methods: We analyzed patients with newly diagnosed or persistent ITP, with corticosteroid-dependence or refractory to steroids and refractory to romiplostim, both in monotherapy. We have considered refractoriness to steroids not reaching platelets higher than 30x10^9/L. Corticosteroid-dependence as the need for ongoing or repeated doses administration of corticosteroids for at least 2 months to maintain a platelet count at or above 30 x10^10/L and/or to avoid diabetes complications. We considered refractoriness to romiplostim not getting platelet counts greater than 30x10^9/L with 10mcg/kg/week for at least 3 consecutive weeks. All patients have been diagnosed in a single center with the same physician responsible for the treatment and follow-up. The initial doses of AZA was 100mg/days (2mg/kg/day) and ROM 10mcg/kg/week. Patients have been evaluated every week until platelets were higher than 30x10^9/L for at least 30 days of combined treatment.

Results: We treated 4 patients (75% female) with a median age at diagnosis of ITP of 53 years old (R: 20-61 years). Treatments received prior to the use of the combination of AZA and ROM were polyclonal immunoglobulins (lg), cyclophosphamide and rituximab. Responses to steroids and romiplostim in monotherapy were: • Median dexamethasone cycles (40mg/days x 4 days) was 2.5 (2-4 cycles, IQR). The initial dose of prednisone was 1-2mg/kg/days with a median treatment day of 31.5 days (28-60 days, IQR). The type of response to steroids was PR with corticosteroid-pendence in one patient, 3 patients NR. • Median time from ITP diagnosis and romiplostim indication was 9.5 weeks (7-48 weeks, IQR). Median platelet counts at the start of romiplostim was 6x10^9/L (2-1x10^9/L, IQR). The median platelet count achieved at maximal doses of romiplostim for at least 2 consecutive weeks was 10x10^9/L (0-1x10^9/L, IQR). Once established the refractoriness to romiplostim, we maintained ROM 10mcg/kg/week and AZA was initiated at 100mg/day. The median time from romiplostim indication to the association with azathioprine was 9.8 weeks (5.5 to 15 weeks, IQR). The median time to response after initiation of combination of AZA and ROM was 21 days (15-35 days, IQR). The types of response were: • One patient did not respond after 60 days of combined treatment. • 1 patient with RC maintains for 7 months in the absence of active treatment. The combined was necessary during 8 months.

Summary/Conclusions: The use of azathioprine and romiplostim in combination could be a safe and effective alternative in subjects refractory to steroids or corticosteroid-dependence and thrombopoietin analogs alone. More studies are needed to clarify the mechanism of complementation between the two drugs.

AGONIST-INDUCED PLATELET REACTIVITY CORRELATES WITH BLEEDING IN HEMATO-ONCOLOGICAL PATIENTS

B. Batman1,*, E.R. van Bladel1, M. van Hamersveld2, P.C. Pasker - de Jong1, S.J. Korporaal1, R.T. Urbanus2, M. Roest3, L.A. Boven2, R. Fijnheer1,3

1Internal Medicine, 2Department of Clinical Chemistry, Meander Medical Center, Amersfoort, 3Department of Clinical Chemistry and Hematology, University Medical Center Utrecht, Utrecht, Netherlands

Background: Prophylactic platelet transfusions are administered to prevent bleeding in hematologic-oncological patients. However, bleeding still occurs, despite these transfusions. This practice is costly and not without risk. Better predictors of bleeding are needed and flow cytometric evaluation of platelet function might aid the clinician in identifying patients at risk of bleeding. This evaluation can be performed within the hour and is not hampered by low platelet count.

Platelets disorders
Aims: Our objective was to assess a possible correlation between bleeding and platelet function in thrombocytopenic hematopoietic oncological patients.

Methods: Inclusion was possible for admitted hematopoietic-oncology patients aged 18 years and above after written informed consent. Furthermore, an expected need for platelet transfusions was necessary. Bleeding was graded according to the WHO bleeding scale. Platelet reactivity to stimulation by either adenosine diphosphate (ADP), crosslinked-collagen-related peptide (CRP-xL), PAR1- or PAR4-activating peptide (AP) was measured using flow cytometry.

Results: A total of 114 evaluations were available from 21 consecutive patients. Platelet reactivity in response to stimulation by all four studied agonists was inversely correlated with significant bleeding. Odds Ratio’s (OR) for bleeding were 0.23 for every unit increase in median fluorescence intensity (MFI) 95% confidence interval (CI) 0.11-0.73 for ADP; 0.59 [0.40-0.87] for CRP-xL; 0.59 [0.37-0.94] for PAR1-AP and 0.43 [0.23-0.79] for PAR4-AP. The platelet count was not correlated with bleeding (OR 0.99 [0.96-1.02]).

Summary/Conclusions: The examinated induced reactivity was significantly correlated to bleeding. Platelet function testing could provide a basis for a personalized transfusion regimen, in which platelet transfusions are limited to those at risk of bleeding.

PB2097
TUMOR NECROSIS FACTOR-A AND TUMOR NECROSIS FACTOR-B SINGLE NUCLEOTIDE POLYMORPHISM AND CHRONICITY IN EGYPTIAN PEDIATRIC PATIENTS WITH IMMUNE THROMBOCYTOPENIA
N. El-Gharbawi1, G. Shahin1, A. Eid1, N. Diaa1, M. El-Ghamrawy2,3
1Clinical and Chemical Pathology, 2Pediatrics, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Although the etiology of immune thrombocytopenic purpura (ITP) remains unclear, both genetic and environmental factors may contribute to the development of the disease. Tumor necrosis factor alpha & beta (TNF-α and TNF-β) are inflammatory cytokines that play a role in regulation of cell differentiation, proliferation and death, as well as in inflammation, innate and adaptive immune responses, and have been implicated in a wide variety of human diseases. We hypothesized that inflammatory cytokine genes polymorphisms (TNF-α and TNF-β) in ITP pediatric patients may play a fundamental role in pathogenesis and chronicity of the disease. It may be of great importance for binary immunomodulatory therapies for chronic ITP (cITP) in children.

Aims: The current case-control study aimed at detecting TNF-α (-308 G/A) and TNF-β (-252 A/G) genes polymorphism in Egyptian children with cITP and studying their possible association with chronic evolution of the disease.

Methods: The current study included 80 Egyptian cITP patients at Pediatric Hematology Unit, Cairo University (mean age 7.08±3.64 years) and 100 matched unrelated healthy controls. Genotyping was performed using polymerase chain reaction restriction fragment length polymorphism technique (PCR-RFLP).

Results: TNF-α genotyping revealed that wild G/G, heterozygous G/A and homozygous A/A genotypes among cITP patients were 81%, 16% and 3.8% respectively versus 79%, 20% and 1% in control group, while TNF-β wild A/A, heterozygous A/G and homozygous G/G genotypes among cITP patients were 55%, 40% and 5% respectively versus 60%, 28% and 12% in control group, with no statistically significant difference between both groups. Patients having the homozygous TNF-α genotype showed statistically significant higher mean age, longer disease duration & lower mean platelet count (p=0.005, 0.024 and 0.008 respectively). TNF-α polymorphism was more frequent among unresponsive patients compared to responsive patients with statistically significant difference. Calculated risk estimation revealed that combined genes polymorphism conferred three fold increased risk of development of cITP (OR=3.491, 95% CI: 1.235-9.869, p=0.015).

Summary/Conclusions: We hereby report a strong association between combined polymorphisms of both TNF-α & TNF-β genes and susceptibility to chronicity of ITP in Egyptian children. Further studies for gene polymorphisms which could affect the pathogenesis of ITP and facilitate the development of new therapeutic modalities are recommended.

PROGNOSTIC FACTORS IN PRIMARY IMMUNE THROMBOCYTOPENIA (CANCER-ASSOCIATED IMMUNE THROMBOCYTOPENIA)
A. Gkoutsias1, T. Palianopoulos1, E. Pappa2, E. Papapetrou3, C. Tsoussi3, N. Chaliasos1, A. Makis1
1Department of Pediatrics, 2Department of Internal Medicine, 3Hematology Laboratory, University Hospital of Ioannina, Greece, Ioannina, Greece

Background: Primary immune thrombocytopenia (ITP) is an immune disorder with varied course. According the duration of the disease, it is distinguished in newly diagnosed (<3 months), persistent (3-12 months) and chronic (>12 months). International studies have highlighted prognostic factors for each form of ITP, but similar studies have yet to be performed in Greece.

Aims: The evaluation of clinical and laboratory parameters and the identification of prognostic markers for the three forms of the disease in children with ITP from an academic reference center in Greece.

Methods: This retrospective study included 57 children with ITP in the past 13 years, aged 1-16 years (median age 5.2). The following data were recorded: age, gender, preceding infection, bleeding type, duration of symptoms and platelet count at the diagnosis, treatment, disease course and immunological markers and comparison was made among the three types of ITP.

Results: 39 children had newly diagnosed, 4 had persistent and 14 had chronic disease. Due to the small number of children with persistent form they were incorporated in the group of children with newly diagnosed ITP. In chronic ITP children are more likely be above 10 years of age (p=0.015) and to have gradual initiation of the disease (p=0.001) compared with newly diagnosed/persistent group (57% vs 21% and 79% vs 9%, respectively). Recent history of infection was found mainly in newly diagnosed/persistent group (79% vs 21%, p=0.013). Platelet count below 10 x 10^9/L at diagnosis was found more frequently in newly diagnosed/persistent group (79% vs 36%, p=0.01). Similar, but not statistically significant difference, was found with mucosal bleedings (70% vs 50%, p=0.81). Children with newly diagnosed/persistent disease had less frequently impaired immunological markers (12% vs 65%, p=0.03) and receptor PAR1 and PAR4 were less frequently found (79% vs 36%, p=0.01). None of the children exhibited severe spontaneous bleeding.

Summary/Conclusions: Even though ITP in children is usually a self-limited disease, with rare serious bleeding complications, the newly diagnosed/persistent and the chronic form of the disease are characterized by different predictive parameters that can be used in clinical practice.

PB2099
CANCER-ASSOCIATED IMMUNE THROMBOCYTOPENIA
G. Pinto1, P. Herrera1
1Hematology, Hospital Ramon y Cajal, Madrid, Spain

Background: Cases of cancer-associated immune thrombocytopenia (IT) have been reported recently, but there are few reports and case series that describe clinical features and response to treatment.

Aims: We report our experience of 10 years at a single hospital in Spain, in patients with IT concurrent with neoplasia.

Methods: We identified the patients by data search of hospital records from 2006 to 2016, with diagnosis of IT with previous diagnosis of cancer, not related with chemotherapy or radiotherapy, not suggestive of bone marrow infiltration, drug-induced, infection of disseminated intravascular coagulation. For the diagnosis, the examination of number of children with persistent was not mandatory.

Results: The two most common cancers associated with IT were bladder and lung neoplasms, but the occurrence of prior cancer (third part of patients) was not uncommon. The IT can appear at any stages of cancer, and it is mainly detected at the first two years after the diagnosis when the patient have been in acceptable antitumoral response. They usually manifest with very low platelet count <20,000, but not always with evident clinical bleeding. The response to therapy was fast and complete with corticoids (usually in the first week) in the majority of patients, but some cases require the combination second line with immunoglobulins or thrombopoietin receptor agonists, and in the follow-up, the response was persistent without recurrence in the first year post-treatment (Table 1).

Table 1.

Summary/Conclusions: The CAIT is a rare hematological paraneoplastic syndrome that occur in solid tumors, usually associated to low platelet count but without life-threatening bleeding, requiring therapy with corticosteroids as first line, and generally related with a benign clinical course with a rapid and persistent response.

PB2100
THE ROLE OF MEAN PLATELET VOLUME IN NEONATAL SEPSIS: AN RETROSPECTIVE CASE CONTROL STUDY IN A LEVEL III NEONATAL INTENSIVE CARE UNIT
A. Srinivasan1, A. Meara1, M. Marron-Corwin1
1Pediatrics, Harlem Hospital Center, New York, United States

Background: The increased mortality associated with neonatal sepsis continues to be of major concern. A better understanding of neonatal sepsis may facilitate the development of new therapeutic strategies. Mean platelet volume (MPV) is a marker of platelet activation, and it has been reported to be predictive of neonatal sepsis. However, the predictive value of MPV in neonatal sepsis has never been investigated.
Background: Sepsis is a relatively common diagnosis in the neonatal period. Apart from blood cultures which are the gold standard, C-reactive protein (CRP), total white blood cell count (WBC) and the ratio of immature to mature neutrophils (I: T) are considered to be useful markers of sepsis in the neonatal period. There are a few studies that show that mean platelet volume (MPV) is elevated in infectious disease processes.

Aims: The aim of this study was to investigate whether mean platelet volume is increased in neonates with sepsis.

Methods: Only term neonates were included in the study. Exclusion criteria included: (a) Any neonate born with a genetic defect, (b) Any neonate with suspected immunodeficiency, (c) Any neonate requiring surgery in the post-natal period, (d) Neonates admitted to NICU for hyperbilirubinemia, (e) Neonates requiring extensive resuscitation at birth resulting in documented Hypoxic Ischemic Encephalopathy or requiring transfer to a Regional Perinatal Center. Medical records were reviewed from March 2015 to June 2016 and a total of 114 eligible neonates were included in the study and they were divided into 2 groups: neonates with clinical sepsis, as defined by either culture positivity and/or clinical features plus treatment with antibiotics exceeding 48 hours) and 75 healthy controls (as defined by neonates in whom antibiotics were never started or discontinued when cultures were negative for 48 hours and the absence of clinical features of sepsis). Total white blood cell count, C-reactive protein, immature to total neutrophil count and mean platelet volume drawn on two occasions (first within 24 hours and the second between 24 to 48 hours after delivery) were compared between the two groups.

Results: There was no statistically significant difference in the mean platelet volume between the study group and the control group (p value 0.9 in the first 24 hours and p value 0.7 in the 24-48 hour sample). There was however, a statistically significant difference between immature to total neutrophil count and C-reactive protein on both samples (p value <0.0001) (Table 1).

| Summary/Conclusions: | In our study there was no statistically significant difference in the mean platelet volume values between neonates with sepsis and healthy controls. C-reactive protein and immature to total neutrophil count continue to be reliable markers of neonatal sepsis. |

PB2101

IS PLATELET TRANSFUSION WARRANTED IN PATIENTS WITH ACUTE TTP REQUIRING CENTRAL VENOUS CATHETER INSERTION? R. Lau1, T. Dufour2, M. Sakr1

1Postgraduate Department, Central Manchester Foundation Trust, Manchester, UK
2The Royal Dhalia Haemostasis and Thrombosis Centre, Royal Liverpool University Hospital, Liverpool, United Kingdom

Background: Thrombotic thrombocytopenic purpura (TTP) has a high mortality rate. The cornerstone of management is plasma exchange (PE) which usually requires urgent insertion of a central venous catheter. Patients often have a platelet count of <50x10^9/L at presentation however, National BCSH Guidance advises against platelet transfusion in TTP due to the perceived high aggregability state and risk of associated fatal thrombosis. The risk of thrombocytopenia related haemorrhage however creates anxiety and dilemma for the team responsible for line insertion and may lead to delays or unnecessary platelet transfusion.

Aims: The aim of the study is determine the average platelet count at time of line insertion and to see if any bleeding complications are observed.

Methods: We retrospectively reviewed all central venous catheter lines inserted in patients presenting to a regional TTP Centre over a 4-year period from 2012-2016.

Results: A total of 48 patients confirmed to have TTP with an ADAMTS13 <5% underwent line insertion: 94 central venous catheter lines were inserted: 40% femoral, 60%–internal jugular vein. The median number of lines inserted per patient episode was 3, with a range of 1-5. Median presenting platelet count for first line insertion was 25x10^9/L (IQR 9-26 x10^9/L). 70% of lines were inserted by critical care and the remaining 30% by interventional radiology. Platelet transfusion does not diminish core line insertion. Platelet bleeding complications were documented during or after line insertion. 5 patients had ‘excessive oozing at the insertion site’ documented, within the first 24 hours of insertion, for which no intervention was required. There were no deaths related to line insertion.

| Summary/Conclusions: | In conclusion, this study shows no significant bleeding risk associated with central venous catheter insertion in thromboticocytopenic patients presenting with TTP. The results support guidance against prophylactic platelet transfusion in this setting and provide reassurance for teams tasked with central line insertion in this critically unwell patient group. |

PB2102

LONG-TERM EFFICACY AND SAFETY OF THROMBOPOIETIN AGONISTS IN ADULT REFRACTORY CHRONIC IMMUNE THROMBOCYTOPENIA M. Kaliou1, E. Gavriilaki1,*, G. Papaioannou1, Z. Bousiou1, M. Iskas1, C. Vadikoliou1, C. Lalayanni1, A. Athanassadou1, R. Saloum1, A. Anagnostopoulos1

1Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: Management of chronic immune thrombocytopenia (cITP) aims not only to increase and maintain platelet counts in safe levels, but also to improve the quality of life. Three thrombopoietin agonists eltrombopag and romiplostim have been approved in refractory ITP. The lack of randomized studies allows only for real-world data comparison on the two agents.

Aims: In the present study we evaluate and compare long-term efficacy and safety of eltrombopag and romiplostim in clinical practice and assess the switching feasibility between the two agonists.

Methods: Treatment with thrombopoietin agonists was initiated in 20 adult patients (pts) with refractory cITP between June 2011-2016. Patients resistant or intolerant to the first agonist switched to the second one. Complete response (CR) was defined as a platelet count of ≥100x10^9/L.

Results: Ertrombopag was administered in 15 pts, 6 male:9 female with a median age of 46 years (19-75 yrs) for 13 months (1-4.54 mo). Patients had received a median of 1 previous treatment (range 1-7); corticosteroids (15/15), intravenous immunoglobulin (5/15), rituximab (2/15), vincristine (1/15), cyclophosphamide (2/15), romiplostim (2/15), danazol (1/15) and splenectomy (1/15). Before eltrombopag treatment, the majority (8/15) showed grade 4 (WHO) thrombocytopenia. Initial dose was 50 mg and increased to 75 mg daily in 3/15 pts and in combination with corticosteroids that were gradually tapered by the 5th week in 12/15. Median platelets value by the 2nd week of administration was 140x10^9/L (5-450x10^9/L); whereas, by the 4th week increased to 185x10^9/L (16-500x10^9/L). At the end of follow-up, all patients but one achieved CR with median platelets of 145x10^9/L (60-400x10^9/L). Regarding adverse events, 1/15 pt presented hemolytic anemia, 1/15 pt hepatotoxicity grade 2 with episodes of thrombocytopenia grade 4 and 1/15 pt pulmonary embolism during the second month of treatment. The latter 2 pts switched to romiplostim. Romiplostim was administered in 9 pts, 4 male:5 female with a median age of 45 years (33-67 yrs) for 14 months (4.4-40.1). They had received a median of 3 previous treatments (range 1-8); corticosteroids (9/9), intravenous immunoglobulin (6/9), rituximab (6/9), vincristine (2/9), cyclophosphamide (2/9), eltrombopag (2/9), danazol (1/9) and splenectomy (2/9). The majority (5/9) presented thrombocytopenia grade 4 before romiplostim. Median platelets number by the 2nd week of administration was 50x10^9/L (9-140x10^9/L); whereas, by the 4th week increased to 115x10^9/L (20-400x10^9/L). At the end of follow-up, 6/9 patients achieved CR with median platelets at 145x10^9/L (110-400x10^9/L). No adverse events associated with romiplostim treatment were reported.

| Summary/Conclusions: | Our real-world data suggest that both eltrombopag and romiplostim are safe, well tolerated and highly effective in refractory ITP. Both agents are effective in patients that switched to the other agonist achieved CR without adverse events. Future studies will determine predisposing factors for adverse events and more accurate classification of patients that will allow for better treatment guidance. |

VITAMIN D RECEPTOR GENE POLYMORPHISMS IN ADULT PRIMARY IMMUNE THROMBOCYTOPENIA M. Sakr1

1Internal Medicine- Hematology, Menoufia University, Cairo, Egypt

Background: Recently, several studies have demonstrated the role of vitamin
Aim: The aim of this study is to assess the association of vitamin D receptor (VDR) polymorphisms in the development of autoimmune diseases. Vitamin D affects both innate and adaptive immune responses that have been blamed in immune thrombocytopenia (ITP) pathogenesis.

Methods: Vitamin D receptor polymorphism BsmI in cases of adult primary idiopathic thrombocytopenia (ITP) was detected by Polymerase Chain Reaction followed by Restriction Fragment Length Polymorphism (PCR–RFLP). Deoxynribonucleic acid (DNA) samples were extracted from peripheral blood of 40 ITP patients and 60 geographically and ethnically matched healthy controls.

Results: Statistically significant difference was found in the BsmI polymorphism between ITP patients and controls ($\chi^2=8.77, P$ value=0.01). The BsmI polymorphism B allele was higher in ITP group than that in controls but in statistically insignificant difference ($\chi^2=2.125, P=0.145$). bb genotype played a protective role in ITP incidence.

Summary/Conclusions: This is the first published report on VDR gene polymorphisms in adult primary ITP patients. The BsmI genotype was associated with increased risk for ITP incidence with no obvious effect on bleeding severity, platelet count nor site of bleeding.

A survey of the treatment of the prevention of NAIT in the UK and Ireland

Background: Neonatal alloimmune thrombocytopenia (NAIT) is caused by maternal antibodies generated against alloantigens carried on fetal platelets, which cross the placenta and induce destruction of platelets in the fetus. In most cases the maternal immunisation is triggered by exposure to fetal platelets at delivery. As a result, the clinical presentation tends to be more severe in subsequent pregnancies. Recent studies and guidelines have suggested that intravenous immunoglobulin (IVIG) with or without steroids can significantly reduce the severity of thrombocytopenia in subsequent pregnancies.

Aims: We set out to establish if there is consistency in the management of the prevention of NAIT across Ireland and the United Kingdom (UK).

Methods: A survey was set up on Survey Monkey and all members of the UK-Ireland Haematology group were contacted by email with a link to the survey in January 2015. In total 90 individual Specialists were contacted across 70 centres.

Results: 30 responses were received to the following questions. Who manages the prevention of NAIT in your centre? 34% of respondents stated that it was managed jointly by haematologist/feto-maternal specialists, with 26% responding it was overseen solely by haematologists and 40% solely by feto-maternal specialists. Secondly what risk stratification each respondent used to decide risk of NAIT in the current pregnancy? 82% stated that they took into account multiple risk factors but 18% stratified risk based only on the outcome of previous pregnancy. Thirdly how many groups do you define after risk stratification? 60% identified 3 strata of risk (standard, high and very high) with 40% classifying two risk groups (standard versus high risk). Fourthly respondents outlined their management of a standard risk group defined as confirmed thrombocytopenia with antibody. 43% give IVIG 1g/kg weekly from 20 weeks, 28% give 1g/kg from 20 to 24 weeks, 32 weeks starting with 1g/kg every two weeks. 23% referred to feto-maternal specialist to decide IVIG. Just 20% give 0.5mg/kg of steroids from 20 or 32 weeks. For high risk pregnancies defined as confirmed antibody positive with previous intracranial haemorrhage (ICH) after 28 weeks: 36% of centres give IVIG 1g/kg from 20 weeks, 36% give 1g/kg from 20 weeks increasing to 2g/kg at 32 weeks with 14% giving 2g/kg from 20 weeks and 14% initiating at 12 weeks. 40% gave 0.5mg/kg of steroids from 20 or 32 weeks. For high risk pregnancies defined as confirmed antibody positive with previous intracranial haemorrhage (ICH) after 28 weeks: 36% of centres give IVIG 1g/kg from 20 weeks, 36% give 1g/kg from 20 weeks increasing to 2g/kg at 32 weeks with 14% giving 2g/kg from 20 weeks and 14% initiating at 12 weeks. 40% gave 0.5mg/kg of steroids from 20 or 32 weeks.

Summary/Conclusions: In chronic ITP, increased levels of ROS are associated with elevated autoantibody production. Autoantibodies are involved in platelet destruction via a highly immunogenic activity. On the other hand, association of H. pylori infection, via chronic inflammation, led to a supplementary increase in ROS levels and increased platelet destruction.

Aims: To evaluate management and results of pregnancy and delivery on pregnant ITP women and on their offspring.

Methods: All women diagnosed of primary ITP (according to international consensus criteria) from 2011 to 2016 in 23 Spanish Haematology Departments who had at least one pregnancy after ITP onset were included in this registry.

Results: We included 270 primary ITP pregnancies from 184 women. At pregnancy diagnosis, we observed a majority of chronic ITP cases (71.4%). At ITP diagnosis, median age of our case-series was 23 years (IQR, 19-29) and median age of our case-series was 23 years (IQR, 19-29) and median age of our case-series was 23 years (IQR, 19-29) and median age of our case-series was 23 years (IQR, 19-29).

Background: Chronic idiopathic thrombocytopenic purpura (ITP) is an acquired disease characterized by a low platelet count caused by an immunological peripheral platelet destruction or a decreased platelet production. Several studies have shown increased reactive oxygen species (ROS) levels in chronic ITP and also a possible association between Helicobacter pylori (H. pylori) infection and immunological peripheral platelet destruction.

Aims: In this study, we evaluated whether patients with chronic ITP and H. pylori infection exhibit higher ROS levels compared to patients with chronic ITP and no H. pylori infection and whether there are statistically significant differences between the two groups.

Methods: We studied 29 patients with chronic ITP (median age 39 years) hospitalized in the Clinic of Hematology, Filantropia City Hospital, Craiova, Romania, between 2014 and 2016 (informed consent obtained). All patients were diagnosed with ITP, other causes of thrombocytopenia having been ruled out by bone marrow aspiration. The patients were divided in two groups: patients with ITP and H. pylori infection (group A) and patients with chronic ITP without Helicobacter pylori infection (group B). 31 patients with chronic ITP were included in both groups (between 2.8 – 3.6 mmol/L H2O2). However, statistically significant differences were found in favour of group A, with higher ROS values than group B. The A group also associated lower platelet counts and more patients pertaining to this group relapsed in comparison to group B.

Summary/Conclusions: Chronic ITP increased levels of ROS are associated with elevated autoantibody production. Autoantibodies are involved in platelet destruction via a highly immunogenic activity. On the other hand, association of H. pylori infection, via chronic inflammation, led to a supplementary increase in ROS levels and increased platelet destruction.

Aims: To evaluate management and results of pregnancy and delivery on pregnant ITP women and on their offspring.

Methods: All women diagnosed of pregnancy (according to international consensus criteria) from 2011 to 2016 in 23 Spanish Haematology Departments who had at least one pregnancy after ITP onset were included in this registry.

Results: We included 270 primary ITP pregnancies from 184 women. At pregnancy diagnosis, we observed a majority of chronic ITP cases (71.4%). At ITP diagnosis, median age of our case-series was 23 years (IQR, 19-29) and median age of our case-series was 23 years (IQR, 19-29).
50.8% of women received corticosteroids, immunoglobulins (IVIG) (16.9%), rituximab (6.8%) and splenectomy (8.4%) vs ITP treatments between or before new pregnancies. On the other hand, 26.4% of women needed treatment for ITP during pregnancy, mainly steroids (13.5%) and IVIG (10.2%). The median platelet-count nadir during pregnancy was 74 x 10^9/l (IQR, 36-172). 127 (47%) pregnancies suffered from non-haemostatic platelet levels (less than 50 x 10^9/l) vs 73 (27.0%) women who achieved less than 30 x 10^9/l. 56 (20.7%) women exhibited hemorrhagic symptoms, being 30 (11.1%) of them severe bleedings.

Regarding type of delivery, this was vaginal in 63.4% of pregnancies and cesarean sections 30.5%. Median platelet count at delivery was 110 x 10^9/l (IQR, 70-181). 43 patients (23.4%) experienced 57 bleeding episodes. We only observed 48 cases (20.4%) of neonatal thrombocytopenia among 235 living newborns.

Summary/Conclusions: Our results are comparable to previously reported studies. No severe bleeding complications during pregnancy or delivery were observed in our case series. Rate of neonatal thrombocytopenia, and therefore, newborn bleeding is low.

Background: Immune thrombocytopenia (ITP) consists of various acquired disorders caused by autoantibodies against platelets resulting in increased platelet destruction and impaired thrombopoiesis. ITP is characterized as primary when an underlying etiology cannot be identified and secondary when a certain etiology exists. Data concerning ITP characteristics at a national level are limited.

Aims: The purpose of the study was to access systematically the demographic, clinical, laboratory and treatment-related data of ITP in Greece based on the national database (ITP registry) operated and supported by the Hellenic Society of Haematology.

Methods: In total, 696 ITP patient data were collected over 2013-2016. The data source is a unique database initiated and managed by the Haematology Department of the University of Crete (UoC) and supported by the Center of Information and Communications Technologies of the UoC. The registry has been configured for national and regional base usage considering hospitals as the core unit. A certain etiology when an underling etiology cannot be access to a platform where he/she can record and study patients’ data. The entire project has been developed using the robust open source tools of operating systems and Relational Data Base Management System (RDBMS) packages.

Results: We analyzed data from 696 adult ITP patients registered from 14 different hospitals of Greece. The median age at diagnosis was 53 years (range 15-97 years). Two peaks were observed at the age of 19-30 and 71-80 years. There was a female (60.89%) versus male (39.1%) predominance with higher frequency of females in younger (19-30 years) and of males in older (71-80 years) ages. Females appeared with more severe thrombocytopenia. The median platelet-count nadir during pregnancy was 74 x 10^9/l (IQR, 36-172). 127 (47%) pregnancies suffered from non-haemostatic platelet levels (less than 50 x 10^9/l) vs 73 (27.0%) women who achieved less than 30 x 10^9/l. 56 (20.7%) women exhibited hemorrhagic symptoms, being 30 (11.1%) of them severe bleedings.

Regarding type of delivery, this was vaginal in 63.4% of pregnancies and cesarean sections 30.5%. Median platelet count at delivery was 110 x 10^9/l (IQR, 70-181). 43 patients (23.4%) experienced 57 bleeding episodes. We only observed 48 cases (20.4%) of neonatal thrombocytopenia among 235 living newborns.

Summary/Conclusions: Our results are comparable to previously reported studies. No severe bleeding complications during pregnancy or delivery were observed in our case series. Rate of neonatal thrombocytopenia, and therefore, newborn bleeding is low.

PRESENTING SYMPTOMS AFFECT OUTCOME IN IMMUNE MEDIATED THROMBOTIC THROMBOCYTOPENIC PURPURA

J. Khwaja1, F. Alwan1, C. Vendramin2, K. Langley2, M. Thomas3, J.P. Westwood4, M. Scully4

1Haematology Department, University College London Hospital, 2Haemostasis Research Unit, University College London, London, United Kingdom

Background: Whilst immune mediated Thrombotic Thrombocytopenic Purpura (TTP) has classically been suspected by the presence of a pentad of symptoms (microangiopathic haemolytic anaemia, fever, disturbed neurological function, renal failure and thrombocytopenia), the limitations of this have long been recognized and a wide variety of symptoms are seen on initial presentation.

Aims: A retrospective review of the significance of specific symptoms and their duration on mortality.

Methods: A retrospective review of all consecutive admissions to a single tertiary center between 2009 and 2015. Only patients who required plasma exchange were included. Patients’ symptoms and their duration were reviewed in addition to presenting anti-ADAMTS13 IgG antibody levels and ADAMTS13 antigen levels, both of which have previously been found to have prognostic significance.

Results: 106 patients (68% female) were included with a median age of 48.58% were Caucasian and 19.8% Afro-Caribbean. The mortality rate was 7.4% (n=8). 47% of patients had neurological symptoms on presentation, 24% reported a bleeding history and 12% a recent infection. The most common presenting symptoms were headache (27.4%), bleeding (24%) spontaneous bruising/petechial (19.8%). The anti-ADAMTS13 IgG level was not however significantly higher in patients with neurological symptoms compared to others suggesting microangiopathic hemiplegia or focal weakness/drop (16%). The highest rates of mortality were seen in patients who experienced loss of consciousness (mortality 33.3%), abdominal pain (morbidity 22.2%) and heavy bleeding (mortality 16.7%). nursery in addition to presenting anti-ADAMTS13 IgG antibody levels and ADAMTS13 antigen levels, both of which have previously been found to have prognostic significance.

Results: 106 patients (68% female) were included with a median age of 48.58% were Caucasian and 19.8% Afro-Caribbean. The mortality rate was 7.4% (n=8). 47% of patients had neurological symptoms on presentation, 24% reported a bleeding history and 12% a recent infection. NOVEL TECHNIQUES FOR MONITORING GALNZZM THROMBASTHENIA PATIENT UNDERGOING SURGICAL INTERVENTIONS A. Barg1,2, H. Hauschner1,2, M. Misgav1,2, E. Avishai1, N. Rosenberg1,2, G. Kenet1,2
1Institute of thrombosis and hemostasis, Sheba medical center, 2Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Background: Glanzmann thrombasthenia (GT) patients undergoing surgical procedures are often treated by platelet transfusion. However many GT patients who have been previously exposed to platelets may form antibodies either against the missing αIIbβ3 antigen or directed against MHC-class molecules thus hampering the efficacy of care. Due to the rarity of disease there is paucity of data regarding platelet transfusion protocols during the perioperative period. We herein describe our experience with monitoring the proportion of donor platelets following transfusion, and their contribution to whole blood clot formation.

Aims: To describe the use of flow cytometry (FC) analysis in order to detect donor transfused platelets in a GT patient undergoing a minor surgical procedure and to assess the correlation between FC analysis and the results of Rotational thromboelastography (ROTEM).

Methods: A nine year old female patient with GT underwent teeth extraction. The patient received platelet transfusion around the procedure. Complete blood counts, ROTEM, FC to detect the number of donor platelets and their ADP dependent activation, were sampled and followed till 7 days post teeth extraction.

Results: Prior to teeth extraction upon injection of local anesthetics patient developed a buccal hematoma probably owing to local blood vessel penetration. The patient did not experience any post extraction bleeding. Hematoma was absorbed within several days. Post transfusion platelets FC demonstrated 20.6% donor platelets equivalent to 55,620 donor platelets. Platelets activation was determined following ADP addition by examination CD62 antigen expression. Seven days post platelet transfusion FC demonstrated 2.6% equivalent to 8,658 donor plantlets. The decline in the number of active platelets was associated with a reduced clot firmness (MCF) and lower ø-angle as assessed by ROTEM (Figure 1).

Summary/Conclusions: Status of c-mpl in ITP is ambiguous. Significant level of positivity in patient group who did not have splenectomy might be useful for splenectomy indication.

CAN HISTOCHEMICAL C-MPL POSITIVITY IN BONE MARROW BE A PREDICTOR FOR SPLENECTOMY IN IMMUNE THROMBOCYTOPENIA? I. Yavasoglu1, N. Gencer1, F. Cantas2, F. Doger3, Z. Bolaman1,2
1Adult Hematology, 2Biostatistics, 3Pathology, Adnan Menderes University Medical Faculty, Aydin, Turkey

Background: Splenectomy is used as the second line therapy in patients with immune thrombocytopenia (ITP). However, there is no parameter predicting splenectomy decision.

Aims: Aim of the present study was to evaluate immune histochemical Cloned Myeloid Leukemia Virus (c-mpl) positivity in bone marrow specimens of ITP patients with or without splenectomy indications.

Methods: Bone marrow specimens were taken from 24 patients who were diagnosed with ITP and who had splenectomy (15 female, 10 male, mean age 50±16) before splenectomy and 30 patients who were diagnosed with ITP but did not have splenectomy (15 female, 15 male, mean age 52±19). c-mpl staining was carried out retrospectively. Immunohistochemical (IHC) staining using Avidin-Biotin complex system (ABC) was conducted. For IHC, sections prepared from blocks were taken onto poly-L-lysine coated slides (MicroSlides SpreCoat X-tra, Surgipath, Richmond, IL, USA) and kept in an incubator at 37 °C overnight. Dissections were treated with IHC-c-mpl Santa Cruz sc-12009 (Santa Cruz-biotech-13187) stain. Cytoplasmic and nuclear staining was observed in megakaryocytes using IHC c-MPL and vitamin D. Evaluation was made based on the intensity of the staining; i.e. negative (0), weak (+1), moderate (+2) and strong (+3) (1). All patients who had splenectomy were in chronic phase of the disease. The present study was supported as a Scientific Research project by Adnan Menderes University (TPF-15027).

Results: c-mpl positivity was statistically significant in patient group who did not have splenectomy (Table 1). In patient group who had splenectomy, c-mpl was not associated with refractory status.

Table 1. c-mpl positivity in patients group who had and did not have splenectomy.

Summary/Conclusions: Status of c-mpl in ITP is ambiguous. Significant level of positivity in patient group who did not have splenectomy might be useful for splenectomy indication.
Summary/Conclusions: Thrombocytopenia is a potential risk of bleeding during the labor. A high IPF indicates either consumptive or recovering thrombocytopenic disorders, such as immune thrombocytopenic purpura, while low IPF is characteristic of bone marrow suppression states. Although not directly used in clinical decision making, the reference range is critical to the introduction of new parameters and the interpretation of laboratory results. Our results suggest that the role was laboratory parameter in the measured and a level <10% might be an independent bleeding factor which can be useful for detecting high risk pregnant patients. It should be corroborated in further studies.

DOES EARLY RESPONSE TO FIRST LINE CORTICOSTEROID THERAPY PREDICT REQUIREMENT FOR SECOND LINE THERAPY IN IMMUNE THROMBOCYTOPENIC PURPURA (ITP) PATIENTS?

S. Kucukyurt Kaya1, 2, S. M. Bakanay1, 3, T. Hacibekiroglu2, 2, A. Akinci1, 2, M. Gündüz1, 3, S. Mara2, 4, A. Senturk Yilmaz1, 1, Dilek1
1Department of Hematology, Ankara Yildirim Beyazit University, 2Department of Hematology, Ankara-Atatürk Training and Research Hospital, Ankara, Turkey

Background: Immune thrombocytopenia (ITP) is an acquired, immune-mediated disease that is characterized by increased destruction of platelets by autoantibodies. ITP is characterized by mucocutaneous bleeding. Rarely, life-threatening bleeding such as central nervous system bleeding can occur. Typically, patients have isolated thrombocytopenia. The diagnosis of ITP is one of exclusion. Corticosteroids are chosen as a first-line therapy for adult patients who require treatment. Responses to first line therapy with corticosteroids is about 80% with approximately 20% to 30% long term complete remission. Most patients finally relapse, requiring second-line therapy. Aims: Our aim was to evaluate the potential of early platelet response to corticosteroid therapy on achieving long term complete remission.

Methods: We retrospectively evaluated 43 ITP patients who were followed-up at our institution. All patients’ thrombocyte counts were below 30 x10^9/L at diagnosis. All patients received initially methylprednisolone (MP) 1 mg/kg/day. For patients who responded with platelet count ≥150 x10^9/L methylprednisolone was tapered over 3 months. Those who were unresponsive to MP or relapsed after a complete response, were treated with second line therapies that splenectomy or medical treatment agents. The platelet counts of the patients on day 0, 3 and 7 were evaluated by complete blood counts and were confirmed with peripheral smears examination. Effect of the platelet counts on day 3 and 7 were compared in terms of second line therapy requirement or not. A platelet count of >30 x10^9/L on day 3 and >100 x10^9/L on day 7 was considered as a complete response. Vaccination against encapsulated organisms was given and imaging was done to detect accessory spleen before splenectomy.

Results: Baseline characteristics of the cohort of 43 patients with an initial diagnosis of ITP are shown in Table 1. The mean age at diagnosis was 51 years (18-84) with female/male : 25/18. All patients presented with severe thrombocytopenia (platelet counts below 30.0 x10^9/L). Most patients presented with mucocutaneous bleeding (n=39), only three patients had genitourinary or gastrointestinal tract bleeding and one patient was asymptomatic. Bone marrow smears and autoimmune screen were negative in all patients. Eighteen patients (41.9%) had positive virology for hepatitis B and C. All cases were under treatment by low dose corticosteroid in addition to another immunosuppression medication. No correlation between measured cytokines and platelet count.

Summary/Conclusions: In era of novel therapies used as second line, comparing a significant association was found in correlation analysis (p<0.05). The higher platelet count achieved early (end of week 1, 2, and 3) after rituximab is suggestive for a better response later (at end of M3). FcγRiIIa RR genotype is predictive for better response to rituximab in ITP patients.

PB2114

IMMUNE THROMBOCYTOPENIA, EGYPTIAN EXPERIENCE WITH STUDY OF IL-17, IFGB, IL-35 AND IL-12 CYTOKINES IN CHRONIC AND PERSISTENT IMMUNE THROMBOCYTOPENIA PATIENTS

N. El Husseiny1, 2
1kasr al aini hospital, cairo, Egypt

Background: The role of T cells in the pathophysiology of immune thrombocytopenia (ITP) is heterogeneous and complex. It has been studied in active and reactive ITP but not to same extend in chronic and persistent type.

Aims: In this study we review the demographic features of 150 immune thrombocytopenic Egyptian patients and for cases who were chronic and persistent with negative both autoimmun screen and virology for hepatitis B and C.

Methods: We measured IL-12, IL-35, IL-17 and TGF-B by ELISA to assess role of subtypes of T cells in the pathophysiology of ITP.

Results: Our results revealed Chronic and persistent cases who fulfilled the criteria for cytokine assay were 45 cases with a mean (± SD) age of 31.60±8.78 years. Thirty two patients were presented with skin manifestations (71.1%). Eight patients presented with mucocutaneous bleeding (18.8%) and five patients presented with genitourinary or gastrointestinal tract bleeding (11.1%). Comparison between the cases studied and control groups revealed statistically significant differences (P value 0.001) being higher in patients achieved CR than who achieved PR or NR.

Summary/Conclusions: The higher platelet count achieved early (end of week 1, 2, and 3) after rituximab is suggestive for a better response later (at end of M3). FcγRiIIa RR genotype is predictive for better response to rituximab in ITP patients.
PB2115

SWITCH OF TPO-MIMETICS IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA: FLORENCE MONOCENTRIC EXPERIENCE

C. Biagiotti1, V. Carrai1, F. Bacchiardi1, A. Bosi1, 1Hematology, Careggi Hospital, Florence, Italy

Background: Primary immune thrombocytopenia (ITP) is an immune-mediated condition characterized by isolated thrombocytopenia, with peripheral blood platelet counts <100.000/µl in the absence of an identifiable underlying cause of thrombocytopenia. Clinical studies in patients with ITP demonstrated that thrombopoietin (TPO) mimetics increase platelet production and can outpace platelet destruction.

Aims: We evaluated patients treated with both TPO-mimetics.

Methods: From November 2008 and February 2017, 65 patients were treated with TPO-mimetics with a median follow up of 29 months (1-96); 39 patients underwent therapy with Romiplostim and 26 to Eltrombopag. In our study we evaluated 18 patients who received both therapies: among patients treated at first with Romiplostim, 10 patients (9/6,1 M) switched to Eltrombopag and 8 patients (3 M, 5 F) switched from Eltrombopag to Romiplostim. In the group of 10 patients treated at first with Romiplostim, 5 patients started Eltrombopag because were no responders, 3, for loss of response and 2 patients because of adverse events. In the group of 8 patients at first treated with Eltrombopag, 4 patients didn’t obtain any response with Eltrombopag and switched to Romiplostim, 1 patient underwent to Romiplostim for loss of response and 3 patients because of adverse events.

Results: Among patients switched from Romiplostim to Eltrombopag, 2 achieved complete response, 4 response and 4 were no responders; among patients switched from Eltrombopag to Romiplostim, 4 obtained complete response, 3 response, 1 was no responder.

Summary/Conclusions: Romiplostim and Eltrombopag stimulate the TPO-R but have different mechanisms of action, therefore, in our limited experience switching from one thrombopoietic receptoragonist to the other could be beneficial in clinical practice for patients with severe chronic immune thrombocytopenia who failed to respond or experienced adverse events to the first treatment.

COEXISTENCE OF GLANZMANN’S THROMBASTHENIA AND MAPLE SYRUP URINE DISEASE: IMPLICATIONS FOR HEMOSTATIC MANAGEMENT

M. Elshinawy1,*, A. Alrawas2, Y. Wali2, 1Pediatric Hematology, SQUH, Alexandria University, Muscat, Oman, Egypt, 2Pediatric Hematology, SULTAN QABOOS UNIVERSITY HOSPITAL, Muscat, Oman

Background: In Oman, autosomal recessive disorders are relatively commoner than western communities due to the high prevalence of inter-tribal marriage. Unfortunately, some patients have got more than one autosomal recessive genetic disorder, owing to complex consanguinity which might further complicate proper management plans.

Aims: To report 2 cases of combined Glanzmann’s thrombasthenia and MSUD, and to review the existing data of platelet function disorders in Oman.

Methods: Case report and retrospective data analysis of all cases with confirmed or suspected platelet function disorders in Pediatric Hematology Unit, Sultan Qaboos University Hospital, Muscat, Oman from January 2006 till December 2016.

Results: Among them, we report 2 cases: 1 girl who has a known case of MSUD. Her parents are double first cousins (from both maternal and paternal sides). At the age of 3 months, she required Gastrostomy tube (G-tube) insertion. Preoperatively, full blood count and coagulation screen were perfectly normal. Unfortunately, she developed profuse bleeding at the site of G-tube insertion, followed by massive hematemesis. The patient received multiple blood products, but bleeding didn’t stop. As an emergency measure, recombinant activated factor VII (rFVIIa) was given and resulted in cessation of bleeding. Platelet aggregation studies revealed defective aggregation with ADP, arachidonic acid, collagen and epinephrine which is consistent with Glanzmann’s thrombasthenia. The diagnosis was further confirmed by platelet cowperometry which showed no activity with CD41 and CD61, indicating absent GPllb/llla complex. The patient experienced a severe bleeding phenotype, which is further complicated by multiple coexisting factors, including the recurrent episodes of metabolic crises which provoked worsening of platelet function, the development of platelet refractoriness at the age of 1 year, and the need for recurrent invasive procedures such as G-tube and central line insertion. Currently, the bleeding episodes are managed by rFVIIa at a dose of 120-180 µg/kg/dose. Excluding von Willebrand disease, we have 38 cases of confirmed or suspected platelet function disorders in our center, including 15 cases with Glanzmann’s thrombasthenia, 7 cases with Bernard-Soulier syndrome, 5 cases with May–Hegglin anomaly and 11 cases of suspected, yet unconfirmed platelet storage pool deficiency.

Summary/Conclusions: In conclusion, children with platelet function disorders still have plenty of unmet needs, ranging from deficient accurate diagnostic factors to the need for consensus management guidelines. The coexistence of another hereditary disorder may result in mutual management difficulties of both diseases. In developing countries, proper registry is needed to establish optimum care of such rare disorders.
ADP is not good enough to detect clopidogrel-mediated platelet dysfunction since it is not specific for the P2Y12 receptor. The addition of PGE1 to the ADP test may increase its sensitivity. VerifyNow® assay seems to overestimate the effect of clopidogrel, since hyper-response data are not reproduced by other techniques. According to our results, a high interindividual variability in response to clopidogrel is observed.

PB2118
THROMBOPOIETIN-RECEPTOR AGONISTS IN ITP - EXPERIENCE OF A CENTER
M. J. Teles1,*, M. Gomes2, F. Ferreira2, J. E. Guimaraes2
1Clinical Pathology, 2Clinical Hemathology, Sao Joao Hospital Centre, Porto, Portugal

Background: Thrombopoietin-receptor agonists (TRA), romiplostim and eltrombopag, are part of the treatment of chronic immune thrombocytopenia (ITP), resistant to first line therapy (corticosteroids and/or immunoglobulins) and with a significant bleeding risk. Both are approved for adult patients, but only eltrombopag was approved for pediatric use. When used before spleectomy, these treatments may serve as a bridge for surgery or even postpone/avoid the procedure.

Aims: In this report, we aim to evaluate the response to TRA treatment in patients with ITP and associated side effects in our center.

Methods: Inclusion criteria: patients with ITP resistant to first line treatment. Patients were treated with one of the TRA (romiplostim or eltrombopag) according to institutional guidelines. Clinical evolution and adverse effects were evaluated by retrospective analysis.

Results: Thirty-eight patients with ITP were treated: 31.4% (12) were male and the median age at diagnosis was 38 years. 44.7% (17) had relapsed/resistant disease after spleectomy and 13.2% (5) were treated with a TRA as a bridge for this procedure. Sixteen (42.1%) of ITP patients were treated with romiplostim: 12 patients (75%) had a response to treatment, and 4 (25%) were resistant. In 11 of these patients, romiplostim was replaced by eltrombopag, either because of resistant disease, or more convenient administration (oral therapy). Thirty-three (86.8%) patients were treated with eltrombopag (5 pediatric cases); 27 patients (81.8%) responded while 8 patients had resistant disease (3 of these were HIV positive). The response rate was higher in patients with previous spleenectomy (91.7% with romiplostim and 92.9% with eltrombopag) compared to those with no previous spleenectomy (25% with romiplostim and 73.7% with eltrombopag). Six patients maintained response after treatment suspension (5 treated with eltrombopag and 1 treated with romiplostim). Generally, both treatments were well tolerated, with only one case of eltrombopag suspension because of a thromboembolic event.

Summary/Conclusions: In the current study, both TRA were effective in the treatment of ITP resistant to several lines of treatment, with similar response rates. As described in the literature, the response rate was higher in patients with previous spleenectomy, and some cases maintained response after treatment suspension. The toxicity profile was acceptable. However, there are some concerns about their safety in long term therapy, namely the development of myelofibrosis, cytogenetic abnormalities and malignant evolution. Consequently, they are an urgent need for prospective studies to define the optimum period of treatment and surveillance, especially in pediatric patients. In our center, the median time of treatment with eltrombopag for all patients was 5.5 months (range between 1 to 34 months) and with romiplostim was 12 months (range between 1.5 to 85 months). The duration of treatment with eltrombopag in children and adolescents was around 6 months.

THE EVALUATION OF REACTIVE OXYGEN SPECIES IN ESSENTIAL THROMBOCYTHENIA AND CORRELATION WITH JAK2V617F MUTATION
M.-A. Gaman1,*, C. Moisâ1, A. M. Gaman1,2,3
1Carol Davila University of Medicine and Pharmacy, Bucharest, Bucharest, 2Emergency County Hospital, Cluj Napoca, Cluj Napoca, 3Hematology, Filantropia City Hospital, 4Pathophysiology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background: Essential thrombocythemia (ET) is a clonal disorder of the hematopoietic stem cells characterized by excessive myeloid proliferation, with predominating megakaryocytic expansion and a potential transformation to acute myeloid leukemia. 50 to 60% of ET cases present a JAK2V617F mutation. 5% to 10% of JAK2V617F negative ET patients have MPL mutations at codon 515 and 50% to 70% of ET patients have non-mutated JAK2 and MPL (double-negative) mutations at exon 9 of CALR. Genetic instability in ET is associated with an increased level of reactive oxygen species (ROS) which also leads to DNA damage. Hematopoietic stem cells of JAK2V617F positive murine models have increased ROS levels compared to healthy controls. Eleven patients had JAK2V617F mutation and twelve were JAK2V617F mutation negative. Significantly higher ROS levels were found in JAK2V617F positive patients compared to JAK2V617F negative patients.

Summary/Conclusions: In our study, patients with ET had increased ROS levels. Cases with JAK2V617F mutation associated higher ROS levels compared to those without JAK2V617F mutation. In our future research, we will focus on the follow-up of these patients for a period of four years and we will try to observe if increased ROS levels enhanced genomic instability and transformation to acute myeloid leukemia.

PB2120
VARIATIONS IN PARAMETERS OF PLATELET COUNT AND PLATELET VOLUME ACCORDING TO GESTATIONAL AGE
S. Akarsu1,*, M. Aydin1, E. Taşkı1
1Fırat Üniversitesi Tıp Fakültesi, Elazığ, 2Fırat Üniversitesi Tıp Fakültesi, Elazığ, Elazığ, Turkey

Background: Reference ranges of haematological parameters in preterm infants are limited. In hematological evaluation not only platelet (PLT) counts but also important platelet volume parameters (mean platelet volume [MPV], platelet distribution width [PDW], plateletcrit [PCT]) are also taken into consideration.

Aims: We wanted to investigate the impact of gestational age by determining variations in platelet volume parameters according to gestational weeks.

Methods: Medical records were prospectively reviewed in preterm infants admitted to Firat University Hospital from January 2001 to December 2007. Study group consisted of only one-hour-old newborns delivered in the clinics of Department of Gynecology, and Obstetrics of our hospital. The exclusion criteria included those with maternal history of antepartum haemorrhage, chorioamnionitis, fever, sepsis, preeclampsia and hypertention; and perinatal history of twin-to-twin transfusion syndrome, feto-maternal transfusion, injury and infection. A hundred and ninety-three newborns with apparent health problems were excluded from our study. Study group comprised 398 preterm infants born between 26-37 gestational weeks, and 63 healthy term (38 gestational weeks) infants. Blood samples from all cases were obtained within the first hours after birth. Blood samples were placed into tubes with EDTA, and analyzed in ADVIA 120â (Japan) hematology analyzer using suitable kits. Data were expressed as mean±standard deviation. Platelet counts, and volume were indicated for each gestational week, and groups of 24-31, 32-36, 37, and 38 weeks. One-way analysis of variance (ANOVA) was used for statistical analysis, and p<0.05 was accepted as the level of statistical significance.

We established the reference ranges of platelet and platelet index in Turkish preterm and term infants. Platelet counts, and platelet volumes continually change as gestational age increases. Increases in platelet counts, and PCT, while decreases in MPV and PDW were detected. The gestational age-related changes in PLT patterns may reflect maturation of platelet regulation.

Summary/Conclusions: We established the reference ranges of platelet and platelet index in Turkish preterm and term infants. Platelet counts, and platelet volumes continually change as gestational age increases. Increases in platelet counts, and PCT, while decreases in MPV and PDW were detected. The gestational age-related changes in PLT patterns may reflect maturation of platelet regulation.
Background: Primary immune thrombocytopenia (ITP) is an autoimmune disorder characterized by immune-mediated platelet destruction and suppressed platelet production. ITP may occur concurrently or precede the occurrence of SLE, which would have great diagnostic significance. ITP may also be the first early sign of the disease. Few studies have addressed the risk of systemic lupus erythematosus (SLE) after ITP.

Aims: To estimate the risk of SLE after ITP in adult Jordanian patients

Methods: All patients diagnosed with ITP and with a platelet count <100 x 10^9/L between September 2002 and January 2017 were included in the study. Patients were retrospectively reviewed for diagnosis of SLE, and inclusion criteria included only those patients who had initial ANA screen at the time of the first presentation of ITP. All patients with the diagnosis of SLE at the time and before the presentation of primary ITP were excluded from the study.

Results: This study included a total of 58 patients (43 females and 15 males) who were followed up for a period of 14 years. Their age at the baseline ranged from 16 to 65 years with a mean (SD) of 31.2 (13.3). ANA was positive in 11 (19.0%) patients. Over the period of follow up, 9 (15.5%) patients developed lupus. The incidence was 13.3% among males and 16.3% among females, with no significant difference (p-value=0.786). There was significant association between ANA and lupus in both genders. Only one patient with negative ANA and 81.8% of patients with positive ANA developed lupus (P<0.005).

Summary/Conclusions: SLE developed in patients with primary ITP in with initial positive ANA titer at presentation. The results suggest that patients with initial positive ANA are at risk for development SLE. Thus, follow up after primary ITP diagnosis with positive ANA titer is of great importance as the risk of SLE is significant.

TREATMENT OF REFRACTORY IMMUNE THROMBOCYTOPENIA WITH THROMBOPOIETIN RECEPTOR AGONISTS: OUR EXPERIENCE IN CHILDHOOD

J. Zanabili Al-Sibai1,*, T. Arias Fernández1, M.P. Palomo Moraleda1, L.R. Morais Bras1, C. Castrafort Fernández1, L.F. Ávila Idrøn1, A. Solé Magdalena1, S. González Muñiz1, M.A. Fernandez Rodríguez1

1Hematology, 2Internal Medicine, 3Medical Microbiology, 4Biostatistics, Duzce University Faculty Of Medicine, Duzce, Turkey

Background: Immune thrombocytopenia (ITP) is an autoimmune disease in which antibodies develop against platelets (plts) and dysregulation of cellular immunity result in premature destruction of plts and impaired plt production. For most affected children, ITP is a self-limiting disease. Approximately, 10% of all ITP patients eventually develop refractory ITP (RTIP). Thrombopoietin receptor agonists (TPO-RA) stimulate thrombopoiesis and are an alternative to Rituximab (Rtx) in patients with positive ANA developed lupus.

Aims: We present 3 different children with RITP treated with TPO-RA, porarily along with fever, renal insufficiency and arterial hypertension, probably related to Ig A deficiency, not previously diagnosed. Romiplostim was indicated, reaching complete remission after 2 doses and it was stopped after the 4th dose, without any adverse reaction. Nowadays, plt count remains within normal limits (Figure 1A). CASE 2. A 5-year-old boy was diagnosed of ITP with cutaneous bleeding. He received treatment with prednison and Ig with short response. Rtx was indicated; after 4 doses, severe mucocutaneous bleeding persisted. Eltrombopag was started with response after 6 weeks of treatment (Figure 1B) and bleeding symptoms recovery. CASE 3. A 4-years-old boy with RITP was referred to our hospital. We decided to initiate treatment with Eltrombopag. He developed response after 4 weeks of treatment with plts count of 75mg/24h. Six weeks later, he presented 600,000/plt/L, but the drug was stopped. We observed a quick descent in plt levels and Eltrombopag was restarted with progressive response (Figure 1C).

Results: In all cases, splenectomy was avoided due to long-term risk of sep- sis, as well as immunosuppressive agents like RTX in 3rd case. In 1st case, TPO-RA was able to stop with sustained response as described in some pub- lications.

Summary/Conclusions: In our experience, TPO-RA appear to be efficacious and well tolerated in children.

PB2123

INVESTIGATION OF PLATELET FUNCTIONS IN PSEUDOTHROMBOCYTOPENIA

B. Onec1,*, S. Cesur2, K. Onec2, E. Caliskan3, S. Cangur4

1Hematology, 2Internal Medicine, 3Medical Microbiology, 4Biostatistics, Duzce University Faculty Of Medicine, Duzce, Turkey

Background: Pseudothrombocytopenia (pseudoTCP), is incorrectly detection of low platelet counts in automatic blood counter devices and is most frequently caused by ethylene diamine tetra-acetic acid (EDTA) induced platelet clumping and in vitro agglutination. Therefore, pseudoTCP which accounts 15-30 of thrombocytopenic admissions, actually is not associated with a bleeding tendency. Detection of pseudoTCP may be detected with a careful investigation of peripheral blood smears (PBS) by experienced clinicians but in centers which does not have these facilities; misleading of worried patients through advanced centers or even unnecessary treatments with steroids and platelet transfusions often occur.

Aims: In theory, formation of platelet clusters in the presence of EDTA requires functional adhesion molecules, so platelet adhesion and aggregation tests are expected to be in normal range. We aimed to investigate the capacity of simple platelet function analyzers for making the distinction between pseudo TCP and real thrombocytopenia.

Methods: Platelet functions were measured as collagen-ADP and collagen-epinephrine closure times (ColADP and ColEPI) by Platelet Function Analyzer (PFA-200™) for all patients who are referred to our clinic as thrombocytopenia (TCP, plt <150 x 10^9/L) and value of this new method for determining pseu- doTCP is compared with PBS which is accepted as the gold standard by using Receiver Operating Characteristic (ROC) curve analysis. PFA-200 system closure time is expected to be longer in true thrombocytopenia and normal in pseudoTCP, but there is no study investigated this system for this purpose. Descriptive analyses were presented using means zstandard deviations for normally distributed variables or median and interquartile range (IQR) for nonparametric continuous variables. An overall p-value of less than 0.05 was considered to show a statistically significant result. This study is supported by Duzce University with project number of 2015.04.03.370 and these are pre- liminary results.

Results: We included 59 patients who were referred to our clinic with throm- bocytopenia (TCP, Plt<150 x 10^9/L) and 11 healthy controls (Plt>150 x10^3/µL). Median age was 54 (IQR:37-68) for thrombocytopenic subjects and 37 (%63) of them were female. Median Plt count was 61 x10^3/µL (IQR:30-90) in TCP group but WBC and Hb were not different from control subjects. Subjects referred with TCP were grouped with PBS as pseudo- TCP and real-TCP. There was no difference in terms of Plt, MPV, PCT, WBC or Hb between these groups but age was younger (median age 46 vs 62, p<0.05) and PDW was higher in pseudoTCP group (med 17.6 vs 16.8, p<0.01). ColEPI and ColADP measures were significantly lower (med 125 vs 287 for ColEPI, med 84 vs 224 for ColADP, p<0.001 for both) at pseudoTCP group. The capacity of ColEPI and ColADP values in predicting pseudoTCP were analyzed using ROC curve analysis. We found that, when the manufacturer’s recommended cut-off value (150 s) was used, the sensi- tivity and specificity were 74.4% and 95%, with overall accuracy of 81.4% for ColEPI (AUC 0.813, %95CI: 0.684-0.933). Similarly sensitivity and specificity were 79.5%, and 95%, with overall accuracy of 84.7% for ColADP using manufacturer’s cut-off value of 100 s (AUC 0.878, SD:0.055, p<0.001, %95CI: 0.770-0.986).

Summary/Conclusions: We concluded that, running PFA tests for everybody with low platelet counts, could be used for differentiating pseudoTCP and realTCP in centers which does not have conditions for proper BS. Especially longer closure times excludes pseudoTCP with a high specificity and could make clinicians quick decisions for further investigations.
BACKGROUND: The investigation and management of patients with Chronic immune thrombocytopenic purpura (ITP) varies widely. Although many treatments have been recommended for ITP, there are no evidence-based recommendations for when different treatments should be used, or when any treatment should be used rather than managing a patient by observation alone.

AIMS: To evaluate the treatment of ITP patients in Department of Hematology, County Hospital, Timisoara.

METHODS: A retrospective study for 350 ITP patients was performed. Patients demographics, medical history, current treatments and side effects, were abstracted from the patient’s medical charts for the 15 months prior to their most recent visit.

RESULTS: The mean age was 45.6 years with 58% women and 42% men. Median time from the diagnosis of ITP to the start of the observational period was 23 months. Regardless of the presence of bleeding symptoms, for majority of patients we started treatment based on plateled count. Treatment was considered when platelet counts are less than 20x10^9/L in patients without bleeding, and less than 30x10^9/L in patients with bleeding. Prior to the observational period, 36% of patients had been splenectomized and the most reported treatment was corticosteroids. During the observational period, 72% of all patients were treated. The most frequent reasons given for treatment were platelet count (58%), followed by bleeding symptoms (42%). Corticosteroids represented 52% of treatments, followed by IVig (20%), azathoprine (12%) rituximab and 8% others. Splenectomies (8% of patients) and platelet transfusions (27% of patients) were performed during the observational period. In the patient survey, 52% of participants were 60 years of age or older and the duration of disease was more than 10 years in 43% of patients. The minimum platelet counts were less than 10x10^9/L in 49% of patients. The most common symptoms of ITP was fatigue (45%). Approximately 60% of patients reported at least one side effect associated with ITP treatment. The side effects were most frequently associated with corticosteroid use (43%). Overall, 40% of patients required hospitalization. Mean duration of hospitalization was 13.5 days.

SUMMARY/CONCLUSIONS: The retrospective study of 350 patients provides the results of treatment practices in our country. It showed that bleeding symptoms remained quite frequent among patients with chronic ITP. Corticosteroids were the most widely used treatment.

IMMUNOLOGICAL THROMBOCYTOPENIC PURPURA AND PREGNANCY: A RETROSPECTIVE STUDY OF 89 PREGNANCIES IN 59 PATIENTS

H. Brahimi1, S. Taoussi1, Z. Bouchetara1, K. Rekrouk1, M. T. Abad1
1Hematolo, EHS ELCC CAC, Blida, Algeria

BACKGROUND: Immunological thrombocytopenic purpura (ITP) occurs for about 1 case for 1000 pregnancies. The risk of onset, aggravation or relapse of ITP during pregnancy is not clearly established.

AIMS: The aim is to describe the prevailing ITP progression profile in pregnant women and to evaluate the risk of neonatal thrombocytopenia in two situations, when ITP was known before pregnancy and when ITP was discovered for first time during pregnancy.

METHODS: It is a retrospective study carried out in the hematology department of CAC Blida, Algeria, between 1993 and 2016. All patients (pts) who had a pre-pregnancy ITP or thrombocytopenia during pregnancy attached to an ITP were included.

RESULTS: The development of 89 pregnancies (PG), including two twins, occurred in 59 women was analyzed. There were one PG in 40 pts, 2 PG: 13 pts, 3 PG : 5 cases, 4 PG : 1 case and 5 PG : 1 case. Of the 59 pts: in 42 cases it was a history of ITP before pregnancy (group 1: G1) with a history of splenectomy in 9 patients, and in 17 cases it was ITP discovered on the occasion of Pregnancy (group 2: G2). The average age at diagnosis was 26.7 years (7-44) and that at delivery was 30.4 years (19-44). The mean platelet count at diagnosis: G1: 34000 / µL, G2: 47000 / µL. In the first group (G1): At the beginning of pregnancy the ITP was chronic in 30 cases, newly diagnosed in 1 case, persistent in 2 cases and transient cured in 7 cases; treatments previously received were: corticosteroid therapy (n=34), splenectomy (n=9), Danazol (n=1), cyclophosphamide in 1 case of cyclophosphamide in 1 case, absence in 7 pts, 2 of whom required corticosteroids during pregnancy. The status of the ITP at the beginning of each pregnancy was: out of treatment (n=8), corticosteroid dependence (n=5), non-response (n=7), PR (n=11), CR (n=24). In the second group (G2): the discovery of thrombocytopenia was in the first trimester (T1) in 4 cases; a retrospective study in the second T1 in 6 cases and in the third T1 in 7 cases: 17 pts had platelet counts <80000 / µL and were included due to the persistence or even worsening and / or necessity to resort to treatment of thrombocytopenia after delivery. In both groups: in 26 pts (G1:16; G2: 10) variable dose and duration treatment were required during pregnancy; at delivery, 19 patients needed a treatment, out of them, a bolus of corticosteroids (n=11)transfusion of platelets (n=4), immunoglobulins in 4 cases and transfusion of platelets alone in 4 cases. At birth, thrombocytopenia was observed in 40 pregnancies (50.6%): platelets <30000 / µL (n=7), between 31000 and 50000 /µL (n=13), between 51000 and 100000/µL (n=20), between 100000 and 150000/µL in 2 cases. All pregnancies were completed: 14 by caesarean section, one for thrombocytopenia, with an average platelet count=95000 / µL and 75 by natural delivery with a mean platelet count=100000 / µL with 4 deaths born, one anencephaly and 88 newborns. No hemorrhagic syndrome was observed in pregnancy; two postpartum hemorrhages were seen in G2 group. Eleven newborns (5 in G1 and 6 in G2) were thrombocytopenic with platelet count <20000/µL in 4 cases; between 20000 and 50000/µL in 7 cases; neonatal thrombocytopenia occurred during the first 7 days. Only 4 newborns were treated, one by corticosteroid and 3 by immunoglobulins, with a good progression and only one of the untreated is always followed for thrombocytopenia.

SUMMARY/CONCLUSIONS: The de novo ITP appearing during pregnancy is an etiological eventually to be evoked in front of a thrombocytopenia of the pregnant woman after elimination of the other causes related to the pregnancy and in front of the non-resolution after the delivery. The pre-existing ITP does not necessarily.
Quality of life, palliative care, ethics and health economics

PB2126
QUALITY OF LIFE AND SYMPTOM BURDEN IN PATIENTS WITH MULTIPLE MYELOMA
B. Sidi Mohamed El Amine1,2, H. Asma1, O. Fouzia1, S.A. Najet1, C. Malkia1, Z. Naima1, Z. Zahia1
1Hematology department, University hospital of Sidi Bel Abbés, Sidi Bel Abbès, Algeria

Background: Multiple myeloma (MM), the second most common hematological cancer, remains incurable. Its incidence is rising due to population ageing. Despite the impact of the disease and its treatments, not much is known about health-related quality of life (QoL) of patients with MM.

Aims: This study aimed to (1) Determine symptom prevalence in patients with MM on disease-modifying treatment, and identify the range and nature of these symptoms within the dimensions of physical, psychological, social well-being. (2) Measure the QoL of patients. (3) Compare the above-mentioned parameters to the general population.

Methods: Adults with multiple myeloma attending the hematology day unit in hematology department from November 2016 to January 2017 were eligible for inclusion in a cross-sectional. Consenting patients completed 2 validated questionnaires; 1) the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) supplement-ed by the myeloma-specific module (EORTC QLQ-MM20).

Results: Forty-seven patients were included for analysis: 51, 1% were male and 48.9% were female. Mean age was 64.7 years (range 42-82, standard deviation 11.9). The QoL scores were significantly lower than the general population (54.7 vs 71.2). The most commonly reported physical symptoms were pain (72%), fatigue (70%) and insomnia (66%). About 61% of the patients were burdened by financial worries. On multivariate analysis, a good performances status (PS≤1) and a response of the disease to therapy (at least a partial response) were associated with high scores of QoL (p=0.01, P=0.03 respectively).

Summary/Conclusions: Patients with MM have a lower QoL than the general population and are symptomatic across physical, psychological and financial domains. They represent a polysymptomatic patient cohort with a complexity of need that merits a holistic multidisciplinary approach, and consideration of specialist symptomatic or palliative care review.

PB2127
QUALITY OF LIFE IN ANEMIC PATIENTS WITH HEMATOLOGICAL MALIGNANCIES
N. Romanenko1,2, S. Bessmeitsev1, A. Romanenko2, N. Potikhonova1, M. Zenina1
1Clinical Hematology, Russian Research Institute of Hematology and Transfusiology, 2Neurology, Children Hospital of St. Olga, Sankt-Peterburg, Russian Federation

Background: Anemia is a common complication of patients with hematological malignancies (HM), which may progress undergoing antitumor treatment significantly decreasing hemoglobin concentration and occur symptoms as fatigue, dizziness, palpitations, dyspnea markedly reduce patient activity, resulting in impaired Quality of Life (QoL).

Aims: To compare of QoL in HM’s patients with different grades of anemia.

Methods: In this study were included following patients (n=326) in the age of 19-82 (Me=65) years: myelodysplastic syndrome (n=37), acute myeloid leukemia (n=20), acute lymphoid leukemia (n=7), primary myelofibrosis (n=23), chronic myeloid leukemia in blast crisis (n=6), multiple myeloma in II and III st. (n=126). Non-Hodgkin’s lymphoma in III-IV st. (n=40) and chronic lymphocytic leukemia in B or C st. (n=67). Patients were examined: 1) clinical blood test (hemoglobin concentration) to assess anemia’s grade; 2) the Functional Assessment of Cancer Therapy-Anemia (FACT-An) scale to measure of QoL. The FACT-An questionnaire consists of a general questionnaire (FACT-G), measuring domains of physical well-being (PF), social/family well-being (SF), emotional well-being (EW), functional well-being (FW), anemia-specific questionnaire – Anemia subscale (AnS), measuring fatigue-associated items – Fatigue subscale (FS) and non-fatigue-associated items – Non-Fatigue subscale (NFS). Patients were divided into six groups according to the Hb concentration: 1) the first group – Hb was 4.0-6.4 g/dl (Me=5.7 g/dl); 2) the second – Hb 6.5-7.9 g/dl (Me=7.2 g/dl); the third – Hb 8.0-9.4 g/dl (Me=8.6 g/dl); the forth – Hb 9.5-10.9 g/dl (Me=10.8 g/dl); the fifth – Hb 11.0-11.9 g/dl (Me=11.4 g/dl); the sixth – Hb 12.0-14.4 g/dl (Me=13.0 g/dl). The sixth group was control.

Results: In the first group of patients (n=34) with severe anemia grade 4 QoL was revealed too poor; number of points in the subscale of PW was 14.0±2.0, in SF/W – 14.2±0.7, EW – 10.3±0.9, FW – 18.5±2.8, AnS – 41.2±1.6, FS – 27.8±1.3, NFS – 13.4±0.6. In the second group of patients (n=53) with anemia grade 3 QoL was poor too; in PW was 13.3±2.0, in SF/W – 14.4±0.6, EW – 9.9±0.7, FW – 18.2±0.6, AnS – 38.5±2.3, FS – 26.8±1.7, NFS – 12.0±0.7. In the third group of patients (n=72) with anemia grade 2 QoL in the subscale of PW was 11.5±0.7, in SF/W – 14.0±0.5, EW – 8.6±0.6, FW – 16.9±0.5, AnS – 36.1±1.9, FS – 25.5±1.4, NFS – 11.6±0.6. In the forth group of patients (n=70) with anemia grade 1 QoL in PW was 11.3±0.7, in SF/W – 14.3±0.6, EW – 8.4±0.8, FW – 16.0±0.7, AnS – 34.7±1.6, FS – 23.7±1.0, NFS – 11.7±0.6. In the fifth group of patients (n=41) with anemia grade 0 QoL in PW was 11.1±0.9, in SF/W – 14.9±0.8, EW – 7.6±0.6, FW – 16.4±0.5, AnS – 34.6±2.2, FS – 23.7±1.6, NFS – 10.9±0.7. In the sixth group of patients (n=56) without anemia QoL in the subscale of PW was 11.9±0.7, in SF/W – 13.6±0.5, EW – 6.4±0.5, FW – 14.8±0.7, AnS – 23.4±1.5, FS – 14.9±1.0, NFS – 8.4±0.6.

Summary/Conclusions: QoL was found too poor in patients with Hb <8.0/g.dl. QoL wasn’t satisfactory in patients with Hb 8.0-11.0 g/dl. But the QoL improvement were greater in patients with Hb levels >11.0-12.0 g/dl (p=0.05). These data suggest that early correct anemia with red blood sells transfusions and erythropoiesis-stimulating agents can improve QoL in a clinically meaningful way.

PB2128
AN ANALYSIS OF THE IMPACT OF LOCAL COSTS OF MEDICINES ON COST EFFECTIVENESS OF THE TREATMENT OF CANCER ASSOCIATED THROMBOSIS.
E. Reimer1,2, D.M.R. Lipp2, M. Gotfredsen1, M. Feuerbach3
1Thrombosis, LEO Pharma, Ballerup, Denmark, 2Haematology and Oncology, 3Health Economy, German Oncology, Hamburg, Germany

Background: New research has surfaced in relation to health care resource utilization and costs in Cancer Associated Thrombosis (CAT). The studies originate from the US and are difficult to transfer directly to other countries. A few studies in Europe focusing on the total cost of CAT seem to indicate that the cost data in the field of CAT varies greatly between regions. To examine the importance of region specific cost elements in relation to research related to CAT, we studied the cost driver in the newest and most relevant health economic research and compared it with the costs from 6 European countries as well as Canada.

Aims: To highlight the importance of localized or regionalized cost inputs as cost drivers when considering cost effectiveness in relation to CAT.

Methods: The cost driver is the medication in a recent analysis by Connell 2016 and thus the focus of our analysis. The American paper incorporates outcomes from 6 RCTs for treatment with LMWH in patients with CAT. The annual medication costs of LMWH for daily treatment in 365 days were 32,120 USD in wholesaler acquisition cost (WAC). For VKA the annual medication cost for 365 days was 44 USD. LMWH is the cost driver but is not cost effective due to the cost of it. The study finds that “The one-way sensitivity analysis shows that LMWH would become the preferred strategy once its annual cost was less than $7177.” In the present analysis, the daily cost acquisition cost Wholesaler Purchasing Price (WPP) (which corresponds to the American WAC ) for LMWH (prefilled treatment syringes with Tinzantra) was gathered in 7 large markets using a data retrieval from IHS global insights systems (Jan 2016). In addition to this, the role of the cost driver was also compared to other publications.

Results: Simply by applying the local unit cost for the treatment with LMWH for these countries, the conclusion becomes notably different. LMWH becomes the cost effective alternative in European countries as well as in Canada with annual costs below 7177 USD. The price for VKA is comparable to that in the US, and does not change the cost effectiveness ratio.

The data from the retrospective cost of CAT study that the cost of the hospitalization of was 19% of the total cost of the CAT and the cost medication 11% of the total cost of CAT. This outlines hospitalization is a cost driver as well and not only the medication. Similar conclusions were reached in other studies. In summary, the role of the cost driver can change as a consequence of the localization of the costs. This outlines the great variation in costs in terms of CAT, and the caution it must be used with (Table 1).

Table 1.

haematologica | 2017; 102(s2) | 843
SUMMARY/CONCLUSIONS: The exercise shows that using local input changes the risk of mucositis which potentially influence local evaluations related to the access for LMWH treatment for CAT. Tinzaparin was found to be a cost effective LMWH over VKA in 6 European Countries as well as in Canada, when local medication costs were used. This was in contrast to the conclusion in the US. Not using localized or regionalized cost inputs could potentially lead misinterpretations about cost effectiveness of CAT treatments.

PB2129

MINIMIZING THE RISK OF MUCOSITIS IN HEMATOLOGICAL PATIENTS WITH TOPICAL PRODUCTS

I. Ursuleac1, Z. Varady1, A. A. Tomescu2, R. Drag6, D. Coriu1

1Hematology, 2Fundeni Clinical Institute, Bucharest, Romania

Background: Mucositis is a frequent severe complication associated to aggressive therapies of hematological malignancies with chemotherapeutics or radiation therapy, conditioning therapy in stem cell transplants. Regularly occurs at 3 to 10 days after chemotherapy and about 6 to 8 weeks after radiotherapy. It is self-limited within 2-4 weeks, but in this period the patient is vulnerable to systemic infections (bacterial and fungal). It could also compromise the optimal timing and dosage of the chemotherapy schedule, induce psychosocial distress, prolonged hospitalization and finally, higher costs.

Aims: Evaluating the efficacy of GelX® in chemotherapy induced mucositis. GelX® is a topical product that contains Zinc gluconate-taurine, with bacteriostatic and anti-inflammatory effect, easy to use for the patient, in order to prevent and reduce pain and severity of oral ulcers, making a barrier for mucositis.

Methods: A retrospective analysis of 77 adult patients: 17 with hematological treatments and 60 with allogeneic stem cell transplantation. 17 were diagnosed and treated between January 2015 and December 2016 with various hematological malignancies (5 AML, 2 ALL – 1 Ph positive, 2 blastic phases of CML, 3 AILT, 2 MMM, 2 CML, 1 MDS, 1 BH), 16 cases of grade 3-4 mucositis has appeared. The conditioning regimen was mieloablative (14 cases) and reduced intensity (3 cases). In 60 patients allografted for various hematological conditions, GelX® was prescribed for treating grade 3-4 mucositis. For the 35 cases with unrelated allotransplant (21 AML, 4 ALL, 2 SA, 2ATLL, 2 MLL, 1 MK, 1 BM, 1 BMF, 1 AML, 1 MDS, 1 BH), the incidence of grade 3-4 mucositis was reported (10 patients (one was initially treated with curative intention and after that with prophylactic regimen). In 60 patients treated for myeloid malignancies, after the conditioning regimen was mieloablative (21 patients), GelX® was indicated as prophylactic treatment for eight patients, because the risk of mucositis was high (aggressive chemotherapy, bad oral condition, risk of prolonged neutropenia). Curative treatment of grade 3-4 mucositis was indicated for 10 patients (one was initially treated with curative intention and after that with prophylactic regimen). In 60 patients treated for lymphoid malignancies, after the conditioning regimen was nonmieloablative (19 patients), GelX® was indicated as prophylactic treatment for 23 patients.

Results: GelX® induced a reduction in the grading of mucositis (grad 1-2) and a shorter period of evolution (5 days) versus grade 3-4 mucositis and prolonged duration of oral lesions for those with curative treatment. From 60 patients allotransplanted, 30 patients experienced grade 3 and 4 mucositis with a medium duration of five days. All of them received GelX® as prophylactic treatment.

Summary/Conclusions: Prophylaxis is the key of successful evolution in mucositis (time to heal shorter than 10 days). Identifying candidates for mucositis is mandatory and the product should be applied starting with the chemotherapy or (in the first 24 hours on the onset of chemotherapy) in order to minimize the risk of mucositis appearance.

PB2130

EUROBLOODNET: THE EUROPEAN REFERENCE NETWORK IN RARE HEMATOLOGICAL DISEASES

M.D. M. Mahu Pereira1,2, V. Gutierrez Valle1, J.L. Vives Corrons1, B. Gubí3, P. M. Serra1

1Red Blood Cell Pathology and hematopoietic defects Unit, Josep Carreras Leukaemia Research Institute, Barcelona, Spain, 2Laboratoire Hospitalier Universitaire de Bruxelles - ULB, Brussels, Belgium, 3Service d’Hématologie Sénior, Hôpital Saint-Louis - Université Paris, Paris, France

Background: Almost all hematological disorders are rare diseases, affecting less than 1 in 2000 individuals, justifying their inclusion in a European Reference Network (ERN). ERN are networks created following the Directive 2011/24/EU on cross border health which includes nationally recognized Centers of Expertise aimed at ensuring the same level of access to health services of patients with rare diseases. By a rare disease is referred to a rare condition (2-5 cases per 10,000 in the European population) which is often complex, chronic and difficult to diagnose. First, the ERN in Rare Hematological Diseases (RHD), results from a joint effort of the European Network on Rare and Congenital Anaemias (ENERCA), the European Hematology Association (EHA), and European hematologist patient organisations representing in both the EURORDIS European Patient Advocacy Groups (ePAGS) and the EHA-Patient Organisations Workgroup. EuroBloodNet gathers 66 highly skilled and multidisciplinary healthcare teams in 15 Member States, and advanced specialized medical equipment and infrastructures which will facilitate concentration of resources for the design, validation and implementation of high-quality and cost-effective services aimed at facing the challenges of RHD. Aims: To achieve EuroBloodNet’s mission: 1) to improve the healthcare and overall quality of life of patients with a RHD by 1) Improving equal access to highly specialized healthcare delivery for RHD across Europe 2) Promoting best practices in prevention, diagnosis and safe clinical care across Europe 3) Disseminating cutting-edge knowledge and facilitating continuous medical education in the field of rare diseases 4) Providing expert opinion in RHD on national and international consensus documents and safe exchange of clinical information 5) Fostering European cooperation in highly specialized procedures for diagnosis, promotion of clinical trials and innovative treatments and research.

Methods: RHD are covered in two main thematic groups: non-malignant diseases including sub-thematised acute leukemias, lymphoproliferative and miscellaneous diseases include 4 sub-thematises: 1) Rare red blood cell defects 2) Bone marrow failure (BMF) and hematopoietic disorders 3) Rare Bleeding-Coagulation disorders and related diseases and 4) Haemochromatosis and hereditary iron metabolism disorders. Malignant diseases include 2 sub-thematises: 1) Myeloid malignancies and 2) Lymphoid malignancies. Methods and tasks aiming to achieve EuroBloodNet specific objectives have been split into five categories of Transversal Field of action (TFA): 1) Cross border health 2) Best practices 3) Continuing medical education 4) Telemedicine 5) Clinical trials and research.

Results: Expected outcomes include reduction of healthcare inequalities for RHD patients identified by EuroBloodNet; by better access to all European border patients, and the EHA-Patient Organisations Workgroup. EuroBloodNet gathers 66 highly skilled and multidisciplinary healthcare teams in 15 Member States, and advanced specialized medical equipment and infrastructures which will facilitate concentration of resources for the design, validation and implementation of high-quality and cost-effective services aimed at facing the challenges of RHD. Aims: To achieve EuroBloodNet’s mission: 1) to improve the healthcare and overall quality of life of patients with a RHD by 1) Improving equal access to highly specialized healthcare delivery for RHD across Europe 2) Promoting best practices in prevention, diagnosis and safe clinical care across Europe 3) Disseminating cutting-edge knowledge and facilitating continuous medical education in the field of rare diseases 4) Providing expert opinion in RHD on national and international consensus documents and safe exchange of clinical information 5) Fostering European cooperation in highly specialized procedures for diagnosis, promotion of clinical trials and innovative treatments and research.

Background: Under diagnosis related to the earlier hemoglobin (Hb) or hematocrit (Hct) diagnostic criterion is one reason to the 2016 revision of the diagnosis of PV in the World Health Organization (WHO) classification of Tumours of Haematopoetic and Lymphoid Tissues. Bone Marrow Biopsy (BM) and molecular markers (JAK2) are recommended to establish the diagnosis in those with the lower threshold (Arber DA et al.2016). This potentially could result in increased numbers and costs of investigations. The lower thresholds would increase the incidence of PV with haematopoietic and potential PV who would then require additional investigations.

Aims: To determine number of patients with young strokes with potential PV on application of the 2016 revised WHO criteria for PV.

Methods: We undertook an analysis of records of patients with ischemic stroke to determine the incidence of PV using the 2016 revised WHO criteria. This registry enrolled adult patients admitted with imaging-confirmed ischemic stroke <2 weeks after symptom onset. The Indo-US Stroke Registry Infrastructure Development Project. This registry enrolled adult patients admitted with imaging-confirmed ischemic stroke <2 weeks after symptom onset. The Indo-US Stroke Registry Infrastructure Development Project, includes 5 geographically diverse centers in India and one in USA. The registry data was entered into a web-based electronic database. From January 2012 to March 2017, 2076 patients with new onset ischemic stroke were evaluated in the Indian arm of the Indo-US Stroke Registry. We compared the incidence of polycythemia as determined that there was a statistically significant difference in the proportion of polycythemics, p = 0.00. Considering the potential of comorbidities in the elderly to confound the association of polycythemia with ischemic stroke, we
separately analyzed only those with young stroke (Age <45). In this cohort there were 420 patients. A total of 6 (1.4%) patients had potential PV based on the 2008 Hb criteria. On applying the 2016 revision; 37 (8.8%) patients fulfilled the Hb criteria. An exact McNemar’s test determined that there was a statistically significant difference in the proportion of polycythemia, p= 0.002. Separate analyses by gender was not significant in females, P=0.5; but significant in males, P<0.001. Male patients were older than females with the revised criteria for polycythemia. The impact of cost in influencing treatment decision from resource limited countries with predominant lack of pocket health expenditure has been earlier reported (Philip C et al, 2015). This revision promotes the routine use of BM and JAK-2. In our analysis we estimate this new criterion would add to the costs to each patient (~ 7000 per our centre estimate).

Summary/Conclusions: The present data shows that there exists a significant difference in the incidence of polycythemia in thrombosis (Ischaemic Stroke) on applying the revised criteria. The requirement to additionally investigate them with BM and molecular markers for PV has potential economic implications.

PATHOPHYSIOLOGICAL MECHANISMS INVOLVED IN THE DEVELOPMENT OF ANEMIA IN PATIENTS WITH NON-HODGKIN’S LYMPHOMA

M.-A. Gaman1,*, A. Papoi2, A. M. Gaman3,4
1"Carol Davila” University of Medicine and Pharmacy, Bucharest, Bucharest, 2University of Medicine and Pharmacy of Craiova, 3Hematology, Filantropia City Hospital, 4Pathophysiology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background: Non-Hodgkin’s lymphomas (NHL) are a group of heterogeneous malignant lymphoid disorders that associate anemia either from diagnosis or during the evolution of the disease. The anemic syndrome can be present at the moment of diagnosis or can develop during the evolution of non-Hodgkin’s lymphomas, with high occurrence in advanced therapeutic stages due to the consumption of iron and/or folate deficiency due to chronic bleeding. Various pathophysiological mechanisms responsible for the development of anemia are depicted in literature: pro-inflammatory cytokines and hepcidin action; bone marrow failure caused by infiltration of malignant lymphomatous cells; cytopenias secondary to chemotherapy, immune peripheral destruction of red blood cells, iron and folate deficiency due to chronic bleeding.

Aims: To evaluate the prevalence of anemic syndrome in patients with non-Hodgkin’s lymphomas and the pathophysiological mechanisms involved in the development of anemia.

Methods: A retrospective study was conducted on 85 patients (informed consent obtained) with non-Hodgkin’s lymphoma, who were admitted to the Clinic of Hematology, Filantropia City Hospital, Craiova, Romania, in between 2013 and 2015, in order to evaluate the prevalence and pathophysiological mechanisms involved in the development of anemia in this study group.

Results: In our study group, the median age at diagnosis of non-Hodgkin’s lymphoma was 64 years, sex distribution was males:females=1:3, and the rural to urban area index=1:2. 85.88% of patients had B type NHL and 14.12% T type NHL. 20% of NHL were indolent lymphomas, aggressive lymphomas in 54% cases, indolent lymphomas in 26%. NHL relapse on stage of disease revealed: type I – 2.35%, type II – 18.81%, type III – 57.64%, and type IV – 21.16%. In our study, group, 84% of patients enrolled had anemia, with the anemic syndrome affecting the 50-60 years and 70-80 years age groups. 59.73% of patients had anemia at diagnosis and 40.27% of patients developed anemia during the evolution of NHL. The pathophysiological mechanisms involved in the development of anemia were: perturbations of iron metabolism and erythropoiesis by infiltration of malignant lymphomatous cells; cytopenias secondary to chemotherapy, immune peripheral destruction of red blood cells, iron and folate deficiency due to chronic bleeding.

Summary/Conclusions: In our study, anemia was present in 84% of NHL cases, more frequently in patients that associated comorbidities and belonged to the 50-60 years and 70-80 years age groups. In half of the cases, anemia was moderately severe. 47.25% of patients had simple chronic anemia due to perturbations of the iron metabolism and of erythropoiesis, and 25% of patients presented anemia due to bone marrow failure. Chemotherapy leads to an anemic syndrome in 18.05% of cases, whereas hemolysis of autoimmune origin in 9.7% of cases. Five patients with anemia induced by chemotherapy and three patients with lymphomatous infiltration of the bone marrow also associated iron and/or folate deficiency.

PB2134

DEPRESSION AS THE PRESENTING SYMPTOM OF CENTRAL NERVOUS SYSTEM LYMPHOMAS IN NORTHERN WESTERN TURKEY

S. Aydogdu1,2, H. G. Umut1,2, D. B. Eser1, M. Boyaci1, A. M. Demir1
1Department of Neurology, Tranya University Faculty of Medicine, Edirne, Turkey

Background: PCNSL represents approximately 4 percent of newly diagnosed primary central nervous system (CNS) tumors, with an age-adjusted incidence rate of four cases per million persons per year. Most cases of non-AIDS related PCNSL are diagnosed in patients between 45 and 65 years of age, with an median age at diagnosis in the fifth decade. The most notable risk factor for the development of PCNSL is immunodeficiency including HIV infection, iatrogenic immune suppression, and congenital immune deficiencies. Antecedent flu-like illness or opportunistic infections are risk factors for the development of autoimmune diseases were reported. Presenting symptoms may include focal neurologic deficits, psychosensitiv symptoms, signs of increased intracranial pressure, seizures or ocular sympotms. Psychosensitiv symptoms like depression, apathy, psychosis, confusion, memory impairment, slowness of thought are generally underdiagnosed or misdiagnosed due to the coexistence of the psychiatric states related to antidepressant use. Diagnosis is based on imaging of the central nervous system (CNS), ideally with contrast-enhanced magnetic resonance imaging (MRI), cerebrospinal fluid (CSF) analysis, unless contraindicated due to elevated intracranial pressure. The radiographic lesion tends to be a solitary non-hemorrhagic mass, situated in the deep white matter adjacent to the ventricular surface.

Aims: We aimed to evaluate the presence of depression and antidepressant use before the diagnosis of CNS lymphoma and emphasize the duration between the diagnosis of depression and lymphoma.

Methods: Data of 40 patients with CNS lymphomas were evaluated in a retro- spective manner. From their national health records, prescription for antidepressant agents was noted. The median age was 60 years. 55% of the patients were male and 45% female. The mean disease duration was 3 years. At the time of diagnosis 30% were on antidepressant medication. The diagnosis of depression was made by a psychiatrist and was based on the Structured Clinical Interview for DSM-IV (SCID). A t-test was used to compare differences in age, duration of illness. A Chi-square test was used for the comparison of sex distribution and the diagnosis of depression with or without antidepressant medication.

Results: Depression was associated with a higher frequency of diagnosis of PCNSL (p<0.001). The mean age of patients with depression was 57 years and of those with no history of depression was 61 years. There were more female patients with depression (65%) compared to those without depression (30%) (p=0.001). No differences were found between patients with depression with or without antidepressant treatment and the duration of disease (p=0.58 and p=0.90 respectively). There was a higher frequency of depression in patients with other comorbidities like MS, cancer, and stroke (p<0.001).

Conclusion: Depression was associated with the diagnosis of PCNSL in our study. The diagnosis was made at an earlier stage of the disease and when the disease was more advanced. Depression was more frequent in female patients and in patients with other comorbidities. Further studies are needed to clarify the role of depression on the prognosis of patients with PCNSL.
from their medical files, type and treatment of lymphoma and survival were recorded. OECD international statistics as well as Turkish Statistical Institute data for national antidepressant use were collected and interpreted.

**Results:** Of the 40 patients, 14 were male (35%) while 26 were male (65%). Mean age was 60.5 years (38-78), 7 patients were alive (17.5%). Method for diagnosis was radiological imaging (magnetic resonance imaging) in 27 patients (67.5%) while in 13 patients, diagnosis was supported with histopathological confirmation (32.5%). Mean survival was 8.6 months (2-24 months). As the complaint for medical help seeking, 4 patients presented with neurophysiologic symptoms while 16 patients presented with headache (40%) and 20 patients (50%) presented with neurologic defects. On the other hand, prior to lymphoma diagnosis, 7 patients were diagnosed as anxiety disorder and 13 as depression (total, 19 patients, 47.5%) and were prescribed antidepressant and anxiolytic medications. The mean duration between prescription of antidepressants and diagnosis of lymphoma was 2.6 months (0-10 months). Within the patients who were on antidepressants, 6 were female and 14 were male.

**Summary/Conclusions:** OECD Health at a Glance data revealed that in 2013, the defined dose per 1000 per day is 35, range of Europe is 21-88. According to our data of Ministry of Health, use of antidepressants in the general population is 10.52%, mostly in women. Within these patients, 42.37% were anxiety disorders and 22.99% were depression. In the last five years’ statistics, 30% of that population was prescribed for an antidepressant. The major group of physicians prescribing these medications was family and general physicians (>45%). The most striking finding of our study was the majority of male patients receiving antidepressants before the diagnosis of CNS lymphoma with a mean delay of diagnosis as 2.6 months (0-10 months). Depression and anxiety disorders are the leading causes of disability and the importance of organic and underlying conditions should not be underestimated relying on the increasing need of antidepressants.

**PB2135**

**IMPACT OF U.S. FDA APPROVAL OF LENALIDOMIDE MAINTENANCE THERAPY IN THE FIRST-LINE TREATMENT OF MULTIPLE MYELOMA AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANT ON TOTAL HEALTHCARE COSTS**

K. Parikh1, J. Xie2, C. Chen3, C. Yang3, A. Farrukh3, P. Cockrum3, A.B. Agarwal1, S. Abouzaid1

1Coresource Corporation, Summit, NJ, 2Analysis Group, Inc, Los Angeles, CA, 3Analysis Group, Inc, Boston, 4Analysis Group, Inc, Boston, MA, 5Analysis Group, Inc., Los Angeles, CA, United States

**Background:** Lenalidomide maintenance therapy after autologous hematopoietic stem cell transplant (auto-HSCT) in the first-line treatment has been shown to improve progression-free survival (PFS) and overall survival (OS) in multiple myeloma (MM) patients.

**Aims:** This study assessed the budget impact of the United States (U.S.) Food and Drug Administration (FDA) approval of lenalidomide maintenance therapy on total healthcare costs of a U.S. health plan.

**Methods:** An economic model was developed to estimate the incremental (additional) total plan costs (in 2016 USD) of maintenance therapy in each year for the first 3 years after lenalidomide monotherapy (R) maintenance therapy approval. The number of post auto-HSCT adult MM pts eligible for initiating maintenance therapy was estimated from published epidemiological data and an analysis of Connect® MM Registry data. Clinical endpoints for R-maintenance, including time on treatment, PFS and OS, were obtained from a meta-analysis of published clinical trials (CALGB, IFM, and GIMEMA). The use of common off-label maintenance therapies was considered. Types of costs included in the model were drug, drug administration, adverse events (AE), AE monitoring, one-time progression and terminal care costs.

**Results:** In a hypothetical U.S. health plan with 1 million members, the number of adult MM pts eligible to initiate post-HSCT maintenance therapy was estimated to be 28. Among them, 14.8 pts initiated R-maintenance in Year 1, 15.2 in Year 2, and 15.3 in Year 3, representing an incremental increase of 2.9%, 4.2% and 4.4% after R-maintenance therapy approval, respectively. After considering additional costs of maintenance, as well as potential offsets resulting from delayed progression the incremental total healthcare costs by year are listed in the Table 1. Results were consistent across all total plan, per patient per year, and per member per month costs. Deterministic sensitivity analysis showed that the model results were robust to the variations of key model inputs.

<table>
<thead>
<tr>

<td>65,000</td>
<td>6.5%</td>
</tr>
</tbody>
</table>

**Summary/Conclusions:** Approval of lenalidomide monotherapy for maintenance after auto-HSCT in the first-line treatment of MM has minimal impact on total plan costs, primarily due to the small incident population and the already common use of lenalidomide in post auto-HSCT maintenance.

**PB2136**

**LAPAROSCOPIC APPROACH CAN EXTEND THE INDICATIONS OF SPLENECTOMY: ANALYSIS OF 31 CONSECUTIVE PATIENTS WITH MALIGNANT HEMOPATHIES**

A. Salaroli1,*, B. Cadire 2, C. Spillebout1, M. Vercruyssen1, A. de Wind3, M. Maevsev1, G. Dapra2, G. B. Cadire1, D. Bron1

1Department of Hematology, Institut Jules Bordet, ULB, 2Department of Digestive Surgery, Hôpital St Pierre, 3Department of Pathology, Institut Jules Bordet, ULB, Brussels, Belgium

**Background:** Surgical resection of large spleens may eliminate a significant amount of tumor, allow definite diagnosis of malignant disorder, ameliorate abdominal symptoms and resolve cytopenia. However, because of short term perioperative events (25%) and long term immunosuppression (increased risk of infections caused by encapsulated bacteria) physicians can be reluctant to choose splenectomy, especially in older patients or patients with comorbidities. The role of laparoscopic splenectomy (LS) in patients with hematological malignancies is still unclear. Nevertheless, the ageing of the world’s population and the increased incidence of Non-Hodgkin’s Lymphoma are increasing the indications for splenectomy, requiring a well-tolerated and less invasive procedure.

**Aims:** The aim of this review is to analyze our single-center experience of LS performed for malignant Hemopathies. Results are compared with LS for benign splenomegaly and the risk of locoregional dissemination or inadequacy of fragmented histological sample were analyzed.

**Methods:** We retrospectively analyzed 50 patients who underwent LS between 2005 and 2016 at Saint-Pierre Hospital. Analysis approach was used in 12 patients whereas in the remaining 38 cases, a semi-lateral position was chosen. All the patients received the triple vaccination (Streptococcus pneumoniae, type B Haemophilus influenzae, and Neisseria meningitidis). Patients characteristics, safety data such as early (<30 days) and late (≥30 days) morbidities and mortality and efficacy (hematological recovery, accuracy of histological diagnosis) were analyzed.

**Results:** 19 patients underwent splenectomy for benign hemopathies (SBH) and 31 patients for malignant hemopathies (SMH). Non-Hodgkin’s lymphomas (12) and idiopathic myelofibrosis (10) were the most common causes of splenectomy found in our sample. Analysis of this retrospective study shows better early and late morbidities. Our data shows that SMH, a significant difference in term of platelets recovery after 1 month from the surgery was shown in patients efficiently Vs inefficiently operated (respectively 387 +/- 125 Vs 138 +/- 90 x 10^3/mL, p<0.05). 8 months and 80% achieved a hematological recovery.

**Summary/Conclusions:** LS is a safe and less-invasive procedure in patients affected by Malignant Hemopathies. This approach is also well tolerated in older patients (median 67yrs) and in patients with large spleen (1515 +/- 660 ml), extending the indication for laparoscopic SHM even in older patient and in patients with high volume spleen. Compared to historical data, LSy for Malignant Hemopathies shows better early and late morbidities. Our data shows however a trend for higher late morbidity in the SMH group, warranting a careful long term follow-up in this subset of patients.
patient due to urgent admission, long duration of stay in hospital, chemotherapy-agents used in the treatment and the disease itself. Evaluating this group of patients for anxiety and depression, providing necessary professional support and revising medical treatment is therefore substantial.

**Aims:** In our study, we aimed to assess the risks of anxiety and depression in newly diagnosed acute leukemia patients who were admitted to hematology clinic to receive chemotherapy and provide necessary professional support along with treatment revisions and follow-up according to our findings.

**Methods:** Our study was performed with newly diagnosed acute leukemia patients, who were admitted to our hospital hematology clinic in a six-month period to receive chemotherapy. Demographic characteristics were noted and Hospital Anxiety and Depression Scale (HADS) was used to assess depression. Hospital Anxiety and Depression Scale (HADS) is an assessment scale developed by Zigmond and Snaith to determine the risks and assess the severity of anxiety and depression. The validation and reliability studies of the scale in Turkey were carried out by Aydemir et al (9). The questionnaire has a total of 14 items; seven of which measure anxiety (odd numbers) and the remaining seven (even numbers) measure depression. Each item is scored from 0 to 3. The scoring order of each item in the questionaire is different. Items numbered 1, 3, 5, 6, 8, 10, 11 and 13 indicate decreasing severity and are scored as 3-2-1-0. On the other hand; items numbered 2, 4, 7, 9, 12 and 14 indicate increasing severity and are scored as 0-1-2-3. The cut-off value for the total score of the odd-numbered questions assessing anxiety is 10; while it is 7 for the even-numbered questions assessing depression.

**Results:** 21 patients were included in the study. 13 of these patients (61.9%) were diagnosed with acute myeloid leukemia (AML) and 8 (38.1%) were diagnosed with acute lymphoblastic leukemia (ALL). Median age of the patients was 45 (range: 21-69). 11 patients (52.4%) were female and 10 (47.6%) were male. 5 patients (23.8%) had comorbidities while 16 (76.2%) did not have anxiety. Anxiety evaluation revealed that 38.1% of all patients in the study experienced anxiety. The rate of anxiety was 38.5% in AML patients and similarly 37.5% in ALL patients. 45.5% of the female patients had anxiety while the rate was only 30% in male patients. The difference was not statistically significant (p >0.05). Depression evaluation revealed that 81% of all patients in the study. The rate of depression was 84.6% in AML patients and 75% in ALL patients. 81.8% of the female patients had depression while it was 80% in male patients. Neither anxiety nor depression had a significant correlation with comorbidities or gender (p >0.05). Correlation analysis revealed a positive correlation between anxiety and depression (r=0.846; p <0.01).

**Summary/Conclusions:** In conclusion, assessing anxiety and depression in patients especially during the stay in the isolation room is important for the treatment of these patients. The process of treatment helps patients to go from the private sphere back to the public one. Recommendations: It seems essential for the patients in the isolation room, undergoing autologous bone marrow transplant, to have therapy sessions with a qualified social worker as part of the holistic care. ‘Having a room of his own’ in the process enables an opportunity to examine the inner self esteem and strengths of the patients thereby patients learn to contribute to themselves from themselves.

**GENDER DIFFERENCE IN ANXIETY FOR THE FIRST BLOOD TRANSFUSION**

Y. Lu1,*, X. Zhang1, X. Li2, Y. Zou1, Z. Lin1

1the third Affiliated Hospital of Sun Yat-Sen University, 2The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

**Background:** Blood transfusion has several risks including allergic reaction, acute hemolysis, infectious diseases and so on. Both physicians and patients are always cautious to decide on blood transfusion.

**Aims:** The purpose of this study was to explore whether there are gender differences in anxiety for the first blood transfusion in patients with different diseases.

**Methods:** 315 patients (153 men and 162 women) were enrolled in this prospective, comparative study and median age was 38 years (range 17-72). The disease consisted of 85 chronic hepatitis B, 73 leukemia, 69 gastric ulcer, 48 chronic renal failure and 40 gynecological oncology. Various blood products including plasma, red blood cells suspension and platelet were infused. Anxiety was evaluated according to the HAMA self-rating anxiety scale (SAS) during the first blood transfusion. Patients got 50 points below were divided into no anxiety group, 50 to 99 points were divided into mild anxiety group, 60-69 points were divided into moderate anxiety group and 70 points or more were divided into severe anxiety group.

**Results:** For patients with the same disease, more female patients were divided into moderate to severe anxiety group than male ones. The number of patients divided into moderate to severe anxiety group was 45 (range: 21-69). 11 patients (52.4%) were female and 10 (47.6%) were male. 5 patients (23.8%) had comorbidities while 16 (76.2%) did not have anxiety. Anxiety evaluation revealed that 38.1% of all patients in the study experienced anxiety. The rate of anxiety was 38.5% in AML patients and similarly 37.5% in ALL patients. 45.5% of the female patients had anxiety while the rate was only 30% in male patients. The difference was not statistically significant (p >0.05).

**Summary/Conclusions:** Women were more anxious than men during the first blood transfusion, which is independent of age, race, education level and kinds of blood product.
Sickle cell disease

HYDROXYUREA INHIBITS MYELOID DIFFERENTIATION VIA NITRIC OXIDE SYNTHASE

T. Subotički1, O. Mitrović Ajtić1, M. Diklić2, S. Vignjević Petrićnović1, M. Budeč1, D. Djikić1, J. Šadić2, V. Cokić2

1Laboratory of neuroendocrinology, 2Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background: Hydroxyurea and nitric oxide (NO) inhibit erythroid differentiation, while hydroxyurea is NO-releasing agent used in therapy of sickle cell diseases in the Chronic Erythroid Hyperplasia (CEH) and β-thalassemia diseases. Additionally, NO has been found to inhibit myeloid differentiation in vitro. Aims: To study the mechanism of hydroxyurea inhibition of erythroid differentiation by exploring NO synthesis (NOS) dependence. Methods: The erythroid differentiation is studied by methylcellulose colony assay in mice, whereas presence and activation of endothelial NOS (eNOS) by immunocytochemistry and immunoblotting, respectively in K562 erythroleukemic cell line. Results: In ex vivo experiments, mice exposed 7 days to hydroxyurea demonstrated significant decrease in the number of nucleated cells per femur, partially reversed by NOS inhibitor N-nitro L-arginine methyl ester hydrochloride (L-NAME). The same, but less prominent reduction has been observed with NO metabolites nitrite (NO2) and nitrate (NO3). Moreover, hydroxyurea demonstrated a large diminution in the number of bone marrow derived myeloid colony-forming unit-granulocyte/macrophage (CFU-GM), burst-forming-units-erythroid (BFU-E) and colony-forming unit-erythroid (CFU-E) colonies in methylcellulose cultures. L-NAME attenuated hydroxyurea reduction of myeloid and erythroid colonies, while by itself increased CFU-E and CFU-GM colonies and slightly BFU-E colonies. NO metabolites NO2 and NO3 generally inhibited myeloid and erythroid colonies, but the reduction was more prominent by NO2 compound. Moreover, the hematological parameters (hemoglobin, hematocrit, mature reticulocytes, platelet, white blood cells count) were similar among studied groups. Hydroxyurea increased NO production and the number of eNOS positive K562 erythroleukemic cells, while phosphorylation of eNOS and activation of AKT/mitOR signaling was not blocked by phosphatidylinositol 3-kinase inhibition. Summary/Conclusions: NO prodruk hydroxyurea demonstrated NOs dependence in inhibition of myeloid / erythroid differentiation, not influencing the hematological parameters.

SLEEP DISORDERED BREATHING IN CHILDREN AND ADOLESCENT WITH SICKLE CELL DISEASE: IMPACT ON EXECUTIVE FUNCTION AND PROCESSING SPEED INDEX

M. Koebel1, J. Kawadler2, H. Stotesbury2, P. Balfour2, F. Kirkham1
1UCL Great Ormond Street Institute of Child Health https://www.ucl.ac.uk/ich, London, United Kingdom, 2Developmental Imaging & Biophysics, UCL Great Ormond Street Institute of Child Health https://www.ucl.ac.uk/ich, London, United Kingdom

Background: Studies in non-syndromic children have shown that sleep-disordered breathing (SDB) increases the risk of neuropsychological deficits and neuronal brain injury. Few authors have investigated the role in cognitive deficits of SDB and the associated hypoxia in children with sickle cell disease (SCD). Snoring and SDB is very common in children with SCD and may affect cognitive function in very young children. Previous data suggested that executive function was worse in older children with SCD and low mean overnight oxygen saturation. Aims: We aim to investigate if SDB could be a potential factor contributing to developmental problems in cognition in children and adolescent with SCD. Methods: We have followed up children and adolescents in the Sleep Asthma cohort who underwent Polysomnography at two different time points (1) 2006-2009 and (2) 2011-2014 and compared the sleep data with subsequent neuropsychological assessment. Results: Worse performance was found for processing speed: PSI (p<0.01) and general intelligence (p<0.05) compared to controls subjects. SDB, measured as apnea and hypoxia index (i.e. AHI >3): Apnoeas and hypopnoeas with more than ≥3% desaturation, was found to impact executive function, as measured with the Tower test. (p<0.05) and PSI (p<0.05). Mean oxygen saturation during total sleep time was significantly associated with lower PSI (p<0.05). Additionally, participants who showed a worsening of their SDB symptoms during total sleep time was significantly associated with lower PSI (p<0.05) and PSI, <0.05) (Figure 1). Summary/Conclusions: SDB symptoms seem to worsen into adolescence and therefore, might have a neurodevelopmental impact if left untreated; appropriate intervention might improve cognition and quality of life.

LUNG FUNCTION IN CHILDREN AND ADOLESCENTS WITH SICKLE CELL ANEMIA: A COMPARISON BETWEEN UK AND ITALY

C. De Pieri1,*, M. Arigliani1, R. Colombatti2, L. Sainati2, K. Vecchiato3, S. Ndono3, P. Gogo1, B. Inusa3
1Department of Clinical and Experimental Medical Sciences, University Hospital of Udine, Udine, 2Clinic of Pediatric Hematology-Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, 3University of Trieste, Trieste, Italy. 4Department of Pediatrics, Evelina Children’s Hospital, London, United Kingdom

Background: Acute and chronic respiratory complications are common in sickle cell anemia (SCA). Subjects with SCA often have a progressive decline of lung function with age that could be influenced by the quality of healthcare and behavioral factors, such as the level of exposure to air pollution. Aims: To compare lung function, evaluated cross-sectionally through spirometry, in children and adolescents attending sickle cell centers in UK and Italy. Methods: Anthropometry and spirometry were recorded in patients with SCA (SS,Sb0) aged 6-17 years of African ancestry followed at the Evelina Children’s Hospital, London, UK, and at the University Hospitals of Padova and Udine, northeast of Italy. Subjects from the British cohort lived in an urban area while those from Italy came from urban and non-urban areas. Exclusion criteria were the presence of SCA-related morbidity within the last two weeks and the inability to perform a spirometry meeting the European Respiratory Society acceptability and repeatability criteria (Miller, Eur Respir J 2005;26:319–338), modified for children (Kirkby, Pediatr Pulmonol 2008;43:1233–1241). Portable spirometers (Pony FX, Cosmed-IT, Easy-on PC, NDD-CH) were used. Z-scores of anthropometric and spirometric data were derived, respectively, from CDC2000 and from the Global Lung Initiative 2012 predictive equations for African Americans (Quanjer, Eur Respir J 2012; 40:1324–1343). Spirometry patterns were classified as normal, obstructive (zFEV1/FVC<-1.64) or restrictive (zFVC< -1.64, zFEV1/FVC ≥ -1.64). Differences between groups were assessed by t-tests and considered statistically significant for p values <0.05. Results: A total of 101 children and adolescents were included (n. 62 in UK; n. 39 in Italy; 42% girls; age-range: 6-21.7 years). We did not find significant differences in mean spirometry indices between the SCA cohort from London and northeast Italy (Table 1). Nevertheless while an obstructive spirometric pattern was more common in the British cohort compared to the Italian one (respectively 22.5% vs 7.7%), the picture was the opposite for the restrictive pattern (respectively 11.2% and 20.5%) (Table 1). In the whole sample age was negatively correlated with both zFEV1 (Spearman’s rho -0.20) and zFVC (Spearman’s rho -0.24).

Table 1.

Summary/Conclusions: Lung function of pediatric subjects with SCA living in London and in the northeast of Italy is overall comparable. Obstructive lung disease is more common among subjects with SCA living in London than in urban and non-urban areas in Italy. Differences in the level of exposure to ambient air pollution and in the prevalence of allergies between the rural and urban environment might have contributed to this finding and need to be further investigated.

PB2143
SICKLE CELL DISEASE: A NEW DISEASE IN MADRID

E. J. Bardón-Cancho1, M. García-Morín1, B. Ponce-Salas1, Y. Aguilar-de la Red1, A. Pérez-Corral2, G. Pérez-Rus2, E. Dulín3, C. Beléndez1, E. Celá4
1Section of Pediatric Hematology and Oncology, Department of Pediatrics, 2Department of Hematology, 3Newborn Screening Laboratory (Community of Madrid), Hospital General Universitario Gregorio Marañón - Facultad de Medicina - Universidad Complutense de Madrid, Madrid, Spain

Background: Sickle cell disease (SCD) was scarcely diagnosed 2 decades ago in Spain, and the Community of Madrid is a paradigm of the adjustments that had to be implemented to attend an increase of cases due to immigration. Aims: The aim of our study was to find out the prevalence of SCD in the referral sickle newborn screening of the Community of Madrid, in addition to the demographic characteristics of these patients. The secondary objectives were to obtain the frequency of specific treatments or prophylaxis accomplished by these patients, and the reasons for loss to follow-up.
Results: The total number of SCD patients included was 209. Ratio boy/girl is 1.3. Most of patients were born in Spain (85%), although 8% and 5.26% were born in Africa or America respectively. Seventy three percent of the progenitors came from Africa and 24% from America. Ninety two percent of those SCD patients born in Spain were detected in the first days of life due to universal screening detection implemented in Community of Madrid since 2003. Median age at first diagnosis was 1.42 years (0-21.4). Median age at the end of inclusion was 9.91 years (range 0.13 to 35.14). SS or S/Betathal was reported in 86%. In addition, 2.39% associated allele genotype, and 1 (0.48%) glucose 6-phosphate dehydrogenase deficiency. No patient had congenital thoracic diathesis. Eighteen patients (8.65%) had human leucocyte antigen (HLA) identical siblings. Hydroxyurea was added to standard treatment in 65 patients (31%) of which 47 continue to be treated to date. Penicillin prophylaxis was communicated in 165 patients (79%). Vitamin-D prophylaxis was initiated in 128 patients. On the contrary, other prophylactic measures were taken in 25 cases (12%) and 9 children (4%) underwent splenectomy. None of these patients had sepsis or meningitis. Cholecystectomy was performed in 9 cases (4%). There were 18 progenitor stem cell transplantations (8.61%) performed between 2.09 to 13.97 years of age (median 6.77 years). Ten patients remained on treatment with mix, and 1 attained a marrow reversion. One patient died of graft-versus-host disease. Patients lost in follow-up summed up 128: 23 for emigrating to other countries, 65 for continuing the monitor of their diseases in other centers or in adults units and 31 for unknown reasons (16.87%).

Summary/Conclusions: Early diagnosis like universal neonatal screening allows an effective health education, and antibiotic and osteopenia prophylaxis with vitamin D and general and specific vaccination can be started.
was a factor of the lower performance in this task. Figure 1. Children’s Performance (Z scores) at Visuo-Spatial, Boston Naming, Phonological Fluency and Semantic Fluency Tests. P-values: Visuo-spatial intelligence: not significant(ns); Boston naming: ns; Phonol-Fluency: 0.004; Semantic fluency: ns.

Summary/Conclusions: Selective language problems may occur in children with SCD in the absence of clear neurological damage to language areas. These problems are explained by the executive dysfunction of patients with SCD and not by environmental factors like bilingualism. Cognitive rehabilitation or extra tuition may aid in overcoming these difficulties.

PB2146
UNDERSTANDING MEDICAL HISTORY, LIFESTYLE AND NEEDS FOR FUTURE THERAPIES FOR PEOPLE LIVING WITH SICKLE CELL DISEASE - IMPLICATIONS FROM A PATIENT SURVEY
A.M. Leitgeb1,*, M. Robinson2, C. Herder1, L. Jendeberg1
1Modus Therapeutics, Stockholm, Sweden, 2Micromatt Consulting Inc, Oviedo, Florida, United States

Background: Sickle Cell Disease (SCD) is an inherited blood disorder affecting millions of people. Sevuparin/DF02 is being developed to treat people suffering from SCD and is currently in clinical phase 2 for the treatment of the acute painful crisis in hospitalized SCD patients with intravenous infusion. This is called the Resolve program. In a second program called EASE, sevuparin/DF02 will be investigated as an on-demand treatment of early symptoms of painful sickle cell crisis in an at-home setting via a subcutaneous injection.

Searching in the literature and discussing with health care providers, it becomes clear that little is known about how the SCD patients sense these early symptoms of a painful crisis. In order to gain increased understanding of how people living with SCD experience daily life, coping with disease, support by health care providers and the demand for new therapies, a patient survey addressing these areas was conducted.

Aims: The aim with this survey was to gain deeper understanding of different aspects of life with SCD by providing a channel for patients to air their own views. The outcome will provide important information and, in combination with future feasibility studies, will guide the design of the first clinical study aimed at treating the early symptoms of pain crises in SCD patients.

Methods: A 29-question survey was created to gather input on a wide variety of topics related to the lives of people living with SCD. This questionnaire was developed by Modus Therapeutics AB, Sweden, in conjunction with Micromatt Consulting Inc., USA. Experts and leaders of community-based organizations participated in two focus group sessions to ensure that the text and structure were ethical and appropriate for the intended purpose. The survey was hosted at www.modustsolipatientquery.com. Patients answered the survey directly, or had their views entered in by a caregiver. The answers are anonymous. During the initial period, survey promotion occurred within the Sickle Cell Warriors online community and later, additional connections within the network of community-based organizations were leveraged. The survey was open for access during the period of January 10, 2017 through March 1, 2017.

Results: An interim analysis was conducted on January 31, 2017. Basic demographic data is presented in Table 1. Responders were located mainly in the US. Medical history related questions indicate that fatigue (40%), aches/pain (37%), irritability (27%) and appetite (20%) are early symptoms and increase just before the onset of a pain crises. However, 7% reported infrequent signs and 19% never experienced an indicator of pain crisis. Patients take initiative at home to manage the onset of an acute crisis and the top 5 home strategies reported were: prescription pain medication (15%), sleep/rest (15%), apply heat using heating pad/blanket/bath/shower (13%), increase fluid intake (12%), and finally avoid stress (9%). Further it is clear, that people living with SCD are motivated to try a new therapy that could provide “significant relief” and “prevent symptoms from happening” due to their SCD.

Background: Hydroxyurea (HU) has lately been used in the treatment of patients with severe sickle cell disease (SCD). Despite documented benefits on laboratory and clinical parameters in SCD patients, there are few reports about drug’s long-term safety and efficacy in pediatric patients with SCD – even more so in the rare patient subgroup of sickle/beta thalassemia.

Aims: A prospective, long term evaluation of HU efficacy and safety in children and adolescents with sickle/beta thalassemia (S/b thal).

Methods: Ten patients with S/b thal aged 3.5-18 years were followed for a 6 year period (Jan 2011- Dec 2016). HU was given at a daily dose that ranged from 10 to 20 mg/kg, with a mean of 14.1 mg/kg. Laboratory follow-up consisted of WBC, Hb, Ht, RBC, reticulocyte count and PLT count measured every 2 weeks until dose escalation to a stable dose, biochemistry assessed every 2 months and Hb F measured every 2-3 months. Patients were clinically evaluated prior to HU treatment and every 12 weeks during the study period. Evaluated data on clinical course included frequency of vaso-occlusive crises, hospitalizations and transfusions, as well as presence of severe clinical events. Hematologic toxicity of hydroxyurea was defined as a more than 20% decline from baseline in Hb, as an absolute neutrophil count of less than 1,000/μl and/or a PLT count of less than 80,000/μl. Moreover, presence of alopecia, rash, skin hyperpigmentation or headache was reported as drug-related toxicity.

Results: A significant reduction in vaso-occlusive crises as compared to prior to HU treatment was noted (median: 1 episode per year before HU, range: 0-2.5 vs median: 0.24 episodes per study year after HU, range: 0-1.33, p=0.011). A significant reduction in hospitalizations was also reported (median: 1 per year before HU, range: 0-3.2 vs median: 0.16 per study year after HU, 0.0083, p=0.005). None of the patients presented with severe clinical events such as acute chest syndrome, avascular bone necrosis, stroke or splenic sequestration during the study period. With regards to hematological parameters, a significant increase in HbF (10.2±6.5% vs 16.6±7.1% p=0.02), MCV (66.1±3.9fl vs 79.3±8.4fl, p=0.001) and MCH (20.9±1.2pg vs 25.3±2.2pg, p=0.001), as well as a decrease in reticulocyte count (7.7±3.3% vs 5.0±1.9%, p=0.039), WBC count (9.566±3.674/μl vs 7.466±3.460/μl, p=0.009) and PLT count (333.778±170.227 vs 272.111±160.304/μl, p=0.007) was noted. Concerning adverse events, one patient presented with mild transaminasemia, one with elevation of serum creatinine levels and one with pancytopenia. Due to persistent pancytopenia HU treatment was discontinued in the last mentioned patient, but was restarted a year later due to frequent vaso-occlusive events - despite the patient being put on transfusions after initial HU discontinuation. Besides the pancytopenia episode, the rest of the mentioned toxicities were short-term and dose-dependent.

Summary/Conclusions: The study indicates that HU has an overall safe profile and results in a marked improvement of clinical course in pediatric S/b thal patients.
IN VITRO AND IN VIVO EVIDENCES OF SICKLING REVERSAL INDUCED BY REHYDRATION WITH HIGH K+-ISOTONIC SOLUTION

O. I. Ajayi1,2, O. Uchegbu2, F. Ozimede1
1Physiology, 2Medical Lab Science, University of Benin, Benin city, Nigeria

Background: Erythrocyte sickling and adhesion are favoured by cellular dehydration, which increases the rate of hemoglobin polymerization and cell sickling. Potassium ions co-transport and calcium-activated potassium channel (Gardos channel) mediate erythrocyte dehydration in sickle cell disease and β-thalassemia. We investigated the in-vitro and in-vivo effects of various concentration of K+ ions in physiological solutions (PSS) as well as in cocos nucifera water (CNw) which is known for its natural high potassium content and isotonicity.

Aims: This study was aimed at ascertain the efficacy of high potassium isotonic solutions in rehydrating sickle cell and possibly reversing the sickling phenomenon in vivo and in vitro situations.

Methods: 1. Erythrocytes from twenty sickle cell anemia (SCA) as well as 46 healthy subjects were studied. One part was treated with sodium metabisulfite (Na2S2O4) solution to induce maximum sickling as controls while the other was subjected to different high concentrations of K+ in PSS as well as Cocos nucifera water (40mM, 80mM and CNw - 65mMOL/L) respectively. The procedure was repeated for the normal HB AA subjects. Also, both groups of subjects were given 10mL/kg body weight of coconut water to drink as a single dose for the in-vivo experiment. Blood samples were collected longitudinally before and after the oral ingestion, at 1hr and at 24hrs for analysis of red cell indices as well as stained blood films used to ascertain the percentage sickled erythrocytes count before and after the treatment in both cases.

Results: Maximum percentage counts of sickled cells after the addition of Na2S2O4 (45%) were observed which decreased significantly (P<0.05, respectively) to about 2% with Cocos nucifera and 10% with 80mM K+PSS. The count in 40mM K+PSS was not statistically significant. In both HB AA and SS subjects, MCHC values remained stable when compared with the pre-ingestion sample (P>0.05, respectively) while MCH increased significantly in both groups as early as 1hr and sustained till the 24th hour. MCHC was equally raised in the in-vitro samples (P<0.05, respectively). The morphology of red cells also indicated a lesser count of sickled red cells after the oral ingestion

Summary/Conclusions: Cocos nucifera water and other high potassium ion solutions can rehydrate the sickled erythrocytes by probably de-activating the Gardos channel to increase the mean corpuscular haemoglobin concentration (MCHC) and thereby restoring the normal red cell shape. We suggest a probable pharmacological value of the cocos nucifera water as well as other formulated high but isotonic fluids in SCA management.

VITAMIN D IN SPANISH CHILDREN WITH HEMOGLOBINOPATHIES. A.M. Bobes Fernández1,2,3,*, B. Ponce1,2, Y. Aguilar1,2, C. Garrido1,2, M. García-Morín1,2, E. Belinchon1,2, 1Hospital Gregorio Marañón, 2Facultad de medicina, Universidad Complutense de Madrid, 3Hospital Clinico San Carlos, Madrid, Spain

Background: Although vitamin D deficiency has been documented as a frequent problem in studies of children, there are limited data on the prevalence of this nutritional deficiency among children who suffer from sickle cells disease (SCD) or thalassemia. Vitamin D homeostasis is important to prevent osteopenia. Furthermore vitamin D deficiency has been associated with increased risk of common cancers, autoimmune diseases, hypertension, and infectious diseases. Vitamin D deficiency is now recognized as a pandemic. The major cause of vitamin D deficiency is the lack of sun. Although Spain has a high rate of sunny hours, we have found low levels of vitamin D in our patients with SCD or thalassemia.

Aims: The purpose of this work is to assess the status of vitamin D in children with SCD and thalassemia in our setting.

Methods: We have recruited children diagnosed with SCD and thalassemia between 1998 and 2016 and we have reviewed their vitamin D levels. We have chose the first vitamin value we obtained and the last one till today. Vitamin D was measured by quantitative determination of 25(OH)D. Deficit of vitamin D was defined by<30 ng/ml. The study enrolled 114 children. Most of them, with SCD diagnosis (94%). The type of anaemia was Hb SS (94 patients), Hb SC (25%) and Hb S-beta-thalassemia (5%). 60% of the children had vitamin D deficiency. We have divided children older than five years old in two groups: those with levels of vitamin D deficiency and those with levels of vitamin D sufficient. We have repeated this procedure for the first year of life.

Results: 60% of the children had vitamin D deficiency. We have divided children into 4 groups depending on the age. When considering vitamin D first determination: mean vitamin D levels in children below 2 years old were 39.5±13.3 ng/dl, 2-5 years old 27.9±13.8 ng/dl, and five years old had a mean vitamin D level of 35.5±14.6 ng/dl. Children aged between five and ten had 26.1±13.5 ng/dl of mean 25(OH)D. Finally in the group older than 10, we observed mean of 7.4±14 ng/dl. When having these low levels of vitamin D, we strongly recommend to start treatment with Cholecalciferol 25000IU/month. Regarding second levels of vitamin D, we have divided patients into those who presumably have the treatment of vitamin D therapy for children who do not. We present the results in the following Table 1.

Summary/Conclusions: The study found a high prevalence of vitamin D deficiency in children older than five years old(in the first determination) with SCD or thalassemia. However, we have significant decrease of levels in those not having vitamin D therapy. It is not well known the physiopathology of this factor deficiency, although it is supposed to be multifactorial. However we confirm that living in a sunny geographical situation with a healthy diet is not enough to maintain adequate 25(OH)D levels. Although vitamin D is the most important of vitamin D levels increase when having correct doses. We have also checked that older children have lower levels of vitamin D than younger boys. This could be explained by the fact that pre-teenagers spend lot of time at home instead of going out. If prophylaxis is made not only the vitamin levels will increase but bone growth also.

KNOWLEDGE OF SICKLE-CELL DISEASE IN HAUTE-NORMANDIE, SOCIO-DEMOGRAPHIC CONTEXT AND HEALTH CHARACTERISTICS: INTEREST OF THE IMPLEMENTATION OF A PATIENT EDUCATION IN SICKLE CELL DISEASE

H. Van Elst1,2, A. Lahary3, J.-M. Kerleau4, H. Levesque2
1Internal Medicine, Hopital Delafontaine, Saint Denis, 2Internal Medicine, 3Hematology, CHU Rouen, Rouen, 4Internal Medicine, Centre hospitalier de Dieppe, Dieppe, France

Background: Sickle cell anemia (SCA) is a genetic disease causing a severe disease manifesting by painful crisis but which can also be marked by organ complications. Mortality is still happening at a young age. Many of these complications may be better taken care of if treated early. The way to manage this disease is probably through Patient Education (PE).

Aims: The Secondary objective was to give them the opportunity to express their expectations of such a program.

Methods: We did an observational multicenter study. A self-questionnaire of 39 items was sent to all patients suffering from SCA followed in Haute-Normandie.

Results: Fifty patients (male / female ratio 0.92) out of 123 (40.6%) responded, mean age 33±10.5 years (SS genotypes [66%], SC[25%], S-beta-thalassemia [9%]), 56% of them were born outside of Metropolitan France, 36% came from French speaking African countries. Age range was 18±10.9 years. Despite the fact that their education has been disrupted by the disease for the majority (69.4% did not complete the level of education “baccalauréat” [9%]), 18% had graduated from high school or achieved a higher level, 18% had graduated from professional education, 10% had a primary / middle school level and 4% were illiterate. 68% of the patients had a job or were students. 48% of patients reported to practice physical activity at least once weekly. Tobacco was consumed on a daily basis by 14%, alcohol 2% and 4% for cannabis. Self-assessment of health status was 6.9 / 10, self-assessment of morale of 7.9 / 10 and impact of the disease on daily life was estimated at 5.4 / 10. The mean age at which specialized follow-up was started was 11±9 years. 88% of the patients stated that they understood everything the doctor said during consultation. Missed appointments were reported by 26% which was justified by forgetfulness, lack of will or physical incapacity. Regarding sources of information regarding SCA, patients declared asking their specialist first and then looking on the internet. 68% of subjects had a first-degree relative suffering from the same disease, 71% were able to talk about the disease with their family. While the triggers of crises and the management of crises were well-identified by patients (average scores of 13.8 and 12/20), “standards” were not met with chronic complications, prenatal diagnosis, and long term treatment (mean scores respectively of 7.4; 4.2 and 2 / 20). Average score on the whole questionnaire was 9/20. Most patients showed interest in PE (52.1%) vs 31.3% that claimed were not interested. 17.7% did not decide.

Summary/Conclusions: A majority of SCA adults followed in Haute-Normandie are first-generation migrants. Even if the disease has heavy impact on everyday life and school access, their education level appeared correct. PE sessions will need to be adapted to patient's perception of the disease, and the triggers of treatment. The majority of adults with SCA are motivated by PE, we will have to adapt to a heterogeneous population in terms of educational level, ethnic origin and knowledge of the disease.

DELAYED HAEMOLYTIC TRANSFUSION REACTIONS: A MASQUERADE OF SICKLE CELL COMPLICATIONS
H.N. Fernandez-Levy1,2, S. Kotsiopoulo1, N. Osugi1, J. Maitland1
1Haematology, Croydon University Hospital, London, United Kingdom
2Haematology, University College London Hospitals, London, United Kingdom

Background: Patients with sickle cell disease (SCD) may require repeated red blood cells (RBCs) transfusion, putting them at risk from minor blood group alloimmunization and the development of delayed haemolytic transfusion reactions.

Aim: To report a prevalence of recognized DTHR syndrome in patients with SCD.

Methods: We reviewed the cases of DTHR in SCD patients in a 5-year period (2010–2016). A total of 10 patients had a clinical picture compatible with DTHR and underwent treatment with high dose steroids, intravenous immunoglobulins (IVIG) or erythropoietin. Any patient received rituximab.

Results: The most common indications for transfusion were anemia due to vasococclusive sickle cell crisis or preoperative anaemia optimization. The cohort received partial exchange transfusion and phenotype matched RBCs. Before transfusion the median of Hb level was 69 g/L (baseline range 80g/L) and the nadir at haemolysis episode was 38 g/L. Ht was 21.9%, WBC was 17.3 × 10⁹ cells/L and mean LDH 1290 IU/L. The median time to develop DTHR was 7 days after the transfusion and approximately 6 days after the surgical interventions (range: 4–12 days) and all cases presented with symptoms of anaemia, jaundice, tiredness and tachycardia. The median age was 29 years with female predominance (6:4). Blood cultures were negative in 80% of patients and only positive in 2 cases. 30% of patients tested positive for viral infection on PCR. Mortality rate in our series was low (zero). Pain episodes and other complications associated with DTHR were treated as required and four cases were successfully monitored in HDU. One patient required noninvasive ventilations and inotropic support. Two patients received RBC transfusion as a high packed RBC. Possibly as their presentation mimics an acute vasocclusive crisis. In all cases haemoglobin stabilized and improved, symptoms resolved and patients were discharged on small course of oral antibiotics (median admission 6 days).

Summary/Conclusions: The symptoms of DTHR can easily be mistaken for other SCD complications, including infection and vasococclusive crisis. The diagnosis of DTHR is based on clinical suspicion, when there is a rapid Hb drop after a recent RBC transfusion with clinical signs of haemolysis. To support the diagnosis, laboratory tests (serial FBCs, haemolysis screen, DAT, measurement of Hb S levels) and exclusion of other aetologies are useful. Whenever a DTHR is suspected, further RBC transfusion should be withheld unless absolutely necessary, as it may precipitate acceleration of the hemolytic reaction. Patients in whom the diagnosis of DTHR is missed may receive repeat transfusions, which may contribute to the complications associated with SCD. The use of more extensive phenotypic matching of blood and minimizing RBC transfusion help to prevent DTHR. The present study emphasizes the importance of early recognition of symptoms and signs in correlation with a recent history of RBC transfusions, as DTHR can be a potentially life-threatening complication.

HBS MONITORING ON TOSOH G8 IN VARIANT HBA1C MODE IN CASE OF URGEN T RCE
S. Van Aelst1, E. Nackers1, K. Desmet1,2, D. Kieffer1,3,*
1Department of Laboratory Medicine, University Hospitals Leuven, 2Department of Cardiovascular Sciences, 3Department of Microbiology and Immunology, KU Leuven, Leuven, Belgium

Background: Pre- and post-transfusion HbS levels are used to document the efficacy of red blood cell exchange (RCE) in patients with sickle cell disease (SCD). In case of urgent RCE a 24/7 STAT analysis, with the ability to identify and quantify hemoglobin (Hb) S, is warranted.

Aims: We evaluated the use of Tosoh Automated Glycohemoglobin Analyzer HLC-723G8 (Tosoh Europe, Amsterdam, The Netherlands) for this purpose, using the variant HbA1c mode. Results were compared to our routine CZE Minicap Flex Piercing (Sebia, Lisses, France).

Methods: Within- and between-run imprecision were assessed using a sickle cell trait and a sickle cell anemia sample, aliquoted and stored at -80°C, twice a week. A linearity study was performed using control samples of HbS concentration (>25%) compared to our routine analyzer. The reference method was Tosoh G8. Good correlation with Minicap Flex Piercing system was found, although results were statistically not interchangeable. Our results suggest that TOSOH G8 in variant HbA1c mode generates lower HbS results in samples with a high HbS concentration (>25%) compared to our routine analyzer.

Results: <25% HbS results on TOSOH G8 differed between -0.34% to +0.36% compared to Minicap Flex Piercing. For samples with a HbS concentration >25%, differences in HbS results ranged from -8.76% to -0.43%.

Summary/Conclusions: In our clinical laboratory, TOSOH G8 is used in variant HbA1c mode to quantify HbA1c. Previous studies demonstrated reliable HbS identification using TOSOH G8 in variant Hba1c mode. Our study showed good analytical performance for HbS quantification using TOSOH G8. Good correlation with Minicap Flex Piercing system was found, although results were statistically not interchangeable. Our results suggest that TOSOH G8 in variant HbA1c mode generates lower HbS results in samples with a high HbS concentration (>25%) compared to our routine analyzer. However, the goal of RCE is to achieve a post-transfusion HbS level of 30% or less. Therefore, results obtained with TOSOH G8 are clinically acceptable to monitor post-transfusion HbS levels. Importantly, HbS on TOSOH G8 can only be requested in case of urgent RCE. Our routine hemoglobinopathy screening will still be performed using CZE Minicap Flex Piercing in combination with CE-HPLC Variant 1TM.

GENDER DIFFERENCES IN THE DEVELOPMENT OF CMR ABNORMALITIES AND CARDIAC COMPLICATIONS: A MULTICENTRIC PROSPECTIVE STUDY IN A COHORT OF SICKLE CELL DISEASE PATIENTS
A. Melton1, L. Pistola1, C. Gerardi2, E. Facchinii3, M. Alì0, M. P. Smacchia5, S. Campisi6, S. Maffei6, V. Vinci6, G. Restaino6, V. Postiano1, A. Pepe1, F. Donzelli1, G. Monasterio1, G. Sciaccia2, A. Azienda Ospedaliera Universitaria di Bologna1, Policlinico S. Orsola-Malpighi2, Bologna, Azienda Ospedaliero ASL5, Crotone, Policlinico Umberto I, Roma, Presidio Ospedaliero “Umberto I”, Siracusa, Azienda Ospedaliera “Garibaldi” Presidio Ospedaliero Nesa, Catania, Fondazione di Ricerca e Cura “Giovanni Paolo II”, Campobasso, Italy

Background: No data are available in literature about the relationship between gender and the development of CMR abnormalities and/or cardiac complications in sickle cell disease (SCD).

Aims: This prospective and multicentre study aimed to assess if there was an association between gender and risk of cardiac iron overload, heart dysfunction and dilation, left ventricular (LV) hypertrophy, and myocardial fibrosis, assessed by Cardiovascular Magnetic Resonance (CMR), and of cardiovascular complications in sickle cell disease (SCD) patients.

Methods: We considered 115 SCD patients (58 females, 34.79±13.26 years), consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network. Myocardial iron overload was assessed by the multislice multi-echo T2* technique. Biventricular function parameters and atrial areas were quantified by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.

Results: Table 1 shows the comparison between sexes in the development of cardiac outcomes. Males and females showed a similar risk of accumulating cardiac iron, but both patients with cardiac iron were females. Compared to females, males showed a significant lower risk of developing LV hypertrophy, although having a similar risk for biventricular dilation and dysfunction and for myocardial fibrosis. No patients with less than 31 years developed LV hypertrophy and iron overload. We considered 115 SCD patients (58 females, 34.79±13.26 years), consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network. Myocardial iron overload was assessed by the multislice multi-echo T2* technique. Biventricular function parameters and atrial areas were quantified by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.

Table 1.

Table 1.
Aims: Here we report our findings following a complete retrospective audit cycle, documenting the timeliness of analgesia administration and post-treatment pain review as per National Institute of Clinical Excellence and College of Emergency Medicine guidelines, in children with SCD presenting to a single inner city London ED over a 14 month period.

Methods: In 2014, we evaluated 48 patient records of children presenting to the ED, with respect to mild, moderate and severe pain scores, time of analgesia administration and pain review. Completing the audit cycle, 97 records were re-audited in 2015. A total of 145 admission records were evaluated.

Results: In 2014 the ED met CEM criteria for the timeliness of analgesia administration in 100% of severe and 95% of the moderate pain category; however fell 33% short of NICE standards. Pain review was poorly performed, identifying an area for improvement. Proportions meeting the aforementioned criteria fell significantly in 2015, except review of moderate pain, which increased by 25%.

Summary/Conclusions: We conclude CEM guidelines prompt timely administration of analgesia in patients with severe pain; however mild pain may be overlooked. NICE avoids this discrimination. Thus we recommend combining the mild and moderate pain categories to acknowledge the fluctuating nature of sickle pain and its tendency to rapidly escalate. In addition, we reiterate the need for regular pain reviews. This is important in ensuring analgesia is closely titrated to pain level.

Background: Acute pain is a hallmark presentation in sickle cell disease (SCD) and frequently requires attendance to the emergency department (ED).

Aims: We conclude CEM guidelines prompt timely administration of analgesia in patients with severe pain; however mild pain may be overlooked. NICE avoids this discrimination. Thus we recommend combining the mild and moderate pain categories to acknowledge the fluctuating nature of sickle pain and its tendency to rapidly escalate. In addition, we reiterate the need for regular pain reviews. This is important in ensuring analgesia is closely titrated to pain level.

Aims: The pantothenic acid level was significantly higher at baseline compared to β-thalassemia minor. Structural Hbpts are the main diagnosis in immigrants. The incidence is still small, although increasing in the last 3 years, so a neonatal screening program is being implemented. Both HPLC and CE are simple, fast and efficient methods in the diagnosis of Hbpts. In our laboratory, the pantothenic acid and malondialdehyde, glutathione and total antioxidant capacity of children with sickle cell disease.

Methods: This study included children with sickle cell disease (HbSS) aged 1-14 years with mean age 7.45±0.0±0.50±0.613 years presenting to the sickle cell clinic unit of Federal Teaching Hospital Gombe, Gombe State. Subjects received sustained release oral L-arginine supplementation of 350mg twice daily for 8 weeks.

Results: L-arginine and nitric oxide levels were significantly higher among sickle cell disease children. There were no statistically significant differences between the baseline and post L-arginine supplementation in the PCV, HbC, RBC and LYM levels of subjects (p>0.05). There was a statistically significant difference between the baseline and post L-arginine supplementation levels among subjects with vaso-occlusive crisis (p=0.002 and 0.000 respectively). The pantothenic acid level was significantly higher at baseline compared to β-thalassemia minor. Structural Hbpts are the main diagnosis in immigrants. The incidence is still small, although increasing in the last 3 years, so a neonatal screening program is being implemented. Both HPLC and CE are simple, fast and efficient methods in the diagnosis of Hbpts.

Background: Sickle cell disease is a global public health problem. As of 2013 about 3.2 million people have sickle-cell disease with 176,000 deaths.

Aims: In this present study, we investigated the effect of 8 weeks, low dose supplementation of sustained-release of nitric oxide generating L-arginine supplement (350mg) given two times daily on the full blood count, L-arginine, nitric oxide, Pantothenic acid, plasma malondialdehyde, glutathione and total antioxidant capacity of children with sickle cell disease.

Methods: This study included children with sickle cell disease (HbSS) aged 1-14 years with mean age 7.45±0.0±0.50±0.613 years presenting to the sickle cell clinic unit of Federal Teaching Hospital Gombe, Gombe State. Subjects received sustained release oral L-arginine supplementation of 350mg twice daily for 8 weeks.

Results: L-arginine and nitric oxide levels were significantly higher among sickle cell disease children. There were no statistically significant differences between the baseline and post L-arginine supplementation in the PCV, WBC, RBC and LYM levels of subjects (p>0.05). There was a statistically significant difference between the baseline and post L-arginine supplementation in the MCV, MCH, MCHC, PLT, NEU, EOS, MON and RDW-SD levels of subjects (p<0.05). The L-arginine and nitric oxide levels were significantly higher post supplementation compared to baseline levels (p=0.002 and 0.000 respectively). There were no statistically significant differences between the baseline and post L-arginine supplementation levels among subjects with vaso-occlusive crisis (p=0.002 and 0.000 respectively).

The Total Antioxidant Capacity and Glutathione levels were significantly higher post supplementation compared to baseline levels among sickle cell disease subjects with vaso-occlusive crisis (p=0.001, 0.01 and 0.05 respectively). The pantothenic acid and malondialdehyde levels at baseline were significantly higher than the post supplementation levels among subjects with vaso-occlusive crisis (p=0.002 and 0.000 respectively). The Total Antioxidant Capacity and Glutathione levels were significantly higher post supplementation compared to baseline levels among sickle cell disease subjects (p=0.05 and 0.000 respectively). The baseline plasma malondialdehyde level was significant higher that the post supplementation levels among the sickle cell disease subjects. There is need for more effort and resources to be dedicated to research especially in supplementation studies involving a larger population aimed at establishing specific treatment for sickle cell disease. It is recommended that L-arginine supplementation be included in the management of patients with sickle cell disease particularly those with vaso-occlusive crisis. We observed a statistically significant negative correlation between the L-arginine levels and the red cell count among sickle cell disease subjects (r=-0.350, p=0.043).

Background: Recent years due to immigration, with an increase in structural Hbpts. In our laboratory, the pantothenic acid and malondialdehyde, glutathione and total antioxidant capacity of children with sickle cell disease.

Methods: This study included children with sickle cell disease (HbSS) aged 1-14 years with mean age 7.45±0.0±0.50±0.613 years presenting to the sickle cell clinic unit of Federal Teaching Hospital Gombe, Gombe State. Subjects received sustained release oral L-arginine supplementation of 350mg twice daily for 8 weeks.

Results: L-arginine and nitric oxide levels were significantly higher among sickle cell disease children. There were no statistically significant differences between the baseline and post L-arginine supplementation in the PCV, WBC, RBC and LYM levels of subjects (p>0.05). There was a statistically significant difference between the baseline and post L-arginine supplementation in the MCV, MCH, MCHC, PLT, NEU, EOS, MON and RDW-SD levels of subjects (p<0.05). The L-arginine and nitric oxide levels were significantly higher post supplementation compared to baseline levels (p=0.002 and 0.000 respectively). There were no statistically significant differences between the baseline and post L-arginine supplementation levels among subjects with vaso-occlusive crisis (p=0.002 and 0.000 respectively). The Total Antioxidant Capacity and Glutathione levels were significantly higher post supplementation compared to baseline levels among sickle cell disease subjects with vaso-occlusive crisis (p=0.001, 0.01 and 0.05 respectively). The pantothenic acid and malondialdehyde levels at baseline were significantly higher than the post supplementation levels among subjects with vaso-occlusive crisis (p=0.002 and 0.000 respectively). The Total Antioxidant Capacity and Glutathione levels were significantly higher post supplementation compared to baseline levels among sickle cell disease subjects (p=0.05 and 0.000 respectively). The baseline plasma malondialdehyde level was significant higher that the post supplementation levels among the sickle cell disease subjects. There is need for more effort and resources to be dedicated to research especially in supplementation studies involving a larger population aimed at establishing specific treatment for sickle cell disease. It is recommended that L-arginine supplementation be included in the management of patients with sickle cell disease particularly those with vaso-occlusive crisis. We observed a statistically significant negative correlation between the L-arginine levels and the red cell count among sickle cell disease subjects (r=-0.350, p=0.043).

Summary/Conclusions: In our area there is a predominance of β-thalassemia minor. Structural Hbpts are the main diagnosis in immigrants. The incidence is still small, although increasing in the last 3 years, so a neonatal screening program is being implemented. Both HPLC and CE are simple, fast and efficient methods in the diagnosis of Hbpts. In our laboratory, the pantothenic acid and malondialdehyde, glutathione and total antioxidant capacity of children with sickle cell disease.

Methods: This study included children with sickle cell disease (HbSS) aged 1-14 years with mean age 7.45±0.0±0.50±0.613 years presenting to the sickle cell clinic unit of Federal Teaching Hospital Gombe, Gombe State. Subjects received sustained release oral L-arginine supplementation of 350mg twice daily for 8 weeks.

Results: L-arginine and nitric oxide levels were significantly higher among sickle cell disease children. There were no statistically significant differences between the baseline and post L-arginine supplementation in the PCV, WBC, RBC and LYM levels of subjects (p>0.05). There was a statistically significant difference between the baseline and post L-arginine supplementation in the MCV, MCH, MCHC, PLT, NEU, EOS, MON and RDW-SD levels of subjects (p<0.05). The L-arginine and nitric oxide levels were significantly higher post supplementation compared to baseline levels (p=0.002 and 0.000 respectively). There were no statistically significant differences between the baseline and post L-arginine supplementation levels among subjects with vaso-occlusive crisis (p=0.002 and 0.000 respectively). The Total Antioxidant Capacity and Glutathione levels were significantly higher post supplementation compared to baseline levels among sickle cell disease subjects with vaso-occlusive crisis (p=0.001, 0.01 and 0.05 respectively). The pantothenic acid and malondialdehyde levels at baseline were significantly higher than the post supplementation levels among subjects with vaso-occlusive crisis (p=0.002 and 0.000 respectively). The Total Antioxidant Capacity and Glutathione levels were significantly higher post supplementation compared to baseline levels among sickle cell disease subjects (p=0.05 and 0.000 respectively). The baseline plasma malondialdehyde level was significant higher that the post supplementation levels among the sickle cell disease subjects. There is need for more effort and resources to be dedicated to research especially in supplementation studies involving a larger population aimed at establishing specific treatment for sickle cell disease. It is recommended that L-arginine supplementation be included in the management of patients with sickle cell disease particularly those with vaso-occlusive crisis. We observed a statistically significant negative correlation between the L-arginine levels and the red cell count among sickle cell disease subjects (r=-0.350, p=0.043).

Summary/Conclusions: In SCD male and female seem to show a comparable risk in developing cardiac complication, although compared to females, males showed a significant lower risk of developing LV hypertrophy. There are no specific guidelines for SCD patients and, as a consequence, the cardiovascular follow-up is conformed to that of thalassemia patients (complete cardiac evaluation performed annually for both genders). Our data not support a different follow up time based on the gender.
Summary/Conclusions: L-arginine supplement should be made available in the paediatric emergency unit, clinic and pharmacy department in high risk communities to obviate the negative effects during vaso-occlusive crisis and potentially reduce the length of stay in the hospital. L-arginine, nitric oxide, total antioxidant capacity, malondialdehyde and glutathione levels should be routinely monitored in sickle cell disease patients particularly those presenting with vaso-occlusive crisis.

Saint-Justine, University of Montreal, Montreal, Canada, 11Hematology Department, Hospital Infantil Universitario Nino Jesus, Madrid, Spain, 12Institute of Hematology and Oncology Paediatrics, Hospices Civils de Lyon, Lyon, France, 13Hospital Sino Libanês, San Paulo, Brazil, 14Division of Stem Cell Transplantation and Immunology, Hospital for Children and Adolescents of Frankfurt, Frankfurt, Germany

Background: Body mass index (BMI) may influence outcome after allogeneic transplantation. Previous studies have demonstrated that being obese or underweight may have a detrimental effect on survival rates after chemotherapy induction in children with acute leukemia. However, the impact of BMI of transplanted patients on survival is still not clear, with conflicting results being reported on this issue.

Aims: To analyze the effect of BMI on UCBT outcomes in children with acute leukemia

Methods: We retrospectively analyzed 517 patients aged from 2 to 20 years with acute leukemia who underwent umbilical cord blood transplantation (UCBT) from 1990 to 2015. Patients were classified according to BMI as normal (5 th-85th percentile), underweight (<5th percentile), overweight (85th-95th percentile) and obese (>95th percentile) by using growth charts for age and gender.

Results: Sixty-one percent (n=314) of patients were in the normal category, 12% (n=63) were underweight, 15% (n=80) overweight and 12% (n=80) obese. All patients received single-unit UCBT after a myeloablative conditioning regimen. Diagnosis was acute lymphoid leukemia in 70% (n=363) and acute myeloid leukemia in 30% (n=154). Median age at UCBT was 7.4 years (range 2-19.6). Cytomegalovirus (CMV) serology was positive in 45% patients; 60% of patients were male. Most patients (92%) were in complete remission at the time of UCBT. Median follow-up was 52 months (range 2-201). Total body irradiation (>6 Gy) was used in 58% of cases; antithymocyte globulin (ATG) in 68% of cases. Median infused total nucleated cell (TNC) dose was 4.2x10^7/Kg (0.3-17.8); 56% of patients received a graft with 0-1 HLA mismatch donor. Four-year overall survival (OS), leukemia-free survival (LFS) and graft-versus-host disease-free, relapse-free survival (GRFS) were 45±2%, 43±2% and 35±2%, respectively. Cumulative incidence function (CIF) of neutrophil engraftment was 88.6% (85.9-91.4%); CIF for acute GVHD was 34% (30.1-38.4%) at 100 days. At 4 years chronic GVHD was 19.1% (15.7-23.3%), relapse incidence was 34.5% (30.1-38.8%) and non-relapse mortality (NRM) was 22.8% (19.2-26.7%). In univariate analysis, no statistically significant difference in OS, LFS, GRFS, neutrophil engraftment, NRM and chronic GVHD between the 4 groups identified according to BMI was identified. Conversely, acute GVHD was 44.3% (33.3-58.8%) for underweight, 36% (31-41.8%) for normal, 26.2% (18.1-38%) for overweight and 23.3% (14.7-37.1%) for obese (p=0.03). Among patients underweight who experienced acute GVHD (n=27), 37.5% had grade III-IV acute GVHD with gut involvement. In multivariate analysis, infused TNC dose >4.2x10^7/Kg was associated with higher neutrophil engraftment (HR=1.46, CI 95% 1.07-2.04, p=0.02), higher incidence of acute grade II-IV GVHD (HR=1.6, CI 95% 1.17-2.17, p=0.03) and female gender (HR=1.5, CI 95% 1.03-2.33, p=0.03) were associated with higher NRM. ATG use (HR=1.6, CI 95% 1.05-2.31, p=0.03) was associated with higher relapse incidence. Moreover, ATG use and positive CMV serology were associated with worse OS (HR=1.6, CI 95% 1.15-2.17, p=0.04 and HR=1.3, CI 95% 1.01-1.69, p=0.001, respectively) and LFS (HR=1.6, CI 95% 1.01-2.51, p=0.03 and HR=1.3, CI 95% 1.04-1.72, p=0.02, respectively). Infused TNC >4.2x10^7/Kg was associated with higher neutrophil engraftment (HR=1.46, CI 95% 1.07-2.04, p=0.02), lack of ATG in the conditioning (HR=2.72, CI 95% 1.63-3.1, p=0.001) and BMI <5th percentile (HR=1.8, CI 95% 1.19-2.78, p=0.001) were associated with higher incidence of acute grade II-IV GVHD.

Summary/Conclusions: In conclusion, we did not find association of obesity with transplant outcomes in this study population. However a BMI <5th percentile at UCBT was found to be associated with higher risk of acute GVHD, highlighting the importance of nutritional status before UCBT.
LATE COMPLICATIONS OF CONDITIONING REGIMENS (CYCLOPHOS- PHAMIDE - TOTAL BODY IRRADIATION vs BEAM) FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN NON-HODGKIN LYMPHOMA.  
S. Paniagua1,2, A. Montero1, C. Gomez Segura1, I. Garcia Cadenas1, A. Esquiro1, R. Martino1, J. Sierra1, J. Briones1  
1Hematology, 2Radiotherapy, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Autologous stem cell transplantation (ASCT) is a frequently used procedure for the treatment of patients with relapsed non-Hodgkin lymphoma (NHL). While chemotherapy-based regimens are now commonly administered, total body irradiation (TBI) was largely used in the past. The current conditioning regimen in our center is BEAM (a combination of carmustine (BCNU), etoposide, cytarabine and melphalan) although we also have a large experience with cyclophosphamide (CFM)-total body irradiation (TBI) since this was the usual conditioning until year 2000.

Aims: To analyze the cumulative incidence of secondary neoplastic complications (grade 3-4 infections, cardiovascular and pulmonary toxicity) after the two conditioning regimens (CFM-TBI vs BEAM) for ASCT.

Methods: We performed a retrospective analysis of patients with NHL that received an ASCT between October 1992 and December 2012. The late complications were defined as those to other previous comorbidity or to aging. Statistical analysis was performed using the IBM SPSS Statistics version 21.0. Cumulative incidences were estimated using EZR version 1.27 (Saitama Medical Center, Jichi Medical University, Omiya, Japan), a graphical user interface for R (version 3.1.1).

Results: A total of 105 allografted patients were analyzed. Patient’s characteristics are in Table 1. The median follow up since ASCT was 73 months (0 – 274 months). Thirty-one percent (n=33) of patients were conditioned with CFM-TBI. The overall 5-years survival (OS) was 68.3% (58-77% - CI 95%) and the 5-year disease free survival (DFS) was 52% (42.6% - CI 95%). There were no differences regarding OS and DFS between the two conditioning regimens. The 5-years cumulative incidence (CI) of relapse was 0.48 (0.37-0.57). CI 95%.

We detected 10 secondary neoplasm (myelodysplasia n=1, skin carcinoma n=2, lung carcinoma n=3, oropharigeal carcinoma n=1, intestinal adenocarcinoma n=1, renal neoplasia n=1, bladder neoplasia n=1). The median time for the neoplastic event was 10.5 years (0-18.5 years). The CI of secondary neoplasias (2nd neoplasia) at 10 years was 10% (1-20%, CI 95%) and at last point of follow up (18.5 years) was 40% (13%>63%, CI 95%). There were no differences in the CI of 2nd neoplasias between BEAM and CFM-TBI. Non-neoplastic complications were present in 10% of patients (n=11). Three cases were infections grade 3-4 related to ASCT. Six cases had cardiac complications (5 acute coronary syndrome, 1 myocarditis) and 2 had pulmonary toxicity. The CI of non-2nd neoplastic complications at 10 year was 10% (1 – 25%, CI 95%). No differences were detected between the two conditioning regimens regarding non-neoplastic complications. (see Figure 1).

Figure 1.

Summary/Conclusions: Autologous stem cell transplantation offers long disease-free survival for half of the patients with a high risk non-Hodgkin lymphoma. In our series, patients conditioned with BEAM or CFM-TBI had a comparable incidence of neoplastic and non-neoplastic events.

PB2158

PROSPECTIVE PHASE STUDY OF REDUCED TOXICITY CONDITIONING CONSISTED OF HIGH DOSE-CYTARABINE, FLUDARABINE, CYCLOPHOSPHAMIDE +/- TOTAL BODY IRRADIATION FOLLOWED BY ALLOGENIC STEM CELL TRANSPLANTATION  
1Hematology, Gifu University Graduate School of Medicine, 2Hematology, Gifu Red Cross Hospital, 3Internal Medicine, Gihoku Kosei Hospital, Gifu, Japan

Background: Allogeneic hematopoietic stem cell transplantation (allo-SCT) using reduced intensity conditioning (RIC) has been widely applied to elderly or frail patients who are not eligible for conventional conditioning regimen. However, benefit provided by reduced toxicity has been often offset by increased incidence of relapse. So far, the optimal conditioning for those patients has not been established.

Aims: Here, to investigate whether addition of high dose cytarabine (Arac) to RIC regimen consisting of fludarabine (Flu) and cyclophosphamide (Cy) +/- total body irradiation (TBI) can be available for elderly or frail recipients, phase II study has been designed.

Methods: This study was conducted from April 2011 to December 2015. The protocol was approved by each institutional review board (Trial identifier: UMIN000007281). Patients aged from 55 to 70, or patients who have some organ damage or a history of SCT aged from 20 to 54 with hematologic malignancies were enrolled after obtaining written informed consent. Bone marrow (BM), peripheral blood (PB), or cord blood (CB) was used as stem cell sources. Pretransplant conditioning regimen consisted of 30 mg/m2 of Flu for 5 days (total 150 mg/m2), 4 g/m2 of AraC for 2-4 days (divided by 2 daily, total 8-16 g/m2) and 50mg/kg of Cy for a day. Four gray of TBI was used for all CB transplant recipients, whereas 2 gray of TBI was used in other stem cell sources. Graft-versus-host disease prophylaxis consisted of cyclosporine or tacrolimus and short term methotrexate were used as GVHD prophylaxis. Donor cell engraftment and 60 day-survival were assessed as a primary end point to evaluate feasibility of this protocol.

Results: Thirty nine patients including 7 recipients with a history of SCT were enrolled. Median age was 61 (28-69), 21 were male, and 18 were female. Nine-teen were acute myeloid leukemia, 11 myelodysplastic syndrome, 6 malignant lymphoma and 3 acute lymphoblastic leukemia. Donors were 4 matched related PB, 8 matched unrelated BM, 5 -Ag-allele-mismatched unrelated BM, and 22 ±2-Ag-mismatched CB. Thirty seven (94.9%) patients have passed 60-day-point post-transplant. In 38 (97.4%) recipients engraftment was obtained, a patient died before engraftment due to sepsis caused by enterococcus faecium (male CB recipient, 55y, day15). Median neutrophil recovery to over 500/μl was obtained on day 19 (16-38). Fourteen blood stream infections (13 bacteremias and 1 candidemia) judged as grade 3 toxicity and 2 cases (1 sepsis and 1 endocarditis) not accounting to each institutional policy. Calcineurine inhibitors (cyclosporine or tacrolimus) and short term methotrexate were used as GVHD prophylaxis. Donor cell engraftment and 60 day-survival were assessed as a primary end point to evaluate feasibility of this protocol.

Figure 1.  

Summary/Conclusions: RIC using Flu/high dose AraC/Cy +/- TBI was well tolerated with acceptable low toxicities and was sufficient to allow donor cell-engraftment post allo-SCT for elderly or frail patients with hematologic malignancies. Longer follow up and another prospective study enrolling more patients regarding non-neoplastic complications. (See Figure 1).

THE MANAGEMENT OF RELAPSED HODGKIN’S LYMPHOMA AFTER HAPLOIDENT STEM CELL TRANSPLANTATION: DONOR LYMHOYCYTE INFUSION AND BRENTUXIMAB.  
I. Sánchez Bazán1,2, A.L. Contento Gonzalo1, M.J. Pascual Cascón1, A.R. Martín Cerezo1, M.Á. Cuesta Casas1, A.I. Heiniger Mazo1  
1Hematology, Hospital Regional de Málaga, Málaga, Spain

Background: Hodgkin’s lymphoma, is an heterogeneous malignancy wich is posible to cure. For those patients who relapse, chemotherapy followed by an autologous stem cell transplantation (autoTPH) offers a second line treatment. Allogeneic transplantation (alo-SCT) is used for patients in relapse after auto-SCT or those with refractory advanced disease. Since 2012, with the experience of the Baltimore group, our Center has chosen the haploidentical family donor as a source for aloSCT in Hodgkin’s disease. Despite the promising results, the rate of relapse is between 25 and 35%, and there is not standard-ized treatment for this situation.

Aims: To analyze the outcome of post-transplant relapse treatment of haploid donor haematopoietic progenitors (haploTPH).
LEED group compared with the MCEC group (72% vs 13%; p < 0.01); (2) more frequent administration of rituximab before ASCT in the LEED group (84% vs 59%; p < 0.01); and (3) less frequent radiation therapy before ASCT in the LEED group (17% vs 37%; p=0.02). The 5-year OS rates were not significantly different between the LEED and MCEC groups (77% vs 88%; p=0.35). Likewise, both the 5-year CIs of relapse and NRM were similar in the two groups (relapse: 39% vs 33%; p=0.61, NRM: 1% vs 5%; p=0.71). In multivariate analysis that included the transplant periods, rituximab administration, and radiation therapy as independent variables, two or more prior regimens was extracted as an independent unfavorable prognostic factor for OS, but not conditioning regimens. Regimen-related toxicities within 100 days after ASCT were (n=3) infections: grade 3-4 nausea (28% vs 8%; p=0.01), diarrhea (36% vs 56%; p=0.02), and liver dysfunction (4% vs 36%; p=0.05). We observed Graft-versus-host disease in four patients, 3 of them presented moderate cutaneous affection, and one of them suffered hepatic graft-versus-host disease stage III, with adequate evolution after treatment.

Summary/Conclusions: It is possible to treat patients who relapsed after haploidentical stem cell transplantation with Brentuximab- DLi, with a very good tolerance. We observed cutaneous graft-versus-host disease in most of the patients who reached completed response after DLi. Despite this findings, we need multicentric studies to perform standarized treatments and protocols.

CONDITIONING REGIMENS BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION FOR PATIENTS WITH MALIGNANT LYMPHOMA – LEED vs MCEC –

H. Shimizu1,*, C. Naitoh2, Y. Osaki1, Y. Miyazawa3, K. Toyama2, H. Koiso1, A. Yokohama1, M. Morio3, H. Ogura4, N. Tsukamoto1, H. Handa1

1Gunma University, Maebashi, Gunma, 2Fujikoka General Hospital, Fujikoka, Gunma, 3Shibukawa Medical Center, Shibukawa, Gunma, 4Maebashi Sekijyu Hospital, Maebashi, Gunma, Japan

Background: High-dose chemotherapy before ASCT has been established as an effective treatment option for high-risk patients with chemo-sensitive ML. Although the therapeutic efficacy of this strategy highly depends on the conditioning regimens before ASCT, the appropriate regimen has been controversial. Thus, we performed a multi-center retrospective study of ASCT recipients with ML, to compare the safety and efficacy of the conditioning regimens LEED and MCEC, which are widely used in Japan.

Aims: The primary objective was to determine the preferable conditioning regimen before ASCT: LEED or MCEC.

Methods: This study analyzed 127 adult patients who underwent ASCT following LEED or MCEC as the conditioning regimen against chemo-sensitive ML at four institutions in Japan between 1997 and 2015. Any type of pathological diagnosis was considered. The LEED regimen consisted of 140 mg/m² PAM (day –1), 500 mg/m² etoposide (days –4 to –2), 60 mg/kg cyclophosphamide (days –4 to –3), and 40 mg/body dexamethasone (days –4 to –1). The MCEC regimen consisted of 200 mg/m² MOPP (days –3 to –1) and 300 mg/m² carboplatin (days –7 to –4), 500 mg/m² etoposide (days –6 to –4), and 50 mg/kg cyclophosphamide (days –3 to –2). Fisher’s exact test was used to compare binary variables. OS rates were estimated by the Kaplan-Meier method and compared using the log-rank test. Cumulative incidence of TRM and RRD were estimated using the competing risk method. Fine and Gray’s method for CI of TRM and RRD was used to evaluate the risk factors on univariate analysis.

Results: Of the 127 patients, 76 were male and 51 were female, and the median age was 56 years (range: 18 to 68 years). Underlying diseases were DLBCL in 74 patients, mantle cell lymphoma in 16, other B-cell lymphoma in 14, Hodgkin lymphoma in 9, and T-NK-cell lymphoma in 14. The disease status at the time of transplant was first complete remission (CR) in 68, advanced CR in 27, and partial remission in 32. As the conditioning regimens before ASCT, 81 patients received LEED and 46 received MCEC regimen. No significant differences in patient characteristics, disease features, or transplant procedures were present between the two groups except for the following three factors: (1) ASCT in the later period (2007–2015) in the
PB2163

IMPROVEMENT IN BIVENTRICULAR CARDIAC MECHANICS NOTED IN PATIENTS UNDERGOING MYELOABLATIVE AUTOLOGOUS-HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR AL AMYLOIDOSIS

S. Heitner1,*, C. Purtell2, E. Scott3
1Knight Cardiovascular Institute, 2Department of Medicine, 3Knight Cancer Institute, Oregon Health and Science University, Portland, United States

Background: Primary amyloidosis (AL) is characterized by extracellular deposition of insoluble protein fibrils often with multisystem organ involvement. The Mayo staging model for determining prognosis in patients with cardiac amyloidosis takes into account troponin, NT-proBNP, and serum free-light chain difference in order to stage patients prior to undergoing autologous hematopoietic stem cell transplant (Auto-HCT). Since amyloidosis often involves the kidneys, serum biomarkers that require renal clearance are less reliable in the setting of significant renal dysfunction. 2D-echo and strain imaging offer non-invasive modalities for identifying early cardiac changes independent of renal function. These changes may also precede symptom improvement as assessed by NYHA classification.

Aims: Our hypothesis is that strain imaging is a feasible biomarker for cardiac response after Auto-HCT in AL amyloidosis.

Methods: Seven patients with biopsy-proven AL amyloidosis who were treated with a Melphalan based myeloablative regimen and Auto-HCT were evaluated retrospectively. Each patient underwent 2D-echo up to 36-days prior to treatment followed by repeat 2D-echo within 14-months. Strain imaging was performed using Echolink@. Chart review was conducted to determine associated NYHA functional classification and Mayo staging. Statistical analysis was performed using SPSS.

Results: Of the 7 patients studied, 3 were Mayo stage I, 2 stage II, 1 stage III, and 1 stage IV. The median follow-up from transplant was 47.4 months. There was one death at 20.4 months. The mean NYHA classification at baseline was 2.3 and after transplant was 1.9. Longitudinal, radial and circumferential left ventricular strain (LV) were evaluated, but only the global longitudinal strain (GLS) showed an improvement (baseline -14.69%; follow-up -16.84%; mean absolute improvement 2.15%; p <0.05) across all four Mayo Stages. There was no difference in GLS within individual stages. In patients with stable NYHA classification after treatment 2.15%; p <0.05) across all four Mayo Stages. There was no difference in response after Auto-HCT in AL amyloidosis.

Discussion: There was no difference in response after Auto-HCT in AL amyloidosis.

Summary/Conclusions: There was no significant improvement in left ventricular ejection fraction (LVEF) (Figure 1).

PB2164

AN ABSOLUTE NUMBER OF CD34+ CELLS IN BLOOD AS A PREDICTOR OF A SUCCESSFUL HARVEST OF HEMATOPOIETIC STEM CELLS IN DIFFERENT MOBILIZATION REGIMENS

I. Gaitseva1, Y. Davydova1, T. Gaponova1, N. Kapranov1, L. Kuzmina1, V. Trolitskaya1, E. Zvonkov1, E. Parovichnikova1, L. Mendeleeva1, V. Savchenko1
1Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Autologous stem cells transplantation (ASCT) has become necessary part in therapy of hematological diseases. Transfusion of at least 2x10^6 CD34+ HSCs per kg of patient’s weight allows achieving an adequate hematopoiesis after high-dose chemotherapy. The most optimal is to collect at least 2x10^6 CD34+ cells/kg with single harvest apheresis. Different mobilization regimens are available in hematopoietic stem cell transplantation (HCT). Since cardiotoxicity is a high risk of complications the determination of possible cardiac changes and their predictive value is very important.

Aims: The aim of the study was to identify significant parameter predicting CD34+ cells collection.

Methods: The study included 142 patients (pts) who underwent ASCT (80 m, 62 f, median age 53 y.o., 81 were diagnosed with multiple myeloma, 10 - Hodgkin’s lymphoma, 51 – non-Hodgkin’s lymphomas). WBC and absolute CD34+ number in the blood before the first apheresis and the number of CD34+ in the apheresis product were determined for each patient. There were three different mobilization regimens: 1) 2x10^6 CD34+ cells/kg for first apheresis. There was 6 pts - 4 g/m2 cisplatin, 60 μg/kg/day G-CSF (DHAP+G-CSF). CD34+ HSCs were evaluated with iSHAGE-protocol by BD FACSauto II flow cytometer. Results are presented as mean±SD. ROC-curve analysis was performed for WBC and the absolute number of CD34+ HSCs in the blood as the predictor markers for HSCs successful harvesting (2x10^6 CD34+ kg for fist apheresis).

Results: WBC mean was higher in pts with G-CSF mobilization scheme compared to Cph+G-CSF and DHAP+G-CSF (28.5±3.5 vs 10.4±0.9 and 9.0±1.8±10^9/l, respectively, p<0.001), but the absolute number of CD34+ HSCs in the blood (26.3±9.3 vs 5.5±5.6 and 93.9±22.3 μl, p=0.03) and the number of CD34+ in the leukapheresis product (1.9±0.7 vs 5.2±10^6 and 6.9±1.3±10^6/kg, p=0.01) were lower. Differences between Cph+G-CSF and DHAP+G-CSF in all parameters were not found. There was not any relationship between WBC and the number of CD34+/kg: the area under ROC-curve (AUC) didn’t differ from 0.5 for all mobilization regimens. Then absolute number of CD34+ in blood was investigated as predictor for harvest success, AUCs were 0.964, 0.938 and 0.979 (p<0.0001) for G-CSF, Cph+G-CSF and DHAP+G-CSF, respectively. In the ROC-analysis showed the optimal CD34+ number in blood was 29 CD34+ cells/μl in G-CSF mobilization, 24 CD34+ cells/μl in Cph+G-CSF and 27 CD34+ cells/μl in DHAP+G-CSF. To calculate universal level of absolute CD34+ number all data from 142 pts was used. In this case AUC was 0.952 and a threshold of successful harvesting was 20 CD34+ cells/μl in blood before apheresis with sensitivity of 96% and specificity of 81%.

Summary/Conclusions: Various mobilization regimens differ in count of leukocytes and CD34+ HSCs in peripheral blood: WBC was significant higher in G-CSF than in Cph+G-CSF and DHAP+G-CSF, but the absolute number of CD34+ cells was higher in chemotherapy-based mobilization and G-CSF than in DHAP-CSF alone. The absolute number of leukocytes in blood before apheresis was not a predictor factor of harvest success in all variants of mobilization regimens. If there is at least 20 CD34+ cells/μl in blood before apheresis it is possible to collect ≥2x10^6 CD34+ kg for single leukapheresis with high sensitivity and specificity independent of mobilization regimen.

PB2165

QUANTIFICATION OF CD34+ CELL AND ITS VIABILITY OF FRESH OR CRYOPRESERVED NUCLEATED CELLS BY IMAGE-BASED CELL COUNTER IS COMPARABLE TO STANDARD FLOW CYTOMETER

1Department of Pediatrics, 2Blood & Marrow Transplantation Center, 3Department of Internal Medicine, Hanyang University Medical Center, 4NanoEntek, Seoul, Korea, Republic Of

Background: As a standard method for quantification of CD34+ stem cells, flow cytometry has been widely used. However, it has some limitations such as

Figure 1.

Summary/Conclusions: We demonstrate that there is a clinically meaningful improvement in cardiac mechanics one year after Auto-HCT, despite no alteration in LVEF. This metric may prove useful in assessing organ response, especially when serum biomarkers are less reliable. Changes in left ventricular GLS occur independent of pre-transplant Mayo stage, although prospective studies are needed for confirmation. We further believe that improvements in RVFWS may predict clinical improvement.
expensive instrumentation, high reagent costs, and poor reproducibility between technicians and laboratories.

**Aims:** We developed and assessed an instrument performance of a newly-developed image-based microscopic cell counter (ADAM II™) for enumeration of CD34+ cell and its viability.

**Methods:** We used samples of fresh and cryopreserved nucleated cells from G-CSF-mobilized peripheral blood stem cells (PBSCs) as well as cord blood (CB). We assessed the reproducibility and linearity of the new device and compared numbers and viabilities of CD45+ cells and CD34+ cells determined with the ADAM II™ and flow cytometer.

**Results:** Each analysis used 10 aliquots from one sample to assess the reproducibility with CV=0.137-0.180: CD34+ cells, 0.08-0.56 CD34%(CD45). The number of CD45+ cells determined by ADAM II™ was sufficiently accurate over the expected range, and the intra-assay coefficient of variation (CV) was ≤10.8%. The linearity of CD34+ cell count was confirmed over a range of dilutions (0.5×-280 cells/sample). Linearity was satisfactory (R2=0.99). The numbers and viabilities of CD45+ cell and CD34+ cell obtained with the ADAM II™ were highly correlated with those obtained with the flow cytometer (R2=0.9841, p<0.0001). In all samples from fresh/cryopreserved PBSC and fresh/cryopreserved CB, there were no significant differences of total numbers and viabilities of CD45+ cell and CD34+ cell counts, also with the flow cytometer.

**Summary/Conclusions:** The newly developed image-based microscopic cell counter (ADAM II™) appears to be suitable for quantification of CD34+ cell and its viability of fresh or cryopreserved PBSCs or CBs.

**PB2166**

**EXTRACORPOREAL PHOTOPHERESIS IN STEROID-DEPENDENT OR REFRACTORY ACUTE GRAFT-VERSUS-HOST DISEASE**

S. Sakellari1, I. Batis1, E. Gavrilaki1,1, A. Panteliadou1, A. Lazarioud1, K. Leontopoulou1, D. Mallouri1, A. Bountia1, V. Constantinou1, E. Yannaki1, C. Smial1, A. Anagnostopoulo1

1Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

**Background:** Extracorporeal photopheresis (ECP) has been incorporated in the management of graft-versus-host disease (GVHD) post allogeneic hematopoietic cell transplantation (allo-HCT) in many centres. The introduction of ECP as an early second-line treatment in steroid-dependent or refractory patients with acute GVHD (aGVHD) remains under study. The rationale of its early use is based on the low incidence of complete responses to corticosteroids and the profound immunosuppression caused by traditional secondary treatments.

**Aims:** Based on our long-lasting experience in chronic GVHD, we aimed to prospectively assess the role of ECP in this high-risk population.

**Methods:** We enrolled consecutive patients with steroid-dependent or refractory grade (gr) II-IV aGVHD post allo-HCT from January 2013 to August 2016. All patients with unrelated or haploidentical donors received thymoglobulin (ATG) 5mg/kg as prophylaxis. Post-transplant GVHD prophylaxis included cyclosporine – methotrexate in myeloablative and cyclosporine – mycophenolate mofetil in reduced toxicity or intensity regimens. ECP was commenced after assessment of response to 5 days of steroid treatment according to our protocol: 2 sessions per week for 1 month, 1 session per week for 3 months, evaluation of response and 1 session/month for 6 months.

**Results:** We studied 20 patients, aged 35 (18-65), post allo-HCT with myeloablative (14), reduced toxicity (4) and intensity (4) conditioning, from sibling (3), matched (8) or one locus mismatched (8) volunteer unrelated and haploidentical (1). Disease risk index was high (10), intermediate (9) and low (1). Acute GVHD was observed at day +17 (8-50) in 15 patients, late-onset at+130 (110-160) in 4 patients and induced at +38 post donor lymphocyte infusion in a relapsed AML patient. Skin, intestine and liver involvement was evident in 6 patients, skin and intestine in 10 and skin only in 4 patients. Nine patients (2 with GvH, 7 with GrvH aGVHD) were steroid-dependent and 11 (8 with GvH, 3 with GrvH) steroid-refractory. ATG was administered simultaneously with ECP initiation in 14 and 13 respectively and other viral in 5 patients. Cumulative incidence of chronic GVHD was 77.4 at 1-year. The numbers and viabilities of CD45+ cell and CD34+ cell obtained with the ADAM II™ were highly correlated with those obtained with the flow cytometer (R2=0.9841, p<0.0001). In all samples from fresh/cryopreserved PBSC and fresh/cryopreserved CB, there were no significant differences of total numbers and viabilities of CD45+ cell and CD34+ cell counts, also with the flow cytometer.

**Summary/Conclusions:** The newly developed image-based microscopic cell counter (ADAM II™) appears to be suitable for quantification of CD34+ cell and its viability of fresh or cryopreserved PBSCs or CBs.

**PB2167**

**RAPID RECONSTITUTION OF NK1 CELLS IS ASSOCIATED WITH THE LOWER INCIDENCE OF GRAFT-VERSUS-HOST DISEASE AFTER ALLOGENIC TRANSPLANTATION**

X. Zhao1,*, L. Xu1, X. Yu1, Y. Chang1, X. Huang1

1Peking University Institute of Hematology, Peking University People’s Hospital, Beijing, China

**Background:** The balance between immunostimulation and immunoregulation in T cell immunity is achieved by a Th1/Th2/Th3/Tr1 and CD4+CD25+ regulatory T (Treg) cell paradigm.

**Aims:** We investigated the production of type1 (IFN-gamma, NK1), type2 (IL-13, NK2), type3 (TGF-beta, NK3) and regulatory cytokines (IL10, Nkr) from human peripheral blood to discuss the cytokine paradigm of NK cells in human allogeneic hematopoietic stem cells transplantation (allo-HSCT).

**Methods:** Forty patients undergoing haploidentical (n=27) and HLA-identical sibling (n=13) allo-HSCT between August 2009 and December 2009 were enrolled in this analysis after being originally selected using a protocol exploring the association of reconstituted donor derived NK1/NK2/NK3/NKr cells to GVHD and CMV reactivation.

**Results:** Expansion of NK2 and NK3 were found post allo-HSCT compared to healthy donor. The levels of Nkr reconstituted to donor’s level since day 15 post allo-HSCT, and the levels of NK1 in recipients post transplantation were consistently lower compared to donors’ levels until day 60 post allo-HSCT. Multivariate analysis showed that the higher levels of NK1 by day 15 were associated with lower overall acute GVHD (HR 0.157, 0.039-0.642, P=0.010) as well as II-IV acute GVHD (HR 0.260, 95%CI, 0.064-1.053, P=0.059). Meanwhile, the higher levels of NK1 by day 15 correlated with lower CMV reactivation (HR 0.011, 0.005-0.348, P=0.003).

**Summary/Conclusions:** These results indicate that rapid reconstitution of NK cells, especially NK1 cells would be helpful to prevent the development of graft-versus-host disease as well as CMV reactivation after allogeneic transplantation.

**Summary/Conclusions:** Our study shows that Bortezomib is a promising therapeutic option for refractory post-transplant autoimmunity with high tolerance and no related toxicities.
PB2169
POST-THAW CELL COUNT PREDICTS ENGRAFTMENT RATE IN CORD BLOOD TRANSPLANTATION
K. Isobe1,*, K. Koh1, R. Kawaki1, T. Ibaisa1, M. Yanagi1, K. Sasaki1, W. Katanabe1, M. Morii1, Y. Arakawa2, R. Hanada1
1Hematology/Oncology, Saitama Children’s Medical Center, Saitama, Japan

Background: The infused cell count in cord blood transplantation (CBT) is an important element for engraftment; however, the number in the prior reports has been based on the pre-thaw cell count. Therefore, the association between post-thaw cell count and engraftment rate, especially in pediatric patients, is unclear.

Aims: The aim of this study is to reveal the association between post-thaw cell count and engraftment rate in pediatric patients in the setting of CBT at our institution.

Methods: We retrospectively reviewed the medical records of 78 patients who underwent CBT between June 1998 and April 2016. We excluded the cases of CBT that required resucing after engraftment failure.

Results: Underlying disease was acute leukemia (AL) in 63 (ALL: 38; AML: 25) patients, chronic myeloid leukemia in one, malignant lymphoma (ML) in two, myelodysplastic syndrome (MDS) in three, aplastic anemia in one, and others (such as primary immunodeficiency syndrome) in eight. In terms of conditioning regimens, myeloablative conditioning was administered to 62 patients and reduced intensity conditioning was administered to 16 patients. The median age at CBT was 3 (range: 0–19) years, and the median follow-up period was 896 (range: 47–6236) days. The engraftment rate was 84.6%, primary engraftment failure was observed in 11 patients (AL:seven; ML: one; MDS: one; neutroblatoma, one; and others, one) and secondary graft failure was observed in one patient (sever congenital neutropenia). The engraftment rate was 55.1%, and 32 patients had died (cause of death: progressing disease in 19 patients). We analyzed the data on 34 patients of whom both of pre- and post-thaw CD34+ cell counts in the cord blood samples were available. The median pre-thaw CD34+ cell count was 1.67 × 10^5/kg and 1.51 × 10^5/kg, respectively, and they were significantly correlated with each other (r=0.73, p=0.52). In our study cohort, the engraftment failure occurred in five patients (primary in all patients). The median post-thaw CD34+ cell count was 1.60 × 10^5/kg in the patients who achieved engraftment and 1.01 × 10^5/kg in the patients who did not achieve engraftment. No statistically significant difference was observed between these two groups (p=0.30). When we defined the cut-off value of the pre-thaw CD34+ cell count as 1.2 × 10^5/kg in the patients who were infused with CD34+ cells more than the cut-off value, the specificity and sensitivity of graft failure was 79.3% and 60%, respectively. When we defined the cut-off value of the post-thaw CD34+ cell count as 0.7 × 10^5/kg in the patients who were infused with CD34+ cells more than the cut-off value, the specificity and sensitivity of graft failure was 96.6% and 40%, respectively.

Summary/Conclusions: We concluded that the risk of graft failure is more precisely predicted by the post-thaw than pre-thaw CD34+ cell count and that if the post-thaw CD34+ cell count is more than 0.7 × 10^5/kg, the risk of graft failure is very low.

COLONYFORMING CAPACITY OF HEMATOPOIETIC STEM CELLS MOBILIZED INTO PERIPHERAL BLOOD WITH VINIRELBINE AND GRANULOCYTE COLONY STIMULATING FACTOR
V. Balashova1, I. Kostroma2, I. Zarpeeva2, V. Ruguál1, S. Bessmeltsev2, A. Chechektin2, S. Griticaev2
1Laboratory of Leukemia Study, 2Hematological Clinic, Russian Institute of Hematology and Blood Transfusion, St. Petersburgh, Russian Federation

Background: One of the alternative method to mobilize stem cells from bone marrow to peripheral blood is using of vinorelibine with granulocyte colony stimulating factor (G-CSF). The specific features of vinorelibine are absence of hematopoietic stem cells.

Aims: The aim of the study was to determine the colonyforming capacity of hematopoietic stem cells mobilized into peripheral blood with vinorelibine and G-CSF.

Methods: Data of 11 patients with multiple myeloma (MM) and 1 patient with Hodgkin lymphoma (HL) were analyzed. Vinorelibine was injected IV in dose 50-70 mg (35 mg/m²). Daily lenograstim dose was 10 mcg/kg. The number of BFU-in 9/11 (75%) patients on 7 day. The number of gained CD34 + was 1.7-7.8×10^6/kg (Me 3.3×10^6/kg). Median number of BFU-E, CFU-GM, CFU-GM

URIC ACID LEVEL MIGHT BE A PROGNOSTIC INDICATOR FOR SURVIVAL IN PATIENTS WHO UNDERWENT ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION. SINGLE CENTER EXPERIENCE
N. Mandac Şanlı1,*, Ş. Şvögün2, L. Kaynar1, B. Eser1, M. Gecik1, A. Ünal1
1Hematology and Bone Marrow Transplant Center, Erciyes University School of Medicine, KAYSERİ, Turkey

Background: Uric acid (UA) is an abundant aqueous antioxidant that accounts for almost two thirds of all free-radical-scavenging activity in human serum. It is released from injured cells during conditioning for allogeneic hematopoietic stem cell transplantation (AHSCT).

Aims: The aim of this study was to evaluate the prognostic impact of pre transplantation uric acid levels on survival and mortality in allogeneic HSCT patients.

Methods: We retrospectively analyze 273 patients with hematologic diseases undergoing AHSCT. The patients were categorized as patients with acute leukemia, myelodysplastic syndrome, lymphoma patients and other hematologic disease diagnoses. A serum uric acid concentration 3.4 mg/dl was considered hypouricemia. Pretransplantation uric acid, creatine, total protein and albumin were analyzed. Univariate, multivariate Cox regression models and log-rank test were performed to uric acid, creatine, total protein and albumin associated with disease-free survival (DFS), overall survival (OS), early non relapse mortality (<30 days) and late non relapse mortality (<100 days).

Results: Pretransplantation low uric acid levels were detected in 57 (%20.8) members and low UA levels were significantly associated with DFS (HR: 0.52; p=0.027). None of the creatine, total protein and albumin were significantly associated with DFS (HR:0.98; p=0.98, HR:0.87=p=0.60, HR:1.15; p=0.66 ). There was no significant association between UA, creatine, total protein and albumin and overall survival (HR: 0.84; p=0.48, HR: 2.10; p=0.057, HR: 0.88; p=0.52, HR: 0.78; p=0.26), early relapse mortality (HR: 1.38; p=0.54, HR:2.16; p=0.29, HR: 0.61; p=0.25, HR: 0.53; p=0.13) and late non-relapse mortality (HR:0.57; p=0.35, HR: 0.21; p=0.29, HR: 1.04; p=0.94, HR: 1.07; p=0.92).

Summary/Conclusions: Uric acid is a natural antioxidant compound. UA reacts with oxygen-derived free radicals and becomes oxidized. Since humans are unable to catabolize UA to the more soluble compound allantoin due to lack of urate oxidase or uricase, the serum UA concentration is higher in humans than almost all other mammals. However, this high UA level in humans has been regarded as being beneficial in the presence of elevated oxidative stress. Our study supports that the uric acid is an antioxidant compound. We conclude that uric acid level is not a useful tool for predicting survival in patients who undergo allogeneic hematopoietic stem cell transplantation. This is the first report demonstrating a positive association between UA levels and survival analyses in allogeneic HSCT patients. Our findings are potentially clinically relevant. Confirmation in independent cohorts and further investigations into underlying mechanisms, such as reduced antioxidative capacity in hypouricemia, are warranted. In the coming years, as a result of increased works on this subject, uric acid may be considered a possible prognostic marker in allogeneic hematopoietic stem cell transplantation.

RISK FACTORS FOR HERPES SIMPLEX VIRUS-1/2 VIREMIA AND CLINICAL OUTCOMES FOLLOWING UNMANIPULATED HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION
F.-F. Tang1, L.-P. Xu1, X.-H. Zhang1, H. Chen1, Y.-H. Chen1, X.-D. Mo1, Y.-Q. Sun1, K.-Y. Liu1, X.-J. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: Herpes simplex virus(HSV)-1/2 can still be reactivated after allogeneic hematopoietic stem cell transplantation (allo-HSCT) even when the prophylactic acyclovir is used. However, the risk factors for HSV-1/2 viremia and the clinical outcomes following unmanipulated haploidentical HSCT remain unknown.

Aims: The aim of this study was to explore the risk factors for HSV-1/2 viremia in patients undergoing allogeneic haploidentical HSCT.

Methods: Nineteen patients with HSV-1/2 viremia and fifty-seven patients without HSV-1/2 viremia were enrolled to analyze whether the systemic HSV-1/2 viremia can act as a risk factor for HSCT. The risk factors for HSV-1/2 viremia included HLA disparity ≥2 loci (p=0.049) and cytomegalovirus (CMV) reactivation (p=0.028). The incidences of platelet engraftment, oral mucositis and severe haemorrhagic cystitis (HC) in patients with and without HSV-1/2 viremia were 77% and 94% (p=0.003), respectively.
78% and 13% (p=0.000), and 25% and 6% (p=0.04), respectively. Moreover, the median time to platelet engraftment in patients with and without HSV-1/2 viremia was 25 d(range, 11–80 d) and 17 d(range, 8–67 d) (p=0.004). In a multivariate analysis, HSV-1/2 viremia was associated with delayed platelet engraftment (p=0.038), a higher incidence of oral mucositis (p=0.000) and severe HC (p=0.038). However, HSV-1/2 viremia was not associated with non-relapse mortality (31.5% vs 31.1%, p=0.26), leukemic-free survival (60.9% vs 57.9%, p=0.46) and overall survival (61.2% vs 60.7%, p=0.37) (Figure 1).

Summary/Conclusions: Our data suggest that Flu/Mel-based RIST was a promising strategy for patients with hematologic malignancy, irrespective of (?) donor or stem cell sources. However, GRFS and OS of MDS were significantly worse than those of AL, and MDS is strongly associated with high NRM even with RIST. This indicates that we should pay more attention to NRM in MDS.

PB2174
INCIDENCE AND RISK FACTORS FOR THE DEVELOPMENT OF HEMORRHAGIC CYSTITIS ON HAPLOIDENTICAL TRANSPLANTATION M. Saez-Perdomo1, M. Perera1,*, J. Viedma1, C. Rodriguez1, A. Suarez1, L. Guerra1, J. Lopez1, T. Molero1, S. Jimenez1
1Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain

Background: Hemorrhagic cystitis (HC) is a serious complication occurring after allogeneic hematopoietic stem cell transplantation (HSCT) more frequent on haploidentical (haplo) HSCT, with an incidence of 10% to 70% (Silva et al. Haematologica 2010;95(7):1183–1190) associated mainly with the effect of cytotoxic agents such as Cyclophosphamide (Cy). The conditioning regimen, BKPyV infection and graft versus host disease have an implication in the incidence. Other authors related the reactivation of CMV and a previous transplantation as risk factors to HC development(Ruggen et al. Transplant Infectious Disease 2015:17:822–830).

Aims: With this study we aim to describe the HC incidence and risk factors in all haplo-HSCT performed in the Canary Islands.

Methods: We analyzed all consecutive haplo-HSCT from family donors performed at our Hospital between 2013 and 2016. The conditioning regimen used for the transplant was the Hopkins haplo protocol with high dose Cy (50 mg/kg on days 3 and 4) posttransplantation (PTCy). We used as HC prophylaxis intense hydration on the Cy administration day and the following 24 hours (using bladder wash only in 1 patient with cardiac dysfunction) and perfused MESNA at 100% of Cy dose beginning 15 minutes before the Cy administration on day 1 post and at 20% of Cy dose at days 0, 4 and 8 hours on all pts. We used SPSS V.23 to determine the cumulative incidence (CI) of HC.

Results: We performed 20 haplo-HSCT, of which 10 were males (1 was transplanted 3 times) and 8 were women. The mean age was 40 (range 16–64). The pts presented the following diagnosis: AML (10), ALL (1), EH (5), NHL (3), AM (1). 45% of pts received the haplo-HSCT in remission, 50% with refractory disease and 5% of pts did not receive previous treatment. 6 pts developed HC (36.5% CI at day +80) (Figure 1a) with a mean time from haplo-HSCT to onset of 23 days (range 3-42), 1 (17%) was grade 1, 4 (66%) grade II and 1 (17%) grade IV. The grade I case did not received the MESNA infusion like most of the other pts. No pts died due to HC and all cases resolved without sequelae. 12 pts received Cy pre- and post-transplant and only 8 pts received PTCy. The CI at day +80 for the pts with PTCy was 33.3% and for Cy pre- and post-transplant 38.3% (Figure 1b). We found no statistically significant difference on the CI of HC between these two groups.

The development of HC was related to Cy in 1 patient, who suffered from this complication on the second and third haplo-HSCT. For the rest of the pts (after day +30) the HC was related to BKPyV infection, as a consequence of the immunosuppression state of the patient, we also observed all these pts had positive serum viral load for CMV.

Summary/Conclusions: The incidence of HC associated to post-HSCT high Cy dose in our series is 15% lower than other ones. Most of them on grade 1 or 2 and without mortality associated. The risk of HC is high, particularly in the setting of highly pre-treated patients (especially those undergoing a 2nd transplant). The development of HC after day +30 is evidently associated to BKPyV as a contributing factor for continuous inflammation and CMV reactivation (as an immunosuppression marker). In our study, HC did not have an impact on the development of HC was related to Cy in 1 patient, who suffered from this complication on the second and third haplo-HSCT. The HC remains frequent with a high morbidity in particular when it is severe, often causing prolonged hospitalization and resource use. We need further studies to recognize the at-risk population early.
OUTCOME OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS UNDERGOING NON-MYELOABLATIVE ALLOGENIC STEM CELL TRANSPLANTATION AFTER TREATMENT WITH THE BRUTON TYROSINE KINASE INHIBITOR IBRUTINIB

D. Dubnyak1,*, N. Risinskaya2, M. Drokov1, N. Kostritsa3, L. Kuzmina1, V. Vucinic1

1Dept. Hematology & Clinical Oncology, University of Leipzig, Leipzig, Germany

Background: Although the Bruton tyrosine kinase (BTK) inhibitor ibrutinib significantly improves the prognosis of CLL patients (pts), allogeneic hematopoietic stem cell transplantation (HCT) remains the only curative option for the underlying disease. Our previous study demonstrated an OS of 87±9.5% at 12 months in 25 patients with clonal lymphocytic leukemia/myeloma (CLL/M), transplanted at our center (1). Here we report our experience with 117 more patients. Treatment with ibrutinib before HCT was investigated.

Methods: 117 CLL pts (median age at HCT 57 years [y], range 50-71 y) were treated. The median ibrutinib treatment lasted median 2.9 months (range 1-8). Conditioning regimen was Fludarabin 30 mg/m² on day -4 to -2 followed by 2 Gy total body irradiation. Disease status at HCT was Binet B (n=33) or Binet C (n=8). Most pts had Richter’s transformation (RT) diagnosed before HCT. Ten pts were in partial remission (PR) at HCT. Five pts were first in relapse. Donors were human leukocyte antigen (HLA) matched related (n=3, MRD) or HLA-matched unrelated (n=8, MUD). Pts received median 3 lines of therapy (range 1-6) including ibrutinib before transplantation. Classical cytogenetic analysis and fluorescence in situ hybridization (FISH) were carried out for every pt. A total of 5 pts had a deletion (del)(17p13) and one a del11q22.3.

Results: The average overall survival (OS) for all pts was 471 days (range 36-812) (Figure 1). The average OS of patients with del(17p13) was 379 days (range 66-628) compared to 456 days (range 36-812) for those without del(17p13), p=0.048. OS was not significantly influenced by the stem cell source (MUD vs MRD, p=0.63) or remission status PR1 vs >PR1 (353 vs 472 days, p=0.79). Non-matched CMV-Status (negative recipient and positive donor or positive recipient and negative donor) had an OS comparable to that of matched CMV-Status (p=0.73). Pts above the median age had a lower OS although this didn’t reach significance (p=0.39). EFS was median 126 days (range 26-628). Pts with or without a TP53 alteration had a similar EFS (p=0.91). Pts undergoing MRD-HCT had better EFS than those undergoing MUD transplantation (p=0.055). CMV-Status or age>median had no prognostic influence on the EFS (p=0.83 and p=0.39 respectively). Non-relapse mortality (NRM) was 32% at 10 months (Figure 1), which was consistent with a previous publication from our unit (Hebenstreit et al). The average OS for all pts was 471 days (range 36-812) (Figure 1). The average OS of patients with del(17p13) was 379 days (range 66-628) compared to 456 days (range 36-812) for those without del(17p13), p=0.048. OS was not significantly influenced by the stem cell source (MUD vs MRD, p=0.63) or remission status PR1 vs >PR1 (353 vs 472 days, p=0.79). Non-matched CMV-Status (negative recipient and positive donor or positive recipient and negative donor) had an OS comparable to that of matched CMV-Status (p=0.73). Pts above the median age had a lower OS although this didn’t reach significance (p=0.39). EFS was median 126 days (range 26-628). Pts with or without a TP53 alteration had a similar EFS (p=0.91). Pts undergoing MRD-HCT had better EFS than those undergoing MUD transplantation (p=0.055). CMV-Status or age>median had no prognostic influence on the EFS (p=0.83 and p=0.39 respectively). Non-relapse mortality (NRM) was 32% at 10 months (Figure 1), which was consistent with a previous publication from our unit (Hebenstreit et al).

Summary/Conclusions: Impact of chimerism in different T-helper subsets still need further investigation. We will continue our research and further results will be reported later.

ADIPOSE TISSUE CHANGES IN LYMPHOMA PATIENTS IN THE PERI-TRANSPLANTATION PHASE

J. Jabbour1,2, B. Manana3, A. Khareddine4, C. Saadeh5, C. Maya6, A. Bazarakarch6, D. Blaise7, E. Cheikh3

1Clinical Nutrition, American University of Beirut Medical Center, Beirut, Lebanon, 2Ecole Doctorale Sciences de la vie et de la santé, Aix Marseille Université, Marseille, France, 3Division of Hematology/Oncology, 4Bone Marrow Transplantation Program, 5Department of Radiology, American University of Beirut Medical Center, Beirut, Lebanon, 6American University of Beirut Medical Center, Beirut, Lebanon, 7Programme de Transplantation et Thérapie Cellulaire, Centre de Recherche en Cancérologie de Marseille, Institut Paoli Calmettes, Marseille, France

Background: Abdominal Visceral Adipose Tissues (VAT) have been shown to have inflammatory activity and have been used to predict cancer outcomes. The ratio of VAT/Total Adipose Tissues (TAT) is a negative predictor of progression free survival in Lymphoma patients on chemotherapy.

Methods: We assessed the changes in adipose tissues among stem cell lymphoma recipients in the peri-transplantation phase.

Results: Institutional Review Board approved this retrospective study for adult patients (age>16 years) having B and T lymphoma who underwent Stem Cell Transplantation (SCT). Each patient was imaged by PET/CT scan pre-SCT and in the 1st months post transplantation. A cross sectional image was analyzed at the level of the L3 to calculate TAT, VAT and Waist Circumference (WC). Data was analyzed by gender since body composition parameters differed significantly between the two categories in the literature.

Results: The study sample consisted of 91 patients [mean age: 37±13.5 years, n=52 (57%) males, n=39 (43%) females]. Patient characteristics were similar across gender categories except for weights (kg) and Body Mass Index (kg/m²): 88.1±28.6 vs 65.2±25.0, in males and females respectively (p=0.003). Changes from pre-SCT to 3 months post SCT revealed that TAT and VAT decreased with mean differences of 33±56 cm² (p<0.01) and 7.0±36 cm² (p=0.17) in males and 16±44 cm² (p=0.01) and 4±14 cm² (p=0.056) in females, respectively. Waist circumference decreased significantly with mean

Background: Although the Bruton tyrosine kinase (BTK) inhibitor ibrutinib significantly improves the prognosis of CLL patients (pts), allogeneic hematopoietic stem cell transplantation (HCT) remains the only curative option for the underlying disease. Data on pre-transplant treatment of CLL with ibrutinib are very limited. Here we present our experience of HCT in pts previously treated with ibrutinib.

Methods: 11 CLL pts (median age at HCT 57 years [y], range 50-71 y) were treated between 2014 and 2016 in our unit with non-myeloablative (nma) HCT after ibrutinib were included. Ibrutinib treatment lasted median 4.0 months (range 1-28). Conditioning regimen was Fludarabin 30 mg/m² on day -4 to -2 followed by 2 Gy total body irradiation. Disease status at HCT was Binet B (n=3) or Binet C (n=8). Two pts had Richter’s transformation (RT) diagnosed before nma-HCT. Ten pts were in partial remission (PR) at nma-HCT. Five pts were in first relapse. Donors were human leukocyte antigen (HLA) matched related (n=3, MRD) or HLA-matched unrelated (n=8, MUD). Pts received median 3 lines of therapy (range 1-6) including ibrutinib before transplantation. Classical cytogenetic analysis and fluorescence in situ hybridization (FISH) was carried out for every pt. A total of 5 pts had a deletion (del)(17p13) and one a del11q22.3.

Results: The average overall survival (OS) for all pts was 471 days (range 36-812) (Figure 1). The average OS of patients with del(17p13) was 379 days (range 66-628) compared to 456 days (range 36-812) for those without del(17p13), p=0.048. OS was not significantly influenced by the stem cell source (MUD vs MRD, p=0.63) or remission status PR1 vs >PR1 (353 vs 472 days, p=0.79). Non-matched CMV-Status (negative recipient and positive donor or positive recipient and negative donor) had an OS comparable to that of matched CMV-Status (p=0.73). Pts above the median age had a lower OS although this didn’t reach significance (p=0.39). EFS was median 126 days (range 26-628). Pts with or without a TP53 alteration had a similar EFS (p=0.91). Pts undergoing MRD-HCT had better EFS than those undergoing MUD transplantation (p=0.055). CMV-Status or age>median had no prognostic influence on the EFS (p=0.83 and p=0.39 respectively). Non-relapse mortality (NRM) was 32% at 10 months (Figure 1), which was consistent with a previous publication from our unit (Hebenstreit et al).
Allogenic hematopoietic stem cell transplantation (allo-HSCT) is an effective therapy for a variety of hematological malignancies. However, a lack of HLA-identical sibling donors or unrelated donors has restricted the application of allo-HSCT in hematological malignancies. Haploidentical HSCT (Haplo-HSCT) offers the benefits of rapid and nearly universal donor availability and, in the past decade, has been accepted worldwide as an alternative treatment for patients with hematological malignancies who do not have an HLA-identical sibling donor or who require urgent transplantation.

Aims: The purpose of this study was to investigate the incidence, causes and factors influencing overall and transplant-related mortality after Haplo-HSCT.

Methods: We analyzed all consecutive patients receiving Haplo-HSCT from family donors at our hospital from 2013 to 2016. The conditioning regimen used for the transplant was the Hopkins haplo protocol with high dose Cy (50 mg/kg on days 3 and 4) posttransplantation. We classified the patients before the Haplo-HSCT according to disease risk index (DRI), ECOG, Sorror score and EBMT risk score to evaluate the correlation between the physical state of the patients before the transplant and the survival (overall mortality (OM) and transplant-related mortality (TRM)). We used SPSS V.23 to calculate the cumulative Mortality incidence by the KM test and the Cox proportional hazards model.

Results: We performed 20 haplo-HSCT. 10 were males (1 was transplanted 3 times) and 8 were females mean age of 40 (range 16-64). Diagnosis: AML (1), AM (1), EH (5), NHL (3), AM (1). Forty five percent of patients received the haplo-HSCT in remission, 50% with refractory disease and 5% of patients died post transplant with an OM of 60%. The cumulative incidence (CI) of OM was 15% at 1 month (m), 35% at 3 m, 45% at 6 m, 55% at 1 year, and 60% at 2 and 3 years (Figure 1a).

Based on these results we create working hypothesis that HLA class II haplotype may predispose to severe post-transplant infectious or non-infectious complications and affect the risk of NRM. Because small number of analysed patients and documented high frequency of these haplotypes in population, further analysis is required.

Figure 1.
ence between OM from the different states of EBOV (p=0.356) and DRI (p=0.07), however we found a statistically significant difference for ECOG (p=0.028) (Figure 1b) and Sorror (p=0.016). On a pairwise analysis of the OM we found no statistically significance for EBOV, and found a statistically significant difference between the patients with low-high DRI (p=0.01), inter-
mediate-high DRI (p=0.001), ECOG-0 (p=0.046) and Sorror-0 (p=0.003). The multivariate analysis showed that ECOG-2 vs 0 (p=0.013, HR=46.59), Sorror 2-3 vs 0-1 (p=0.041, HR=19.55) and Sorror 4-5 vs 0-1 (p=0.005, HR=282.48) were significantly related with a higher incidence of OM. Five patients died of infection (41.67%), 3 of disease progression (25%), 1 of relapse (8.33%) and 3 of other causes (25%). Six patients died of TRM (50%).

The CI of TRM was 10.5% at 1 m and 31.6% at 3 m, 6 m, 1, 2 and 3 years (Figure 1c). When we analyzed the TRM depending on the physical status scores we only found a statistically significant difference between TRM incidence from the different states of ECOG (p=0.038) (Figure 1d) and no statistically significant difference for EBOV (p=0.366), DRI (p=0.372) and Sor-
ror (p=0.17). Furthermore the analysis we found statistically significant differences between ECOG-1-2 (p=0.018) and EBOV-1-5 (p=0.046), for Sorror we found a marginal statistical significant correlation between 0-1 (p=0.052), 0-2 (p=0.052) and 0-5 (p=0.052), for DRI we found no statistically significant differ-
ence. On the multivariate analysis we found no statistically significant cor-
relation between TRM and the physical status scores.

Summary/Conclusions: Despite the fact that Sorror, EBOV and DRI scores are widely validated to establish the risk of patients undergoing HSCT, in our experience ECOG remains a useful score for assessing the risk of TRM on patients receiving Haplo-HSCT. We think further studies with a larger sample would be necessary to confirm our results.

**PB2180**

**A SIMPLIFIED METHOD OF CRYOPRESERVATION OF PERIPHERAL BLOOD STEM CELLS WITH OVER 10% GRANULOCYTE CONCENTRATION FOR LESS THAN 36 MONTHS**

1Transfusion and Cell Therapy, 2Hematology, Aomori prefectural central hos-

tial, Aomori, 3Gastroenterology and Hematology, Hirosaki University Hospital, Hirosaki, Japan

**Background:** The long-term stability of cryopreserved peripheral blood stem cells (PBSCs) is an important concern for patients experiencing disease relapse. However, the quality of long-term cryopreserved PBSCs stored at -80°C by using simplified method has not been elucidated in detail. Cryopre-

served PBSCs undergo cell damage and decrease in viability, and those con-
taining granulocytes might influence cell loss.

**Aims:** The aim of this study was to evaluate the effect of cryopreservation for less than 36 months and the number of granulocytes in the cryopreserved PBSC products on CD34+ cells.

**Methods:** We examined the effects of cryopreservation on the viability of CD34+ cells that were stored for less than six months and those stored for 7–

24 months, and 25-36 months, and the change of CD34+ cell viability with higher granulocyte content. We also evaluated the correlations between the number of granulocyte in the cryopreserved PBSC products and the time to engraftment of lymphocyte or platelet. Informed consent was obtained prior to the procedure from all the patients following institutional guidelines.

**Results:** A total of 65 PBSC samples were collected. We compared three groups based on the cryopreservation period: (1) less than 6 months, (2) 7–24 months, and (3) 25-36 months. The median (range) viability of CD34+ cells after thawing was 81.8% (59.2–94.4), 80.5% (56.6–92.8), and 76.1% (54.5–89.6) in the three groups, respectively. No significant difference in the viability of the cells in either frozen period was observed (p=0.14, respectively). We compared the effect of granulocyte concentration (over 10% concentration against less than 10% concentration) on CD34+ cells viability. The median (range) viability of CD34+ cells containing >10% granulocytes was 76.6% (54.5–93.0%), and that for cells containing <10% granulocyte was 82.1% (59.1–

94.4%), respectively. There was significant difference in the viability of CD34+ cells between the two groups (p=0.02, respectively).

Second, we analyzed 81 autologous PBSC transplants after stored at -80°C by using simplified method. We studied two groups based on the granulocyte concentration (over 10% concentration against <10% concentration). No significant difference in the days to leukocyte >1.0x10^9/L and to platelet >20x10^9/L in either granulocyte concentra-
tion was observed. However, the median (range) time to platelet >50x10^9/L containing >10% granulocytes was 27.2(12-87), and that for cells containing <10% granulocyte was 20.3(10-51), respectively. There was a signifi-
cant difference in the days to platelet >50x10^9/L between the two groups (p=0.04, respectively).

Summary/Conclusions: Long-term cryopreservation represents a means of holding a potential therapeutic modality in reserve for use at a future date. In our study, PBSCs can safely be stored for at least36 months with a simple cryopreservation method at -80°C. The loss of the viability of CD34+ cells was greater when the granulocyte content was over 10% than in cells with less than 10% of granulo-
cytes. The effect of reduced CD34+ cells viability seems important for engraft-
ment. Difference in the day to platelet >50x10^9/L between the two groups based on the granulocyte concentration (>10% concentration against <10% concentra-
tion) was observed. Thus, a lesser granulocyte content could give a more reli-
able graft with better quality. Further research is necessary to observe the effect of long-term cryopreservation period and granulocyte content on the via-

bility of stored CD34+ cells.

**PB2181**

**LYMPHOCYTE RECONSTITUTION AFTER ALOGENIC TRANSPLANTATION, DOES EARLY RECOVERY HAVE ANY INFLUENCE IN SURVIVAL RATES?**

V. Verdugo1,*, M.A. Correa Alonso1, V. Rubio Sanchez1

1Hematology, Hospital Jerez de la Frontera, El Puerto de Santa Maria, Spain

**Background:** Immune reconstitution after AloTPH has significant influence on the procedure final success. Studies have established that early lymphocyte recovery can influence survival rates, associated to a reduction in mortality unre-

lated relapse (NMR) and, in some studies, also to a reduction in relapse rate.

**Aims:** Analyze our patients survival rates in terms of lymphocyte reconstitution in absolute value on day+30 and+60 post-HSCT. Check if there is any relationship between the number of transfused CD34+ progenitors and LT3+ and see if that possible link affects the speed of recovery after transplant t- lymphocyte count.

**Methods:** Analysis of the lymphoid recovery in a retrospective study of 63 of 71 patients transplanted (ALO, and Haplo Unrelated Donor) by AML and ALL between 2008- 2015. (8 died before the day+60). Table 1 shows the characteristics of the pre-transplanted patients and analyze the influence of the parameters of the infused product (CD34x10^6 and LTx10^8/kg r), type of transplantation modality) could affect the post-transplant survival. It has made a statistical - analysis of OS and DFS in relation to the number of lym-
phocytes on day +30 and +60 with Kaplan Meier compared the results with long-rank test and subsequent analysis of the variables collected with Cox Regression.

**Results:** After analyzing the product infused we observe a relationship between LT and lymphocyte recovery on day+30 (p=0.059, HR=2.48) and day +60 (p=0.059, cor. 0257) but not with the CD34x10^6 kg+ Figure 2 shows the patient characteristics in lymphocyte absolute count in the day +60. We analyzed the overall survival (OS) and disease - free survival (DFS) and a decrease in OS with statistical difference was evident in patients with <300 (p=0.0029) on day +60 and day+30 (p=0.05), a decline also in DFS, with no statistically significant difference (p=0.1). Multivariate analysis to determine which factors could influ-
ence the lymphoid recovery on day +60 and SG, we observed that the type of unrelated donor, myeloablative conditioning and ATG administration can influ-
ence a delay in a recovery. No differences were observed in the rest of the variables.

**Summary/Conclusions:** A delay in lymphocyte recovery is associated with a decrease in survival rates in our patients. Measures favoring an accelerated lymphocyte recovery (prophylactic use of thymoglobulin, adequate donor selection, and transplantation modality) could affect the post-transplant survival. It appears that the amount of infused product could play an important role in reconstitution, so it would be a factor to take into account prior to infusion.
PB2182

SUCCESFULL AUTOLOGOUS STEM CELL TRANSPLANTATION AFTER VELCADE-BASED REFRACTORY MULTIPLE MYELOMA PATIENTS

V. Martínez-Robles1; B. Ballina2; S. Cerda3; N. de las Heras4; J.A. Rodríguez-García3; F. Escalantes1

1Hematologia, Complejo Asistencial Universitario de León, LEON, Spain

Background: The optimal induction treatment for Newly Diagnosed Multiple Myeloma Patients needs combinations with Bortezomib-Based (Bor-based) schemes. Primary Refractory patients include patients with progressive disease or rapid (<60 d) relapse after these optimal induction approach have a very bad prognosis. Lenalidomide-Dexamethasone (LenDex) were usually the next step in the treatment of these patients, until the recent introduction of triplets combination LenDex-based. Autologous Stem Cell Transplantation (ASCT) have shown efficacy in NDMM younger patients that have got at least a partial response (PR) after the induction therapy. There are few data about toxicity and response of ASCT in primary refractory patient that can obtain a response with LenDex rescue treatment.

Aims: Analysis of tolerance, response and overall survival of ASCT-candidates that are primary refractory to Bor-Based induction treatment.

Methods: Retrospective analysis of our database. From 2010 to Nov-2016, 53 ASCT-Candidates (for 1st or 2nd ASCT procedures) were included. Median Age for diagnosis was 62 (46-71). Median Age for ASCT procedure was 63 (46-72). 12 of these 53 patients (22.6%) were considered primary refractory and considered candidates to get Bor-Based conditioning. 6 of them (50%) were woman. Characteristics of Disease: IgG kappa (4), IgG-lambda (3), IgA kappa (3), IgA lambda (1), Light Chain lambda (1). ISS I/III/I: 5/2/5. Induction treatment: VelDex (4), VTD (6), VCD (2). Median of cycles administered: 6 (2-8). Best Response to induction treatment: >PR (6), Minimal Response (1), progressive disease (3) relapsed (12). Plus to disease progression and two were successfully salvaged and are in complete remission (CR) with full donor chimerism (FDC).

Results: Morbidity or mortality (M&M) (0%) of ASCT procedure in refractory patients is similar to non-refractory patients. After a median follow up of 46 months from diagnosis for all ASCT-candidates group, the refractory patients got an overall survival of 46.2 months (3-72 m). Any of them have relapsed yet. 2 of them are in biological relapse without need of treatment.

Summary/Conclusions: Patients refractoriness to induction may receive ASCT after a rescue treatment LenDex based, as is effective in this group cohort. New combinations (triplet) with new drugs with LenDex-based treatment may improve the responses rates and overall survival before and after of ASCT procedure in these group.

PB2183

SAFETY AND EFFICACY OF TBF CONDITIONING IN PATIENTS UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION: A RETROSPECTIVE SINGLE CENTER EXPERIENCE.

R. Massoud1; N. Moukalled1; B. Haffar1; A. Zahreddine1; A. Bazarbachi1; J. El-Cheikh1

1Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon

Background: The optimal intensity of myeloablation with a reduced-toxicity conditioning (RTC) regimen to decrease relapse rate after allogeneic stem cell transplantation (allo-SCT) without increasing non-relapse mortality (NRM), has not been well established.

Aims: In this retrospective study at the American University of Beirut medical center (AUBMC) we aimed to evaluate the outcomes of patients who underwent allo-SCT with thiopeta, busulfan and fludarabine (TBF) as RTC.

Methods: We included twenty four consecutive patients with hematological malignancies who received TBF as conditioning for a-SCT from January to December 2016. All patients and transplant characteristics are listed in Table 1. All patients received the myeloablative conditioning regimen consisting of thiopeta (50mg/kg/day) infused on day 7 and -6, fludarabine (30mg/m2/day) infused on day 7 -5 to 6 and -2, and busulfan (130mg/m2/day) infused on day 7 -5 to day 3. All patients received 2.5mg/kg/day intravenous rabbit antithymocyte globulin (ATG) on days -2 and -1. GVHD prophylaxis for patients transplanted from haploidentical donors consisted of post-transplant cyclophosphamide 50mg/kg/day on day +3 and +4, cyclosporine started at 3 mg/kg/day on day +6 and readjusted according to level, and mycophenolate mofetil 500mgx4/day started on day +6 to +28. Patients transplanted from matched related donor, received cyclosporine as of day +1.

Results: Twenty three patients (96%) engrafted, with 14 days (range, 10-18) and 13 days (range, 4-8) as median time for neutrophil and platelet engraftment respectively. One patient who underwent haploidentical donor transplant with persistent disease for AML (karyotype 45,XY,-7) failed to engraft and died due to disease progression on day +22. After a median follow up of 10 months (range, 1-22) post-allo-SCT, the cumulative incidence of Grade-Iv acute GVHD (aGVHD) was 26%. One patient developed chronic limited GVHD (cGVHD). All the complication post allo-SCT are listed in table 1. Five patients (24%) relapsed post allo-SCT at a median of 163 days (range, 55-384), of log-rank test (1%) died due to disease progression and two were successfully salvaged and are in complete remission (CR) with full donor chimerism (FDC) at last follow up. Two patients developed JC virus progressive multifocal leukoencephalopathy, one of them died a full recovery and the other died in CR. The day 100 NRM was 0%. At last follow up 20 patients (83%) are alive in CR, with negative minimal residual disease and FDC.

Summary/Conclusions: Our results show that this TBF conditioning regimen appears to be safe, allows high rate of engraftment and low NRM rate among high-risk patients and can lead to a long-term disease control.

COMPLETE REMISSION STATUS BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION AS PROGNOSTIC FACTOR IN PATIENTS WITH NON-HODGKIN LYMPHOMA

A. Pinto1; A. Roque1; M. Gomes1; E. Cortesão1,2; A. Espadana1; A.B. Sarmento1,2; C. Geraldes2; M.L. Ribeiro2

1Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra, 2Faculty of Medicine and CIMAGO, University of Coimbra, Coimbra, Portugal

Background: High dose chemotherapy (HDC) followed by autologous stem cell transplantation (ASCT) is commonly used for treatment of relapsed or refractory non-Hodgkin’s lymphoma (NHL), as well as for first-remission consolidation in patients with mantle cell lymphoma. Disease status before ASCT is variable and is unclear whether complete response before ASCT or after ASCT correlates with better survival.

Aims: To evaluate the prognostic effect of disease status before ASCT - complete remission (CR) vs partial remission (PR) - in a cohort of patients with NHL.

Methods: Retrospective analysis of patients with NHL treated with HDC and ASCT between 2007 and 2016 in a single institute. All patients received peripheral blood stem cell support after conditioning with BEAM regimen (carmustine 300mg/m2, etoposide 800mg/m2, Ara-c 1600mg/m2 and melphalan 140mg/m2). Response was assessed according to The Lugano Classification. The Kaplan-Meier method was used to estimate progression free survival (PFS) and overall survival (OS) and comparison between risk groups was performed by using the log-rank test. Univariate analysis was performed and significant predictors at the level of 0.05 were used to adjust a multivariate Cox regression model.

Results: We included 83 NHL patients, mainly males (72.3%) with a median age at diagnosis of 51 years (18-65). The most prevalent pathological subtypes were diffuse large B cell lymphoma (53.0%), mantle cell lymphoma (36.1%) and follicular lymphoma (15.7%). The median number of therapeutic lines was 2 (1-5). Patients with diffuse large B cell lymphoma and follicular lymphoma were mainly treated with R-CHOP/R-CVP (82.5%) at first-line. For those who did not achieve a CR or relapsed after first-line treatment, (R)-ESHAP/DHAP/FICE (78.8%) was performed as second-line followed by ASCT as salvage therapy in order to achieve and consolidate CR. The majority of patients with mantle cell lymphoma received R-CHOP/R-DHAP (55.0%) followed by consolidation with ASCT in first remission. With a median follow-up time from ASCT of 39.66 months (0.3-117.6), OS at 2 and 5 years was 84.8%.
and 74.5% and PFS was 76.8% and 58.2%, respectively. Before ASCT, 60 patients (72.3%) were in CR and 23 (27.7%) were in PR. After ACST, 4 patients were not assessed for response due to early death by toxicity. Of the remaining, 70 (88.6%) achieved a CR, 4 (5.1%) a PR and 5 (6.3%) failed to respond. Patients in CR before ASCT presented significantly longer PFS compared with those in PR (107.9 vs 44.0 months, p=0.01). Besides that, patients that obtained CR after ASCT also had longer OS and PFS compared with those in PR (107.9 vs 8.0 and 107.9 vs 7.3 months, p<0.001). However, these patients had significantly lower PFS compared to patients that continued in CR after ASCT (45.3 vs 107.9 months, p=0.04). Univariate analysis indicated that remission status predicts OS (HR for CR vs PR) is a significant predictor of PFS after ASCT (HR 0.3; 95% CI 0.19-0.82, p=0.013). Multivariate Cox regression model showed that this factor retains prognostic value after adjustment for age, histological sub-type, Ann Arbor stage and number of previous lines of treatment.

Summary/Conclusions: Our results highlight the relevance of the obtained CR after ASCT in the OS. Furthermore, we conclude that patients with NHL who are in CR before ASCT have a better PFS than those in PR before ASCT. Additionally, continued CR after ASCT may also be an important prognostic factor. Our results suggest that the use of more effective induction regimens in order to improve initial response may be advantageous in terms of clinical benefits post-ASCT.

PB2185

AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MANTLE CELL LYMPHOMA: SINGLE CENTER EXPERIENCE

S.K. Toprak1, E. Atilla1, P. Ataca Atilla1, S. Civriz Bozdag1, M. Kurt Yusuf1, P. Topcuoglu1, T. Deminer1, O. Arslan1, M. Ozcan1, M. Arat2, O. Ilhan1, H. Akan1, M. Beksac1, N. Konur1, A. Uysal3, G. Gunnal1

1Ankara University School of Medicine Department of Hematology, Ankara, 2Florence Nightingale Hospital, Istanbul, 3Koru Hospital, Ankara, Turkey

Background: Mantle cell lymphoma accounts for relatively small proportion (3%-10%) of non-Hodgkin lymphoma. High-dose chemotherapy (HDT) and autologous-stem cell transplantation (ASCT) has played a critical role in the treatment of mantle cell lymphoma. Regardless of that, mantle cell lymphoma remains largely a relapsing/remitting disease.

Aims: Our aim is to present our mantle cell lymphoma patients who underwent ASCT.

Methods: We retrospectively evaluated our 21 mantle cell NHL patients. The patients were followed after ASCT for relapse.

Results: Patients were followed by a median time of 56.9 months (range, 6-170 months). The median age at diagnosis was 45 (range, 18-69), female to male ratio: 5/16. The stages and MIPI scores at diagnosis were as follows: 5% stage I, 19% stage III, 76% stage IV; Low MIPI 29%, intermediate MIPI 48% and high MIPI 23%. First-line treatments were R-CHOP for 6 cycles in 52% of patients (29%) and R-CHOP for 3 cycles followed by R-DHAP in 15 patients (71%). The median time to ASCT was 20 months (range, 7-46 months). All patients were in at least partial remission at the time of ASCT. The transplant conditioning regimen was CBV in 5 patients (24%) and R-/ICE in 5 patients (24%), R-/ ICE/BEAM in 11 patients (52%). Six patients (29%) achieved complete remission. Four patients (19%) died within three months of ASCT due to infection. Eleven patients (52%) was relapsed with a median time of 39 months (range, 4-123 months). Ten patients received BORID (bortezomib, rituximab, dexamethasone) and 1 patient received lenalidomide as salvage therapy and six of them achieved complete remission. Three patients underwent autologous hematopoietic stem cell transplantation as well as two patients underwent autologous hematopoietic stem cell transplantation and followed in remission. The median follow-up time was 7.3 months.

Summary/Conclusions: ASCT is a part of initial treatment strategy in fit patients with mantle cell lymphoma however 19 patients in our series had transplant related toxicity. Today, novel agents may present a less intense approach for achieving response.

PB2186

ALLOGENEIC STEM CELL TRANSPLANTATION IN CHILDREN WITH AUTISM

A. Gomes1, A. B. Mafra1, A. Zanette1, V. Rocha1

1Hematopoietic Stem Cell Transplantation, Hospital Sirio Libanês, Sao Paulo, Brazil

Background: Autism Spectrum Disorders (ASD) are severe heterogeneous neurodevelopmental abnormalities characterized by dysfunctions in social interaction and communication, restricted interests, repetitive and stereotyped verbal and non-verbal behaviors. The etiology of ASD remains unknown, but recent studies suggest a possible association with altered immune responses and ASD. Inflammation in the brain and Central Nervous System has been reported with microglia activation and increased cytokine production in post-mortem ASD brains. Several studies have demonstrated a correlation between ASD and family history of autoimmune diseases, associations with MHC complex haplotypes, and abnormal levels of various inflammatory cytokines and immunological markers in the blood. The paracrine, secretome, and immunomodulatory effects of stem cells would appear to be the likely mechanisms of application for ASD therapeutic.

Aims: Evaluation the benefits of HSCT in patients with ASD.

Methods: We describe two cases of patients with ASD who underwent HSCT for acute lymphoblastic leukemia (ALL) and whose symptoms were markedly decreased like an improvement of social interaction, communication, and behavior.

Results: The first patient was an 11-year-old girl with ASD who was diagnosed with Ph-positive ALL in October 2011 (at the end of treatment, BCR-ABL remained positive). She underwent a matched sibling HSCT in March 2015. The conditioning regimen was total body irradiation (TBI) and cyclophosphamide. During the 20-month follow-up period, we observed improvement in social interaction, communication, and behaviors. According to The Childhood Autism Rating Scale – CARS, prior to HSCT, she had a score of 39 (Severe Symptoms of ASD Disorder), and she currently scores 30 (Mild-to-Moderate Symptoms of ASD). The second case is a 7-year-old boy with ASD, Asperger Syndrome, who was diagnosed with ALL in September 2012. He presented with bone marrow and testicular relapse in May 2015 and underwent a matched unrelated HSCT in November 2015. The conditioning regimen was Etoposide, ATG and TBI. During the 12-month follow-up period, we observed improvement in social interaction, communication, and behaviors. According to CARS, prior to HSCT, he had a score of 39 (Severe Symptoms of ASD Disorder), and he currently scores 24 (Minimal-to-No Symptoms of ASD). There is no treatment for ASD thus every effort to minimize the symptoms are valuable. In both cases, social interaction was significantly increased, and the aggressive behaviors decreased. Clinical cases have reported responses in autistic children receiving cord blood CD34+ cells.

Summary/Conclusions: Several incurable neurological disorders have shown benefits with cellular therapy. Thus, autism should be explored as an indication. Clinical studies are an immediate need to fully explore its potential in autism.

RELATIONSHIP BETWEEN URIC ACID LEVELS AND CARDINAL FINDINGS IN A LARGE COHORT OF β-THALASSEMA MAJOR: GENDER-RELATED DIFFERENCES

A. Meloni1, C. Vassalle1, L. Pistola1, T. Gipp02, M. G. Bisconte3, G. Palazzì4, M. P. Smacchia5, N. Dello Iacono5, R. Ndreu1, A. Olivi5, V. Positano1, A. Pepe1
1Fondazione G. Monasterio CNR-Negro Toscana, Pisa, 2Azienda Ospedaliera Regionale San Carlo di Polenza, Potenza, 3Azienda Ospedaliera Cosenza - Presidio Ospedaliero “Annunziata”, Cosenza, 4Modena, Policlinico di Modena, 5Policlinico Umberto 1, Roma, 6Ospedale Casa Sollievo della Sofferenza IRCCS, San Giovanni Rotondo, Italy

Background: Iron overload, secondary to recurrent transfusions and ineffective erythropoiesis, induces oxidative stress in thalassemia (TM). Uric acid (UA), a major blood antioxidant, may act either as an antioxidant or pro-oxidant.

Aims: Our aim was to evaluate the role of UA in TM and its association with cardiac iron, dysfunction, fibrosis, and complications, and cardiovascular risk factors in a large cohort of TM patients of both sexes.

Methods: 397 TM patients (200 men, mean age 32.8 years) enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network were considered. Myocardial alterations in this study were quantified by the T2* technique. Atrial dimensions and biventricular function were quantified by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.

Results: As expected, UA resulted significantly higher in male respect to female TM patients (4.74 ± 1.3 vs 4.04 ± 1.0 mg/dL, P = 0.001). UA levels directly correlated with BMI (R = 0.25, P = 0.003), and triglycerides (TG) (R = 0.20, P = 0.005) in female patients. Moreover, female which presented myocardial fibrosis showed higher levels of UA (4.4 ± 1.3 vs 3.9 ± 0.9 mg/dL, P = 0.03). The multiple regression model identified BMI (T-value 3.7, P = 0.003), TG (2.1, P = 0.04) and cardiac fibrosis (2.5, P = 0.01) as independent correlates of UA level in women. In men, UA levels were positively correlated with BMI (R = 0.17, P = 0.02), TG (R = 0.38, P < 0.001), and inversely with HDL (R = -0.20, P = 0.006) and glycemia (R = -0.15, P = 0.04). Interestingly, UA was also directly correlated with global heart T2* values (R = 0.3, P < 0.001). After multivariate analysis adjustment, global heart T2* and UA were still directly correlated (R = 0.17, P = 0.01), and BMI (1.9, P = 0.05) remained as independent determinants of UA in male TM patients.

Summary/Conclusions: UA levels correlate with factors related to metabolic dysfunction in TM patients of both sex, while a more strong correlation between UA and cardiac fibrosis was observed only in females, and a direct relationship between UA and T2* global heart only in males. The differences in male and female TM patients imply some gender-specific mechanisms, providing biochemical basis for the epidemiological differences between sexes.

PB2189

CHARACTERIZATION OF HEMORHEOLOGICAL ALTERATIONS IN THALASSEMIA BY A CHROMATIC METRIC APPROACH

P. Caprari1, C. Bozzi1, S. Materazzi2, R. Risoli2
1Haematology, Oncology and Molecular Medicine, Istituto Superiore di Sanità, 2Department of Chemistry, “Sapienza” - University of Rome, Rome, Italy

Background: Several studies reported a high incidence of thromboembolic events in β-thalassemia, more frequent in thalassemia intermedia than in regularly transfused thalassemia major. In these patients a chronic hypercoagulable state is evident and the red blood cells exhibit impaired flow properties that facilitate micro-circulatory disorders.

Aims: Since many abnormalities described in thalassemia may determine rheological alterations, we investigated the viscoelastic profiles of red blood cells from patients with β-thalassemia. The hemorheological profiles of blood samples obtained from healthy subjects and thalassemic patients were studied by chrometric methods in order to develop a model of prediction of circulatory disorders according to the viscoelastic behaviour.

Methods: Blood samples from 45 β-thalassemia patients and 48 healthy individuals, after informed consent, were analyzed. Hemorheological profiles were investigated at 37 °C at native and normalized hematocrit. The evaluation of RBCs viscoelastic properties was performed by determining storage modulus G', loss modulus G'' and complex modulus G* in oscillation mode as a function of angular frequency ω in the range 0.1-10 Hz. Multivariate statistical analysis was performed on the resulting G', G'' and G* curves and Principal Components Analysis was used as display method.

Results: The hemorheological profiles of patients affected by β-thalassemia and healthy subjects showed significant differences and the chrometric analysis allowed to investigate a clearly identifiable signature of anemic status according to viscoelastic profile. Increased G', G'' and G* modula were observed in thalassemic patients demonstrating a reduction in deformability and impaired flow properties.

Summary/Conclusions: In this study a characterization of haemorheological alterations in thalassemia patients has been performed by a chrometric approach. The achieved results permit to consider the viscoelastic properties as promising predictive new indices of microvascular damage in β-thalassemia and to explain the increased incidence of vascular complications in these disorders.

HEPATITIS E IN TRANSFUSION-DEPENDENT THALASSEMA PATIENTS, IN GREECE. A SINGLE CENTER EXPERIENCE

P. Kloniazikis1, G. Gioula1, A. Meldrou1, M. Exindari1, G. Karavalkis2, C. Apostoloiou1, E. Gigi1, E. Vetsiou1, A. Kotsiafti1, E. Vlachaki1
1Aristotle University of Thessaloniki, 2Papagenouloou General Hospital, Thessaloniki, Greece

Background: Hepatitis E (HE) is nowadays considered an emerging disease that may be a threat in both developing and industrialized countries all over the world. The causal agent is an RNA virus, transmitted mainly through the fecal-oral route. Nevertheless, there are additional patterns of transmission, including the transfusion of infected blood products. The risk of developing chronic HE infection following transfusion of infected blood–derived products is higher among immune-compromised individuals. Transfusion-dependent Thalassemia patients consist a distinct category of immune-compromised patients, but the data regarding transfusion-transmitted HE infection are limited for this group of patients. Accordingly, there is, as yet, no consensus on whether blood products should be systematically screened for markers of the HE virus

Aims: The aim of this study was to assess the status of Hepatitis E infection in the transfusion-dependent Thalassemia patients, followed up in a single Thalassemia Unit, in Northern Greece.

Methods: Over a one-month period, we retrospectively evaluated 96 consecutive patients, from a registry of 150 adult TDT patients followed at a single Thalassemia Unit, in Northern Greece. The mean age of the study population was 36.4 ± 10.2 years, 42% were male and 58% female. Among the patients' blood transfusion history, the participants had been transfused with 47.376 blood units during the last 14 years, whereas during the last year the same patient population had been transfused with 3.384 blood units. The detection of HEV RNA was performed by Real-Time RT-PCR method (hepatitis2c/cecr

Results: HEV RNA was not detected in any of the 96 samples, whereas the IgG anti-HEV antibodies were also negative in all measured samples. The negative HEV RNA, in all the participants of this study, indicates the absence of an active HE infection, whereas the negative IgG anti-HEV antibody titre implicates that there was no history of previous HE infection. According to the literature, IgG antibodies may be detectable following an HE infection for a time period that varies from one year to 14 years.

Summary/Conclusions: This is the first assessment of the HE virus seroprevalence in the population of TDT patients in Greece, over the last two decades. Our results suggest that TDT patients are not at a high risk for HE infection. Further studies are necessary to evaluate the clinical importance of the transfusion-transmitted HE infection in TDT patients and clarify whether screening of blood donors is necessary for countries with a lower or higher prevalence of HE.

A PRELIMINARY STUDY OF THE CARDIAC EFFECT OF PPAR GAMMA IN BETA THALASSEMA MAJOR WITH IRON OVERLOAD

P.M. Eldredrowy1, P.N.A. Hamed1, D.D. Ehlnley2, D.O. Ghallab1, M.A. Khalifa1
1Hematology, 2Clinical Pathology, Alexandria Faculty of Medicine, Alexandria, Egypt

Background: Peroxisome proliferator–activated receptor (PPAR)-gamma leads to a molecular regulator involved in the expression of probably hundreds of genes. One of PPAR gamma gene polymorphisms is Pro12Ala which is present in at least 80% of Egyptians. Pro12Ala polymorphism may reduce the risk of cardiovascular complications. Consistently, Ala12 allele carriers were found to have lower carotid intima- media thickness and reduced risk of myocardial infarction in type 2 diabetes patients. Pharmacological agonists of PPAR-gamma leads to a molecular
switch providing alleviating myocardial injury through modulating oxidative, inflammatory and apoptotic signaling pathway.

Aims: Our aim was to investigate the frequency of Pro12Ala polymorphism (substitution of proline to alanine at codon 12 in exon B of PPARγ gene in Egyptian β-thalassemia major (β-TM) with iron overload. Untreated transfusion induced iron overload in thalassemia major is fatal, usually as a result of cardiac complications.

Methods: 30 β-TM patients and 10 healthy volunteer matched for age, sex and body weight were involved in this study. β-TM patients followed up was in the “outpatient clinic of Hematology unit, at Alexandria main university hospital". Seventeen were males and thirteen were females with ages ranging from 16 – 39 years (21.5±4.44). Blood samples from β-TM patients and healthy controls were analyzed for PPARγ gene polymorphism using polymerase chain reaction-restriction fragment length polymorphism.

Results: The mean value of serum ferritin in β-TM was 4976.30±2216.41 ng/L which was significantly higher than that in controls (102.60±12.69 ng/L). The mean value of ejection fraction were 62.23±3.46% and 63.80±4.34 in cases and controls respectively. Pro12Ala polymorphism was present in 2 out of 30 (6.67%) β-TM patients with osteoporosis. One patient had heterozygous 12Ala polymorphism and the other had homozygous 12Ala polymorphism. Both had normal body mass index, lipid profile, ejection fraction and elevated serum ferritin (4923 ng/L in heterozygous patient and 4886 ng/L in homozygous patient). Ejection fraction was 70% in heterozygous patient and 68% in homozygous patient. Only one male control (10%) has homozygous 12Ala polymorphism (Table 1).

Summary/Conclusions: This study suggests that Pro12Ala polymorphism may have a cardioprotective effect in Egyptian thalassemic patients since we find the highest value of ejection fraction among the two positive cases. Further studies on a larger population of patients are still needed to confirm this finding.

PB2193

THALASSEMSIA MAJOR AND INTERMEDIA IN PATIENTS OLDER THAN THIRTY-FIVE YEARS - FROM A FATAL TO A CHRONIC DISEASE

O. Pasvolsky1,*, L. Shargian Alon1, P. Raanani1
1Beilinson Hospital, Petach Tikva, Israel

Background: During the past four decades beta thalassemia major (TM) and beta thalassemia intermedia (TI) have transformed from a universally fatal disease at a young age, into a chronic disease, with a constantly increasing life expectancy. This is attributed, amongst others, to the use of improved chelation therapy. Since prolongation of life expectancy has occurred only in recent years, there is little data regarding the older population with TM and TI.

Aims: We aimed to characterize disease and patients’ characteristics in patients above 35 years of age in an adult thalassemia center in Israel.

Methods: We conducted a retrospective analysis of 14 adult patients over the age of 35 years with TM (N=10) and TI (N=4) treated in a single center, specializing in the care of adult thalassemia patients. We used descriptive statistics to describe characteristics of disease and patients and the Mann-Whitney test to compare between patients with TI and patients with TM.

Results: Between 2006 and 2016, 14 adult patients older than 35 years with TM (n=10) and TI (n=4) were followed and treated in our center. Median patients’ age was 37 (range, 35-51) years, with 66% males and 50% of Arab ethnicity. Most of the patients had at least high school education (85%), and 78% were employed. Thirteen patients (all TM patients and 3 out of the 4 TI patients) were treated regularly with blood transfusions. All patients received chelation treatment. Median hemoglobin (Hb) levels and mean corpuscular volume (MCV) levels were lower in patients with TI compared to TM (8.1±1.1 mg/dL, p<0.002 and 72.4±84 fl, p=0.004, respectively). Median LDH levels and indirect bilirubin levels were higher in patients with TI compared to TM (603±330 μL, p=0.004 and 2.02±1.1 mg/dL, p=0.06, respectively) indicating increased hemolysis. All patients underwent splenectomy and had secondary thrombocytosis. All but two patients were treated with at least two different chelation modalities, either as single agent, including subcutaneous (SC) or intravenous (IV) deferioxamine (DFO), deferiprone (DFP), or deferasirox (DFX), or as various combination therapy options. The median number of chelation treatment lines was 3. All patients treated with chelation suffered from at least one adverse event, necessitating temporary discontinuation and usually substitution of treatment. The median number of adverse events was 1.5 per patient. Nine patients (64.2%) had good compliance with current chelation therapy. Four patients with acute heart failure secondary to cardiac iron overload, and all four improved with intensified chelation treatment. Four TM patients (40%) were hypothyroid, half of them requiring thyroid hormone replacement therapy. All TM patients had hypogonadism. All females had amenorrhea and were treated with hormone replacement therapy, and none of them tried to conceive. Six of the seven male TM patients were treated with monthly testosterone injections, and three of them fathered children. All TM patients had osteoporosis, and three TI patients (75%) had metabolic bone disease. Figure 1 shows the relative rates of symp-tomatic cardiac iron overload and endocrine dysfunction in the cohort. Three patients (21.4%) had significant liver overload according to liver T2* MRI, necessitating chelation treatment intensification. None of the patients in our cohort underwent allogeneic hematopoietic stem cell transplantation and none developed secondary malignancy during follow-up.

Figure 1.

Summary/Conclusions: Advances in the treatment of thalassemia patients have enabled the majority of these patients prolonged survival into adulthood. However, this has brought a new set of challenges for both patients and health-care. This study delineates the challenges faced while treating adult patients with TI and TM in the new era.

EVALUATION OF LIVER IRON CONCENTRATIONS IN CHILDREN WITH BETA THALASSEMIA INFECTED WITH HEPATITIS C VIRUS BEFORE AND AFTER SPIRULINA THERAPY BY MAGNETIC RESONANCE IMAGING

M. El-Shanshory1,*, M. Awad1, R. El-Shafey2, A. Alsharkawy3
1Pediatrics, 2Radiology, Faculty of Medicine, Tanta University, 3Pediatrics, Ministry of Health, Tanta, Egypt

Background: Magnetic resonance imaging (MRI) assessment of liver iron concentration (LIC) is necessary for quantitative staging of iron overload in children with β-Thalassemia. There is no enough evidence about the effect of spirulina therapy on LIC.

Aims: To assess LIC by MRI in multi-transfused β-Thalassemic children infected with HCV before and after Spirulina Therapy.

Methods: Thirty multi-transfused β-thalassemic children infected with HCV, were subjected to clinical evaluation, appropriate laboratory investigations and assessment of LIC by MRI. They were classified according to LIC into mild, moderate or severe LIC.

Summary/Conclusions: LIC was higher in patients with TI compared to TM. Median LIC levels were higher in patients with TI compared to TM (603±330 μL, p=0.004 and 2.02±1.1 mg/dL, p=0.06, respectively) indicating increased hemolysis. All patients underwent splenectomy and had secondary thrombocytosis. All but two patients were treated with at least two different chelation modalities, either as single agent, including subcutaneous (SC) or intravenous (IV) deferioxamine (DFO), deferiprone (DFP), or deferasirox (DFX), or as various combination therapy options. The median number of chelation treatment lines was 3. All patients treated with chelation suffered from at least one adverse event, necessitating temporary discontinuation and usually substitution of treatment. The median number of adverse events was 1.5 per patient. Nine patients (64.2%) had good compliance with current chelation therapy. Four patients with acute heart failure secondary to cardiac iron overload, and all four improved with intensified chelation treatment. Four TM patients (40%) were hypothyroid, half of them requiring thyroid hormone replacement therapy. All TM patients had hypogonadism. All females had amenorrhea and were treated with hormone replacement therapy, and none of them tried to conceive. Six of the seven male TM patients were treated with monthly testosterone injections, and three of them fathered children. All TM patients had osteoporosis, and three TI patients (75%) had metabolic bone disease. Figure 1 shows the relative rates of symp-tomatic cardiac iron overload and endocrine dysfunction in the cohort. PB2195

COMBINATION OF DEFERASIROX AND DEFEROXAMINE - A SUCCESSFUL CHELATION THERAPY IN B-TALASSEMA MAJOR PATIENTS

F. Petropoulou1,*, K. Ventiadi1, G. Leveta1
1Thalassaemia Unit, General Hospital of Athens “G.Gennimatas”, Athens, Greece

Background: Frequent transfusions required for β-thalassemia major patients cause iron overload. Without the appropriate chelation therapy, iron toxicity can cause significant heart, liver and endocrine morbidity.

Aims: In this case series we estimated the safety and efficacy of iron chelation with the combination of deferasirox (DFX) and deferoxamine (DFO) in transfusion dependent thalassemia (TDT) patients attending the Thalassemia Unit in a tertiary hospital in Athens, Greece.

Methods: 10 TDT patients were treated with a combination chelation therapy of DFX (30 ±10mg/kg/d) and DFO (44±12mg/kg/d for 2-6 days/wk in 12hr or 24hr infusion rates). Reasons for starting this combination treatment included: 1) treatment with one chelating agent did not succeed in decreasing heart and liver iron, 2) agranulocytosis or severe neutropenia due to deferiprone (DFP) monotherapy is not effective or not well tolerated.

Results: Five of the 10 patients had significant liver hemosiderosis (LIC >15 mg Fe/gr d.w.) and 3 had heart iron overload, of which one significant (T2* 1.9 ms) in patients with β-Thalassemia of moderate to severe group as compared to those of the mild group before treatment. The mean values of serum ferritin (SF) was statistically insignificantly higher among patients of mild group. There was no significant correlation between different MRI parameters and SF level. There was negative correlations between LIC and T2* and positive correlation between LIC and R2*. There was significant decrease in values of LIC accompanied with significant improvements in SF after spirulina therapy as compared to their pretreatment values in patients of the moderate to severe group.

PB2196

EVALUATION OF THREE AUTOMATIC DEVICES FOR HEMOGLOBINOPATHY DIAGNOSTICS IN MULTI-ETHNIC POPULATIONS

C. Harteveld1,*, Y. Daniel2, G. Bakker-Verweij1, G. Ivaldi3
1Clinical Genetics, Leiden University Medical Centre, 2Leiden, Netherlands, 2Special Haematology, Guy’s Hospital, London, United Kingdom, 3Laboratorio di Genetica Umana, Ospedale Galliera, Genoa, Italy

Background: We have tested three different dedicated haemoglobin separation devices for their capacity of performing the diagnostics of hemoglobinopathies. These involve the Variant II™ HPLC (BioRad), the Capillarys™ capillary electrophoresis (Sebia) and the most recently introduced HPLC, Premier Hb9210™ High Resolution HPLC of Trinity Biotech (Menarini).

Aims: As the latter device is new to the market a multisite precision study was performed testing the reproducibility of the system across three test sites (Leiden, Genoa and London) using the same set of samples for several following days. The results between these three sites were compared and evaluated. Moreover we have tested the capacity to detect the most common structural haemoglobin variants, such as HbS, HbC, HbD, HbE and less common Hb variants important to be diagnosed in multi-ethnic populations found in the U.K., The Netherlands and Northern Italy as well as elevated Hba2, as indicator for beta-thalassaemia carriers.

Methods: Hb variant separation using he Variant II™ HPLC (BioRad), the Capillarys capillary electrophoresis (Sebia) and the most recently introduced HPLC, Premier Hb9210™ High Resolution HPLC of Trinity Biotech (Menarini).

Molecular analysis to verify the hemoglobin variants found.

Results: We present the data of the comparison studies using the replicates of the three different sites for the Premier Hb9210™ and of 100 normal samples and 217 patient samples for a variety of beta-thalassemia trait and haemoglobin (Hb) variants, including the molecular data of the beta-thalassemia mutations and Hb variants.

Summary/Conclusions: All three apparatus identified the common Hb variants and beta-thalassemia trait in carriers, homo- hetero- and compound hemoglobin variants, such as HbS, HbC, HbD, HbE and less common Hb variants.

PB2197

RED BLOOD CELL EXTENDED PARAMETERS IN HAEMOGLOBINOPATHIES

M. Stamou1, E. Petridou1, A. Kotanidou1, A. Agorasti1,*, 1Laboratory Haematology, General Hospital of Xanthi, Xanthi, Greece

Background: Sysmex® XE-5000 analyzer incorporates new research Red Blood Cell (RBC) parameters, derived from flow fluorescence cytometry technology, including %HYPO-H, which indicates the percentage of RBC with haemoglobin (Hb) content <17 pg, and %MicroR which indicates the percentage of RBC with mean cell volume <60 fl.

Aims: The aim of this study was to establish the reference range of our Laboratory for the parameters %HYPO-H & %MicroR, to investigate their values in haemoglobinopathies and their correlation, if any, with Hb A2 levels in heterozygous β-thalassaemia.

Methods: Reference ranges were obtained from 175 healthy adult subjects (27 men, median age of 34 years & 148 women, median age of 30 years); control group (group A), 89 haemoglobinopathie heterozygotes (32 men, median age of 29 years & 57 women, median age of 30 years) were included in the study and classified into three groups; group B: β-thalassaemia heterozygotes, N=46; group C: α-thalassaemia heterozygotes, N=21 and group D: Hb O-Arab heterozygotes, N=22. We retrospectively recorded the results of full blood count and analysis on Sysmex® XE-5000 analyzer including %HYPO-H & %MicroR, of Hb pattern analysis (TOSOH®, G7) and ferritin levels (Roche®, cobas e411). All subjects included in the study presented ferritin levels within the normal range for age and gender. Statistical analysis: one-way ANOVA (Tukey post hoc), Mann-Whitney, Pearson’s correlation tests were applied. Reference ranges were calculated as the means±SD of the distribution. P value <0.05 was considered to be statistically significant. Data refer as median (percentiles).

Results: The reference ranges of our Laboratory for the parameters %HYPO-H & %MicroR are 0.0 – 0.6% & 0.2 – 2.9%, respectively, and they are independent of gender and age (P=0.715, P=0.168 & P=0.073, P=0.843). There was a statistically significant difference between the groups determined by one-way ANOVA for both parameters (all P <0.0001). Heterozygous β-thalassaemia presents statistically significantly higher %HYPO-H and %MicroR values [11.6 (4.2 - 27.6)] as compared to groups A [0.3 (0.2 - 0.3)], C [1.9 (0.6 - 6.4)] and D [0.6 (0.4 - 0.8)] (all P <0.0001), while there was no statistically significant difference of %HYPO-H values between heterozygous Hb O-Arab and groups A and C (P=0.965 & P=0.134, respectively) based on Tukey post hoc test. Heterozygous β-thalassaemia presents statistically significantly higher %MicroR values [41.5 (22.9-58.7)] as compared to groups A [1.5 (1.1-2.0)], C [10.8 (7.9-20.5)] and D

The combination treatment was well tolerated without adverse events or effects on liver and kidney function.

The combination treatment was well tolerated without adverse events or effects on liver and kidney function.
Background: Diagnosing α-thalassaemia requires second line diagnostics involving DNA analysis. Multiplex ligation probe amplification® (MLPA®) is a molecular technique introduced as a diagnostic tool for α-thalassaemia. This semi-quantitative technique determines the relative copy number of up to 60 DNA sequences and is able to detect deletions and duplications in a DNA sample. A novel commercial tool, the α-Globin StripAssay®, aims to detect the most common α-thalassaemia deletions and point mutations. The test involves three steps: DNA isolation, PCR reaction and a hybridisation step to test strip containing allele-specific oligonucleotide probes immobilised as an array of parallel lines.

Aims: Our objective was to evaluate the α-Globin StripAssay® as a useful alternative for MLPA® in second line α-thalassaemia diagnostics.

Methods: Eight samples, including 7 known deletions (α3.7_homozygous, α4.2_heterozygous, α20.5) and 1 mutation (Hb Constant Spring) were analysed using multiplex Gap-PCR (deletions) and Sanger sequencing (point mutation) at the Leiden University Medical Center. These samples were anonymised and analysed in duplicate by MLPA® and α-Globin StripAssay® for comparison. A comparison of diagnostic performance, interpretation, turnaround time (TAT) and costs (reagent and labour) was conducted.

Results: There are no significant differences between the MLPA® and the α-Globin StripAssay® results and identification corresponded to the result of the reference lab in Leiden. MLPA® however provided additional information about underlying polymorphisms. Interpretation of the α-Globin StripAssay® was easier and faster compared to MLPA®. The α-Globin StripAssay® proved to have a shorter TAT, but on the other hand, the costs for MLPA® were significantly less.

Summary/Conclusions: Despite its straightforward interpretation, shorter TAT and the ability of detecting both (known) deletions and point mutations, the significantly higher costs of the α-Globin StripAssay® may hinder its routine use. Specialised laboratories are usually acquainted with the MLPA technique and in these settings the ability to detect both known and unknown deletions is a plus for research purposes.
spleenectomy. None of these patients had sepsis or meningitis. Three Thal patients underwent progenitor stem cell transplantations and three remain on complete chimerism in the present moment. Patients lost to follow-up summed up 14; 3 emigrated to other countries, 2 continue the monitor of their diseases in other centers or in adults units and 7 for unknown reasons. There was one death (3.22%) for a cause unrelated to his illness.

Table 1.

Summary/Conclusions: Early diagnosis derived from universal neonatal screening for sickle cell disease allows an effective health education and prompt therapy to other hemoglobinopathies, and a correct and thorough follow-up of these patients.

PB2201
PREVALENCE AND CAUSES OF CLOTTING TIMES PROLONGATION IN PATIENTS WITH TRANSFUSION DEPENDENT BETA THALASSEMIA
I. Tartaglione1,*, M. Caiazzia3, A. Bonadies1, D. Roberti1, M. Casale1, S. Scianqueta1, F. Rossi1, S. Perrotta1
1Dipartimento della Donna, del Bambino e della Chirurgia generale e specialistica, Università della Campania “Luigi Vanvitelli”, Naples, Italy

Background: Thalassemia is traditionally known to be a thrombophilic, rather than hemorrhagic, disorder. In spite of this, prolongation of clotting times are often reported. Understanding if there is a real risk of bleeding, and what this risk can be associated to, is crucial, especially in relation to the frequent referral to surgery (e.g. for splenectomy, cholecystectomy). Hepatopathy due to iron overload or HCV infection has been addressed as a main cause of this finding, even though disorders in the clotting profile are often reported also in patients with no alterations of hepatic function. The impairment of factors XI and XII often reported has been hypothesized to be secondary to intravascular haemolysis or multiple transfusions (Caocci et al, Acta Haematol 1978, Mfadyen et al, Ann Hematol 2014), but no data are available to confirm this supposition.

Aims: To determine the prevalence of clotting disorders in a group of Transfusion dependent Thalassemic (TDT) patients and to assess the correlation with hepatopathy, degree of the hemolysis, transfusion frequency, erythroblastosis, iron chelation.

Methods: TDT patients followed at our center whom clotting tests were available were included. From chart review data were collected regarding clotting times, demographics, disease history, comorbidities and concomitant medications, iron chelation therapies, iron overload (serum ferritin, LIL, cardiac T2*), liver function tests, hemolysis parameters, hemocromocitometric values. Patients on anticoagulation therapy were excluded.

Results: 114 TDT patients (female 55,35%) were enrolled in our study, mean age 26.02±13.38 years, 17 of them were pediatric. In 20/56 patients (35,71%) TDT patients (female 55,35%) were enrolled in our study, mean (p=0,045); none of the patients in Group A was splenectomized (p=0,042).

Summary/Conclusions: In our population clotting disorders were not correlated with hepatic disease, nor hemolysis or transfusions. The mild correlation with lower Hb values and with the lacking splenectomy could be consistent with the known effect of low Ht on lab procedures for clotting tests. In relation to this observation in patients with altered coagulation tests the repetition of clotting test after blood transfusion could be advisable to overcome the low Hb effect.

PB2202
COMPOUND HETEROZYGOSITY FOR HAEMOGLOBIN ADANA AND A-THALASSEAEMIA IN GREECE. CLINICAL PHENOTYPE AND GENETIC COUNSELING
S. Theodorou1,*, A. Tei2, E. Yfantis, T.A. Vyzantiadis1, E. Economou2
1Thalassemia Unit, Hippokration General Hospital, 2First Department of Pediatrics, Aristotle University, Thessaloniki, 3Thalassemia Centre, Laikon General Hospital, Athens, 4First Microbiology Department, Aristotle University, Thessaloniki, Greece

Background: Haemoglobin (Hb) Adana (HBA2q.C.179>A) in interaction with deletional and nondeletional α-thalassaemia mutations leads to HbH or, less commonly to thalassaemia intermedia with clinical manifestations varying from asymptomatic forms to severe anemia. First line screening tests are unable to detect the highly unstable variant. Aims: We report two cases of Hb Adana co-inheritance with the α-thalassaemia 3.7 kb deletion - the only α-thal and Hb Adana double heterozygosity cases diagnosed in subjects of Greek origin. Methods: The first case concerns a 3 year old girl, born from parents referred for genetic counseling at the 11 th week of a second gestation. The mother showed an Hb of 10.7g/dl, MCV 80,7 fl, MCH 26.4 pg, Hb A2 2.8% and Hb F 1%, with positive inclusion bodies, and her ethnic (Greek) and regional background was of high risk for thalassaemia. The partner came from the same region, and he showed an Hb of 13.8g/dl, MCV 8.8 X 1012/L, MCH 73,1 fl, MCHC 23.5 pg, Hb A2 2.4% and Hb F 2.3%, while her ferritin levels were 228ng/ml and inclusion bodies were found. On clinical examination she was found to be of normal weight and height for her age, but presented with paleness, icteric sclera and mild splenomegaly. Genetic analysis revealed that the mother carried the α-thalassaemia 3.7 kb deletion defect. The father carried the rare non deletional Hb Adana. As suspected from the haematological data, their offspring was a compound heterozygote for Hb Adana variant and α-thal 3.7 kb deletion. At the age of 8 years. At diagnosis, findings were compatible with a very mild phenotype and growth was not impaired. The boy retained a mild hypochromic microcytic anemia (Hb~10g/dl; MCV 71 fl, MCH 23 pg, RDW 18.6%, reticulo 5%), until adolescence but at the age of 11 transfusion initiation was decided due to marked splenomegaly and limited weight and height gain. For the following years he was transfused approximately once a month, necessitating chelation therapy. Weight, height and pubertal development were normal by the age of 15, but splenomegaly persisted. Splenectomy was decided and transfusions were stopped shortly afterwards. During the following months the boy retained an Hb of 9.5 g/dl; however, he complained of constant fatigue and impaired physical activity and asked to get back on a transfusion program. Results: In both cases diagnosis was incidental highlighting the mild phenotype. However, the co inheritance of Hb Adana with the 3.7 kb α+ thal deletion is rare, with only the presenting cases in Greece, and in a few other families in Turkey, Southeast Asia, Philippines and Albania. The clinical phenotype of the combination seems to be a mild disease with a non-transfusion-dependent thalassaemia intermedia phenotype. Nonetheless, clinical severity prediction is always a difficult issue and phenotypes may change overtime as demonstrated by the second case described above. Summary/Conclusions: Long follow-up of such rare cases is necessary in order to gain as much information as possible, so as to offer the best management to the patients and the most accurate genetic counseling.
ANTITHROMBOTIC EFFECTS OF PEPTIDE PGPL IN EXPERIMENTAL THROMBUS FORMATION

M. Grigorjeva1,*, L. Lyapina1, T. Obergan1
1Biology, Lomonosov Moscow State University, Moscow, Russian Federation

Background: Previously, it was established that proline- and glycine-containing peptides have fibrinolytic, anticoagulant activity, inhibit platelet aggregation and thrombin activity in vitro and in vivo. Besides, it is known that short peptides of this family also have antithrombotic effects.

Aims: To study the influence of Pro-Gly-Pro-Leu (PGPL) and amino-acid leucine on fibrinolytic and anticoagulant blood activity, platelet aggregation and to estimate their possibility to reduce the formation of experimental blood clots.

Methods: Experiments were carried out on white rats (200-250 g) according to the ethical principles of the Helsinki Declaration. Peptide PGPL (1 mg/kg), leucine (0.33 mg/kg - equivalent to its content in PGPL) and saline (control rats) were intranasal entered to rats within 3 days. 1 hour after the last drugs administration we induced the formation of thrombus in v jugularis (Wessler model). The degree of thrombus formation was estimated on thrombus weight. Fibrinolytic activity and activity of tissue-plasminogen activator (t-PA) of blood plasma were measured by fibrin plate method. Anticoagulant activity (APTT-test) and ADP-induced platelet aggregation were detected by standard methods.

Results: Our experiments demonstrated that preliminary intranasal administration of PGPL (before formation of thrombus) leads to increase of APTT, fibrinolytic and t-PA activity on 18%, 62%, 35% respectively from control rats. Besides, we observed the decrease of platelet aggregation. Also we indicated the reduction of thrombus weigh in PGPL-treated rats on 68.5% comparatively with control rats. The thrombus weigh after leucine treatment decreased on 30% compared with control rats. But administration of leucine did not change the haemostasis system parameters.

Summary/Conclusions: Thus administration of PGPL enhanced of anticoagulant, fibrinolytic and antplatelet activity in rats blood plasma. PGPL pretreatment lead to prevention of experimental venous thrombus formation. Therefore, PGPL may be used as a perspective anticoagulant and fibrinolytic agent with direct antithrombotic effect.
Background: Antiphospholipid antibodies (APLs) have been implicated in vascular (arterial, venous or both) thrombosis. Diabetes Mellitus (DM), as a disease entity has been associated with hyper-coagulable and pro-thrombotic states, with studies showing an increased procoagulate state and thrombotic events especially in poorly controlled Type 2 Diabetes Mellitus (T2DM). Aims: The aim of the study is to assess the APLS and HbA1C levels and evaluate the correlation between APLS levels and HbA1C in T2DM patients with diabetic vascular complications.

Methods: This was a cross-sectional study of subjects with T2DM attending the diabetic clinic of University of Nigeria Teaching Hospital. A total of two hundred and ten (210) subjects were recruited for this study. There were grouped into two categories, those on T2DM, un-complicated T2DM and health control. Each had 70 subjects matched for sex and age. Lupus anticoagulant (LA) was assayed using DRVVT (technoclon GmbH Austria) IgGβ2GPI-ACA was assayed using ELISA test kit (Genway Bio-tech San Diego USA), HbA1C was assayed using D10TM haemoglobin analyzer. Ethical clearance was obtained from the ethical committee UNTH.

Results: The prevalence of LA was 7.1%, 4.3% and 4.3% for complicated T2DM, uncomplicated and healthy control subjects respectively, while the prevalence of IgG-B2GPI ACA was 4.3% in all groups. The mean HbA1C were 8.2(1.5), 8.0 (1.7), 5.6 (0.38) for complicated, uncomplicated T2DM and control subjects respectively. ANOVA showed a significant difference in mean position on the risk of acute coronary syndrome (ACS).

Methods: The study included 112 patients of ACS; 31 with unstable angina (UA) and 81 with myocardial infarction (MI) as well as 118 healthy controls. vWF: Ag level was measured by ELISA. The gene analysis was carried out by polymerase chain reaction using restriction fragment length polymorphism (RFLP-PCR) principles.

Results: vWF: Ag levels were significantly higher in MI (111.68±24.77 IU/dl) and UA (110.27±23.44 IU/ml) patients compared to healthy controls (71.13±13.72 IU/dl), p<0.001 for both groups. The majority of patients with UA (80.6%) were Ala789 homozygous, 6.5% were Thr789Ala heterozygous and 12.9% were Thr789 homozygous. Regarding the Mi group, Ala789 genotype was present in 34.6%, Thr789 allele was the predominant genotype and was seen in 48.1% of patients and Thr789 homozygous was present in 17.3% of patients. The genotype frequency in the control group was as follow; 47.6% were Ala789 homozygous, 33.1% were heterozygous and 19.5% were Thr789 homozygous. The genotype distribution was significantly different among the 3 groups, p<0.001, and between the groups with UA and MI, p<0.001. Ala789 homozygous genotype was an independent risk factor for UA while the Thr789 allele was shown as an independent risk factor for MI. Summary/Conclusions: vWF Thr789Ala single nucleotide polymorphism is thought to affect factor level and function. Aims: This study aimed to investigate the associations of genetic variants at that position on the risk of acute coronary syndrome (ACS).

Results: We found 10% of toxicity with Dabigatran, a 7% with Rivaroxaban and a 5% with Apixaban. We conducted a retrospective study with 227 patients who received direct oral anticoagulants (DOACs) between January 2015 and December 2016. One hundred eighteen patients (52%) receive Rivaroxaban, fifty patients (22%) receive Dabigatran and fifty nine patients receive Apixaban (26%). We analyzed the variables that’s increases the bleeding risk for each DABIGATRAN, RIVAROXABAN and APIXABAN. The major bleeding was defined as intracranial bleeding, stroke or systemic bleeding of ≥30 cm³. The results showed a significant difference in the risk of bleeding between the three drugs.

HEREDITARY RISK FACTORS OF VENOUS THROMBOEMBOLISM IN YOUNG WOMEN TAKING ESTROGEN DRUGS
A. Chechulova1,*, S. Kapustin2, S. Karpich2, V. Shmeleva2, V. Soldatenkov2, L. Papayam2, V. Sorokal1, P. Chechulo2
1Vascular surgery, Dzhanadelie Research Institute of Emergency Medicine, St. Petersburg, 2Russian Research Institute of Hematology and Transfusiology, 3Dzhanadelie Research Institute of Emergency Medicine, St. Petersburg, St. Petersburg, Russian Federation

Background: Estrogens are recognized as the most common risk factor of venous thromboembolism (VTE) in young women. The cumulative risk of VTE in patients taking estrogens is significantly increased in carriers of inherited thrombophilia. However, the known hereditary risk factors – mutations FVL Leiden and FII G20210A could be detected in only 20-30% of patients with VTE.

Methods: We examined 133 young women with acute VTE (mean age 37.4 years; 16-45), who were genotyped by PCR-RFLP method for DNA polymorphism in 9 genes: F1-A Thr371Ala, F1-B -455G/A, F1I 20210 G/A, F1II 4670C/T, F1IVal85Glu, PAI-1 -675 4G/5G, EPCR Ser219Gly, TPA 311bp Del/Ins. We compared the distribution of studied genotypes in three groups of patients with VTE: taking estrogens (n=30, group 1), with idiopathic VTE (n=42, group 2) or having other risk factors (n=61, group 3). Intergroup differences in genotype frequencies were assessed by Fisher’s exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated with SPSS software version 17.0 (SPSS Inc, Chicago, IL, USA).

Results: The frequencies of prothrombotic genotypes in groups 1, 2 and 3, respectively, were: F1I 1691G/A – 20.0%, 21.4% and 13.1%; F1II 20210 G/A – 10.0%, 9.8% and 7.1%; F1-B -455G/A – 10.0%, 2.4% and 1.6%; F1II 4670C/T – 13.3%, 14.3% and 13.1%; TPA 311bp Ins/Ins – 16.7%, 28.6% and 31.1%; PAI-1 -675 4G/4G – 36.7%, 42.9% and 27.9%; EPCR 219Ser/Gly – 16.7%, 19.0% and 23.0%; F1II 4670T/CT – 3.3%, 7.1% and 0.0%; FXII 481T/T – 13.3%, 0.0% and 9.8%; FXIII A 34 Leu/Leu – 3.3%, 21.4% and 9.8%. Significant differences between the groups have been detected only for the FXII A 34 Leu/Leu variant. We compared the distribution of the studied genotypes in three groups of patients with VTE: taking estrogens (n=30, group 1), with idiopathic VTE (n=42, group 2) or having other risk factors (n=61, group 3). Intergroup differences in genotype frequencies were assessed by Fisher’s exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated with SPSS software version 17.0 (SPSS Inc, Chicago, IL, USA).

Summary/Conclusions: There is a need to upscale knowledge attitude and practice of the use anticoagulation agents especially the NOACs through well-articulated CME educational activities. A limitation of this study is the relatively small number of study participants and some subspecialties that were not reflected in this survey.

INTERLEUKIN -10 GENE POLYMORPHISMS AND THE RISK OF UNPROVOKED DVT IN EGYPTIAN PATIENTS
H. Elithly1,*, G. Shaheen2, S. Elmoamly1
1Internal medicine- clinical Hematology Unit, 2Clinical pathology, Kasr Al-Ainy school of medicine- Cairo university, Cairo, Egypt

Background: Thrombosis is often multifactorial, caused by both genetic and acquired risk factors. The inflammatory process is linked to pathogenesis of venous thrombosis. Venous thrombosis is considered to be mediated by an imbalance in proinflammatory as compared with anti-inflammatory mediators. One of the important anti-inflammatory cytokine is interleukin-10 (IL-10) with important immunoregulatory functions. Primarily, IL-10 counterbalances the potentially harmful effects of tumor necrosis factor α (TNFα) and other pro-inflammatory mediator such as IL-1, IL-6, and IL-8 from monocytes/ macrophages. Three important single nucleotide polymorphisms were studied in the IL-10 expression, including: 1082 A/G, 819 C/T, and 592 C/A. Studying the association between genetic polymorphisms of anti-inflammatory cytokines such as IL-10, and venous thrombosis may suggest using of polymorphisms as a predictive genetic marker of future VTE.

Aims: The objective of this study was to evaluate a possible association between IL-10 -1082A/G, and -592C/A polymorphisms with DVT.

Methods: The study was conducted on 115 patients with symptomatic DVT proved by venous duplex ultrasound; divided into two cohorts: group A included

and aPTT, therapeutic level of the drug and creatinine measurement, within the emergency and control laboratory tests in patients that receive DOACs.

KNOWLEDGE AND ATTITUDE OF MEDICAL DOCTORS ON ANTICOAGULATION THERAPY IN TERTIARY HOSPITALS IN NIGERIA
T.U. Nwagha1,*, R. Anakwue2, O. Ukpbai3, E. Onwubuya4, N. Obeke4, I. Okoye5, B. Azubuike5
1Haematology & Immunology, 2Internal medicine, University Of Nigeria Teaching Hospital, Enugu, 3Internal medicine, Abia state Teaching Hospital, Umuahia, 4Internal medicine, Nnamdi Azikiwe Teaching Hospital, Nnewi, 5Internal medicine, Federal Medical Center, Abakiliki, Federal Medical Centre Umuahia, Abia State Teaching Hospital, Aba, Amaku Specialist hospital, Akwa, Nigeria

Background: Thromboembolic and hypercoagulable diseases are common life-threatening but treatable problems in hospital practice. The most effective and economical approach to decreasing the burden of VTE is to prevent the development of DVT and PE in patients especially in acutely ill hospitalized medical patients. Health care providers in Nigeria may have significant gaps in their anticoagulation knowledge that could affect their decision to prescribe anticoagulation therapy as there are no national guidelines on the use of anticoagulation in Nigeria.

Aims: The purpose of this present study was to examine the knowledge and attitude of medical doctors on anticoagulation in tertiary hospitals in Nigeria.

Methods: The present study is a multicentre survey of the use of anticoagulants among clinicians in South East Nigeria. A pretested questionnaire was administered to clinicians in six tertiary hospitals in the south-east of Nigeria. The following institutions participated in the survey: University of Nigeria Teaching Hospital Enugu, Federal Medical Centre, Abakiliki, Federal Medical Centre Umuahia, Abia State Teaching Hospital, Aba, Amaku Specialist Hospital, Akwa and Nnamdi Azikiwe Teaching Hospital, Nnewi. The Likert scale which is in grades from one to five: 1 strongly disagree, 2 disagree, 3 neutral, 4agree, 5 strongly disagree was used. To determine the agreement degree three levels were identified (high medium and low).

Results: There were 528 respondents. 378 of them were males (71.6%) and 150 were females (28.4%). 31.1% of the respondents, were junior residents and the consultants represented only 20.6% of the respondents. Most of the respondents, 189 (35.8%) had less than 5 years clinical experience while the least of the respondents (8.7%) had between 16-20 years clinical experience. We observed that most respondents irrespective of their job grades didn’t know about Fondaparinux and the DOAC (except those in the specialist - registrar job grades) as the overall p=(0.000),<0.05 and were significant. The p value for other indications for anticoagulation >0.05 and was not significant. The majority knew of protrombin test and p value was 0.03, less than alpha value of 0.05 and was significant. On the contrary, Majority does not know about anti-Xa assay, p-value=0.02, <0.05, was also significant. Their affirmative response on the mode of action as one of the differences showed a p=0.000, <0.05, was significant. On the contrary, the non-affirmative response to drug and food interaction, p=0.03, was also significant. Based on results of the statement analysis, the variables were ranked according to the value of their mean. All except one variable had p-values of <0.05. The statement “Do you think anticoagulation therapy/prophylaxis is clinically important” had the highest mean of 4.60 and had a high degree of agreement. The statement “Should hospital inpatient with >3 days admission routinely receive anticoagulation?” had the lowest mean of 2.27 with a p-value of 0.015 had a low degree of agreement.

Summary/Conclusions: There is a need to upscale knowledge attitude and practice of the use anticoagulation agents especially the NOACs through well-articulated CME educational activities. A limitation of this study is the relatively small number of study participants and some subspecialties that were not reflected in this study over.
60 patients with unprovoked DVT, and group B included 55 patients with pro-
provoked DVT. Gene mutations for IL-10 -1082 AG, and -592 C/A were performed using PCR-restriction fragment length polymorphism assay. We studied the association between IL-10 gene polymorphisms and occurrence of either pro-
provoked or non-provoked DVT. We also investigated the link between these poly-
morphisms and the recurrence of DVT and family history of DVT.

Results: Among 60 patients with unprovoked DVT, 18 patients (30.0%) were negative for screening tests done for sickle cell disease and PNH. The Haematological correlates were identified in 19%

CATASTROPHIC ANTI-PHOSPHOPLID SYNDROME TRIGGERED BY SEPSIS. A PROSPECTIVE CASE STUDY HIGHLIGHTING BIOLOGICAL CONCEPTS AND MANAGEMENT STRATEGIES IN THIS COMPLEX AND LIFE THREATENING DISEASE

M. Hua1,*
1Haematology, Liverpool Hospital, Sydney, Australia

Background: Catastrophic antiphospholipid syndrome (CAPS) is a rare and life threatening event characterized by widespread intravascular thrombosis and intracranial haemorrhages followed by concurrent extensive cerebral infarction. Respiratory symptoms worsened with progressive interstitial ground glass changes on CT consistent with atypical pulmonary infection. Shortly after low therapeutic anti-coagulation she developed acute abdominal pain and hypotension. CT showed significant bilateral adrenal haemorrhages.

Results: In 3 patients with experimental MS these effects were preserved, besides, platelet aggregation was decreased by 27% (Pro-

HAEMATOLOGICAL CORRELATES OF ISCHEMIC STROKE AND TRANSIENT ISCHEMIC ATTACK : LESSONS LEARNED

G. Unnasekera1,2, I. Pathiraja2
1Health, Teaching Hospital- Kegalle, Kegalle, 2Health, Provincial Department of Health Services, North Western Province, Sri Lanka

Background: Haematological abnormalities are known to cause ischaemic Stroke or Transient Ischemic Attack (TIA). The identification of haematological correlates plays an important role in management and secondary prevention.

Aims: The objective of this study was to describe haematological correlates of stroke and their association between stroke profile. The haematological correlates screened were Lupus Anticoagulant, Dysfibrogenemia, Paroxysmal nocturnal haemoglobinuria (PNH), Sickle cell disease, Systemic Lupus Erythe-

Summary/Conclusions: The Haematological correlates were identified in 19% of our study sample. Among stroke profile only presence of past thrombotic events was statistically significant associated with haematological disorders (P= 0.04). Therefore haematological disorders appear to be an important factor in etiological work up of stroke patients particularly in patients with past thrombo-

Summary/Conclusions: We concluded that intranasal administration of tripeptides Pro-Arg-Gly and Gly-Arg-Pro to organism of healthy rats and in rats with experimental MS show antplatelet and fibrinolytic effects of the blood. Thus, arginine-containing peptides could potentially be used as antithrombotic drugs that protect the organism from the blood coagulation and thrombus formation.

PB2218

THE PRINCIPAL COMPONENT ANALYSIS USING CALIBRATED AUTOMATED THROMBOGRAM PARAMETERS AS A POTENTIAL QUALITY CONTROL FOR MEASURING PROCOAGULANT ACTIVITIES OF IMMUNOGLOBULINS

H. Oh1,*, C. Ahn1, S. Han1, H. Song1, K. Han1, G. Min1, J. Kim1, S. Park1, K. Jung1
1Blood Products Division, National Institute of Food and Drug Safety Evaluation, Cheongju-si, Korea, Republic Of

Background: The calibrated automated thrombogram (CAT) is a method to monitor the generation of thrombin. It can be described by four variables: lag time, peak thrombin, time to peak, and velocity index. Currently, due to thromboembolic event related risks of immunoglobulins, the CAT is widely used to quantify the thrombogenic potential associated with immunoglobulin manufacturing processes and products. However, there is currently no officially approved method for such assessments and even this results are highly variable in inter-laboratories comparison. In this study, to obtain a summary score, we applied the principal component analysis (PCA) for these four outcomes measured from CAT method. The PCA is a statistical procedure concerned with elucidating the covariance structure of a set of variables. In particular it allows us to identify the principal directions in which the data varies.

Aims: In this study, our interest is to apply PCA method in order to find appropriate dose related with CAT variables and to reduce variation of procoagulant values in Immunoglobulin products.

Methods: The CAT are measured in a 96 well plate fluorometer equipped with a 390/460 filter set and a dispenser. Usually experiments are carried out in triplicate. During the measurement, a dedicated software program, Thrombinoscope compares the readings from the trigger wells and the calibrator wells, calculates thrombin concentration and displays the thrombin concentration in time. Outcomes from CAT were analyzed in the principal component analysis (PCA) which is a statistical procedure that allows us to summarize high dimensional data with a smaller number of representative variables that collectively explain most of the variability. Statistical analyses were performed with R 2.5.

Results: Four variables measured from CAT have different distribution and too large variations. For example, the mean(sd) of each variable (lag time, peak thrombin, time to peak, and velocity index) are 24.66(8.01), 80.16(94.52), 31.28(9.78), 19.08(28.86), respectively. Therefore, to remedy such high variation among variables and to find a score, PCA method is applied. Then the dose values calculated based on the PCA scores have mean 0.393 and a much smaller variation (sd=0.583) (Table 1).

Summary/Conclusions: The PCA value showed a good agreement with four CAT outcomes and less variation. The PCA method could be used to monitor the process of immunoglobulin manufacturing.

PB2219

PRIMARY THROMBOPHILIA IN MÉXICO XII: MISCARRIAGES ARE MORE FREQUENT IN PERSONS WITH THE STICKY PLATELET SYNDROME

1Hematologia, Centro de Hematologia y Medicina Interna, 2Universidad de las Americas Puebla, 3Laboratorios Clínicos de Puebla, 4Centro de Hematología y Medicina Interna, Puebla, Mexico

Background: The sticky platelet syndrome (SPS) is an inherited condition which leads into arterial and venous thrombosis. There is scant information about the association between the SPS and obstetric complications.

Aims: To assess the relationship of the SPS and fetal loss in a single institution.

Methods: The obstetric history of all the consecutive female patients prospectively studied along a 324 month period, in a single institution with a history of thrombosis and a clinical marker of primary thrombophilia was reviewed.

Results: Between 1989 and 2016, 268 consecutive patients with a clinical marker of primary thrombophilia and a history of arterial or venous thrombosis were studied; of these, 108 were female patients. Within this subset of thrombophilic female persons, 77 (71%) had been pregnant at some moment. Twenty eight of these 77 patients (37%) had had a spontaneous abortion and 24 out of these (86%) were found to have the SPS. On the other hand, in a subset of 73 female patients with the SPS who had been pregnant, 32% had miscarriages. These figures are significantly higher than the prevalence of abortions in the general population of pregnant women, which is 12-13% (chi square=7.47; p=0.0063). Accordingly, the relative risk of having a miscarriage is 2.66 times higher in female patients with the SPS than in the general population (p=0.0014) (Figure 1).

Summary/Conclusions: In México, female patients with the SPS experience significantly more spontaneous abortions than the general population. Since the treatment of the SPS is simple and effective and could in turn prevent adverse obstetric outcomes, its investigation in women studied because obstetric complications may be useful and deserves further research.

PB2220

CROSS-SECTIONAL ANALYSIS OF VENOUS THROMBOEMBOLISM IN YOUNG INDIAN MALES; NEW INSIGHTS INTO AN OLD PROBLEM

S.K. Das1,*, Y. Uday1, R. Kapoor1, T. Verma1, S. Das1, V. Nair1
1Hematology, Army Hospital (Research & Referral), New Delhi, India

Background: Venous thromboembolism (VTE) comprising of deep vein thrombosis (DVT) and pulmonary embolism (PE) is one of the major cardiovascular causes of death along with MI and stroke. Though earlier work suggested that DVT is rarer in Asian population, recent studies have revealed that this might not be so. Most of the studies conducted in Asia in general and India specifically has been on hospitalized patients with minimal representation of young healthy individuals.

Aims: We aimed at studying the disease variables of VTE in young healthy males of Indian origin and compare the same with other Indian studies as well as the global statistics.

Methods: Hospital records of 176 Color Doppler Flow Index (CDFI) and/or Contrast Enhanced Computed Tomography (CECT) proven VTE patients being followed up in a tertiary care hospital was analyzed retrospectively to document cause (provoked/ unprovoked), venous systems involved, thrombophilia profile, duration of anti-coagulation and recurrence.

Results: Among the study population, 49.8% had a provoked VTE. 90.9% subjects had DVT, mostly of the lower limb, 15.3% had PE with DVT, 2.8% had PE alone and 6.2% had splanchnic vein thrombosis including portal vein thrombosis. In the subjects who had undergone thrombophilia profile, 41.9% had Protein C, 58.1% Protein S and 25.9% Antithrombin III deficiency. Lupus anti-coagulant screen was positive for 13% of the screened subjects. The average duration of anti-coagulation was 18 months with majority (98.2%) patients on Vitamin K antagonist. The recurrence rate in our study population was found to be 11.4% (Table 1).

Summary/Conclusions: Young Indian males have different disease variables
for VTE as compared to western population. The exact pathophysiology of such differences needs to be studied further to formulate strategies for effective screening and prevention.

Table 1.

PB2221

A PRELIMINARY STUDY ON THE EFFECTS OF AMPHIBIAN CRUDE SKIN SECRETIONS ON SOME PARAMETERS OF HEMOSTATIC SYSTEM

I. Nikolaeva1,*, O. Marushchak1, O. Osyko1, T. Halenova1, O. Savchuk1, Biochemistry, Educational and Scientific Centre "Institute of Biology and Medicine", Taras Shevchenko Kyiv National University, Ukraine, Kyiv, Ukraine

Background: A lot of bio-chemical compounds from secretion of the amphibian skin glands with various biological activities have been isolated and characterized. Several recent studies indicate that amphibian skin secretions can be a source of molecules affecting the platelet activity. We are interested to look for other bioactive components of the amphibian skin which exhibit ability to influence on diverse parameters of hemostatic system.

Aims: We performed a preliminary study of the some effects of amphibian skin secretions on hemostasis.

Methods: Adult specimens (both sexes) of Bombina bombina, Bombina variegata, Bufo bufo, and Bufotes viridis were collected from outdoors in Kyiv region of Ukraine. The crude skin secretions were collected by washing with ultrapure water and centrifuged to remove debris. The supernatants were lyophilized and kept at −20 °C till use. In the experiments we used fresh prepared water solution of lyophilized skin secretions. Protein concentration was measured by coagulometer (Rayto, RT-2201C) using corresponding standard protocols. Platelet fraction (PF) was purified by gel-filtration on Sephadex G 50 column. Platelet aggregation was measured by aggregometer AT-02 (Medtech, Russia). Coagulation parameters (prothrombin time (PT), thrombin time (TT), as well as activated partial thromboplastin time (APTT)) were measured by coagulometer (Rayto, RT-2201C) using corresponding commercial kits (Renam, Russia).

Results: The lyophilized B. bufo skin secretions in dose-dependent manner induced platelet aggregation in both PRP and purified PF. Its final concentration of 50 mg of total protein/mL caused the same effect as 5x10⁻⁶M ADP. These results indicated that skin components acted directly on platelets, maybe through their surface receptors. The lyophilized skin secretions of B. variegata and B. bufo also activated platelet aggregation but their effects were lower than B. bufo skin secretions. The skin secretions from all studied amphibian did not influence on PT and TT except B. viridis which prolonged TT by 40%. The values of APTT were significantly enhanced in 3.4 and 2.3 times under the influence of crude skin secretions (final concentration of 0.2 mg total protein/mL, plasma) of B. bombina and B. variegata, respectively.

Summary/Conclusions: The obtained results indicate the prospects of the search for potential modulators of hemostatic system among the amphibian skin bioactive compounds. To establish their physiological and functional mechanisms of action, the further purification and characterization of components from the skin gland secretions are necessary.

THE TREATMENT OF HEREDITARY TROMBOPHILIA DURING PREGNANCY

M. Theodosiou1,*, I. Ionita1, E.-C. Budai1, C. Hategan1, D.-N. Oros1,2, E.-C. Fenes1, R.-S. Buriman1, H.-M. Ionita1,2

Hematology, Spitalul Clinic Municipal de Urgenta Timisoara/Municipal Emergency Hospital Timișoara, Timișoara, Romania

Background: Thrombophilias are genetic conditions that increase the risk of thromboembolic disease. The use of anticoagulant therapy during pregnancy is challenging because of the potential for both fetal and maternal complications. The most common complication is venous thromboembolism.

Aims: This study is conducted in order to assess the importance of treatment during pregnancy for women with hereditary thrombophilia, the risks of not treating the disease or treating incorrectly.

Methods: This study includes a total of 207 women, from which 83% were treated with low molecular weight heparin and Aspirin during pregnancy regardless if it was their first pregnancy or not and the rest 17% remained untreated during pregnancy. The success of the treatment is based on the completion of the pregnancy and the good health of the fetus.

Results: A total of 207 women were included into the study, 172 were treated with low molecular weight heparin and Aspirin while 35 were treated with just Aspirin. Out of 172 patients in the low molecular weight heparin group 155 managed to give birth which accounts for a 90% success rate with a reported case of fetal growth restriction and 2 cases of abortion while the remaining 17 women which represent 10% of all the patients were unsuccessful in completing their pregnancy with 14 women presenting pregnancy loss on the first trimester and 2 having late fetal loss, only one case of preeclampsia was recorded. Out of the 35 women who did not receive treatment with low molecular weight heparin and only with Aspirin, 21 managed to complete their pregnancies representing the 60% out of which 2 cases presented with Abrupption and 4 cases with fetal growth restriction, out of the 14 women who represented the 40% who were unsuccessful in completing their pregnancies 7 cases were recorded during the first trimester while 3 more had late fetal loss and 4 cases of preeclampsia.

Summary/Conclusions: Women treated for thrombophilia had a lower percentage of fetal loss than their no treatment group counterparts. There is an urgent need for appropriate guidelines for these patients in our medical center.

PB2224

LEARNING ABOUT VALIDATIONS OF THE DVT SCREENING TEST IN PATIENTS WITH SUSPECTED UPPER LIMB THROMBOSIS: A PERSPECTIVE FROM THE CLINICAL PRACTICE

H.N. Fernandez - Leyva1,*, 1Haematology, Croydon University Hospital, London, United Kingdom

Background: Deep vein thrombosis (DVT) of the upper limbs represents 1-4% of DVT, most of them related to central venous catheter and/or malignancy. Thrombosis involving the deep veins (ie, subclavian, axillary, brachial) can lead to complications as pulmonary embolism (PE) and long-term sequelae. PE from upper extremity sources accounts for about 6% of cases. Initial treatment in acute context include fibrinolysis and subsequent anticoagulation (Grade 2C). When symptomatology is mild and/or onset of symptoms underdetermined (>2 weeks), minimum anticoagulation 3 months is recommended. If there are associated anatomical abnormalities, the possibility of surgical vascular thoracic decompression must be assessed.
Aims: To ascertain D-dimer diagnostic accuracy for upper extremity DVT.

Methods: A retrospective audit was undertaken to determine the aetiology and clinical presentation on patients which UDVAT at presentations. Patients with a formal malignancy confirmed before the diagnosis was excluded. A D dimer (DD) with a cut off cut off levels validated for lower limb DVT was performed.

Results: A total of 18 patients were identified in the period of 2012 to 2016. All the cases investigations included Doppler US or CT/MRI and in 30% of the patients the thrombosis was confirmed via contrast venography as a reference standard test. The gender predominant was male in this group the symptomatology were related to physical efforts in a 60% (Paget-Shroëtter Syndrome) whereas in female serie the predominant was thromboembolic defects (factor V Leiden).

The average age was 33 years (ranging from 21 to 68 years) and 2 elderly patients a new diagnosis of cancer was confirmed (thyroid and lung) (odds ratio, 3.24; 95% CI, 1.13-9.38). The 85% of the patients had an unprovoked event; four patients have a diagnosis of cather related thrombosis and four cases of unknown etiology (Factor V Leiden) were diagnosed and participated by anticoagutive. Two patients had a diagnosis of SLE. We had four cases of positive DD screening (both were marginally elevated, P <0.01). The risk of re-thrombosis was non significant but in the subanalysis of relapsing thrombotic event populations the risk of relapse increased proportionally in relation of thromboembolic defect and high BMI. A trend towards a higher rate of recurrent thrombosis (was observed among patients with BMI>25 (42.6%) compared to those with a BMI <25 (33%). This difference reached statistical significance in women with BMI>25, who had recurrent event in 51.7% of the cases vs those with BMI <25 (29.7%) (p <0.05 CI 0.03, 0.41).

Background: Many plants have an effect on the blood clotting system. It is known that there are heparin-like substances in some types of peony roots (Paeonia lactiflora, Paeonia suffruticosa). It proved that there is an anticoagulant activity by APTT test, antplatelet, total fibrinolytic activity (TFA), fibrindepolymerizing activity (FDPA). Experiments were carried out in accordance with ethical principles and documents recommended by the Declaration of Helsinki of the humane treatment of animals. We used an animal model with thrombosis development and thromboembolia.

Aims: The intention is to show the inhibitory effect of the extract of Paeonia lactiflora roots (EA) on processes fibrin and thrombus formation.

Methods: We used the standard coagulographic methods for determining anticoagulant activity by APTT test, antplatelet, total fibrinolytic activity (TFA), fibrindepolymerizing activity (FDPA). Experiments were carried out in accordance with ethical principles and documents recommended by the Declaration of Helsinki of the humane treatment of animals. We used an animal model with thrombosis development and thromboembolia. A retroactive analysis included Doppler US or CT/MRI and in 30% of the patients the thrombosis was confirmed via contrast venography as a reference standard test. The gender predominant was male in this group the symptomatology were related to physical efforts in a 60% (Paget-Shroëtter Syndrome) whereas in female serie the predominant was thromboembolic defects (factor V Leiden).

The average age was 33 years (ranging from 21 to 68 years) and 2 elderly patients a new diagnosis of cancer was confirmed (thyroid and lung) (odds ratio, 3.24; 95% CI, 1.13-9.38). The 85% of the patients had an unprovoked event; four patients have a diagnosis of cather related thrombosis and four cases of unknown etiology (Factor V Leiden) were diagnosed and participated by anticoagutive. Two patients had a diagnosis of SLE. We had four cases of positive DD screening (both were marginally elevated, P <0.01). The risk of re-thrombosis was non significant but in the subanalysis of relapsing thrombotic event populations the risk of relapse increased proportionally in relation of thromboembolic defect and high BMI. A trend towards a higher rate of recurrent thrombosis (was observed among patients with BMI>25 (42.6%) compared to those with a BMI <25 (33%). This difference reached statistical significance in women with BMI>25, who had recurrent event in 51.7% of the cases vs those with BMI <25 (29.7%) (p <0.05 CI 0.03, 0.41).

Background: Many plants have an effect on the blood clotting system. It is known that there are heparin-like substances in some types of peony roots (Paeonia lactiflora, Paeonia suffruticosa). It proved that there is an anticoagulant activity by APTT test, antplatelet, total fibrinolytic activity (TFA), fibrindepolymerizing activity (FDPA). Experiments were carried out in accordance with ethical principles and documents recommended by the Declaration of Helsinki of the humane treatment of animals. We used an animal model with thrombosis development and thromboembolia.

Aims: The intention is to show the inhibitory effect of the extract of Paeonia lactiflora roots (EA) on processes fibrin and thrombus formation.

Methods: We used the standard coagulographic methods for determining anticoagulant activity by APTT test, antplatelet, total fibrinolytic activity (TFA), fibrindepolymerizing activity (FDPA). Experiments were carried out in accordance with ethical principles and documents recommended by the Declaration of Helsinki of the humane treatment of animals. We used an animal model with thrombosis development and thromboembolia.

Results: It was shown that after administration of the indicated doses thromboplastin occurs hypercoagulability in blood plasma of animals (APTT decreased by 23% SFA - 15%, FDPA -12%; increased platelet aggregation by 16% compared to control animals not receiving thromboplastin). Normalization of blood clotting is installed in the experimental rats after application EP (recovery of platelet aggregation to 98%, APTT to 100%, up to 95% SFA- FDPA and up to 67% compared with control). The high degree of FDPA indicates the ability of EP to obstruct the process of the formation of fibrins and thrombosis. Heparin components in EP interact with fibrin monomers which do not participate in their conversion to fibrin polymer. As a result, stable fibrin polymer or thrombus is not formed.

Summary/Conclusions: Consequently, the extract of Paeonia lactiflora roots containing heparinoid contributes to the restoration of coagulation properties in blood of animals in prothrombotic condition and prevents thrombosis. In the initial stages of fibrin formation, it causes the thrombus dissolution.
Results: A total of 528 clinicians were involved in the survey. There were more males 378 (71.6%) than females, 150 (28.4%). The clinicians who practiced for less than 5 years are in the majority 189 (35.8%) and those with 15-20 years of practice 46(8.7%) are in the minority. Only 52 (%) of the respondents (9.8%) claimed their institutions had an anticoagulation policy while 274 (51.9%) of them said there was no such policy and 168 (31.2%) do not know of any policy. Unfractionated heparin was the most frequently used (96.8%) and fondaparinux was the most infrequently used (42%). Most of the prescribings were done by younger clinicians who are the highest in number. The consultants prescribed heparin and warfarin most, with the newer anticoagulants taking the rear position. Only 193 (36.6%) of the respondents routinely prescribed anticoagulation therapy when indicated. 412 (78%) of respondents believe the risk of anticoagulation outweighs the benefits while 439 (83.1%) identified cost is an important variable in prescribing anticoagulation agent. Anti-coagulation prophylaxis was the most frequently used for patients immobilized or bedridden (94.1%); malignancy and atrial fibrillation were the most infrequent reasons for using anticoagulation agents (50.6%). A total of 63 respondents (11.9%) were not satisfied and 219 (41.5%) were not very satisfied with the laboratory monitoring tool available in their institutions. Bleeding is the most common complication of anticoagulation while the least encountered complications are skin and jaw necrosis among the respondents (50.6%); malignancy and atrial fibrillation were the most infrequent reasons for using anticoagulation agents (50.6%). A total of 63 respondents (11.9%) were not satisfied and 219 (41.5%) were not very satisfied with the laboratory monitoring tool available in their institutions. Bleeding is the most common complication of anticoagulation while the least encountered complications are skin and jaw necrosis among the respondents (50.6%); malignancy and atrial fibrillation were the most infrequent reasons for using anticoagulation agents (50.6%). A total of 63 respondents (11.9%) were not satisfied and 219 (41.5%) were not very satisfied with the laboratory monitoring tool available in their institutions.

Summary/Conclusions: This survey has shown the lack of anticoagulation policies among the centers that participated. Our survey has also shown deficiencies in the areas of practice of anticoagulation among the clinicians in the Southeast of Nigeria. These gaps can be remedied by continuous medical education and by the establishment of anticoagulation policies.

UMBILICAL CORD BLOOD PLASMA INFUSION PROMOTES BLOOD CELL RECOVERY IN INPATIENTS WITH ACUTE LEUKEMIA UNDERGOING CHEMOTHERAPY
Y. Lu1,*, X. Zhang1, X. Li2, Y. Zou1, Z. Lin1
1The Third Affiliated Hospital of Sun Yat-Sen University, 2 The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Umbilical cord blood plasma (UCBP) is separated from umbilical cord blood. UCBP contains a variety of hematopoietic growth factors which can stimulate hematopoiesis.

Aims: The aim of this work is to explore the influence of UCBP infusion on blood cell recovery in patients with acute leukemia undergoing chemotherapy.

Methods: Patients with the diagnosis of acute leukemia were included in this study and they were randomly distributed to experimental group and control group. Patients in experimental group received infusion of 100ml UCBP with the same ABO and Rh blood type every day after chemotherapy for five days and patients in control group received placebo for the same time. Blood routine tests were tested every day until WBC >4.0×10^9/L and PLT >20×10^9/L.

Results: 25 patients were included in the study of which 23 were brought into statistics. 13 patients were in experimental group and 10 in control group. There were no difference in age, gender and dose intensity of chemotherapy between the two groups (P>0.05). The average recovery time of the blood neutrophil granulocyte >0.5x10^9/L in experimental group and control group were respectively (6.52±3.26) days versus (12.92±4.75) days (P<0.05) and that of PLT >20x10^9/L was respectively (9.24±3.88) days versus (13.13±5.76) days (P<0.05). No UCBP transfusion-related side effects were found.

Summary/Conclusions: UCBP administration is safe as treatment for cytopenia and could promote blood cell recovery in patients with acute leukemia undergoing chemotherapy.

PB2229
TOWARD BETTER BLOOD TRANSFUSION PRACTICE: A SUCCESSFUL RED BLOOD CELL UTILIZATION TOOLS IN A TERTIARY CARE HOSPITAL
A. Aly1, G. Mawad1, E. Alzaabi1, A. Aly1,*
1Mafraq Hospital, Abu Dhabi, United Arab Emirates

Background: The need for blood in hospitals continues to exceed the volume collected by the transfusion services. The gross over-ordering of blood, in excess of actual and anticipated needs leads to substantial costs and a burden to the transfusion services. In addition, over-ordering leads to non-availability of cross-matched units for other patients who might be in urgent need of transfusion.

Aims: We are aiming to reduce the Cross-match-to-transfusion ratio (C:T ratio) & improve blood utilization at Mafraq Hospital.

Methods: In 2011 the ordering practice at Mafraq Hospital, a designated Trauma Centre, had been evaluated. Data collected retrospectively over a one year period and a C:T ratio was adopted by the American Association of Blood Banks for all various subspecialties including Surgery, Internal Medicine, Pediatrics and Obstetrics and Gynecology. All procedures related to hospital transfusion practice were reviewed and re-evaluated to address gaps. Policy of maximum surgical blood ordering (MSBO) was implemented based upon both results of audits and by discussion and agreement between medical teams. Focused training and education has been followed to increase the awareness of the health care workers. Plus monitoring of C:T ratio on monthly basis, blood bank team had arranged meetings with the departments that were over-ordering cross-matches to explain that group & save test is a safe, effective and financially beneficial strategy. Communicating with the physicians had been the most challenging aspect of implementing the policy changes. Regular audits had been conducted to measure the compliance and effectiveness of the blood management practice.

Results: Compared to the international guidelines, C:T ratios in 2010 was beyond the acceptable target and ranged between 2.5 to 3.2 highlighting the over-ordered cross-matched blood in certain sub-specialties. This practice of ordering was probably because of the fear that blood will not be available, if needed. Following implementation of control and continuous monitoring measures while establishing proper procedures such as transfusion guidelines, administration of blood and blood products and Maximum Surgical Ordering Practice, Mafraq blood bank, supported by the Transfusion and Tissue & Quality & Patient Safety Committees, achieved a great success in reducing C:T ratio <2 all through 2016 Figure 1. The reduction of C:T ratio had improved blood inventory control and reduced the workload of the blood bank staff. Because fewer units of cross-matched PRBC are being ordered, the blood bank has been able to decrease the number of expired units and reducing money loss Figure 1. The savings in technologist time is particularly significant since the blood bank is most of the time at a minimal staffing level.
SAFETY AND EFFICACY OF A PROTHROMBIN COMPLEX CONCENTRATE PB2230

M. Marcos Jubilar1,*, J.A. Garcia Erce2, N. Martinez Calle1, J.A. Paramo1

Background: Prothrombin complex concentrates (PCC) are highly purified mixtures of plasma coagulation factors that contains vitamin K dependent and anticoagulopathy factors, they are approved for urgent reversal of vitamin K antagonists (VKA). Massive bleeding-associated coagulopathy guidelines include PCC in their management, although as an off-label indication.

Aims: The aim of the present work is to evaluate safety and efficacy of PCC in a case series of VKA reversal and refractory coagulopathy associated with major bleeding.

Methods: Retrospective review of cases treated with a four-factor PCC between January 2010 to January 2016 in two tertiary University Hospitals. As safety endpoints we evaluated infusion reactions and incidence of thromboembolic events by self reported registry. The efficacy endpoints were studied in two separate cohorts: 1) INR correction for VKA reversal and 2) coagulopathy correction and early mortality (24 hours) in major bleeding coagulopathy.

Results: 328 patients were included (47.25% male), median age 78 years (range 19-102), PCC was used in the following cases: 1) 66.67% in VKA reversal indication (181 patients due to hemorrhage and 33 prior to emergent surgery), mean dose of PCC 1333.51 IU; 2) 30.54% in refractory coagulopathy in major bleeding (181 patients due to hemorrhage and 33 prior to emergent surgery), mean dose of PCC 1681.63 IU was used. Safety endpoint: Two infusion reactions were reported potentially related to PCC use, they were not specified neither as anaphylaxis nor as pulmonary edema, and 8 thrombotic episodes were observed (2.4%); 5 pulmonary embolism, 2 deep venous thrombosis and 1 portal thrombosis. 75% of the events appear in the group of VKA reversal. Efficacy endpoint: VKA reversal in bleeding patients was effective in 97% of them, 76.5% with complete reversal of INR value (INR<1.5), 34.25% of patients required red blood cell (RBC) transfusion, with a mean of 1.32 RBC. Prior to invasive procedure VKA reversal was effective in 83% of patients, all procedures taking place with no bleeding complication, 36.3% of patients needed RBC with a mean of 1.12 units, 24 hours mortality in refractory coagulopathy associated in major bleeding was 31.6%, having a worse outcome (40% rate of death) those who suffer a massive bleeding coagulopathy, all death related with absence of bleeding control. A global INR correction happen in 76.7% of patients, complete correction in 40.7%. 63.26% received previous to PCC fresh frozen plasma. Invasive hemostatic procedures were required in 20% of the whole series.

Summary/Conclusions: A four-factor prothrombin complex was safe and effective as adjuvant treatment in refractory coagulopathy due to major bleeding as well as for the emergent reversal of VKA.

NON-HEMOLYTIC FEBRILE POST-PLATELET-TRANSFUSION REACTIONS IN HEMATOLOGICAL PATIENTS

A. Rakhmani1,2, E. Mikhailova1, I. Dubinkin1, V. Troitskaya2, O. Kalmikova3, M. Danilevskaia3, T. Gaponova1

Background: Platelet concentrate (PC) transfusions are the main method of thrombocytopenia correction in hematological patients, but multiple transfusions could trigger alloimmunity and refractoriness to transfusions.

Aims: Comparison of post-transfusion reactions in hematological patients with individual matching and without individual matching receiving PC transfusion support.

Methods: In 2015-2016, we observed 948 hospitalized patients, who received 12.344 PC transfusions. Individual matching of PCs was performed by cross-matching on the Galileo-Neo (Immucor) analyzer. Statistical processing was performed using the chi-squared test with Yates' correction.

Results: 107 of 948 patients developed refractoriness to PC transfusions (12% of total patients). Out of them, 21 patients received 389 PC transfusions without individual matching, 86 patients with individual matching. 86 patients with individual matching had 1705 PC transfusions. During transfusions without individual matching to non-refractory patients, 0.003% of non-hemolytic febrile reactions (NHFR) have been record-

Figure 1.

Summary/Conclusions: There is a tendency to order blood in excess, either by asking for an increased number of units or as a standby precautionary measure. Adherence to MSBO & transfusion guidelines, hospital can achieve C:T ratios below 2.0. The introduction of strategies for improved blood utilization has been shown to be cost effective and safe. Future comparison analysis with facilities with well-established blood management program can enhance the current program and ensure continuous proper utilization.
ed, after matching to refractory patients the frequency was 0.002%. Before matching to refractory patients, the frequency of NHFR was (0.03%) (Table 1).

RARE DONORS AND MALARIA

A. Berzuini1,*, B. Foglieni1, M. Spreafico1, D. Pratti1
1Department of Haematology and Transfusion Medicine, Ospedale A. Manzoni, Lecco, Italy

Background: Migratory flows of sub-saharan (SSA) persons throughout the world are expected to continuously increase. A significant proportion of SSA citizens are affected by Sickle Cell Disease (SCD), condition requiring repeated blood transfusions. Many centuries of malaria pressure have induced in SSA native, homogeneous selection of peculiar haematologic characteristics, such as the absence of high frequency red cell antigens (defining a rare blood) that cannot be found in donors of European descent so that many SCD transfused patients experience the fearful occurrence of red cell alloimmunization. For these reasons haematologists are expecting to access to Rare Blood Banks in order to assure a full match between donor and recipient’s blood, that may be obtained from donors sharing the same ethnicity. Unfortunately SSA donor recruitment is counteracted by the widespread diffusion of infections contracted before migration: one of these is malaria. In SSA malaria may occur sublinically and is characterized by a slow antibody clearance. This peculiar condition, the so-called semi-immunity, has been induced by a strong genetic pressure, and is a kind of co-evolutionary process characterized by the co-existence and persistence of small entity of Plasmodium genome with relative antibodies. Molecular techniques are unreliable to detect a small number of Plasmodia, which may otherwise be sufficient to induce a transfusion transmitted malaria (TTM). The serologic assessment, despite the low specificity, remains the most sensitive and reliable method to detect the semi-immune status in blood donors (1).

Aims: The aim of this study was to assess the prevalence of malaria immunity in a cohort of healthy SSA citizens.

Methods: Since 2010 in our Department of Haematology and Transfusion Medicine we recruited 184 SSA citizens, in good health, who agreed to undergo clinical and laboratory investigations to become a blood donor. All of them were born in SSA Africa and lived there for at least the first 5 years of life. 70% of subjects didn’t recognize any previous malaria fever. The last travel/stay in Africa was from 200 years ago (3 yrs), and 43% of returning people had received prophylaxis. Malaria serology was determined by a commercial enzyme immunoassay kit (Malaria EIA Ab, BioRad). The frequency of NHFR in groups with refractoriness with individual matching is significantly lower (10 fold) compared to groups with refractoriness before the matching (P<0.01)*.

Results: Overall 75% of persons were positive for malaria antibodies. Serologic positivity was found in 75% of persons no more exposed in 5 recent years and even in 83% (19/23) persons settled in Italy since 10-20 years. Serologic positivity was present in 100% of people from Benin, 85% from Burkina Faso, 78% from Ivory Coast and Cameroon, 63% from Senegal. We followed antibody concentration in 50 persons (136 assays), and we observed a slightly negative trend that, in most cases, was followed by a prolonged phase of low antibody levels. 4/50 became negative after three years.

Summary/Conclusions: The identification of malaria antibodies is essential in SSA native donors and, by far, irreplaceable in order to avoid the risk of TTM. Until pathogen inactivation techniques will become available, we have a very low expectation to introduce SSA blood in Blood Bank inventories. Haematologists have to adapt some years for forthcoming SSA second generation that will allow to fully match the entire SCD patient community.

EFFICACY AND INFLUENCE OF IRON CHELATION THERAPY ON RED BLOOD CELL TRANSFUSIONS

A. Parvu1,2,*, M. Iancu2, A. Vasilache2, T. Tokor2, I.-A. Zoldos2, M. Zdrengeha2, L. Petrov2, C. Seles2, L. Urán2, A. Todicna2, C. Truica2, A. Bojan2
1Hematology, "Iuliu Hatieganu" University of Medicine and Pharmacy, 2Hematology, Prof. Irion Chiricuta" Oncological Institute, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, 4Hematology, Baia-Mare County Hospital, 5Hematology, "Iuliu Hatieganu" University of Medicine and Pharmacy, Baia-Mare, Romania

Background: Chelation therapy is recommended for transfused patients that have an elevated serum ferritin level (over 1000 microgl/l), evidence of iron overload or received over 20 units of red blood cell transfusions (RBCT). Deferasirox showed efficacy and safety in maintaining or reducing body iron (assessed by liveriron concentration or serum ferritin).Iron chelation therapy was associated with hematopoiesis improvement in transfusion-dependent patients and interruption of Deferasirox treatment of transfusions dependent myelodysplastic patients produced loss of erythron response.

Aims: Aim of the study: to assess the results of Deferasirox efficacy, side effects and to study if the number of RBCT decreased after starting Deferasirox.

Methods: We have done a retrospective, transversal study including all the adult politransfused patients treated with Deferasirox in three counties Hema
tology Departments of North-West Romanian hospitals. Criteria of Deferasirox treatment: over 20 RBCT, serum ferritin level over 1000 microgl.

We created a data collection sheet including: demographic, information on patients’ disease, serum ferritin level at start of and during treatment, Deferasirox dose, data about dose modification, adverse effects of Deferasirox and their management, reasons for treatment discontinuing, evaluation of comorbidities that could increase serum ferritin level, number of RBCT before and after starting the treatment.

Results: We included 40 politransfused patients treated with Deferasirox, age average 63. The diagnosis included mielodysplastic syndromes (most of patients), thalassemia, other anemias. Myelodysplastic patients were treated with low dose chemotherapy, epigenetic treatment, RBCT and Deferasirox. Other type of patients were transfused. The baseline value of ferritine was between 1075 - 6187 microgl. Deferasirox dose: 20-30 mg/kg. There was a significant reduction in serum ferritine from baseline for all the patients. Ferritine median at start, 3631 microgl decreases at 1537 microgl/after 6 months of treatment and at 894 microgl after 12 months of treatment. There were 8 patients with a reduction of ferritine, but during infectious episodes the ferritine increases for a short period of time. Digestive adverse events appeared in three cases (two cases of diarrhea and one case of digestive hemorrhagic episode). In all these cases the treatment was temporarily discontinu
eed. In three cases, treatment was stopped because low ferritin level (under 500 microgl). RBCT were administered before (mean 2.43 units/month) and after starting Deferasirox (mean 1.39 units/month), the difference is statistically significant (Student Test, t(39)=6.98, p<0.001). After starting Deferasirox treatment mean number of RBCT decreased, mean of differences (95% CI) was 1.04. We analyzed the group of 23 patients treated with Deferasirox less than 12 months, and the patients treated more than 12 months, 15 patients. In both groups the difference of RBCT means (before and after the start of the treat
tment) are statistically significant (for the patients treated less than 12 months: Student Test, t(23)=8.12, p<0.001 and for the patient treated more than 12 months: Student test, t(15)=3.03, p=0.008).

Summary/Conclusions: Analyzing our group of 40 patients, Deferasirox proves to be effective and safe. Adverse effects that determined a temporary stop of the treatment were mild/medium short time digestive reactions. The number of red blood cell transfusion significantly decreased after starting Deferasirox treatment.

PB2235

LIBERAL VS RESTRICTIVE COMPARATIVE TRANSFUSIONAL STUDY IN ONCOLOGICAL POPULATION

M.I. Touzón Andión1,*, M. Gestal 1, A. Varela1, M. Castro1, C. Moinelo1, R. Garcia de Villascausa1
1Transfusion , Centro Oncológico de Galicia, La Coruña, Spain

Background: Allogeneic transfusion therapy is perhaps one of the most widely used treatments without good evidence support, despite many years of appli
cation in clinical practice. This, coupled with blood shortages, the impossibility of a sufficient zero risk, the lack of evidence that transfusion may increase con
sumption or decrease tissue oxygen debt and the existence of an association with an increase in morbidity and mortality have favoured that we join efforts towards its optimal use.

Aims: Optimal use in our adult oncological population and evidence that restric
tive transfusion (TR, Hb 7-9 gns / dl) is not greater or lower to the liberal trans
fusion (TL, Hb 8-10 gns / dl), keeping hemoglobin in safe levels for the patient.

Methods: A research was performed from October 1st, 2015 through December 31st, 2016. We analyzed the proportion of patients receiving packed red

cells (CH) and the number of units transfused as well post-transfusion control in order to describe the outcome of the CH versus TL strategies in the cancer population under the study.

Results: See Table 1.

Summary/Conclusions: The results obtained in our series of 311 cancer
patients indicate that the restrictive strategy has been equally effective and probably superior to the liberal one maintaining Hb at a safe level in each patient, as well as quality of life and comfort in a subgroup with advanced and terminal cancer.

**HIGH RISK OF HBV INFECTION IN VACCINATED POLYTRANSFUSED CHILDREN**

M. El-Sayed1,*, D. Soydemir1, M. Yanaşık1, A. Akcay2, G. Ozturk3

1Pediatric Department, Ain Shams University, Faculty of Medicine, 2Microbiology Department, Faculty of Medicine (for girls), Al-Azhar University , 3Community Medicine Department, National Research Center, Cairo, Egypt

**Background:** Children receiving chemotherapy for neoplastic diseases are still susceptible to Hepatitis B virus (HBV) infection despite the national HBV vaccination program coverage for all infants since 1992. This study aimed to analyze immunity against HBV and occurrence of HBV breakthrough infections in polytransfused children who had been vaccinated during infancy.

**Methods:** The study included 89 children with hematological disorders and malignancies, who were categorized into group (A): 37 receiving chemotherapy (M:F 20:17; mean age: 7.5±4 years) and group (B): 52 polytransfused children (M:F 31:21; mean age:7.6±3.2). A matched healthy control group (n=162) was also included. All patients and controls had received their primary vaccination against HBV in infancy. Quantitative anti-HBs were tested for patients and controls. Patients’ sera were tested for HBsAg, anti-HBC, and HBV-DNA (nested PCR for surface, core & x-regions).

**Results:** Levels of anti-HBs between 10-100 IU/L and ≥100 IU/L were found among 13.5% and 21.6% [group (A)]; 44.2% and 11.5% [group (B)] and 32.1% and 10.5% of controls respectively. There was a significant difference in HBsAb between patients receiving chemotherapy [group (A)] and both groups B patients (p<0.008) and controls (p=0.032). However, there was no difference found between polytransfused children [group (B)] and controls.

HBsAg was positive in 21 (67.7%) children under chemotherapy [group (A)] compared to 10 (32.2%) polytransfused children [group (B)] (p=0.0005). Overall, 49 patients (55%) were HBV-DNA positive; 44 c-region positive, 7 s-region positive; 2 positive for both c and s-regions and one positive for c and x-regions. Of those, only 21 patients (42.8%) were also positive for HBsAg; while 28 (47.2%) had occult HBV infection (HBsAg-negative). There was no significant difference between patients receiving chemotherapy [group (A)] and polytransfused children [group (B)] (p=0.157), regarding the rate of HBV DNA. Anti-HBs ≥10 IU/L was observed in 38.7% (123/31) of HBsAg positive patients and 49% (24/49) of HBV-DNA positive patients.

**Summary/Conclusions:** Children with neoplastic diseases vaccinated during infancy were at a high risk for HBV infection. The effect of immunosuppression on the HBV protective level favored overt HBV infection in children receiving chemotherapy. The co-existence of anti-HBs with HBsAg and/or HBV-DNA demonstrated a possible residual transfusion-transmission risk with mutant HBV strains.

**THE ISOHEMAGGLUTININ TITERS OF BLOOD BANK DONORS: THE EXPERIENCE OF ISTANBUL FACULTY OF MEDICINE**

Z. Karakas1,*, D. Soydemir1, M. Yanaşık1, A. Akcay2, G. Ozturk3

1Pediatric Hematology-Oncology, Istanbul University Institute Medicine Faculty, 2Pediatric Hematology-Oncology, Acıbadem University, 3Pediatric Hematology-Oncology, Acıbadem University, Istanbul, Turkey

**Background:** Isohemagglutinins that develop against ABO blood group antigens are very important in transfusion and transplantation medicine. Today, 30-40% of allogeneic stem cell transplantsations are ABO incompatible transplantation, 20-25% of which are major, 20-25% are minor and remaining bi-directionally incompatible transfusion. Our study; based on the knowledge that isohemagglutinins play an important role in blood transfusion policies in patients undergoing ABO incompatible hematopoietic stem cell transplantation (HSCT) has been shaped by the assumption that each healthy blood donor may be a potential transfusion donors for ABO incompatible HSCT transplant recipients.

**Aims:** In this study, we investigated the isohemagglutinin titer values of the individuals with A, B and O blood groups; the distribution of the isohemagglutinin titers according to the decades and gender. Also we examined the possibility of determining the isohemagglutinin cut off value in Turkish society.

**Methods:** One thousand five voluntary blood donors (48 female, 957 male), randomly chosen from the donors, providing the criteria to be a standard blood donor in Blood Center Department, Istanbul Faculty of Medicine were studied. This study was approved by the Ethics Committee of Istanbul Medical Faculty. In the donor population group; blood group A (%40) was the most common and blood group AB was the rarest blood group. According to the Rh D phenotypes; 85% of the population was Rh D positive and 15% of the population was Rh D negative. The frequency of our blood group was determined similar with other European countries. The most common age range of one thousand five voluntary blood donors, including the same rate individuals with blood group A, B and O, was the age range between 26 and 35 years. Forward and reverse blood group determination were performed to these donors and also we identified the Anti-B Ig M and Ig G isohemagglutinin titer values for blood group A; Anti-A Ig M and Ig G titer values for blood group B; eventually both Anti-A Ig M / Ig G and Anti-B Ig M / Ig G isohemagglutinin titer values for blood group O by using column agglutination methods. Statistical analysis was performed with NCSS (Number Cruncher Statistical System) 2007 (Kaysville, Utah, USA).

**Results:** While the titer value of Anti-A Ig M isohemagglutinin was 1:128 for female individuals with blood group B; the titer values of both Anti-B Ig M (1:128 and 1:256) , Anti-B Ig G (1:1024) and Anti-A Ig M (1:256) isohemagglutinins were statistically significance in female individuals rather than male ones. The levels of isohemagglutinin in the blood groups A, B and O are shown in Table 1.

**Background:** Isohemagglutinin titers of blood bank donors have been shaped by the assumption that each healthy blood donor may be a potential transfusion donors for ABO incompatible HSCT transplant recipients.
The use of eculizumab out of indication in typical HUS and whether the disease follow-up and to try to prevent possible relapses. The need to request levels of ADAMTS13 in patients diagnosed with TTP or to possible given that the unfortunate prognosis of these patients. It is to be noted the part played by the approval of Shiga toxin in those patients who eventually developed typical HUS.

Results: The process plasma fractionation is largest industry segment in manufacture of therapeutic concentrate of plasma proteins. We developed a technological scheme that involves fractionation plasma of blood in combinations of classical methods of protein precipitation and two chromatographic steps: ion exchange and affinity chromatography. Of all plasma fractionation methods, chromatography is the best candidate for purification of factor coagulation, especially FVIII. The methods adsorption/precipitation permits the fractionation of large volumes of plasma, but the quality of the product obtained by chromatography is superior. We offer: fresh frozen plasma – adsorption of proteins on the barium citrate – adsorption of proteins on Al(OH)₃ – adsorption to proteins PEG-4000 – viral inactivation (solvent-detergent method) – ion exchange chromatography on DEAE-Sepharose – viral inactivation (ammonium thiocyanate) – dye-ligand affinity chromatography (Diaso-Active Scarlet Damask 4GT). We got the drug of FVIII with specific activity 69.65±2.4 IU/mg protein.

Summary/Conclusions: we developed technological scheme of plasma fractionation and reached a high degree of purification of coagulation FVIII.

PB2239
PRIMARY TROMBOTIC MICROANGIOPATHIES. REVISION IN A CENTER OF THE LAST 8 YEARS
T. Castaño1,*, S. Sanchez1, T. Arquero1, M. Yuste1, E. Askari1, P. Llamas1 1 Fundación Jiménez Díaz, MADRID, Spain

Background: Thrombotic microangiopathies are a group of rare diseases characterized by non-immune microangiopathic hemolytic anemia, thrombocytopenia and involvement of organs of varying intensity, mainly renal and CNS damage. TTP and HUS are the most important forms of TMA and without adequate treatment administered early are associated with high morbidity and mortality.

Aims: To review our experience in the management of the primary TMA and to raise a series of questions that perhaps could improve the understanding of these pathologies

Methods: We made a retrospective, descriptive analysis of ten cases diagnosed of primary thrombotic microangiopathy (TTP n=5; typical HUS n=3; atypical HUS n=2) over the last eight years, 70% of which were women with an average age between 40-60 years. Only three cases had previous records of autoimmune diseases (MTC, RA and HIV), all of which would eventually develop TTP. We requested ADAMTS13 levels on all cases, they were low (<5-10%) only in those patients diagnosed with TTP, and on the other hand confirming the positivity for Shiga toxin in those patients who eventually developed typical HUS.

Results: Regardless of the diagnosis, 10-12 plasma exchanges were performed to improve the biological parameters of hemolysis, requiring the placement of a central catheter, most commonly at the right jugular vein (70%) due to the lower risk of thrombotic and infectious complications. Although renal involvement is frequent in HUS, only two of the patients required dialysis without recovery of baseline renal function. It is to be noted the part played by the approval in 2011 of eculizumab and how patients eight years ago suffered a torpid course, requiring a greater number of plasmapheresis and the side effects this carries. However, we still do not know its repercussions out of indication. In our study, it was used in a patient with a diagnosis of HUS associated with an infection with good evolution, although perhaps this result is due only to the natural evolution of the disease. Another controversial point is the use of antibiotics, which are known to worsen the clinical course of these processes, but because of a concomitant infection or new positive determination of the Shiga toxin, as occurred with two of our patients of diagnosis of HUS had to be used. Finally, 30% of the patients have relapsed after the first episode with a primary diagnosis of a TTP.

Summary/Conclusions: Thrombotic microangiopathies are a group of processes of enormous complexity, in addition to the low frequency with which they are usually present in our usual clinical practice requiring a large deployment of means to reach an early diagnosis and begin treatment as soon as possible given that the unfortunate prognosis of these patients. With this study we have raised a series of questions to improve the management of this type of diseases: The need to request levels of ADAMTS13 in patients diagnosed with TTP or to repeat the determination of Shiga toxin in patients with typical HUS as part of the disease follow-up and to try to prevent possible relapses. The use of eculizumab out of indication in typical HUS and whether the improvement in the picture is due to the drug or by natural evolution of the disease. Th e need to request plasmapheresis in patients diagnosed with typical HUS. The use of antibiotics and possible harm to the diagnosis made.

**NOVEL SMALL MOLECULE INHIBITORS CO-TARGETING CKIα AND P-TEFb DISRUPT SUPER-ENHANCERS AND ERADICATE ACUTE MYELOID LEUKEMIA IN A MOUSE MODEL**

W. Minzel1, I. Alkalay1, A. Fink1, A. Venkatachalam1, E. Hung1, D. Li2, J. Vaccar2, F. Mercuro3, M. Oren4, E. Pikarsky1, Y. Ben-Neriah1

1Immunology and Cancer Research, Hebrew University of Jerusalem, Jerusalem, Israel, 2Chemistry, WuXi AppTec, Shanghai, China, 3BioTheryX Inc, San Diego, United States, 4Molecular Cell Biology, Weizmann Institute, Rehovot, Israel

Background: Whereas p53 is mostly non-mutated in AML, various oncogenic pathways, frequently through enhancing the activity of its major antagonist Mdm2, suppress its activity. We have previously showed that genetic ablation of CKIα robustly activates p53 (doi:10.1038/nature09673). However, with no selective CKIα inhibitors for in vivo use, the therapeutic value of CKIα inhibition in hematologial malignancies cannot be validated.

Aims: To develop small molecule CKIα inhibitors and assess their effect in mouse models of human leukemia.

Methods: CKIα inhibitors were identified via cell-based screening based on p53 activation. We focused on a small class of pyrazole-pyrimidine scaffolds, which through extensive medicinal chemistry yielded derivatives with high affinity binding, validated by crystallography studies, potent CKIα inhibitory activity and a good pharmacokinetic profile. Anti-leukemia activity was assessed by oral treatment in mouse models of AML. MLL-AF9 and Bcr-Abl Blast Crisis Results: We first demonstrated the inhibitors' anti-leukemia effect by single oral dose treatment, robustly inducing p53 activation and blast cell cytoreduction (Figure 1).

Figure 1.

These inhibitors distinguished leukemic from normal hematopoietic stem cells: they did not affect normal hematopoietic CFUs, but eliminated leukemic CFUs at an IC50 3-9M. We tested the long-term oral therapeutic effects of the inhibitors in MLL-AF9 leukemic mice. Whereas all vehicle-treated mice succumbed to the disease within a month, 40-50% of inhibitor-treated mice survived with no signs of disease up to 5 months' observation, nor had the surviving mice any sequela of long-term treatment; all had normal blood counts and normal organ morphology and histology. Long-term leukemia control with possible cure, attesting to eradication of LSCs and preservation of normal HPSCs was demonstrated by transplanting leukemia-treated BM into lethally irradiated mice: all transplanted mice recovered and none showed any evidence of residual disease within 6 months. To elucidate the mechanisms by which the inhibitors distinguished leukemia from normal hematopoietic cells, we profiled the kinome affinity of the inhibitors and further studied their signaling effects in vitro and in vivo. We found that CKIα inhibitors having potent anti-leukemia activity are distinguished from less active analogues by their capacity to co-target CDK9 and suppress the RNA Pol II elongation factor P-TEFb (CDK9-CyclinT1 complex). This property, validated by co-crystallography studies, enables the inhibitors to disrupt super-enhancers (SE), demonstrated by suppression of chromatin H3K27 acetylation and Brd4 association. As a result, transcription of SE-dependent major anti-apoptotic leukemia oncogenes including Mdm2, Bcl-2 and Mcl-1 was nearly abolished and inhibitor-treated leukemia cells underwent apoptosis. Strikingly, brief drug exposure (10mins in vitro, 2hrs in vivo) results in prolonged (24hrs) SE suppression. This unique property, which is at variance with the current occupancy-driven pharmacological paradigm, likely contributes to the dramatic therapeutic effect of co-targeting CKIα and P-TEFb in leukemia.

**Summary/Conclusions:** We developed a new class of small molecule inhibitors that co-target CKIα and P-TEFb. These inhibitors induce very rapid, robust activation of p53 in synergy with shutdown of leukemic super-enhancers, resulting in a lasting, powerful and specific anti-leukemic therapeutic effects in vivo, with cure potential.

**CRYPTIC INSERTIONS OF IMMUNOGLOBULIN LIGHT CHAIN ENHANCER REGIONS ACTIVATE CCND3 AND CCND2 IN CYCLIN D1-NEGATIVE MANTLE CELL LYMPHOMAS**

1IDIBAPS, Barcelona, 2Universidad de Oviedo, Oviedo, Spain, 3The Maria Skłodowska-Curie Institute - Oncology Research Center, Warsaw, Poland, 4Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, 5University of Würzburg, Würzburg, Germany, 6Massachusetts General Hospital and Harvard Medical School, Massachusetts, 7Cleveland Clinic Foundation, Cleveland, 8University of Nebraska Medical Center, Omaha, NE, United States, 9University of Toronto and Sunnybrook Health Sciences Centre, Toronto, Ontario, Canada, 10Department of Pathology, City of Hope National Medical Center, Duarte, CA, United States, 11UVU University Medical Center, Amsterdam, Netherlands, 12HMSD Laboratory, Leeds Teaching Hospitals NHS Trust, St James’s Institute of Oncology, Leeds, United Kingdom, 13Department of Pathology, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 14Barcelona Supercomputing Center, 15Genetic and Functional Genomics Centre for Genomic Regulation, 16IMIM-Hospital del Mar, 17Hospitalet de Barcelona, Barcelona, Spain, 18Institute of Human Genetics, University of Ulm, Ulm, 19Robert-Bosch-Krankenhaus, and Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, 20Institute of Pathology, Eberhard-Karls-University of Tübingen, Tübingen, Germany, 21National Cancer Institute, National Institutes of Health, Bethesda, United States

Background: Mantle cell lymphomas (MCL) are characterized by the primary translocation t(11;14)(q13;q32) involving CCND1 and IG genes in virtually all cases. Recently, a small subset of cyclin D1-negative (cyclin D1− MCL) has been recognized. About half of these cases have CCND2 gene rearrangements and overexpression of this gene. However, the only oncogenic event in cyclin D1−/cyclin D2−MCL still remain elusive.

Aims: To identify potential mechanisms driving the pathogenesis of cyclin D1−/cyclin D2−MCL.

Methods: We investigated 66 cyclin D1−/SOX11+MCL cases by a combination of fluorescence in situ hybridization (FISH), gene expression profiling by Affymetrix U133+2.0 and qPCR (n=51), and copy number arrays (n=47) (Agilent CGH 1M, Affymetrix Oncoscan and 500K). Six cases were investigated by whole-exome sequencing including 4 mate-pair whole-genomes, 4 whole genome-wide sequencing including 4 mate-pair whole-genomes, 4 whole exomes, and 1 whole-genome sequencing. The male/female ratio was 2.5:1 and median age at diagnosis 66 years.

Results: Most cyclin D1− MCL (49/51, 96%) showed overexpression of other G1 cyclins: CCND2 in 33/36 (92%); CCND3 in 12/21 (54%), and moderate overexpression of both CCNE1 and CCNE2 in 35/36 (11%), CCND2 rearrangements were detected by FISH in 25/33 cases (76%) with CCND2 overexpression, but the remaining CCND2+ cases and those with CCND3 overexpression did not show CCND2, CCND3 and IG rearrangements using currently used break-apart probes. Interestingly, by mate-pair whole-genome and whole-exome sequencing analyses we discovered cryptic insertions of IG light chain regions including the enhancer regulatory elements (2 IGK and 1 IGL) near CCND1, CCND2, and CCNE1 and CCNE2 in 33/50 (66%), CCND3 in 12/21 (54%), and moderate overexpression of both CCNE1 and CCNE2 in 35/36 (11%). CCND2 rearrangements were detected by FISH in 25/33 cases (76%) with CCND2 overexpression, but the remaining CCND2+ cases and those with CCND3 overexpression did not show CCND2, CCND3 and IG rearrangements using currently used break-apart probes. Interestingly, by mate-pair whole-genome and whole-exome sequencing analyses we discovered cryptic insertions of IG light chain regions including the enhancer regulatory elements (2 IGK and 1 IGL) near CCND1, CCND2, and CCNE1 and CCNE2 in 33/50 (66%), CCND3 in 12/21 (54%), and moderate overexpression of both CCNE1 and CCNE2 in 35/36 (11%). CCND2 rearrangements were detected by FISH in 25/33 cases (76%) with CCND2 overexpression, but the remaining CCND2+ cases and those with CCND3 overexpression did not show CCND2, CCND3 and IG rearrangements using currently used break-apart probes. Interestingly, by mate-pair whole-genome and whole-exome sequencing analyses we discovered cryptic insertions of IG light chain regions including the enhancer regulatory elements (2 IGK and 1 IGL) near CCND1, CCND2, and CCNE1 and CCNE2 in 33/50 (66%), CCND3 in 12/21 (54%), and moderate overexpression of both CCNE1 and CCNE2 in 35/36 (11%). CCND2 rearrangements were detected by FISH in 25/33 cases (76%) with CCND2 overexpression, but the remaining CCND2+ cases and those with CCND3 overexpression did not show CCND2, CCND3 and IG rearrangements using currently used break-apart probes.

Summary/Conclusions: We have identified a novel IG light chain locus-associated rearrangement, consisting of cryptic insertion of IG enhancer near CCND3 and CCND2, which sheds light to cyclin D1−/cyclin D2−MCL. Moreover, 32% cases had chromothripsis at least in one chromosome.

**Legend:**

Figure 1. Single-door inhibitor effects treated for 4hrs (BM Western blot and blood smear) and 1hrs (tissue records), in heavily leukemic mice, showing strong cytoreduction in the spleen and bone marrow and pro-apoptotic signaling of chemically induced inhibitory effects (CCND1 and CCND3, evidenced by RNA Pol II phosphorylation), inhibition and activation of DNA damage response (pH2AX) and p53.
Background: 1q (1q21 gain) is a common high-risk subtype of multiple myeloma (MM), which drives MM progression, confers drug resistance, and correlates with inferior outcome. However, the molecular mechanism underlying the adverse prognostic roles of 1q remains largely unclear. Recently, 1q has been linked to hypoxia and resulting drug-resistant gene expression.

Methods: To understand the function and clinical significance of hypoxia-induced factor-1B (HIF-1B), a gene located in the 1q21 region, in 1q MM and hypoxic microenvironment.

Results: In a cohort of 180 NDMM patients, median OS (mOS) was 29 and 43 months for cases with (w) or without (w/o) 1q (P=0.038), among which 24.3, 43.3, and 43.8 months for 1q copy number ≥3, ≥2, and ≥1 (P=0.030), respectively; whereas Btz-based therapy displayed a marked increase in response rate (≥VGPR) it failed to improve mOS of 1q patients significantly (28.5 and 33.9 months for patients w or w/o Btz treatment, P=0.983); in contrast, Btz treatment dramatically prolonged mOS in patients w/o vs w 1q (53.7 and 28.5 months, P=0.016). To explore the molecular basis for the adverse effect of 1q on prognosis, expression of the 1q21 genes related to drug resistance was examined. Notably, robust expression of HIF-1B at protein level was found in 1q− or drug-resistant MM cells, or under hypoxia. The function of HIF-1B was evaluated using genetic means and pharmacological inhibitors.

Conclusions: Inhibiting HIF-1B in 1q− or drug-resistant MM cells, or under hypoxia, halted Btz sensitivity in a dose-dependent manner. HIF-1B knockdown not only reduced cell viability, but also restored sensitivity to Btz in 1q− or drug-resistant MM cells. The restoration of Btz sensitivity was confirmed in the in vivo model. Importantly, Btz treatment dramatically prolonged mOS in patients w/o vs w 1q (P=0.038), indicating that inhibiting HIF-1B could potentially improve clinical outcome in 1q− MM patients.

Background: CTL019 is an investigational chimeric antigen receptor (CAR) T-cell therapy with a high rate of durable complete responses (CRs) and a manageable safety profile in a previously reported single-center trial in adult patients (pts) with R/R DLBCL. Aims: Results of a planned interim analysis of a single-arm, open-label, multicenter, global phase 2 trial of CTL019 in pts ≥18 y with R/R DLBCL (JULIET; NCT02445248) are reported. Methods: Industry-manufactured CAR T-cells were provided to pts at 27 centers on 4 continents using a global supply chain. Pts had received ≥2 lines of chemotherapy and had disease progression after or were ineligible for autologous hematopoietic stem cell transplantation (AH SCT). Autologous CAR T-cells were thawed, expanded for 14 days in a lentiviral vector encoding an anti-CD19 CAR, expanded, cryopreserved, shipped, and infused at study sites. The primary endpoint (centrally reviewed by an independent review committee) was best overall response rate (ORR: CR + partial response [PR]). Results: 148 pts were enrolled. Following restaging, bridging therapy, and lymphodepleting chemotherapy (fludarabine 25 mg/m²/cycle; cyclophosphamide 250 mg/m²/day × 3 days or bendamustine 90 mg/m²/day × 2 days), 85 pts received a single dose of CTL019 transduced cells (median, 3.1 × 10⁸ [range, 0.1-10⁸]) cells. Median time from infusion to data cutoff (20 December 2016) was 7 mo (range, 0.1-17). Median follow-up was 25 mo (range, 2-103). Median number of CAR T-cells infused was 4 × 10⁹ cells. Median ORR was 43% with 1 CR and 4 PR. Summary/Conclusions: CTL019 was generally well tolerated. Among 51 pts with ≥3 mo follow-up or earlier discontinuation, best ORR was 55% (95% CI, 44% to 70%, with 43% CR and 16% PR; the primary endpoint was not met. CR and PR rates at 3 mo were 37% and 8%, respectively. All pts in CR at 3 mo remained in CR at data cutoff. Of 24 pts, 9 (38%) had CNS involvement at data cutoff, and 8 (33%) had CNS CAR T-cells detectable in peripheral blood by quantitative PCR for up to 355 days in responders. Cytokine release syndrome (CRS) was graded using the Penn grading system. CRS of CR at 3 mo remained in CR at data cutoff. Efficacy was observed across all subgroups. Median duration of response was not reached. CTL019 was detectable in peripheral blood by quantitative PCR for up to 355 days in responders. Cytokine release syndrome (CRS) was graded using the Penn scale and managed by a protocol-specific algorithm. CRS occurred in 57% of infused pts (17% grade 3; 9% grade 4); no CRS-associated deaths occurred. 16% of pts received tocilizumab for CRS management. 13% of pts had grade 3/4 neurologic adverse events (AEs); managed with supportive care; no cerebral edema was reported. Grade 3/4 cytopenias lasting ≥28 days and grade 3/4 febrile neutropenia occurred in 21% and 14% of pts, respectively. Grade 3 disease progression within 30 d of infusion. No deaths were attributed to CTL019. Summary/Conclusions: This planned interim analysis of a global study of CTL019 in adults with R/R DLBCL confirms the high response rates and durable CRs observed in the previous single-center experience in a cohort of highly pretreated patients. Centralized manufacturing was feasible. CTL019 was generally well tolerated without instance of treatment-related mortality. CRS and other AEs could be effectively and reproducibly managed by appropriately trained investigators.

Background: T-cell acute lymphoblastic leukemia (T-ALL) is a disease of T-cell progenitors, which mainly affects children and young adults. Numerous genomic alterations such as NOTCH1/FBXW7 overexpression or TLX1/TAL1 deletion are known to induce survival, proliferation and differentiation block in T-ALL cells. Interactions between leukemic cells and their microenvironment also contribute to T-ALL pathogenesis. Cell-cell contacts - Delta-Like/Jagged-Notch1, integrin LFA1/ICAM1 - and secreted factors - such as interleukin 7 and cAMP - are key players in T-ALL development. In the course of the disease, T-ALL cells settle in various environments such as thymus, bone, blood, bone marrow (BM), pleura or lymph nodes, which differ in terms of cell content, extracellular matrix and secreted factors. To what extent these distinct niches imprint niche-specific features on T-ALL cells is not well understood. Aims: Compare the growth of leukemia cells from human and mouse T-ALL in various BM sites. Uncover novel mechanisms of chemoresistance, in relation with the BM microenvironment.

Methods: We used grafts of human and mouse T-ALL in immune-deficient and normal mice, respectively. We explored the behavior of leukemic cells ex- and in vivo and whether they differed from that of T-ALL cells from the primary cell body (femurs, Thorax and Tail vertebrae). We tested their respective chemoresistance to conventional drugs (dexamethasone, vincristine, cytarabine).

Results: We observed that mouse and human T-ALL develop slowly in tail vertebrae BM compared to thorax vertebrae and femur BM. T-ALL recovered from tail BM display lower cell surface marker expression and decreased metabolism and cell cycle progression, demonstrating a dormancy phenotype. Functionally, tail-derived T-ALL exhibit a deficient short-term ex vivo growth and a delayed in vivo propagation. These features are non-cell autonomous as T-ALL from tail and thorax share identical genomic abnormalities and functional disparities disappear in vivo and in prolonged in vitro assays. Importantly, tail-derived T-ALL display the higher intrinsic resistance to the dormancy phenotype. The dormancy phenotype disappears at data cutoff associated with quiescence and decreased response to cell cycle dependent chemotherapies indicating that adipocty-rich aged BM or pathologies enhancing BM adipocty content may help leukemia escaping drug treatment.
