**Word of Welcome**

On behalf of the EHA Board and the Scientific Program Committee we are pleased to introduce to you this year’s Abstract Program. The richness of the program is a testament to EHA’s spirit: unity through diversity.

The Scientific Program Committee has compiled an exciting program of Simultaneous Oral and Poster Sessions from close to 2500 submitted abstracts representing all fields of hematology. For the second year, a number of presenters will have the opportunity to pitch their abstract. These Poster pitches are an exciting opportunity to promote basic science and research, and to invite delegates to the poster walks.

The six Best Abstracts will be presented during the Presidential Symposium on Friday afternoon. This will be a session not to miss. During this plenary session EHA is also awarding, for the first time, the best abstracts by trainees in four categories in basic and clinical hematology research. These awardees and the travel grant winners can be found on the next page. YoungEHA are the future of hematology!

The late breaking abstract submission is an integral part of the scientific program. The late breaking submission is intended for abstracts with “hot” data that were not available by the time of the regular submission deadline. Only few abstracts, with the most exciting results are selected for a presentation in the Late Breaking Oral Session on Sunday morning.

A selection of abstracts will be presented during the regular Poster Walks. The Poster Session consists of two parts: the Poster Walk and dedicated Poster Browsing Time. This setup guarantees sufficient time for discussion of the important research presented, so look out for the Poster Walk Moderators in their red baseball caps! There will also be E-posters available on the E-poster screens, for which a specific time is allocated during the Poster Browsing Time at the end of each Walk. The Simultaneous Oral Sessions are spread over three days (Friday to Sunday) providing you with ample opportunity to attend a number of these important sessions.

All posters can be viewed on the E-poster screens from Friday morning to Saturday evening. All the abstracts are also available on the EHA Learning Center, for which you have complimentary access after the congress: learningcenter.ehaweb.org.

On behalf of the EHA Board, the committees and all the people involved in this year’s EHA Congress, we thank you for coming to Madrid and wish you a great meeting.

Shai Izraeli
Chair Scientific Program Committee 22nd Congress
Travel Grant Winners

For this Congress 140 travel grants have been awarded to junior members of EHA, based on the mean score of their abstracts. EHA congratulates the following persons with their travel grants:

Agrawal M, Germany
Anagnostou T, USA
Arriazu E, Spain
Barcia Duran JG, USA
Beekman R, Spain
Bhoi S, Sweden
Binder M, USA
Birgisdóttir AM, Iceland
Blunt M, United Kingdom
Botthof J, United Kingdom
Bouillon AS, Belgium
Brockelmann P, Germany
Buffiere A, France
Burney C, United Kingdom
Cabal-Hierro L, USA
Carafini V, Austria
Casado Izquierdo P, United Kingdom
Cerchione C, Italy
Churchy G, India
Cleary R, USA
De Bie J, Belgium
De la Morena-Barrio ME, Spain
De Paepe K, United Kingdom
Di Marcantonio D, USA
Dimohamed A, the Netherlands
Dominguez Rodriguez M, Spain
Duran-Ferrer M, Spain
Eisfeld AK, USA
Escriba Garcia L, Spain
Eskelund C, Denmark
Fancelli L, Belgium
Farina F, Italy
Fattizzo B, Italy
Fernandez MC, Spain
Ferrero S, Italy
Figueroa R, Spain
Flasinski M, Germany
Gabeli M, Italy
Ganuza Fernandez M, USA
Garcia Ramirez P, Spain
Geelen I, the Netherlands
Giannoni L, Italy
Gugliotta G, Italy
Hansen J, Denmark
Hasibeder A, Germany
Healey M, United Kingdom
Hermetet F, France
Herrmann O, Germany
Hu B, USA
Iskander D, United Kingdom
Jaafar S, United Kingdom
Jentzsch M, Germany
Jetani H, Germany
Kampen K, Belgium

YoungEHA Best Abstract Awards

One of the primary missions of the European Hematology Association is to support young hematology clinicians and researchers. This year we are proud to announce the launching of the YoungEHA Best Abstract Awards. These will be awarded to the highest ranking abstracts in the following four categories: Clinicians or medical students training for a PhD degree, PhD research students, postdoctoral fellows and clinical hematology trainees. We are honored that these outstanding YoungEHA trainees will be presenting during the EHA congress – they are the future of Hematology!
Information for readers, authors and subscribers

Haematologica (print edition, pISSN 0890-6078, eISSN 1592-8721) publishes peer-reviewed papers on all areas of experimental and clinical hematology. The journal is owned by a non-profit organization, the Ferrata Storti Foundation, and serves the scientific community following the recommendations of the World Association of Medical Editors (www.wame.org) and the International Committee of Medical Journal Editors (www.icmje.org).

Haematologica publishes editorials, research articles, review articles, guideline articles and letters. Manuscripts should be prepared according to our guidelines (www.haematologica.org/information-for-authors), and the Uniform Requirements for Manuscripts Submitted to Biomedical Journals, prepared by the International Committee of Medical Journal Editors (www.icmje.org).

Manuscripts should be submitted online at http://www.haematologica.org/.

Conflict of interests. According to the International Committee of Medical Journal Editors (http://www.icmje.org/#conflicts), "Public trust in the peer review process and the credibility of published articles depend in part on how well conflict of interest is handled during writing, peer review, and editorial decision making". The ad hoc journal’s policy is reported in detail online (www.haematologica.org/content/policies).

Transfer of Copyright and Permission to Reproduce Parts of Published Papers. Authors will grant copyright of their articles to the Ferrata Storti Foundation. No formal permission will be required to reproduce parts (tables or illustrations) of published papers, provided the source is quoted appropriately and reproduction has no commercial intent. Reproductions with commercial intent will require written permission and payment of royalties.

Detailed information about subscriptions is available online at www.haematologica.org. Haematologica is an open access journal. Access to the online journal is free. Use of the Haematologica App (available on the App Store and on Google Play) is free. For subscriptions to the printed issue of the journal, please contact: Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, e-mail: info@haematologica.org).

Rates of the International edition for the year 2017 are as following:

<table>
<thead>
<tr>
<th></th>

Advertisements. Contact the Advertising Manager, Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, e-mail: marketing@haematologica.org).

Disclaimer. Whilst every effort is made by the publishers and the editorial board to see that no inaccurate or misleading data, opinion or statement appears in this journal, they wish to make it clear that the data and opinions appearing in the articles or advertisements herein are the responsibility of the contributor or advisor concerned. Accordingly, the publisher, the editorial board and their respective employees, officers and agents accept no liability whatsoever for the consequences of any inaccurate or misleading data, opinion or statement. Whilst all due care is taken to ensure that drug doses and other quantities are presented accurately, readers are advised that new methods and techniques involving drug usage, and described within this journal, should only be followed in conjunction with the drug manufacturer's own published literature.

Direttore responsabile: Prof. Edoardo Ascari; Autorizzazione del Tribunale di Pavia n. 63 del 5 marzo 1955.
Printing: Tipografia PI-ME, via Vigentina 136, Pavia, Italy. Printed in June 2017.
TABLE OF CONTENTS

Simultaneous sessions I
New advances in plasma cell disorders and implications for therapy S100 - S104 p. 1
Aggressive Non-Hodgkin lymphoma - 1st line S105 - S109 p. 4
MRD directed treatment in AML S110 - S114 p. 6
New insights into chronic lymphocytic leukemia biology S115 - S118 p. 9
Pathogenesis of MDS S119 - S123 p. 11
Lymphoma biology S124 - S127 p. 13
Thalassemia S128 - S132 p. 15
AML Biology I: Towards molecular therapies S133 - S136 p. 17
Hematopoiesis, stem cells and microenvironment S137 - S140 p. 19
Gene therapy, cellular immunotherapy and vaccination I S141 - S145 p. 21

Presidential Symposium
Best abstracts S146 - S150 p. 23

Poster sessions I
Acute lymphoblastic leukemia - Biology 1 P151 - P159 p. 26
Acute lymphoblastic leukemia - Clinical 1 P160 - P170 p. 30
Acute myeloid leukemia - Biology 1 P171 - P180 p. 35
Acute myeloid leukemia - Biology 2 P181 - P190 p. 39
Acute myeloid leukemia - Clinical 1 P191 - P199 p. 43
Acute myeloid leukemia - Clinical 2 P200 - P207 p. 48
Acute myeloid leukemia - Clinical 3 P208 - P215 p. 52
Aggressive Non-Hodgkin lymphoma - 1st line P216 - P225 p. 56
Bone marrow failure syndromes incl. PNH - Biology P226 - P235 p. 60
Chronic lymphocytic leukemia and related disorders - Biology 1 P236 - P244 p. 65
Chronic lymphocytic leukemia and related disorders - Clinical P245 - P254 p. 69
Chronic myeloid leukemia - Clinical I P255 - P263 p. 74
Hematopoiesis, stem cells and microenvironment P264 - P274 p. 78
Hodgkin lymphoma P275 - P283 p. 82
Iron metabolism, deficiency and overload P284 - P294 p. 86
Lymphoma biology P295 - P304 p. 91
Multifaced aspects of bleeding disorders P305 - P312 p. 96
Myelodysplastic syndromes – Clinical 1 P313 - P319 p. 98
Myeloma and other monoclonal gammopathies - Biology P320 - P329 p. 102
Myeloma and other monoclonal gammopathies - Clinical 1 P330 - P339 p. 107
Myeloma and other monoclonal gammopathies - Clinical 2 P340 - P349 p. 112
Myeloproliferative neoplasms - Clinical I P350 - P359 p. 117
Platelet disorders: Basic P360 - P368 p. 122
Quality of life, palliative care, ethics and health economics 1 P369 - P378 p. 125
Stem cell transplantation - Clinical 1 P379 - P386 p. 130
Thalassemia P387 - P390 p. 135
Transfusion medicine P401 - P406 p. 140
## TABLE OF CONTENTS

### Simultaneous sessions II

- Front-line combinations in multiple myeloma and amyloidosis
- Hodgkin and indolent lymphoma - Clinical
- Biology of MPN - JAK2 and beyond
- Clinical trials including treatment discontinuation in CML
- AML Biology II: Epigenetic targets
- Acquired and inherited platelet disorders
- Acute lymphoblastic leukemia - Biology
- Thrombotic disorders
- Stem cell transplantation - Experimental
- New drugs for rescue in relapsed/refractory multiple myeloma
- Improving prognostication and front-line therapy in chronic lymphocytic leukemia
- Aggressive Non-Hodgkin lymphoma - Relapsed/refractory
- Targeted treatment of AML
- Immunotherapy in ALL
- Biology and disease monitoring in CML
- Prognostic markers and new treatment in MDS
- Stem cell transplantation - Clinical 1
- Bone marrow failure and PNH
- Quality of life, palliative care, ethics and health economics

NEXT GENERATION SEQUENCING METHODOLOGY FOR DETERMINING CYTOGENETIC RISK STATUS IN THE DARATUMUMAB PHASE 3 CASTOR AND POLLUX STUDIES IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA

C. Chiu1,*, D. Soong1, I. Spicka2, M. Beksaç3, M. Schaffer1, J. Schecter4, N. J. Bahlis5, M. A. Dimopoulos6

1Janssen Research & Development, LLC, Spring House, PA, United States, 2First Faculty of Medicine, Charles University, Prague, Czech Republic, 3Ankara University, Ankara, Turkey, 4Janssen Research & Development, LLC, Raritan, NJ, United States, 5Tom Baker Cancer Center, University of Calgary, Calgary, Alberta, Canada, 6National and Kapodistrian University of Athens, Athens, Greece

Background: Cytogenetic risk status in multiple myeloma (MM) studies is traditionally determined by using fluorescence in situ hybridization (FISH) or karyotyping to assess chromosomal abnormalities. However, these technologies have limited resolution and a narrow target range, and reproducible interpretation may be confounded by inter-laboratory variation.

Aims: To describe the NGS methodology used to determine cytogenetic risk status in the daratumumab phase 3 CASTOR and POLLUX studies in RRMM.

Methods: Bone marrow aspirates were collected at screening and assessed centrally via NGS. Whole exome sequencing (exome-seq) and RNA sequencing (RNA-seq) was performed using the Illumina HiSeq platform to identify the presence or absence of defined risk markers: t(4;14), t(14;16), or del17p. The use of RNA-seq allowed for investigation of chromosomal translocations in expressed genomic locations at a higher resolution than FISH, and exome-seq data was used to derive the copy number status in coding regions across the genome. RNA-seq was performed using total RNA and rRNA removal to capture translocations involving coding and intronic regions. Translocation calls were made using two fusion callers, and gene expression was quantified to allow for evaluation of genes associated with translocation events. For t(14;14) translocations, the detected events involved RNA-seq reads fused between IgH and WHSC1 or FGRF3. For t(14;16), the detected translocations involved IgH and WWOX. Manual inspection of patients with t(4:14) showed higher WHSC1 or FGRF3 expression, whereas t(14;16) patients showed higher MAF and CCND2 expression. For del17p detection, exome data of each tumor was compared against 100 peripheral blood mononuclear cell (PBMC) control samples from CASTOR and POLLUX studies. Copy number variation data from two callers were compared to utilize information on relative read depth, systematic biases (observed in pooled normal controls), as well as SNP allele frequency (indicative of loss of heterozygosity events). A del17p event was detected when >50% of the 17p region was deleted.

Results: Based on the RNA-Seq and exome results, cytogenetic risk status in the CASTOR and POLLUX studies was defined as high risk with either t(4;14), t(14;16), or del17p, and standard risk with the confirmed absence of these molecular abnormalities. Comparisons of NGS with FISH showed high concordance for t(4;14), t(14;16), and del17p in both studies (Table 1).

PFS analyses investigating differences between treatment groups and between risk groups using FISH-derived risk and NGS-derived risk showed consistent results between FISH and NGS, with improvements in PFS being associated with the addition of daratumumab to standard-of-care regimens in both high- and standard-risk subgroups (Figure 1).

Summary/Conclusions: These studies represent the first, comprehensive use of NGS in global phase 3 clinical trials in RRMM. The NGS methodology accurately identified the presence of defined risk populations t(4;14), t(14;16), and del17p and showed good concordance with FISH. As FISH was performed locally with different probes and pathologists, the high degree of concordance between FISH and NGS is notable and supports the use of NGS for determining cytogenetic risk in patients with RRMM. The utility of NGS in these clinical studies extends far beyond the detection of cytogenetic abnormalities and additional analysis are planned to interrogate these datasets in the identification of novel biomarkers.

EFFICACY BY CYTOGENETIC RISK STATUS FOR DARATUMUMAB IN COMBINATION WITH LENALIDOMIDE AND DEXAMETHASONE OR BORTEZOMIB AND DEXAMETHASONE IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA

1Clinica Universidad de Navarra-CIMA, IDISNA, Pamplona, Spain, 2Universitätsklinikum Tübingen der Eberhard-Karls-Universität, Abteilung für Innere Medizin II, Tuebingen, Germany, 3Saint James’s Institute of Oncology, Leeds Teaching Hospitals NHS Trust and University of Leeds, Leeds, United Kingdom, 4Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel, 5Japanese Red Cross Medical Center, Department of Hematology, Tokyo, Japan, 6Division of Hematology, Mayo Clinic, Rochester, MN, United States, 7Department of Experimental, Diagnostic and Speciality Medicine, University of Bologna, Bologna, Italy, 8Unite de Genomique du Myelome, CHU Rangueil, Toulouse, France, 9University of Melbourne, St. Vincent’s Hospital, Victoria, Australia, 10mandade Da Santa Casa De Misericordia De São Paulo, São Paulo, Brazil, 11Division of Hematology/Oncology, Columbia University, New York, NY, United States, 12Department of Haematology, University Hospital Ostrava and Faculty of Medicine and Faculty of Science, University of Ostrava, Ostrava, Czech Republic, 13Department of Hematology, Erasmus MC, Rotterdam, Netherlands, 14Janssen Research & Development, LLC, Spring House, PA, 15Janssen Research & Development, Raritan, NJ, United States, 16National and Kapodistrian University of Athens, Athens, Greece

Background: Daratumumab (D) is a human CD38-targeting monoclonal antibody that exerts its antimyeloma activity through both direct (on-tumor) and indirect (immunomodulatory) mechanisms of action. Two randomized phase 3 trials in patients with relapsed or refractory multiple myeloma (RRMM) demonstrated that combining D with the standard-of-care regimens lenalidomide + dexamethasone (Rd, POLLUX) or bortezomib + dexamethasone (Vd, CASTOR)
significantly improved progression-free survival (PFS) and achieved higher overall response rates (ORRs) compared to the respective standard-of-care regimen alone (Dimopoulos MA et al., *N Engl J Med* 2016;375(14):1319-1331; Palumbo A et al., *N Engl J Med* 2016;375(8):754-766.). Due to its novel mechanisms of action, addition of D to standard-of-care regimens may benefit RRMM patients who have poor prognoses resulting from high-risk cytogenetic abnormalities.

**Aims:** To examine the efficacy of DRd and DvD in RRMM patients with standard or high cytogenetic risk status.

**Methods:** Bone marrow aspirates were collected at screening visits from 311/569 patients from POLLUX and from 353/498 patients from CASTOR, and cytogenetic abnormalities were detected via next-generation sequencing (NGS). Patients were considered to be of high cytogenetic risk if they had ≥1 of the following abnormalities: t(4;14), t(14;16), or del17p; patients were considered to be of standard cytogenetic risk if they lacked these abnormalities. Minimal residual disease (MRD) was assessed at suspected complete response (CR) at 3 sensitivity thresholds (10⁻⁴, 10⁻⁵, and 10⁻⁶) using the ClonoSEQ™ NGS-based assay (Adaptive Biotechnologies, Seattle, WA). Efficacy analyses included PFS, ORR, and MRD-negative rates.

**Results:** For POLLUX, the median follow-up was 17.3 months. Treating high-risk patients with DRd significantly prolonged median PFS vs Rd (top panel Figure 1) and numerically increased ORR (85% vs 67%; *P*=0.14). Responses to DRd vs Rd included CR or better in 33% vs 6% of these patients, and very good partial responses (VGPR) or better in 63% vs 31%. In standard-risk patients, DRd vs Rd also resulted in significant improvements in median PFS (Figure 1) as well as ORR (95% vs 82%; *P*=0.0020). Responses to DRd vs Rd included CR or better in 52% vs 24% of these patients, and VGPR or better in 84% vs 51%. At 10⁻⁵ sensitivity threshold, MRD-negative rates for DRd vs Rd were 18% vs 0% (*P*=0.0027) among high-risk patients and 30% vs 10% (*P*=0.0001) for standard-risk patients. For CASTOR, the median follow-up was 13.0 months. Treating both high- and standard-risk patients with DvD vs Vd significantly prolonged median PFS (bottom panel Figure 1) and increased ORR (high risk: 82% vs 62%; *P*=0.039; standard risk: 85% vs 64%; *P*=0.0003). Responses to DvD vs Vd among high-risk patients included CR or better in 30% vs 9% of patients and VGPR or better in 64% vs 34%; among standard-risk patients, responses included CR or better in 25% vs 8% of patients and VGPR or better in 84% vs 27%. At 10⁻⁵ sensitivity threshold, MRD-negative rates for DvD vs Vd were 14% vs 0% (*P*=0.0018) among high-risk patients and 12% vs 2% (*P*=0.0011) for standard-risk patients.

**Summary/Conclusions:** Adding D to Rd or Vd improved treatment outcomes irrespective of cytogenetic risk status in patients with RRMM. Both DRd and DvD appear to benefit RRMM patients who have poor prognoses due to high-risk cytogenetic abnormalities. Updated data, including analyses based on individual cytogenetic abnormalities, will be presented at the meeting based on longer follow-up.

**S102**

**MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY IN TRANSPLANT ELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: RESULTS FROM THE EMM02/HO95 PHASE 3 TRIAL**

S. Oliva,1 D. Hofste en Bruinink,2 L. Rihova,3 S. Spada,4 B. van der Holt,5 T. Troja,1 M. Gambella,1 L. Pantani,2 S. Grammatico,2 M. Gilestro,2 M. Offidani,2 R. Ribolla,3 M. Galli,5 R. Hajek,6 A. Palumbo,5 M. Cavo,5 P. Omedè,1 V. van der Velden,5 M. Boccadoro,5 P. Sonneveld2

1Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy, 2Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, 3Department of Hematology, University Hospital Brno, Brno, Czech Republic, 4Department of Hematology, Erasmus MC Cancer Institute, HOVON Data Center, Rotterdam, Netherlands, 5Italian Multiple Myeloma Network, GIMEMA, Italy, 6Department of Haematoncology, Faculty of Medicine, University of Ostrava and University Hospital of Ostrava, Ostrava, Czech Republic. 7Myeloma Unit, Division of Hematology, University of Torino – Currently Takeda Pharmaceuticals Global, Torino, Italy, Switzerland, 8Department of Immunology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands.

**Background:** Multiple myeloma (MM) is still an incurable disease and patients may relapse despite achievement of complete remission (CR). Available data show that MRD detection is a sensitive strategy to appropriately measure response in MM patients.

**Aims:** We evaluated MRD by MFC in patients with newly diagnosed MM enrolled in the EMN02/HO95 phase 3 trial.

**Methods:** Patients were ≥65 years of age and treatment consisted of Bortezomib-Cyclophosphamide-Dexamethasone (VCD) induction, mobilization and stem cell collection, intensification with Bortezomib-Melphalan-Prednisone (VMP) vs High-Dose-Melphan (HDM) followed by stem cell transplant, consolidation with Bortezomib-Lenalidomide-Dexamethasone (VRD) vs no consolidation, and Lenalidomide maintenance. MRD was assessed in patients achieving at least a very good partial response (VGPR) before starting maintenance (after HDM, VMP or VRD) and during maintenance every 6-12 months; samples were centralized to 3 European labs. MFC was performed on bone marrow according to Euroflow-based methods (8 colors, 2 tubes) with a sensitivity of 10⁻⁵. Quality checks were done to compare sensitivity and to show correlation between protocols (Hofste en Bruinink D, ASH 2016 abstract 2072).

**Results:** A total of 316 patients could be evaluated before maintenance: median age was 57 years (IQR: 52-62), 18% (57/316) had ISS III and 22% (70/316) had high risk cytogenetic abnormalities defined as presence of either one of the following del17, (4;14) or (14;16); 63% (199/316) had received HDM and 37% (117/316) VMP: thereafter 51% (160/316) had received VRD. After a median follow-up of 30 months from MRD enrolment, 76% (239/316) patients were MRD-negative: 64% (153/239) in the HDM vs 36% (86/239) in the VMP groups. The 3-year PFS was 50% in MRD-positive vs 77% in MRD-negative patients (HR 2.87, 95% CI: 1.75 - 4.72; p<0.001). Subgroup analyses were carried out to assess the risk factors for MRD-positivity according to baseline characteristics and therapies: high risk cytogenetic abnormalities were the most important risk factors (HR 9.87, 95% CI: 4.3 - 22.63; interaction-p=0.001). Finally, 48% of MRD positive patients at pre-maintenance who had a second MRD evaluation after at least 1 year of lenalidomide became MRD-negative.

**Summary/Conclusions:** MRD by MFC is a strong prognostic factor in MM patients receiving intensification with novel agents or transplant; lenalidomide maintenance further improved depth of response; high risk cytogenetic abnormalities are the most important prognostic factors in MRD-positive patients.

**PHASE I, OPEN-LABEL TRIAL OF ANTI-BCMA CHIMERIC ANTIGEN RECEPTOR T CELLS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA**

W. Zhang1, W. Zhao1, J. Liu1, A. He1, Y. Chen1, X. Cao1, N. Yang1, B. Wang1, P. Zhang1, Y. Zhang1, F. Wang1, B. Lei1, L. Gu1, Y. Yang1, J. Bai1, R. Zhang1, X. Wang1, X. Ma1, J. Wang1, J. Wang1, L. Wei1, J. Zhang1, X. Zang1, C. Zhuang1, F. X. Fan2

1Hematology, Second Affiliated Hospital of Xi’an Jiaotong University, Xi’an, 2Nanjing Legend Biotech, Nanjing, China

**Background:** Immunotherapy has emerged as a potentially curative treatment in hematological malignancies. Uniformly expressed in plasma cells, B-cell maturation antigen (BCMA) is an appropriate target antigens for CAR T-cell therapies in multiple myeloma.

**Aims:** This phase I, open-label trial was conducted to assess the efficacy and
safety profile of LCAR-B38M anti-BCMA CAR T cells in patients with relapsed/refractory multiple myeloma.

Methods: All patients underwent leukapheresis to obtain peripheral blood mononuclear cells and their T cells were engineered to express anti-BCMA CAR. Three doses of 300 mg/m² cyclophosphamide were administered on day -5, -4, and -3 (before recruitment, patients took the same chemotherapy to identify they were refractory to cyclophosphamide monotherapy) and engineered-T cells were reinfused on day 0, 2, and 6. This trial was divided into the dose escalation stage and expansion cohort. Toxicity and responses were assessed according to the Common Terminology Criteria for Adverse Events (version 4.0) and International Myeloma Working Group (IMWG) Uniform Response Criteria for Multiple Myeloma, respectively.

Results: As of the February 20th, 2017 data cut-off, 22 patients had been enrolled, two of whom were diagnosed as plasma cell leukemia. The male:female ratio was 11:11 and median age was 53.5 years. Chromosomal abnormalities were detectable by FISH in eight patients, two of whom involved in the deficiency of p53. Eleven patients were triple refractory (chemotherapy, proteasome inhibitors, and immunomodulatory drugs), 11 resisted to double prior treatments (chemotherapy and proteasome inhibitors/ immunomodulatory drugs), and four relapsed after autologous hematopoietic stem cell transplant. The median number of infused CAR T cells was 4.0×10⁶ (range, 1.5×10⁶-7.0×10⁶) per kg. The median follow-up was 131.5 (range, 29-327) days. 100% of patients achieved an objective response. The first six patients achieved complete responses with flow MRD-negative; 14 patients achieved very good partial responses; one patient, with renal failure, achieved partial response; all these 22 patients had kept their best response at the end of follow-up. The pictures we enclosed were the subcutaneous nodules in one patient with extramedullary plasmacytoma. We found that the nodules were obviously decreased after the infusion and disappeared finally. Another one achieved transient partial response, which lasted for 12 days. He then took the secondary infusion but failed since the post-operation large-dose administration of corticosteroid for spinal meningoma. He terminally died of the progression of myeloma. The most common toxicity attributable to CAR T cells was cytokine release syndrome (CRS). Toxicities were minimal except for two grade 3 CRS and one grade 4 CRS. All CRSs were controllable with nonsteroidal anti-inflammatory drugs (NSAIDs) or tocilizumab and no dose-limiting toxicities or treatment-related deaths were observed (Figure 1).

Figure 1. Summary/Conclusions: Our findings demonstrated the safety and antmyeloma activity of LCAR-B38M anti-BCMA CAR T cells.

S104

PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS TREATED WITH NEO001 ACHIEVE RAPID ORGAN RESPONSES THAT ARE INDEPENDENT OF PREVIOUS PLASMA CELL–DIRECTED THERAPIES

1Mayo Clinic, Rochester, 2Tufts Medical Center, Boston, 3Memorial Sloan Kettering Cancer Center, New York, 4Boston University School of Medicine and Boston Medical Center, Boston, 5University of Pennsylvania, Philadelphia, 6Karmanos Cancer Institute, Detroit, 7JW Consulting, Hillsborough, 8Prothena Biosciences Inc, South San Francisco, 9Stanford University School of Medicine, Stanford, United States

Background: Light chain (AL) amyloidosis is a rare and often fatal disease caused by the accumulation of misfolded light chain (LC) aggregates that can lead to progressive failure of critical organs, causing significant morbidity and mortality. Patients’ survival depends upon rapid suppression of the misfolded LC and stabilization or recovery of organ function. Current therapies limit LC production; however, ~75% of patients have persistent organ dysfunction. NEO001 is a novel investigational monoclonal antibody that targets misfolded LC and may neutralize circulating LC aggregates and clear insoluble deposits.

Aims: To assess the association between responses and time, depth, number or type of previous plasma cell–directed (PCD) treatments and organ response.

Methods: Inclusion criteria for this trial were: completed ≥1 PCD treatment before enrollment, attained partial hematologic response (HR) or better to any previous therapy, and have persistent organ dysfunction. NEO001 was administered intravenously every 28 days. During the dose-escalation phase, 27 patients received NEO001 at 0.5, 1, 2, 4, 8, 16, or 24 mg/kg in a 3+3 study design. In the expansion phase, 42 additional patients with renal, cardiac, or nerve involvement were enrolled and treated (24 mg/kg). We assessed cardiac and renal best responses based on consensus criteria. Peripheral nervous system (PN) responses were assessed at month 10 (after 9 infusions) using the Neuropathy Impairment Score—Lower Limbs (NIS-LL). We explored the potential impact on organ response of the number and type of organs affected and the number of, type of, and time since previous therapies at baseline.

Results: In the overall population (N=69), the median age was 61 years (61% male). Median (range) time since diagnosis was 2.9 (0.4-16.0) years, and 45% of patients underwent ≥3 previous PCD regimens. Median time to first best response was 1.8 (cardiac), 3.7 (renal), and 1.0 (PN) months. Best response rate indicating organ response was observed in 53% of cardiac-evaluable patients (n=19/36) and 64% of renal-evaluable patients (n=23/36). PN responses were observed in 82% (n=9/11) of PN-evaluable patients. Time from patients’ best HR to previous PCD treatment was not related to the attainment of NEO001 organ response (responder/stable: 35.6/36.6 months [cardiac] and 30.6/32.5 months [renal]; P>0.05). Depth of patients’ best HR also was not related to the attainment of NEO001 organ response (percentage of patients with organ response in CRS/GPR/PR after PCD: 47.1/66.7/42.9% [cardiac] and 68.8/63.6/62.5% [renal]; P>0.05). Similarly, time or depth of patients’ last HR did not impact the NEO001 organ response rate (P>0.05). Patients with NEO001 organ responses were no more likely to have had their last PCD therapy <6 than ≥6 months from their first NEO001 dose. Patients’ previous PCD treatment type was not related to the corticosteroid for spinal meningoma: stem cell transplantation, 55.6/61.1% [cardiac/renal]; bortezomib-based therapy, 52.0/68.8%; or other chemotherapy, 50.0/57.1%; P>0.05. Exploratory analyses showed no association between the time to response or percentage of responders and the number of previous PCD treatments.

Summary/Conclusions: NEO001 specifically targets disease-causing, misfolded LC aggregates in AL amyloidosis. Organ responses in patients treated with monthly NEO001 infusions were achieved rapidly and independently of time since previous chemotherapy, depth of hematologic response, or predominant type of PCD treatment.

**RITUXIMAB MAINTENANCE AFTER AUTOLOGOUS TEM CELL TRANSPLANTATION PROLONGS SURVIVAL IN YOUNGER PATIENTS WITH MANTLE CELL LYMPHOMA: FINAL RESULTS OF THE LYMA TRIAL OF THE LYSA/GOELAMS GROUP**

---

**Background:** Mantle cell lymphoma (MCL) is currently an incurable disease. In spite of high complete response rates (CR) after initial immunochemotherapy induction followed by autologous stem cell transplantation (ASCT), MCL patients experience iterative relapses.

**Aims:** We investigated whether or not rituximab maintenance (RM; 375 mg/m² every 3 months for 3 years) after ASCT prolongs response duration.

**Methods:** This phase III trial included 299 patients (<65y) at diagnosis, of whom 240 were randomly assigned to RM or observation after ASCT. The primary end point was event-free survival (EFS) (progression, relapse, death, severe infection during RM) after ASCT.

**Results:** After 4 courses of immunochemotherapy induction (R-DHAP; Ritu-ximab, dexamethasone, cytarabine, platinium derivative), overall response and CR rates were 89.3% and 77.3%, respectively. ASCT was performed in 257 patients. Median follow-up from randomization after ASCT was 50.2 (46.4-54.2) months. Starting from randomization, 4-year EFS was 78.9% (95%CI: 68.1%-85.7%) in the RM arm versus 63.7% (95%CI: 54.9%-71.4%) in the observation arm. At the data cut-off, median EFS was 85.6 (95%CI: 78.7%-90.0) months for RM versus 72.8 (95%CI: 65.3%-85.2) months for observation (p=0.0007). The overall survival rate (95%CI) was 88.6% (95%CI: 83.2%-91.9%) for RM versus 84.0% (95%CI: 78.7%-88.8%) for observation (p=0.0005). The estimated event-free survival ratio (HR=0.5; 95%CI, 0.3-0.98) was achieved for patients in the observation arm.

**Summary/Conclusions:** The LyMa trial demonstrates for the first time that ASCT after RM prolongs EFS, PFS and OS. Thus, 4 courses of R-DHAP plus ASCT (without TBI) followed by RM maintenance (one infusion every 3 months for 3 years) is a new standard of care for young MCL patients.

**POLA-R-CHP: POLATUZUMAB VEDOTIN COMBINED WITH RITUXIMAB, CYCLOPHOSPHAMIDE, DOXORUBICIN, PREDNISOLONE FOR PATIENTS WITH PREVIOUSLY UNTREATED DIFFUSE LARGE B-CELL LYMPHOMA**

---

**Background:** In spite of high complete response rates (CR) after initial immunochemotherapy induction followed by autologous stem cell transplantation (ASCT), DLBCL patients experience iterative relapses.

**Aims:** To evaluate the safety and efficacy of pola-R-CHP as first-line treatment in patients with DLBCL.

**Methods:** Five pts of the dose escalation phase and the 40 pts of the expansion phase were included in this analysis. All pts provided informed consent to participate in the study. All had newly diagnosed DLBCL and were treated with pola at 1.8 mg/kg and R-CHP at standard doses every 21 days for 6 or 8 cycles. Investigator assessments for anti-tumor activity were performed according to IWG 2007 following 4 cycles and at the end of study treatment (EOT).

**Results:** All 45 pts received at least one dose of study drug. The median age was 57 years (range, 21-75). 55% of pts were >60 years, 33% were ≥70, 82% Stage III/IV, and 78% had IPI 3-5. Of the 29 pts with cell of origin (COO) status by digital gene expression, 11 (38%) were ABC, 14 (48%) were GCB, while 4 (14%) were unclassified. Fourty patients completed 6 or 8 cycles (23 and 17 pts respectively). All pts experienced at least one AE. Grade (Gr) 3/4 AEs occurred in 58%, and one pt experienced a Grade 5 atrial fibrillation. Gr 3/4 neutropenia and febrile neutropenia (FN) occurred in 27% and 11%, Serious adverse events (SAEs) were reported in 17 pts (38%) including 3 FN, and 2 each of neutropenia, pneumonia, pulmonary embolism and influenza A. Peripheral neuropathy (PN) occurred in 18 (40%) pts. Among patients assigned to RM, 12 pts were Gr 1, 4 pts were Gr 2, and 2 were Gr 3. All Gr 2/3 PN and neutropenia in 1 pt occurred during the following reasons: Gr 5 atrial fibrillation (after C2, not attributed to pola by investigator), E.coli UTI (C5), worsening essential tremor (C3), PN (C7). During treatment, 6 pts had dose reductions in pola and 1 pt had cyclophosphamide and doxorubicin dose reductions. ORR by PET at EOT was 91%; 78% had a CR and 13% PR. 3 pts progressed and 1 was un evaluable. In the COO determined population, CR was 91% in ABC and 86% in GCB pts. At the data cutoff of November 4, 2016 with a median study duration of 9.5 months, (range 1.3-28 months), only 1 pt had a disease progression in follow up.

**Summary/Conclusions:** Pola at 1.8 mg/kg in combination with R-CHP in 1L diffuse large B-cell lymphoma provided an acceptable safety profile and produced promising response rates at the end of treatment. The majority of the patients in this trial represented a poor prognostic group by age and IPI. In this context, treatment response to this regimen may warrant further exploration.

**ANALYSIS AND CHARACTERIZATION OF HEMATOLOGIC CANCERS USING A COMPREHENSIVE NGS PANEL COMPRISED OF DNA AND RNA TARGETS TREATING 704 GENES**

A.R. Carson1, B.A. Patay1, V. McClain1, Z. Xie1, T. Stenzel1,2,3,*, J.E. Miller1,2,3

**Aims:** Preliminary analyses of diagnostic samples from MCL2 and MCL3, show that TP53 mutations are associated with significantly poorer outcome. Recently, deletions of TP53 and CDKN2A was shown to confer negative impact in a cohort similar to the Nordic. (Delfau-Larue et al., 2015) Thus, in this study we aim to describe the prevalence and impact of deletions of TP53 and CDKN2A in the light of TP53 mutations.

**Methods:** Fresh frozen DNA from diagnostic bone marrow samples from MCL2 and MCL3 were analyzed. In both trials, patients received intensified first-line induction therapy with alternating courses of R-CHOP and R-hd-Cytarabine and consolidation with high-dose therapy and ASCT. (Geisler et al., 2008; Kolstad et al., 2014). Targeted NGS of ATM, CCND1, TP53, KMT2D, NOTCH1, NOTCH2, WHSC1 and BIRC3 was performed by Ion Torrent Technology. Cut-off for calling of deletion was defined as >3% of median coverage was >2700X. Copy Number Variations (CNVs) of TP53 and CDKN2A were measured by droplet digital PCR by commercially available assays, and RPP30 used as a standard control.

**Results:** We investigated the presence of CDKN2A and TP53 deletions in diagnostic samples from 175 and 157 patients, respectively. Patients treated <66 years (median 58, range 37-65). Fifty-three percent were either MIPI intermediate- or high-risk, 17% had blastoid morphology and 42% had <66 years (median 58, range 37-65). Thirty-five percent were either MIP Intermediate or high-risk, 17% had blastoid morphology and 42% had <66 years (median 58, range 37-65).

**Background:** As next-generation sequencing (NGS) methodologies improve, so does the ability to characterize hematopoietic and lymphoid neoplasms. This promises to revolutionize oncology, allowing more accurate and precise classification of patients and potentially leading to novel targeted and combination therapies with improved outcomes.

**Aims:** We constructed a custom targeted sequencing panel, MyHEME™, to comprehensively identify and characterize DNA and RNA changes in a broad range of hematologic malignancies, including Non-Hodgkin lymphoma (NHL).

**Methods:** The MyHEME targeted sequencing panel is comprised of two independent bait sets that target a combined 704 genes known or predicted to contain mutations of TP53, MITF, TP53, and CDKN2A, and to cross-confirm novel variants of interest.

**Results:** We identified a novel t(9;22) translocation causing a fusion gene, useful for classification and potentially leading to novel targeted therapies. For example, we identified a novel t(9;22) translocation causing a fusion gene, useful for classification and potentially leading to novel targeted therapies. We identified a novel t(9;22) translocation causing a fusion gene, useful for classification and potentially leading to novel targeted therapies.

**Summary/Conclusions:** MyHEME is an extensive panel for sensitively and specifically identifying SNV, indel and SV mutations in 704 target genes. This panel can comprehensively characterize mutations in multiple diverse hematologic cancer samples, including Non-Hodgkin Lymphomas, AML, ALL and Multiple Myeloma. By utilizing a high depth of coverage, MyHEME can accurately detect clones present down to 5% of a patient’s sample. In addition, by targeting both DNA and RNA, MyHEME contains a built-in validation method to cross-confirm novel variants of interest.

**TP53 MUTATIONS, BUT NOT DELETION OF TP53 AND CDKN2A, HAVE INDEPENDENT PROGNOSTIC VALUE IN MANTLE CELL LYMPHOMA TREATED BY THE NORDIC (MCL2 AND MCL3) REGIMEN**

C.W. Eskelund1,2, C. Dahl1, J. W. Hansen1, M. Westman1, C. Montano1, C. Freiburguas1, S. Ek1, A. Pedersen1, L. B. Pedersen1, C. Niemann1, R. Räty3, P. Brown1, A. Kolstad4, C.H. Geisler1, M.K. Andersen1, P. Guldberg1, M. Jerkeman3, K. Grenbaek1

1University Hospital of Copenhagen, 2Danish Cancer Society, Copenhagen, Denmark, 3University Hospital of Lund, Lund, Sweden, 4University Hospital of Helsinki, Helsinki, Finland, 5University Hospital of Oslo, Oslo, Norway

**Background:** During the past decade, the outcome of MCL treatment has improved substantially in younger patients. However, the course of disease remains heterogeneous, and there is a need for better stratification of patients with poor responses from those with durable responses. The Nordic trials, MCL2 and MCL3, represent standard-of-care regimens for younger MCL patients.

**Aims:** Preliminary analyses of diagnostic samples from MCL2 and MCL3, show that TP53 mutations are associated with significantly poorer outcome. Recently, deletions of TP53 and CDKN2A was shown to confer negative impact in a cohort similar to the Nordic. (Delfau-Larue et al., 2015) Thus, in this study we aim to describe the prevalence and impact of deletions of TP53 and CDKN2A in the light of TP53 mutations.

DEEP MOLECULAR RESPONSE TO GILTERITINIB IMPROVES SURVIVAL IN FLT3 MUTATION-POSITIVE RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

1Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, 2University of Pennsylvania, Philadelphia, 3University of Texas MD Anderson Cancer Center, Houston, 4University of California San Francisco, San Francisco, 5Mayo Clinic, Rochester, 6Astarlas Pharma US, Inc., Northbrook, 7University of Chicago, Chicago, 8Weill Cornell Medical College of Cornell University, New York, 9Vanderbilt-Ingram Cancer Center, Nashville, 10Roswell Park Cancer Institute, Buffalo, United States, 11University Clinic Giessen Marburg, Marburg, Germany, 12University of Bologna, Bologna, Italy, 13The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, United States

Background: Mutations in Fms-like tyrosine kinase 3 (FLT3) are common in patients with acute myeloid leukemia (AML) and are associated with an aggressive disease course and a poor prognosis. Notably, FLT3 internal tandem duplications (ITD) predict early relapse and short overall survival (OS) after chemotherapy. Gilteritinib, a highly selective FLT3/AXL inhibitor, has displayed antileukemic activity in FLT3 mutation-positon (FLT3mut+) relapsed/refractory (r/r) AML in the CHRYSLIS Phase 1/2 study (NCT02014558), specifically at doses ≥80 mg/d.

Aims: To assess molecular response to gilteritinib in a CHRYSLIS subpopulation.

Methods: This exploratory analysis evaluated molecular response in patients aged ≥18 years with FLT3mut+/r/r AML who had been treated with 120 or 200 mg/d gilteritinib. These doses were identified due to their ability to induce high clinical response rates, and consistent, potent FLT3 inhibition in correlative assays. Molecular response was assessed in patients who had bone marrow aspirates obtained at baseline and at ≥1 additional time point. FLT3-ITD and total FLT3 were quantified by next-generation sequencing to assess molecular response. A Cox regression model of OS by Kaplan-Meier estimation established a FLT3-ITD:total FLT3 ratio (ITD signal ratio) of 10−2 as the threshold for improved survival.

Results: Of the 147 FLT3-ITDmut+ patients who had received gilteritinib 120 or 200 mg/d, 80 patients had bone marrow aspirates at baseline and at ≥1 additional time point. FLT3-ITD and total FLT3 were quantified by next-generation sequencing to assess molecular response. A Cox regression model of OS by Kaplan-Meier estimation established a FLT3-ITD:total FLT3 ratio (ITD signal ratio) of 10−2 as the threshold for improved survival.

Summary/Conclusions: Molecular responses to gilteritinib in FLT3ITDmut+/r/r AML correlated with clinical response and improved OS. This is the first demonstration of a robust molecular response to a FLT3 inhibitor in AML. These data suggest that the ITD signal ratio may predict a durable clinical benefit of gilteritinib therapy and validate FLT3 as a critical therapeutic target in AML.

S111

RISK-ADAPTED, MRD-DIRECTED THERAPY FOR YOUNG ADULTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA: RESULTS OF THE AML1310 TRIAL OF THE GIMEMA GROUP

A. Venditti1,*, A. Picicchio2, A. Candonsi3, L. Melillo4, V. Calafati5, R. Cairolo6, FLT3-ITDmut+ patients who had received gilteritinib 120 or 200 mg/d gilteritinib. A Cox regression model of OS by Kaplan-Meier estimation established a FLT3-ITD:total FLT3 ratio (ITD signal ratio) of 10−2 as the threshold for improved survival.

Summary/Conclusions: Molecular responses to gilteritinib in FLT3ITDmut+/r/r AML correlated with clinical response and improved OS. This is the first demonstration of a robust molecular response to a FLT3 inhibitor in AML. These data suggest that the ITD signal ratio may predict a durable clinical benefit of gilteritinib therapy and validate FLT3 as a critical therapeutic target in AML.

Background: A comprehensive AML risk assessment, based on the integration of cytogenetic/genetic data and minimal residual disease (MRD) status, can help optimize patients’ (pts) therapeutic post-remission allocation.

Aims: To evaluate the feasibility and results of a phase II trial of intensive chemotherapy in which risk-assignment and post-remission therapy of young patients with AML was based on pre-treatment cytogenetic/genetic data and post-consolidation levels of MRD.

Methods: Between January 2012 and May 2015, 515 pts with de novo AML, 18 to 60 years old, seen at 55 GIMEMA institutions were enrolled in the trial. Induction consisted of i.v. daunorubicin 50 mg/m2 daily on days 1, 3 and 5; i.v. cytarabine 50 mg/m2 every 12 hours on days 1 to 6. In pts belonging to ELN low or intermediate-risk category, peripheral blood stem cell collection was attempted by initiating, on day 20 from the start of consolidation therapy, G-CSF until completion of stem cell collection. Post-consolidation therapy was based on risk-allocation. Low-risk pts (NPM1 positive FLT3-ITD negative or CBF/ANM positive); intermediate pts (intermediate karyotype or FLT3-TKD positive or CBF beta/ANM positive to intermediate category (=AuSCT)). In 27 pts (8%) belonging to the intermediate-risk category, a leukemia associated phenotype was not found and they were to receive AuSCT. Overall, 109 (33%) and 123 (36%) of 341 pts received AuSCT and ASCt depending on the levels of MRD, measured by flow cytometry after consolidation therapy. Allocation to ASCt required the procedure to be performed whatever the source of stem cells (identical sibling, unrelated, cord blood, haploidentical).

Results: Of the 500/515 pts started treatment and were available for the analysis. Median age was 49 (18-61) years and 52% were males. Of 429 evaluable pts, ELN cytogenetic distribution was: low-risk 11%, intermediate-risk 73% and poor-risk 16%. RUNX1/RUNX1T1 was detected in 5% of 499 evaluable cases, CBFbeta/MYH11 in 7% of 496, FLT3-ITD in 25% of 497 and NPM1 in 37% of 499. In 494 evaluable pts, complete remission rate (CR) was 73% (361), 18% had refractory AML and 9% died early during induction. Three hundred-forty one pts completed the consolidation phase and were risk allocated: 114 (33%) to the low-risk category (=AuSCT), 123 (36%) to the intermediate category (=AuSCT or ASCt). In complete remission rate was 78.8% and 63.8%, respectively; in the intermediate-risk category MRD negative 78.6% and 61.4%, respectively; in the intermediate-risk category MRD positive 89.8% and 66.6%, respectively (Figure 1).

Summary/Conclusions: A program of risk-adapted, MRD-driven therapy is feasible in a multicenter, cooperative setting. In the intermediate-risk category,

GRAFT VERSUS LEUKEMIA EFFECT OF ALLOGENIC STEM CELL TRANSPLANTATION AND MINIMAL RESIDUAL DISEASE IN PATIENTS WITH AML IN FIRST COMPLETE REMISSION

J. Versluis1,2, J. Pasweg1, C. Grau2, M. Manz2, M.-C. Vekemans6, B. Biemond2, M.-C. Legede6, M. van Marwijk Kooy1, J. Janssen2, T. Pahl6, B. Lowenberg2, M. Jongen-Lavrencic6, G.J. Schuurhuizen2, G. Ossenkoppele2, J. Cornelissen1

1Erasmus Medical Center Cancer Institute, Rotterdam, 2VU University Medical Center, Amsterdam, Netherlands, 3University Hospital Basel, Basel, Switzerland, 4Mont-Godinne, Yvoir, Belgium, 5University Hospital Zürich, Zürich, Switzerland, 6Cliniques universitaires Saint-Luc, UCL, Brussels, Belgium, 7Aademic- Medical Center, University of Amsterdam, Amsterdam, 8Medisch Spectrum Twente, Enschede, 9Isala Hospital, Zwolle, Netherlands, 10Inselspital, Bern University Hospital, Bern, Switzerland

Background: The detection of minimal residual disease (MRD) in patients with acute myeloid leukemia (AML) may improve future risk-adapted strategies of AML treatment. The presence of MRD after induction treatment has firmly been shown to predict for relapse and overall outcome, irrespective of type of post-remission treatment (PRT). Currently it is unknown whether and how the presence or absence of MRD should guide the application of allogeneic hematopoietic stem cell transplantation (alloHSCT) as PRT.

Aims: We addressed whether and to what extent alloHSCT quantitatively reduces relapse as compared to conventional post-remission treatment (PRT) in upfront treated patients with MRD positive or MRD negative AML in first hematological complete remission (CR1).

Methods: A total of 1,151 patients were treated in subsequent HOVON/SAKK AML trials of whom 547 patients obtained a CR1, received PRT and had available flow cytometric MRD prior to PRT. MRD positivity was defined by more than 0.1% cells with a leukemia associated phenotype within the white blood cell compartment. A status was not known by clinicians during AML treatment. PRT consisted of alloHSCT (n=282), or conventional PRT by a third cycle chemotherapy (n=228). Results showed that MRD+ patients (n=282) and conventional PRT by a third cycle chemotherapy (n=228) or conventional PRT by a third cycle chemotherapy (n=228) or conventional PRT by a third cycle chemotherapy (n=228) or conventional PRT by a third cycle chemotherapy (n=228). A time-dependent covariate alloHSCT with the cumulative incidence of relapse and non-relapse mortality (NRM) at 4 years. A time-dependent covariate alloHSCT with the cumulative incidence of relapse and non-relapse mortality (NRM) at 4 years. A time-dependent covariate alloHSCT with the cumulative incidence of relapse and non-relapse mortality (NRM) at 4 years.

Results: MRD was positive in 120 (24%) patients after induction chemotherapy before proceeding to PRT. The latest European LeukemiaNET risk classification was similarly distributed among MRD negative and MRD positive patients. No differences were present in transplant characteristics in MRD positive and MRD negative patients. OS and RFS was significantly better in patients without MRD prior to PRT as compared to MRD positive patients (65±2% compared to 50±5% at 4 years, p<0.002, and 58±3% compared to 38±4%, p<0.001, respectively).

Improved outcome was mainly caused by a lower cumulative incidence of relapse in MRD positive patients (32±2% compared to 54±2% at 4 years, p<0.001), while NR was not significantly different and estimated 10±1%. NRM split by EBMT risk score showed less NRM in patients with a low EBMT-risk score as compared to patients with a high EBMT risk score (s2 compared to >s2, 10±2% compared to 22±4%, p<0.005, respectively). Multivariable analysis with adjustment for covariates showed that the incidence of relapse was significantly reduced following alloHSCT as compared to chemotherapy or autologous HSCT (HR 0.36, p<0.001), which was similarly exerted in MRD negative and positive patients (HR 0.38, p<0.001 and HR 0.35, p<0.001). RFS was also improving following alloHSCT as compared to chemotherapy or autologous HSCT (HR 0.53, p<0.001), while no significant differences were found for OS (Figure 1).

Summary/Conclusions: The graft-versus-leukemia effect of alloHSCT is equally present in MRD positive and MRD negative patients, which advocates a personalized application of alloHSCT taking the risk of relapse determined by AML risk group and MRD status as well as the counterbalancing risk of NRM into account.

S113

LEUKEMIC STEM CELL FREQUENCY COMBINED WITH MRD IS AN IMPORTANT BIOMARKER TO PREDICT RELAPSE IN ACUTE MYELOID LEUKEMIA. RESULTS FROM A PROSPECTIVE H102 STUDY

W. Zeijlemaker1,2, R. Meijer1, A. Kelder1, J. Carbaat-Ham1, Y. Oussoren-brockhoff3, S. Smil3, D. Veldhuizen1, W. Schollen1, J. Maertens3, D. Breems4, T. Pabst5, M. Manz6, V. Van der Velden7, J. Slomp8, P. Vanl9, J. Cloos1, B. Lowenberg2, G. Ossenkoppele2, G.J. Schuurhuizen1

1Hematology, VU University Medical Center, Amsterdam, 2Clinical Trial Center, the latter group. When investigating the impact of MRD/LSC status, 68% (SE 9), 53% (SE 8), and 100%, respectively, with 17 patients dead and 3 respectively. Similar results were found for OS: 3-year OS was 66% (SE 4), 53% (SE 7), and 100% (SE 0), respectively. Similar results were found for OS: 3-year OS was 66% (SE 4), 53% (SE 7), and 100% (SE 0), respectively. Summary/Conclusions: The graft-versus-leukemia effect of alloHSCT is equally present in MRD positive and MRD negative patients, which advocates a personalized application of alloHSCT taking the risk of relapse determined by AML risk group and MRD status as well as the counterbalancing risk of NRM into account.

Figure 1.
all different currently used risk categories. These data urge to include both MRD and LSC in future AML risk classification to better inform post-remission treatment.

DEFINITION OF PARTIAL RESPONSE IN YOUNGER AML PATIENTS AFTER FIRST INDUCTION COURSE MAY BE EXTENDED BY INCLUSION OF IMMUNOPHENOTYPIC DETECTION OF MEASURABLE RESIDUAL DISEASE IN CR

1Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, 2King’s College London School of Medicine, London, 3Centre for Trials Research, Cardiff University, Cardiff, 4North Bristol NHS Trust, Bristol, 5University Hospital of Wales, 6Cardiff University School of Medicine, Cardiff, 7Isle of Arran, Isle of Arran, 8Nottingham University Hospital, Nottingham, United Kingdom

Background: In AML response by morphology after a first cycle of induction therapy is used to guide further therapy including second cycles of induction and choice of consolidation. It is still uncertain how the quality of response post cycle 1 with inclusion of MRD assessment impacts on outcomes within AML risk subgroups including NPM1 wild type standard risk and whether this adds information to MRD status in CR post cycle 2.

Aims: To quantify the effect of MRD positivity for response after each cycle of induction therapy in younger patients with AML.

Methods: As part of the UK NCRI AML17 trial (ISRCTN: 55675535) for patients with AML or high risk MDS up to the age of 60, prospective flow cytometric MRD (MFC-MRD) monitoring was performed after each course of induction. Any level of MRD detected was considered MRD+(sensitivity thresholds: ~0.02% by tracking diagnostic leukemic aberrant phenotypes /LAIP, ~0.05-0.1% by “different-from normal” blast LAIP). Clinicians were not informed of MFC-MRD results. Following their first cycle of induction with daunorubicin/ara-C based therapy, patients were allocated a risk group by a validated score (comprising cytogenetics, WBC, age, secondary disease, blast response to cycle 1 and mutation status). Poor risk patients received intensified therapy in cycle 2 with a view of proceeding to SCT.

Results: MFC-MRD results after either induction course are available for 1555 patients randomised from 4/09-12/14 (median age 51, range 0-73). Cycle 1 (C1) response data with MFC-MRD was available for 1,400 patients. 70% achieved morphological CR at this time-point; 14% had resistant disease (RD) and 16% were in partial remission (PR) according to clinician. Of patients in CR (n=984) 56% had detectable MFC-MRD (MRD+). Excluding poor-risk patients 14% of patients did not achieve CR (7% RD, 7% PR), 51% of patients in CR were MRD+. 5 year OS for MRD- vs MRD+ was 63% vs 44% vs 37% vs 25% for all patients; 69% vs 51% vs 50% vs 30% excluding poor risk patients and 66% vs 49% vs 49% vs 30% for standard risk alone (Figure 1). The similar OS in this group between CR MRD+ and PR at C1 was maintained in NPM1wt standard risk patients and if censored at stem cell transplant. 771 patients were in CR post cycle 2 (C2) and provided MFC-MRD data. As expected, there were significant differences in 5 year OS between CR MFC MRD+ vs CR MFC MRD- for all patients (35% vs 63%) and excluding poor-risk (38% vs 70%, n=512). Importantly post cycle 2 MFC-MRD status also differentiated OS for NPM1wt standard risk patients with 5 year OS of 32% vs 64% (P=0.002) for MRD+ vs MRD- (Figure 1). In stratified analyses, there was some evidence that the effect of MRD positivity on OS was lower in poor-risk patients (test for trend p=0.02 for both C1 and C2). The effect of MFC-MRD status on relapse and OS appeared greater at C2 (relapse, OR 2.00(1.56-2.55), p<0.001; survival, OR 1.80(1.42-2.28) p<0.001) than C1 (relapse, OR 1.69(1.37-2.07), p<0.001; survival, OR 1.46(1.19-1.79) p<0.001). In patients with data for both time points, C2 MRD remained significant on OS when adjusting for C1 response. 24 patients converted from C1 MRD- to C2 MRD+, with a poor prognosis (15 relapses, 13 deaths). C1 MRD-/C2 MRD- had the best prognosis.

Summary/Conclusions: MFC-MRD in CR post cycle 1 has similar outcomes to partial remission in younger patients with AML, particularly in patients with good and standard risk disease. Assessment of MFC-MRD post cycle 2 appears to provide additional discrimination to cycle 1: MFC-MRD in courses 1-2 may be useful in further stratifying standard risk patients.
New insights into chronic lymphocytic leukemia biology

CLINICAL IMPACT OF THE SUBCLONAL ARCHITECTURE AND MUTATIONAL COMPLEXITY IN CHRONIC LYMPHOCYTIC LEUKEMIA

Background: Recent studies have revealed the presence and prognostic impact of small mutated subclones in chronic lymphocytic leukemia (CLL) (Rossi et al 2014, Nadeu et al 2016, Rasi et al 2016). Although these studies focused only on a small subset of 5 genes, their results opened a new perspective where the proportion of cells carrying each specific driver mutation may be relevant to the evolution of this disease. Moreover, the subclonal and mutational complexity estimated by the presence of subclonal driver alterations (Landau et al 2013, Landau et al 2015) or the accumulation of driver alterations (Puente et al 2015) have been proposed as promising indicators of clinical behavior.

Aims: The goal of this study was to determine the relevance of the quantitative subclonal architecture and mutational complexity in the evolution of CLL integrating the deep sequencing analysis of a large panel of driver genes and DNA copy number alterations (CNA).

Methods: The mutational status of 28 driver genes was investigated in 406 previously untreated CLL patients by targeted-deep next-generation sequencing (NGS). Mutations present in less than 1% of tumor cells were identified. All low frequency mutations were verified by allele-specific PCR or a second round of NGS. CNAs were analyzed by SNP-arrays. Alterations were classified as clonal if their CCF was ≥85%, and subclonal otherwise. All patients gave informed consent.

Results: Using a highly sensitive NGS strategy we observed that small subclonal mutations were the sole alteration in 22% of the mutated cases, and were frequently detected in nearly all investigated genes. We identified three gene-specific patterns that linked the magnitude of the mutated clones (or mutated cancer cell fraction, CCF) with the prognosis of the patients: i) CCF-independent pattern: mutations at any CCF had prognostic value, ii) CCF-gradual pattern: the poor prognostic impact was a continuous variable directly related to the size of the clone, and iii) CCF-clonal pattern: only mutations with a CCF above a certain threshold impacted the outcome of the patients. Combining mutations and driver CNAs, patients were characterized at least on one alteration, in 66% of the patients. However, subclonal driver alterations were present in 60% of the patients. The mutational complexity (accumulation of 1 to 4 driver alterations), but not the presence of subclonal driver populations, gradually shortened the time to first treatment independently of the IGHV mutational status and Binet stage. Conversely, the subclonal complexity, defined as the accumulation of driver alterations with the presence of at least one driver subclone, predicted for a worse overall survival independently of the IGHV and Binet stage. Patients with a pure clonal population (presence of one or more driver alterations in all tumor cells) had a similar overall survival than patients without any alteration.

Summary/Conclusions: Our study shows that the prognostic impact of different driver mutations is related to the size of the mutated population. Therefore, the clinical evaluation of gene mutations should consider the quantitative representation of the mutations and not only their presence or absence. In addition, the mutational complexity predicts for shorter time to first treatment independently of the IGHV and Binet stage, whereas the subclonal complexity confers an independent adverse impact for overall survival. Altogether, the integration of the subclonal architecture and mutational complexity in prognostic indexes may improve the stratification of CLL patients.

FBXW7 MUTATIONS LEAD TO ACCUMULATION OF NOTCH1, HIF1-ALPHA AND C-MYC IN CLL CELLS

V. Meyer-Pannwit1,2,*, S. Estenfelder2, E. Tausch2, S. J. Kugler1,2, M. Reichenzeller1,2, S. Stilgenbauer3, D. Mertens1,2

1Department of Molecular Genetics (B061), Cooperation Unit “Mechanisms of Leukemogenesis”, DKFZ, Heidelberg, 2Internal Medicine III, Ulm University, Ulm, Germany

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with recurrent mutations that are of pathogenic and prognostic relevance. Mutations in FBXW7 are among the most common mutations in CLL; yet their functional consequences are unknown. FBXW7 is an E3 ubiquitin ligase that ubiquitylates oncoproteins like NOTCH1, HIF-1α and c-MYC and thereby targets them for proteasomal degradation.

Aims: To determine the prevalence of FBXW7 mutations in CLL patient cohorts and characterize its functional role. Methods: FBXW7 mutation status was determined by CRISPR/Cas9 in the CLL cell line HG3, which does not harbor a FBXW7 mutation. For functional analysis of the CRISPR/Cas9 in the CLL cell line HG3, which does not harbor a NOTCH1 mutation. Both in this CRISPR/Cas9 mutated cell line and in primary CLL cells with FBXW7 mutations, the protein levels of FBXW7 substrates were examined. In addition, we quantified NOTCH1 and HIF-1α activity with Luciferase reporter assay in FBXW7 mutated HG3 cells.

Results: Heterozygous mutations in FBXW7 were found in 4/905 (4.5%) of CLL patients. The most common mutations of FBXW7 were missense mutations (32/41) that target the substrate binding domain of the FBXW7 protein as well as non-sense mutations (4/41). Interestingly, 5 patients harbored two concurrent missense mutations of the PolyPhen-2 software, all except one missense mutation in FBXW7 were predicted to be most likely damaging. No mutations in FBXW7 were found in the CLL, MCL and LCL cell lines analyzed. To determine the functional consequence of FBXW7 mutations in CLL, we induced either a heterozygous or a homozygous truncation of FBXW7 in the CLL cell line HG3, resulting in the loss of the substrate binding site of the WD40 domain. The homozygous truncation of FBXW7 resulted in an increase of NOTCH1, HIF1-α and c-MYC protein levels, whereas no difference of Cyclin E protein amount was detectable. In addition, an elevation of NOTCH1 activity was found in both the heterozygously and homozygously truncated mutant cell lines in comparison to the wildtype HG3 cell line. To confirm this finding, protein levels of 5 CLL patients with FBXW7 mutations were analyzed with a similar outcome.

Summary/Conclusions: Mutations in FBXW7 are frequently found in CLL, especially missense and nonsense mutations affecting the WD40 domain. We hypothesize that this has functional consequences on FBXW7 substrate binding and consequently affects accumulation of oncoproteins. Although truncation of the WD40 domain of FBXW7 in the HG3 cell line resulted in the accumulation of protein substrates and corresponding increase of their activity implicated in the pathogenesis of CLL. Taken together our data show that FBXW7 can target proteins for degradation that are commonly disregulated in CLL and that drive disease progression.
of CLL in relation to the mutational, transcriptional and three-dimensional (3D) chromatin landscape.

Methods: Seven CLL patients with distinct clinico-pathological features and five mature B-cell subpopulations were extensively analysed using (i) ChIP-seq of six different histone marks with non-overlapping features (H3K27ac, H3K4me1, H3K4me3, H3K9me3, H3K27me3 and H3K36me3); (ii) single stranded RNA-seq; iii) transposase-accessible chromatin assays (ATAC-seq) and iv) whole-genome bisulfite sequencing (WGBS), creating a unique reference epigenome for CLL. These data were complemented with the 3D chromatin landscape in one CLL case measured by high-throughput chromatin conformation capture (HiC-seq) and promoter capture Hi-C (PCHi-C). Furthermore, we mapped the active chromatin landscape of 100 CLL patients by H3K27ac ChIP-seq and ATAC-seq. Whole-genome sequencing data was available for 44 of these patients. We applied a broad range of bioinformatic tools to analyze the data in an integrative way.

Results: CLL is distinct from normal B cells for all layers of the reference epigenetic landscape (7 CLLs) and the active chromatin landscape (100 CLLs). CLL though is closer to naive and memory B cells than to germinal center B cells and plasma cells. Interestingly, in CLL we not only saw activation of regions that are active in naive and memory B cells, but also an unexpected activation of genomic regions that are specifically active in germinal center B cells and plasma cells. Changes in activation in these and other regions could furthermore distinguish the two major clinical subgroups of CLL with unmutated and mutated immunoglobulin heavy chains (IGVH). CLls did not only differ from normal B cells regarding the separate layers of information, but also using combined patterns of histone marks, which for example can define regulatory elements as active promoters (H3K4me3 and H3K27ac) or active enhancers (H3K27ac and H3K4me1). More specifically, we detected 534 genomic regions with de novo gain (n=498) or loss (n=36) of active regulatory regions in CLL. Large regions (>10kb) showing de novo gain of regulatory elements in CLL (n=51), were located into, close to, or interacted in 3D space with genes important for CLL pathogenesis, e.g., LEF1, BCL2 and FMOD. Interestingly, non-coding somatic mutations in IGVH mutated CLLs accumulate in these and other active regulatory regions, likely being off-target effects of the somatic hypermutation machinery. Besides changes in regulatory elements, we observed that CLLs lose poised promoters, which are replaced by repressed/desaturative regions. This change, mainly occurring in developmental genes, does not affect gene expression levels, as these genes are already silent in normal B cells. It may however represent loss of plasticity during CLL pathogenesis in which these genes become permanently inactive.

Summary/Conclusions: With this integrative study, we generated new conceptual avenues to understand the complex link among the epigenetic, mutational, transcriptional and 3D chromatin landscape in CLL. In addition we provide the community with an extensive resource of epigenetic information of this lymphoid neoplasm.

THERAPEUTIC DISRUPTION OF THE BAFF-B-CELL RECEPTOR CROSS-TALK IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

C. Paiva1, T. Rowland1, B. Sreekantham1, O. Danilova1, A. Danilov1,*
1Oregon Health and Science University, Portland, United States

Background: Although small molecule inhibitors of BCR-associated kinases (BCRi) revolutionized therapy in CLL, they provide incomplete responses. Tumor necrosis factor receptor superfamily ligands BAFF and APRIL induce NFκB, which in turn upregulates pro-survival Bcl-2 family proteins and thereby drives anti-apoptotic responses, potentially accounting for resistance to BCRi. The exact roles of the individual NFκB pathways, as well as the implications of targeting BCR in context of BAFF signaling in CLL remain understudied.

Aims: We explored the mechanistic underpinnings of CLL cell survival in response to BAFF signaling.

Methods: We established a novel BAFF-expressing stromal co-culture model and targeted inhibitors of Bruton tyrosine kinase (BTK, ibrutinib), phosphoinoside-3 kinase (PI3K, idelalisib) and spleen tyrosine kinase (SYK, entospletinib). We quantified CLL cell apoptosis, migration, NFκB activity, protein and mRNA expression by flow cytometry, immunoblotting, ELISA, RT-PCR and immunocytochemistry.

Results: CLL cells co-cultured with BAFF-expressing stroma were resistant to spontaneous apoptosis (12.3±3.2% after 24 h, vs 34.8±6.2% off stroma) and chemotherapy agents (bendamustine, fludarabine). Gene expression profiling exposed the NFκB pathway gene targets as the most significantly upregulated upon BAFF stimulation (p<0.0001). We and others have shown that BAFF-expressing stroma induces canonical and non-canonical NFκB in CLL. By contrast, while BAFF led to strong activation of the non-canonical NFκB with processing of p100 (to p52) by 4 h and a 5-fold increase in p52 DNA-binding activity by 24 h, canonical NFκB (RelA) activation was less pronounced. BAFF predominantly induced Mcl-1, compared to CD40L which strongly upregulated Bcl-X. BCR is a major driver of non-canonical NFκB signaling in CLL. Thus, we studied whether BAFF co-opted BCR signaling in CLL. BAFF induced rapid (15 min) phosphorylation of the proximal BCR kinases SYKand LYN, sustained for up to 4 h, as well as ERK, in CLL cells. AKT acti-

LOW MYBL2 EXPRESSION OBSERVED IN MYELODYSPLASTIC SYNDROME PATIENTS WITH WORSE PROGNOSIS IS ASSOCIATED WITH ALTERED DNA REPAIR MECHANISMS IN HAEMATOPOIETIC STEM CELLS

R. Bayley1, L. Canciani1, C. Ward1, G. Volpe1, S. Dumon1, J. Gujar1, G. Stewart1, E. Petermann1, P. Garcia1,*

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of disorders that are characterized by ineffective hematopoiesis and progressive cytogenetic evolution. Mutations in genes involved in DNA repair pathways, such as ARID2, contribute to the emergence of further genetic abnormalities by deregulation of the cell cycle and genome integrity. MybL2 is a transcription factor with roles in the cell cycle and DNA repair.

Methods: In this study, we used mouse model in which animals express ~50% normal levels of Mybl2 (Mybl2+/−). We characterised the activity of HSCs from young (7 weeks) and old (70 weeks) animals to respond to in vivo ionising radiation. We examined DNA repair, apoptosis, and colony formation ability. We measured the activation of the two main DNA repair pathways operating in the cells to deal with DSB: the error prone non-homologous-end-joining (NHEJ) and the error-free homologous recombination (HR) by assessing 53BP1 and Rad51 recruitment by immunofluorescence, respectively. Finally, we analysed the frequency of chromosome abnormalities present in the progeny of MybL2+/− HSC that have previously been irradiated to determine the long term effects of changes in DNA repair.

Results: We observed that Mybl2+/− HSCs had limited proliferative potential and displayed an increased sensitivity to ionizing radiation which increased during ageing. MybL2+/− HSCs also displayed altered kinetics of 53BP1 and Rad51 recruitment and clearance, including retention of 53BP1 foci at later time points following irradiation and decreased levels of Rad51 foci when compared to Mybl2+/+HSCs. Using plasmid functional assays, we showed that Mybl2+/− HSCs repair quite efficiently by NHEJ, but this efficiency is disrupted when cells are challenged with ionising radiation. Furthermore, MybL2+/− HSCs have increased sensitivity to inhibition of DNA-PKcs (required for NHEJ) but not ATM (required by HR). We also observed that after ionizing irradiation MybL2+/− HSC progeny displayed an increased percentage of chromatids with fragile telomeres. Moreover, by making use of publically available RNA-seq data from MDS cells, we have identified a clear association between low MYBL2 levels and low expression of DNA-repair genes in patients with worse prognosis.

Summary/Conclusions: In summary, we have shown that decreased expression of Mybl2 in hematopoietic cell lines and bone marrow mononuclear cells. Since no homozygous deletion or mutation of ARID2 was identified, we transduced shRNA in neo-plastic and healthy hematopoietic cells to obtain disease models with partial reduction of ARID2 expression. Two myeloid cell lines (HL60 and K562) in which ARID2 expression was knocked down showed significantly lower cell counts compared to those with normal ARID2 expression, compatible with more apoptotic cells in knockdown experiments. Flow cytometric analysis of the cell lines with reduced ARID2 expression revealed increased cell-surface maturation markers, CD11b and glycoprotein A (GPA), suggesting that reduced expression of ARID2 resulted in more differentiation in myeloid and erythroid lineages. Knockdown of ARID2 failed to reduce colony formation in bone marrow mononuclear cells. These results indicate that reduced ARID2 expression might induce more differentiation in myeloid/erythroid lineages and more apoptosis to reduce cell populations without reduction of proliferation capacity in hematopoietic progenitor cells. Finally, we examined morphological findings associated with knockdown ARID2 expression. Compared to control cells, K562 cells with reduced ARID2 expression formed more hypolobated megakaryocytes, which confirmed morphological findings seen in ARID2 and U2AF1 defects.

A NOVEL GENETIC AND MORPHOLOGIC PHENOTYPE OF ARID2-MEDIATED MYELODYSPLASTIC SYNDROMES

H. Sakai1,2, N. Hosono1,3, H. Nakazawa2, B. Przychodzen1, C. Polprasert1, M. Makishima1,5,*

1Institute of Cancer and Genomic Science, University of Birmingham, Birmingham, United Kingdom

Background: Clinical heterogeneity of myelodysplastic syndromes (MDS) and related myeloid neoplasms reflects molecular diversity. Most common genetic associations with distinct clinical or pathomorphologic phenotypes have been described. However, many other rare genetic lesions exist and their clinical context still remains elusive. At rich interactive domain 2 (ARID2), which is located on chromosome 12q, encodes a component of the SWI/SNF complex that is involved in chromatin remodeling. In recent years multiple groups detected ARID2 mutations in a variety of solid tumors.

Aim: We present whole exome sequencing-guided identification of novel ARID2 mutations in myeloid neoplasms. Specifically, in addition to copy number analysis and deep targeted and exome sequencing, here we include RNA sequencing and splicing analyses of the roles of spliceosomal mutations in ARID2 missplicing and gene expression.

Methods: Bone marrow aspirates or blood samples were collected from 1,473 patients with MDS (n=445), myelodysplastic/myeloproliferative neoplasms (MDS/MPN) (n=201), myeloproliferative neoplasms (MPN) (n=56), and primary myeloid leukemia (pAML) (n=540) at the Cancer Clinic and The University of Tokyo; the registered data at The Cancer Genome Atlas were also included. Diagnoses were classified using World Health Organization criteria. Informed consent for sample collection was obtained according to a protocol approved by each Institutional Review Board in accordance with the Declaration of Helsinki.

Results: By comprehensive genetic investigation of these cases, we characterized here cases (10%) in which decreased expression of ARID2 mediated their clinical effects in MDS and other myeloid neoplasms via multiple kinds of genetic lesions. We showed that insufficient ARID2 expression mainly in MDS arose from ARID2 mutations, deletions, and missplicing due to U2AF1 mutations that yielded defec- tive ARID2 transcripts. Clone architecture analyses showed that ARID2 mutations and deletions occurred as initial events of MDS or myelodysplastic/myeloproliferative neoplasms, and not during progression to acute myeloid leukemia. Morphologically, progressive maturation in myeloid and erythroid lineages and hypolobated megakaryocytes (indicated by arrow heads in Figure 1) were common in cases with ARID2 mutations and deletions, and were also found in cases with U2AF1 mutations. Functionally, we utilized in vitro knockdown models of ARID2 expression in hematopoietic cell lines and bone marrow mononuclear cells. Since no homoz- gous deletion or mutation of ARID2 was identified, we transduced shRNA in neo-plastic and healthy hematopoietic cells to obtain disease models with partial reduction of ARID2 expression. Two myeloid cell lines (HL60 and K562) in which ARID2 expression was knocked down showed significantly lower cell counts compared to those with normal ARID2 expression, compatible with more apoptotic cells in knockdown experiments. Flow cytometric analysis of the cell lines with reduced ARID2 expression revealed increased cell-surface maturation markers, CD11b and glycoprotein A (GPA), suggesting that reduced expression of ARID2 resulted in more differentiation in myeloid and erythroid lineages. Knockdown of ARID2 failed to reduce colony formation in bone marrow mononuclear cells. These results indicate that reduced ARID2 expression might induce more differentiation in myeloid/erythroid lineages and more apoptosis to reduce cell populations without reduction of proliferation capacity in hematopoietic progenitor cells. Finally, we examined morphological findings associated with knockdown ARID2 expression. Compared to control cells, K562 cells with reduced ARID2 expression formed more hypolobated megakaryocytes, which confirmed morphological findings seen in ARID2 and U2AF1 defects.

Figure 1.

Summary/Conclusions: ARID2 is a MDS-suppressor gene whose expression is attenuated by multiple mechanisms as it shapes the distinct morphological phenotype of a subset of myelodysplasia.

Analysis, Human Genome Center, The University of Tokyo, Tokyo, Japan, 4Department of Molecular Genetics, Cleveland Clinic, Cleveland, United States

Results: By comprehensive genetic investigation of these cases, we characterized here cases (10%) in which decreased expression of ARID2 mediated their clinical effects in MDS and other myeloid neoplasms via multiple kinds of genetic lesions. We showed that insufficient ARID2 expression mainly in MDS arose from ARID2 mutations, deletions, and missplicing due to U2AF1 mutations that yielded defective ARID2 transcripts. Clone architecture analyses showed that ARID2 mutations and deletions occurred as initial events of MDS or myelodysplastic/myeloproliferative neoplasms, and not during progression to acute myeloid leukemia. Compared to control cells, K562 cells with reduced ARID2 expression formed more hypolobated megakaryocytes, which confirmed morphological findings seen in ARID2 and U2AF1 defects.

Figure 1.

Summary/Conclusions: ARID2 is a MDS-suppressor gene whose expression is attenuated by multiple mechanisms as it shapes the distinct morphological phenotype of a subset of myelodysplasia.
BACKGROUND: The 2016 revision of the WHO classification for myeloid malignancies includes numerous molecular markers for classification and prognostication. Next generation sequencing allows analyzing relevant genes in one panel.

RESULTS: Analyzing 39 genes, we found ≥1 molecular change in 90% of patients (500/556) with a definite morphologic diagnosis (median: 2 genes; max: 7). In de novo AML, 212/229 (93%) patients showed ≥1 molecular hit, of which 211 (92%) had aberrations that define WHO categories or have prognostic (according to ELN/MRC) or predictive value. More than 1 mutation was found in 166/229 patients (72%), including information of adverse impact (e.g. of 68 NPM1 positive patients, 17 had DNMT3A mutations and 20 FLT3-ITD). Following NPM1, RUNX1 was the second most frequently mutated gene (46/225; 20%) and mutations were significantly more common in patients with ≥3 aberrations (37/92; 40%) compared to patients with ≥2 aberrations (83/167; 50%; p < 0.01). A similar RUNX1 pattern was found in s-AML and t-AML. In the cohort of “possible AML” (including MDS overlap), 45/48 (94%) patients had ≥1 hit. Most frequently mutated were ASXL1 (16/48; 33%), TET2 (32%; 14/44) and SF3B1 (29%; 14/48; 16%) had all three mutated. This combination is also one of the three-way common interactions in CML (10/14; 23%). In MDS, 124/157 (79%) cases showed mutations, of which 108 had ≥1 prognostic change (according to Bejar, 2015). The prognostically favorable SF3B1 mutation was present in 31/157 (20%) and significantly enriched among cases with ring sideroblasts (p < 0.001). Overall, TET2 showed the highest mutation rate (25%) and was also the most commonly mutated gene in cases with “possible” MDS (36/190; 19%), reactive morphologic changes (17/201; 8%) or even unclear morphology (19/116; 17%). Of these three subsets, five patients had only the TET2 mutation with <10% burden, which is observed in clonal hematopoiesis of indeterminate potential (CHIP), too. However, using panel sequencing in cases with possible MDS, unclear or reactive morphology revealed at least one molecular marker for clonal disease in 47% (91/199), 36% (43/118) or 17% (36/211) of cases, respectively (excluding only s-ASXL1, DNMT3A, TET2 mutations with <10% burden).

Summary/Conclusions: WHO 2016 requires information on numerous genes for diagnosis, prognosis and therapeutic decisions. This challenges conventional approaches and suggests panel sequencing. We demonstrate the feasibility in routine settings for a broad spectrum of myeloid malignancies and identify 1) relevant patterns and mutation interactions; 2) genetic aberrations supporting diagnosis for samples with borderline morphology or poor quality and 3) patient-specific clonality useful for follow-up.

BACKGROUND: The myelodysplastic syndromes (MDS) are disorders of the hematopoietic stem cell (HSC) and patients suffer from anaemia and other cytopenias and show increasing bone marrow blasts over time. Mutations in spliceosomal genes (including SF3B1, SRSF2 and U2AF1) occur in >50% of MDS patients.

Aims: We aimed to identify the deregulated pathways and gene ontology (GO) categories associated with aberrantly spliced genes in CD34+cells and in different cell subpopulations of MDS-affected lineages isolated from the bone marrow of MDS patients harboring genetic mutations.

Methods: Transcriptome data were generated using RNA sequencing (RNA-seq) and splicing factor mutant cases were compared to wildtype cases and to healthy controls. Aberrant (including cryptic) splicing events were identified using rMATS. Deregulated pathways and GO themes were identified using Ingenuity Pathway Analysis and GOseq.

Results: RNA-Seq was performed on CD34+ cells obtained from the bone marrow of 91 MDS patients (including 28, 8 and 6 cases with SF3B1, SRSF2 or U2AF1 mutations, respectively) and 8 healthy controls. The aberrant splicing events associated with each mutated splicing factor tended to affect different sets of genes (although shared genes were observed). Aberrantly spliced genes associated with SF3B1, SRSF2 or U2AF1 mutations showed a marked convergence of significantly enriched ontology themes: 26 of the top 30 most significant GO categories, including ‘RNA processing’ and ‘transcription’, in the comparison of mutant cases for each splicing factor gene to healthy controls (18 of 30 in the case of SF3B1) were common to all three mutated splicing factor genes. Pathway analysis revealed deregulated pathways (e.g. ‘oxidative phosphorylation’ and ‘mitochondrial dysfunction’) that were common to more than one mutated gene (i.e. SF3B1 and SRSF2), and pathways specific for one mutated splicing factor gene (e.g. protein ubiquitination in SF3B1 mutant cases). An analysis of upstream transcriptional regulators showed a significant overlap between the aberrantly spliced genes associated with each mutated splicing factor gene (in the comparison to both wildtype cases and to healthy controls) and genes regulated by several transcription factors, including E2F1. RNA-Seq was also performed on CD34+ cells. Transcriptional changes were observed in redfield, granulocytic and monocytic cell populations isolated from the bone marrow of each of 7 SF3B1 mutant MDS cases, 7 wildtype cases and 5 healthy controls, in order to explore similarities/differences between aberrantly spliced genes and deregulated pathways and GO themes in cells of different lineages. There were many aberrantly spliced genes in one cell population that did not overlap with aberrantly spliced genes in other populations.

A small proportion (i.e. <5%) of aberrantly spliced genes were common to all four cell populations. GO analysis of the aberrantly spliced genes identified that 6 of the top 30 most significant categories (including ‘RNA binding’ and ‘transcription’ in the comparison to SF3B1 mutant cases to healthy controls) were common to all four cell populations studied. Pathway analysis revealed that several pathways were deregulated in specific cell populations (e.g. mTOR signaling in erythroid cells), and some pathways (e.g. EIF2 signaling), involved in protein synthesis initiation were deregulated in all four cell populations studied.

Summary/Conclusions: Our study has identified aberrantly spliced genes and deregulated pathways associated with spliceosomal mutations in the HSCs and the major cell lineages affected in MDS, providing new insights into how these mutations impact cellular processes in this disorder.

BACKGROUND: Myelodysplastic syndromes (MDS) and related myeloid disorders (“myelodysplasia”) are a heterogeneous group of clonal hematopoietic disorders with a highly variable clinical outcome.

Aims: The purpose of this study was to establish a novel gene expression-based classification of myelodysplasia for better prognostication.
Methods: We performed transcriptome sequencing of bone marrow mononuclear cells (BMMNCs) and/or CD34+ cells obtained from patients with myelodysplasia. Consensus clustering was used to identify stable patient clusters. A classifier of the gene expression-based subgroups was constructed using the 100 CD34+ cell samples as a training set, followed by validation in an independent cohort of 183 MDS patients. Another classifier was constructed using BMMNC samples from 51 patients, who had been assigned to the subgroups by the gene expression data of their CD34+ cells. Prognostic significance of the model was tested in 114 patients of myelodysplasia.

Results: Unsupervised clustering of gene expression data of bone marrow CD34+ cells from 100 patients identified two subgroups (Class-I and Class-II). The patients in the Class-II subgroup had higher percentages of bone marrow blasts compared to those in the Class-I subgroup (median 2% vs 11%, P <0.01). Pathway analysis revealed up-regulation of many signaling pathways in the Class-I subgroup. The Class-II subtype showed highly significant up-regulation of the genes related to erythroid lineages. The erythroid signature was rather suppressed in the Class-II subtype, which was characterized by increased expression of genes related to progenitor cells. Compared to the Class-I subtype, the Class-II subtype was associated with a significantly shorter survival in both univariate (hazard ratio [HR] 5.0 [95% CI, 1.8–14], P <0.001) and multivariate analysis (HR 6.8 [95% CI, 1.5–32], P=0.015). High frequency of leukemic transformation in the Class-II subgroup (38%) contrasted to no leukemic transformation in the Class-I subgroup. The prognostic significance of our classification was validated in an independent cohort of 183 patients.

We also constructed a model to predict the subgroups using gene expression profiles of BMMNCs. The model was applied to 114 patients with BMMNC samples, of whom 47 (41%) were predicted to be Class-I subgroup. Compared to the predicted Class-I subgroup, the Class-II subgroup was associated with a significantly shorter survival in univariate analysis (HR 7.2 [95% CI, 3.0–17], P <0.001). Again, association was more pronounced for leukemia transformation (HR 18 [95% CI, 4.2–80], P <0.001) than for overall survival. Multivariate analysis also demonstrated that the predicted Class-II subgroup was independently associated with leukemia transformation (HR 7.3 [95% CI, 1.3–41], P=0.024). Finally, we compared the prognostic value of our model with that of the LSC17 score, which has recently been proposed to predict a subset of poor risk acute myeloid leukemia based on the expression levels of 17 genes related to a leukemic stem cell signature. Our model outperformed the LSC17 score in predicting clinical outcomes of myelodysplasia, especially leukemia progression. The Class-II signature was shown to be more dramatically up-regulated during clonal evolution of myelodysplasia than the LSC17 score, which might be the basis of a better prediction of leukemia progression in our model.

Summary/Conclusions: Comprehensive transcriptomic analysis identified two subgroups of myelodysplasia with biological and clinical relevance, which could improve risk prediction and treatment stratification of myelodysplasia.

**GENETIC ALTERATIONS INVOLVING PROGRAMMED DEATH LIGANDS IN EPSTEIN-BARR VIRUS-ASSOCIATED LYMPHOMAS**

1Department of Pathology and Tumor Biology, Kyoto University, Kyoto, 2Department of Pathology, Kurume University School of Medicine, Kurume, 3Pathology Project, Academic Targeted Medicine Institute, Tokyo Medical and Dental University, Imagine Institute, Paris, France, 4Department of Pathology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, 5Laboratory of DNA Information Analysis, The University of Tokyo, Tokyo, 6Department of Advanced Diagnosis, Nagoya Medical Center, N8730, 7Department of Pediatric Hematology and Oncology Research, National Centre for Child Health and Development, 8Department of Pathology, Tottenon Hospital, Tokyo, Japan

**Background:** Checkpoint blockade using anti-PD-1/PD-L1 antibodies is a highly promising therapy for cancer, frequently showing dramatic anti-tumor responses in a wide variety of tumor types. Particularly, an exceptional response to anti-PD-1 antibodies has been demonstrated for classical Hodgkin lymphoma (HL), which is characterized by frequent copy number gains/amplifications involving PD-L1 and PD-L2, the close association between PD-L1/PD-L2 genetic alterations and the therapeutic response to these agents. Recently, we have reported frequent structural variations (SVs) in adult T-cell leukemia/lymphoma (ATL) caused by human T-cell leukemia virus type-1 (HTLV-1). These SVs invariably affect 3′-untranslated region (UTR) of PD-L1, leading to promi-nent overexpression of PD-L1/PD-L2, especially focus-ing on EBV-associated lymphomas.

**Aims:** Epstein-Barr virus is a DNA tumor virus closely associated with various human cancers, including B- and natural killer (NK) T-cell lymphomas, in which genetic alterations involving PD-L1/PD-L2 may also be relevant to cancer evo-lution in this study, to assess this hypothesis, we interrogated a variety of lymphomas for genetic abnormalities affecting PD-L1 and PD-L2, especially focusing on EBV-associated lymphomas.

**Methods:** SVs and other genetic lesions affecting PD-L1 and PD-L2 were ana-lyzed using targeted-capture sequencing with cRNA baits designed for captur-ing the entire sequences of PD-L1 and PD-L2 genes, including exons, introns, and 5′- and 3′-UTRs. More than 400 samples were analyzed obtained from differ-ent subtypes of non-Hodgkin lymphomas, including EBV-associated lymphomas, such as EBV-positive diffuse large B-cell lymphoma (DLBCL) and NK/T-cell malignancies.

**Results:** SVs and/or focal copy number gains involving PD ligands were suc-cessfully detected in various B-cell and T/NK-cell lymphomas, albeit at generally low frequencies (<10%). These lesions were the most frequently observed in PMBCs, with the highest frequency (17−57%) of PD-L1/PD-L2-involving abnormalities being observed in mature NK/T-cell neoplasms, including extranodal NK/T-cell lymphoma, aggressive NK cell leukemia, and EBV-positive T-cell lymphoproliferative disorder, all of which were positive for EBV. Moreover, a substantial proportion (22%) of EBV-positive DLBCL cases possessed these lesions, whereas EBV-negative cases rarely exhibited these alterations (2%, P<0.01). For both PD-L1 and PD-L2 SVs, despite a large diversity of SV type (deletions, inversions, tandem duplications, and translocations), most of SVs resulted in 3′-UTR truncation, while the replacement of PD-L1 or PD-L2 promoter with an ectopic regulatory element was rarely observed. Interestingly, PD-L1 SVs were detected in both B- and T-cell lymphomas, whereas PD-L2 SVs were found exclusively in B-cell lymphomas.

**Summary/Conclusions:** We delineate the entire picture of genetic alterations involving PD-L1 and PD-L2, the close association between these lesions and EBV-associated lymphomas. Our finding help to understand their pathogenesis and develop a new diagnostic strategy to identify patients who potentially benefit from PD-1/PD-1 blockade therapy in non-Hodgkin lymphomas.

**FOXO1 CONTROL CD20 EXPRESSION AND INFLUENCE B-CELL LYMPHOMA RESPONSE TO RITUXIMAB-BASED IMMUNOTHERAPY**

M. Dwojak1,*, B. Pyrzynska1, A. Zerrouqi1, G. Morlino2, P. Zapala1, N. Miazek1, M. Dwojak1

1Department of Immunology, Medical University of Warsaw, Warsaw, Poland, 2The Francis Crick Institute, London, United Kingdom

**Background:** Recurrent somatic mutations of N-terminal region of FOXO1,
shown previously to increase FOXP1 nuclear localization and activity, have been linked to diminished survival in DLBCL patients uniformly treated with rituximab-based immunotherapy. Although the contribution of FOXP1 mutations to the therapeutic resistance of B-NHLs becomes apparent, the molecular mechanism underlying this phenomenon has not been explained so far. The diminished levels of CD20 on the cell surface of tumor cells are among several potential mechanisms underlying the resistance to treatment with anti-CD20 monoclonal antibodies.

Aims: We have recently reported that the tonic BCR signaling activates FOXP1, and that inhibitors of the downstream BCR signaling pathways downregulate CD20 expression. Therefore, here we sought to determine whether FOXP1 might regulate the abundance of CD20 on the surface of tumor cells thus influencing the response to rituximab-based therapies.

Methods: We used CRISPR/Cas9 genome editing technology and lentiviral transduction to study the role of FOXP1 protein in CD20 regulation. qRT-PCR and Dual Luciferase Assays was done to determine the influence of FOXP1 on CD20 mRNA expression. Next, to investigate the consequences of FOXP1 and CD20 promoter we performed EMSSA and ChIP experiments. For animal studies we used SCID Fox Chase mice model. All in vivo experiments were carried out at the animal facility of The Francis Crick Institute in accordance with the guidelines and were approved by the Ethics Committee.

Results: To determine the potential role of FOXP1 in the CD20 regulation, we disrupted FOXP1 focus using the CRISPR/Cas9 genome editing technology in Raji cells. In in vitro complement-dependent cytotoxicity assay we show that ablation of FOXP1 results in upregulation of CD20 levels and improves the rituximab efficacy. To see whether FOXP1-dependent up-regulation of CD20 translation directly affects tumor cell survival, we used in vivo model in which we injected tumors into mice with normal and FOXP1 knockout cells. Consistently, using clinically tested PI3K-AKT inhibitors - MK-2206 and GDC-0068 – in a set of CLL primary tumors we show that also pharmaceutical inhibition of FOXP1 activity upregulated surface CD20 levels. Moreover, we demonstrated that FOXP1 regulate the CD20 promoter activity. In different B-cell lymphoma cell lines MK-2206 and GDC-0068 significantly downregulated the levels of MS4A1 transcript (encoding CD20). Finally, using both EMSSA and ChIP assays we detected specific binding of FOXP1 to the MS4A1 promoter to the extent comparable to other known FOXP1 target genes.

Summary/Conclusions: Collectively, our results indicate that FOXP1 is strong negative regulator of CD20 expression and add new insights into the mechanisms underlying the contribution of FOXP1 mutations to the resistance of B-NHLs to R-CHOP therapy. In light of current knowledge and our observations presented in this study, FOXP1 inhibition represents a novel strategy to increase the efficacy of anti-CD20 monoclonal antibodies.

Background: ALCL is a high grade lymphoma characterized by anaplastic morphology, expression of CD30 (K-1) and T- or null cell phenotype. In 60% of systemic ALCL, the translocation t(2;5)(p23;q35) leads to expression of the oncoprotein NPM-ALK. NIPA is a F-box protein, important in the cell cycle control and is an F-box-Protein contributing to the timing of mitotic entry by defining an oscillating ubiquitin E3 ligase. NIPA deficient mice are viable but sterile due to impaired DNA double strand break repair. Co-expressed with NPM-ALK, NIPA is constitutively phosphorylated. However, the role of NIPA in NPM-ALK induced lymphomagenesis and the functional impact of this interaction remain unknown.

Aims: In this study, we aim to investigate the effect of NIPA deficiency on NPM-ALK driven cell proliferation and transformation in order to characterize the function of the protein in ALCL-induced lymphomagenesis.

Methods: Primary Nipa-/-MEFs infected with NPM-ALK were plated in soft agar assays to evaluate their transformation ability. Moreover, NIPA was downregulated through targeted genetic approaches in Karpas299 and NPM-ALK infected BarF3 cells, which were analyzed regarding proliferation, signaling, and apoptosis. To assess the impact of NIPA deletion in vivo, we used a retroviral bone marrow transplantation model resembling human ALCL. Based on a Cre/loxP system under the LCK-Promotor, NPM-ALK expression and Nipa-deletion are restricted to early T cells. In wildtype background, mice die of systemic Thy1.2 lymphoma with a latency of 4-6 months, developing neoplastic T-cell infiltration of bone marrow and lymphatic organs. Lymphomas were analyzed regarding immunophenotype and clinical presentation.

Results: Primary Nipa-/-MEFs infected with NPM-ALK were plafted in softagar showed significantly reduced colony formation potential upon NPM-ALK expression (38 vs 79 CFUs; p<0.001). These results were substantiated in human and murine cell lines, where significantly reduced proliferation ability was observed in NIPA downregulated NPM-ALK K-expressing BarF3 cells (74% of ctr; p<0.001) as well as in Karpas299 cells infected with NIPA miR (66% of wt growth; p<0.01). Moreover, treatment with the ALK inhibitor TAE-684 gave evidence of possible synergistic effects of ALK inhibition and NIPA knockdown. Mice transplanted with Lck-CreTG/GERMSNAIE infected bone marrow cells showed significantly prolonged disease development and prolonged survival (121 vs 12 d, in wt). Morphologically, mice presented with enlarged thymus, sphenomegaly, lymphadenopathy, and bone marrow infiltration. Immunophenotyping showed a pure T-cell phenotype in Nipa-/- lymphomas, thus resembling wildtype. In a long-latency model of NPM-ALK expression in enriched HSCs, a significantly prolonged survival (110 vs 80 days; p<0.01) and reduction of spleen colonies (10 vs 28 colonies/spleen; p<0.001) in mice transplanted with M nghiêmNPM-ALKNipa-/- bone marrow compared to control animals were observed, thereby suggesting a crucial role of NIPA in NPM-ALK driven lymphomagenesis. To investigate the precise mechanism underlying these results, we performed cell cycle analyses as well as cell viability assays. Indeed, we were able to detect significant differences in the cell viability in Nipa deficient NPM-ALK expressing cells, whereas cell cycle distribution seems not to be altered in knockout cells.

Summary/Conclusions: Taken together, we were able to show that NIPA is crucial for cell proliferation and transformation upon NPM-ALK expression. Investigations of the NIPA knockout mouse in a clinically relevant ALCL model highlight the importance of the NIPA/NPM-ALK axis in lymphoma development. Further analyses may thus elucidate NIPA as a novel molecular target for therapeutic intervention.

S128 THERAPEUTIC TARGETING OF THE BETA THALASSEMIA/β-TERT HYPER-METHYLATION CONTEXT AS A NOVEL THERAPEUTIC STRATEGY

1Haematology and BMT Unit, 2Pediatric Immunohematology, 3San Raffaele Telethon Institute for Gene Therapy, San Raffaele Scientific Institute, Milano, 4Pediatric Department , San Gerardo Hospital , Monza, 5Pediatric Clinic/DH, Fondazione IRCCS Ca’ Granda, Milano, 6Department of Biomedical Science and Biotechnology, University of Cagliari, Cagliari, 7Blood Transfusion Service, San Raffaele Scientific Institute, Milano, 8Immunohematology and Transfusion Medicine Service, Fondazione IRCCS Policlinico S. Matteo, Pavia, 9Rare Disease Center, Fondazione IRCCS Ca’ Granda, Milano, Italy

Background: Gene therapy for transfusion dependent beta-thalassemia, as an alternative cure to allogeneic HSCT, is based on the autologous transplantation of hematopoietic stem cells (HSCs) engineered by lentiviral vectors expressing a transcriptionally regulated human beta-globin gene.

Aims: Our contribution to this field was devoted to the clinical development of a gene therapy protocol based on high-titer vector GLOBE, use of lenograstim and plerixafor as source of HSCs and a conditioning regimen based on myeloablative treosulfan and thiotapec favoring efficient engraftment of corrected cells with reduced toxicity (TIGET-BTHAL; EudraCT number 2014-004860-39).

Methods: On the basis of extensive efficacy and safety preclinical studies, the clinical trial TIGET-BTHAL was approved and started in 2015 at Scientific Institute San Raffaele, Milano, Italy. The clinical study foresees treatment of 10 patients: 3 adults followed by 7 minors, with a staggered enrolment strategy based on evaluation of safety and preliminary efficacy in adult patients by an independent data safety monitoring board before inclusion of pediatric subjects. The chosen route of administration of gene modified HSCs is intraosseous in the posterior-superior iliac crests, bilaterally, with the aim of enhancing engraftment and minimizing first-pass intravenous filter.

Results: As of February 2017, seven patients (3 adults and 4 pediatric patients with different genotypes (β0/β0, β+/β+ and β0/β+) have been treated with GLOBE-transduced CD34+ cells at a dose of 16x10^6-19.5x10^6 cells/kg and a vector copy number (VCN)/cell ranging from 0.7 to 1.5. The procedure was well tolerated by all patients, with no product-related adverse events. Multilineage engraftment of gene-marked cells was observed in all tested peripheral blood and bone marrow samples. Polyclonal vector integrations profiles have been detected in the first 3 patients tested.

Summary/Conclusions: So far, the clinical outcome indicates reduction in transfusion requirement in adult patients and greater clinical benefit in younger patients. Follow up analysis are ongoing and updated clinical outcome will be presented.

S129 LUSPATERCEPT INCREASES HEMOGLOBIN AND DECREASES TRANSFUSION BURDEN IN ADULTS WITH B-TALASSEMA

1Turin University, Turin, 2Second University of Naples, Naples, 3Arcispedale S. Anna, Cona, Ferrara, Italy, 4Laiko General Hospital, Athens, Greece, 5Ospedale “A. Perrino”, Brindisi, 6AORN “A. Cardarelli”, Naples, 7ARNAS Garbaldi, Catania, 8CEMEF, Medicina 2, Modena, Italy, 9Accelarion Pharma Inc, Cambridge, 10Celgene Corporation, Summit, United States

Background: Luspatercept (ACE-536), a fusion protein containing a modified activin receptor type IIb, is being developed for the treatment of β-thalassemia. Luspatercept binds to select TGF-β superfamily ligands (such as GDF11) reducing aberrant Smad2/3 signaling and promoting late-stage erythroid differentiation and increased hemoglobin (Hgb). Luspatercept corrected the effects of ineffective erythropoiesis in a mouse model of thalassemia (Surargani R, Blood, 2015). Increased Hgb levels have been tolerated in a phase 1 study in healthy volunteers (Attie K, Am J Hematol, 2014).

Aims: This ongoing, phase 2, multicenter, open-label study followed by a long-term extension (ext) study evaluates the effects of luspatercept in patients (pts) with either transfusion-dependent (TD) or non-transfusion dependent (NTD) β-thalassemia with key endpoints of erythroid response (including Hgb increase) and pt-reported quality-of-life (QoL) in NTD patients, and reductions in RBC transfusion burden in TD patients.

Methods: Inclusion criteria: age ≥18 yr and either TD (≥4 RBC U/8 weeks prior

haematologica | 2017; 102(s2) | 15

Madrid, Spain, June 22 – 25, 2017
to first dose, confirmed over 6 months) or NTD (≤14 CRC U/8 weeks prior to first dose with baseline Hgb <10 g/dL). Pts were treated every 3 weeks subcutaneously for up to 5 doses; 8 cohorts were treated at dose levels from 0.2-1.25 mg/kg. Pts in the expansion cohort and those who rolled over to the ext study were treated at ≥0.8 mg/kg with titration up to 1.25 mg/kg (base complet-

Results: In total, 64 pts were enrolled in the study (31 TD and 33 NTD), and of those, 51 enrolled in the ext study (24 TD, 27 NTD). Median (range) age (yr) was 38.5 (20-62); 67% had prior splenectomy. For TD pts, at baseline, median (range) transfusion burden was 8 U/12 weeks (4-18 U); mean (SD) liver iron concentration (LiC; mg/g dw) was 5.0 (5.3). For NTD pts, at baseline, median (range) transfusion burden was 18.5 g/dL (8.3-9.8; mean (SD) LiC L1-L4, FN) was 5.4 (3.8). In base and ext, respectively, 22/31 (71%) and 20/24 (83%) TD pts achieved ≥33% and 17/35 (51%) and 17/24 (71%) achieved ≥35% reduction in transfusion burden over any 12-week period compared to baseline. Median duration of ≥33% reduction was 6.3 months (treatment ongoing). In base and ext, respectively, 17/21 (81%) and 20/24 (83%) achieved ≥1.0 g/dL and 7/21 (33%) and 14/27 (52%) achieved ≥1.5 g/dL increases in mean Hgb over any 12-week period compared to baseline. Median duration of Hgb increase ≥1.0 g/dL over 12 weeks in responders was 13.5 months (treatment ongoing). Increases in mean Hgb over a 12-week period consisted of ≥1.0 g/dL in 15/21 (71%) pts, and few grade 3 related AEs: bone pain, myalgia, headache, musculoskeletal pain, arthralgia, and injection site pain. Of note, long-term lusopate treatment with β-thala-

S131 LONG-TERM HEALTH STATUS AFTER HSB TRANSPLANTATION FOR THALASSEMAIA: THE FRENCH EXPERIENCE

I. Rahal1, C. Galarimun1, Y. Bertrand2, C. Paillard3, P. Frange4, C. Pondarré5, P. Frange

Background: Clinical practice, allogeneic hematopoietic stem cell trans-

plantation (HSCT) is the only treatment offering a definitive cure for patients with beta-thalassemia. Its outcome has improved over the last 3 decades with current 5-year disease-free survival rates of 90% when HSCT is performed in childhood from an HLA-identical sibling. Few data are available on long-term toxicity and frequency of chronic complications after transplant.

Aims: The purpose of this study was to evaluate the long-term health status after a successful allogeneic HSCT for beta-thalassemia major in a national cohort of patients.

Methods: This French retrospective study included patients who successfully received allogeneic HSCT between 1985-2012 and were alive at least 2 years after HSCT. Study was based on data collected in the national registry of patients with beta-thalassemia and conducted in collaboration with the French Society of Hematology and the French Society of Pediatric Hematology.

Results: A total of 134 patients had received allogeneic HSCT for beta-tha-

lausma from France in 1985 to 2012. 107/134 patients experienced successful HSCT (6 after a second transplant) and were alive 2 years after transplantation. Six were not analyzed (back to their country or lost of follow-up) and two died of chronic complications before onset of long-term effects. Median age at HSCT was 5.9 years (8 month-26 years). The source was bone marrow in 85% of cases and a matched sibling donor was used in 90% of cases. Conditioning mostly consisted (85%) of busulfan and cyclophosphamide (oral busulfan in 52%). Median age at the last visit was 19 years. Chronic com-

lications, similar to those observed in patients treated with transfusion and chela-

tion therapy occurred after transplant in 12% of patients: 7 hypertrophic, 2 heart failure, 5 diabetes. 2 patients had chronic respiratory failure related to trans-

plant. The height SDS improved after HSCT if performed at a young age. Weight

S131 LONG-TERM HEALTH STATUS AFTER HSB TRANSPLANTATION FOR THALASSEMAIA: THE FRENCH EXPERIENCE

I. Rahal1, C. Galarimun1, Y. Bertrand2, C. Paillard3, P. Frange4, C. Pondarré5, P. Frange

Background: Clinical practice, allogeneic hematopoietic stem cell trans-

plantation (HSCT) is the only treatment offering a definitive cure for patients with beta-thalassemia. Its outcome has improved over the last 3 decades with current 5-year disease-free survival rates of 90% when HSCT is performed in childhood from an HLA-identical sibling. Few data are available on long-term toxicity and frequency of chronic complications after transplant.

Aims: The purpose of this study was to evaluate the long-term health status after a successful allogeneic HSCT for beta-thalassemia major in a national cohort of patients.

Methods: This French retrospective study included patients who successfully received allogeneic HSCT between 1985-2012 and were alive at least 2 years after HSCT. Study was based on data collected in the national registry of patients with beta-thalassemia and conducted in collaboration with the French Society of Hematology and the French Society of Pediatric Hematology.

Results: A total of 134 patients had received allogeneic HSCT for beta-tha-

lausma from France in 1985 to 2012. 107/134 patients experienced successful HSCT (6 after a second transplant) and were alive 2 years after transplantation. Six were not analyzed (back to their country or lost of follow-up) and two died of chronic complications before onset of long-term effects. Median age at HSCT was 5.9 years (8 month-26 years). The source was bone marrow in 85% of cases and a matched sibling donor was used in 90% of cases. Conditioning mostly consisted (85%) of busulfan and cyclophosphamide (oral busulfan in 52%). Median age at the last visit was 19 years. Chronic com-

lications, similar to those observed in patients treated with transfusion and chela-

tion therapy occurred after transplant in 12% of patients: 7 hypertrophic, 2 heart failure, 5 diabetes. 2 patients had chronic respiratory failure related to trans-

plant. The height SDS improved after HSCT if performed at a young age. Weight

CD34+AND HUMAN INDUCED PLURIPOTENT STEM CELL DIFFERENTIATION TO TRANSFUSION READY RED BLOOD CELLS
M.-J. Claessen1,2,*, E. Varga1, M. Hansen1, P. Burger1, S. Heshusius1, T. Wust1, J. Zuber3, G. Superti-Furga1,6, F. Grebien2
1Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria, 2Department of Genetics and Molecular Medicine, MedUni Vienna, Vienna, Austria, 3IMP - Research Institute for Molecular Medicine, Gaslaturm Donausiedl, Vienna, Austria, 4MTA TTK Lendület Complexity Research Group, Budapest, Hungary, 5Department of Internal Medicine , Division of Hematology & Hemostaseology, Medical University of Vienna, 6Center for Physiology and Pharmacology, Medical University of Vienna, Vienna, Austria
Background: Donor-derived red blood cells (RBC) are the most common form of cellular therapy. However the source of cells is dependent on donor availability with a potential risk of allo-immunization and blood borne diseases.
Aims: We aim to produce unlimited numbers of cultured RBC with a defined ‘universal donor’ phenotype for transfusion purposes.
Methods: To this end we prepare for a clinical test using autologous cultured RBC to test their in vivo stability. In parallel we develop methods for unlimited production of cultured RBC. An immortal source to produce in vitro cultured RBCs (cRBC), such as iPSCs would allow selection of ‘universal donor’ RBC, or provide an autologous end product with the absence of immune reactions.
Results: The in vitro production of RBC has proven to be successful, however there are barriers to overcome prior to clinical application, e.g. xeno-free culturing methods, scale up cultures to obtain transfusion units (1-2×1012 erythrocytes), and for iPSCs we need virus- and transgene-free reprogramming protocols. To solve the above mentioned issues a customized humanized GMP-grade medium (Cellquin) was generated in order to control erythroid culture parameters and to reduce culture costs. This medium allowed 1-105 times erythropoiesis from PBMCs to pure adult EBL cultures within 25 days, comparable to non-GMP commercial media. To generate iPSCs, a non-integrative polyclonstric episomal vector containing (OCT4-SOX2-KLF4-cMYC-LIN28) was used to reprogram PBMC-expanded EBLs to iPSC, displaying pluripotency potential and normal karyotype. iPSCs were adapted to single cell passage allowing directed colony differentiation using a feeder-free monolayer approach. From day 6 of differentiation Cellquin was applied with lineage-specific growth factors, resulted iPSC differentiation to EBLs which was initiated by the appearance of hemoglobin endothelium following hematopoietic specification. Our differentiation method resulted in ~150×106 CD1-CD41-CD71+CD235a+CD36- expanded EBLs from 1200iPSCs within 21 days (12 days of iPSC diff. +9 days of expansion). Further maturation of iPSC-EBLs yielded CD71+CD235a+CD36- pure orthochromatic normoblasts expressing mainly gamma globin chains (fetal) and small amount of beta globins (adult) in agreement with literature. Currently we are testing enucleation potential of matured iPSC-EBLs.
Summary/Conclusions: Here we showed that our monolayer approach is simple, highly controlled and compatible withUpscaling. Avoiding virus-, integrative reprogramming, feeders and with our GMP-grade media we maintained a cost effective system moving toward clinical application.

CEBPA-MUTANT ACUTE MYELOID LEUKEMIA IS SENSITIVE TO SMALL-MOLECULE-MEDIATED INHIBITION OF THE MENIN-MLL INTERACTION
L. Schmidt1,2, E. Heyes1, T. Eder1, J. Grembecka2, F. Grebien1
1Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria, 2Department of Pathology, University of Michigan, Ann Arbor, United States
Background: The CEBPA gene - encoding for the transcription factor C/EBPa - is mutated in 9% of patients with acute myeloid leukemia (AML). CEBPA N-terminal mutations lead to selective loss of full length C/EBPa p42 expression without affecting translation of a balanced of the shorter p30 isoform. As a result, C/EBPa isoforms is crucial for hematopoietic homeostasis, depletion of p42 leads to increased cell growth and blocks myeloid differentiation, resulting in the development of AML. We have recently shown that the p30 variant of
C/EBPα can act as a gain-of-function allele with distinct molecular properties. However, the mechanistic basis of C/EBPα p30-induced leukemogenesis is incompletely understood.

Aims: We hypothesized that the interaction between the oncogenic C/EBPα p30 isoform and the MLL/SET histone methyltransferase complex is required for p30-dependent epigenetic and transcriptomic changes that contribute to leukemogenesis. Therefore, we aimed to investigate the sensitivity of CEBPα mutant MLL to perturbation of MLL/SET function.

Methods: We used CRISPR/Cas9-mediated mutagenesis to interfere with the MLL/SET complex in myeloid progenitor cells from a Cebpa<sup>p30/p30</sup> AML mouse model. Cellular competition assays were used to assess changes in proliferative capacity and myeloid differentiation. Further, MLL activities was inhibited by two small molecules that block the Menin-MLL interaction. In both cases, proliferative and myeloid differentiation and apoptosis were used as readouts. Global changes in gene expression were measured by RNA-seq.

Results: We initially confirmed, via ChiP, that C/EBPα and MLL co-localize on the Cebpα<sup>p30</sup> allele, and that MLL activity is functionally coupled to gene regulation. To investigate the importance of different, annotated functional domains within the MLL protein in the context of CEBPα p30 expression, we introduced targeted mutations across the MLL gene in Cebpa<sup>p30/p30</sup> cells using the CRISPR/Cas9 system. This analysis revealed a strong dependence of Cebpa<sup>p30</sup> expression on the expression of an intact MLL protein. Surprisingly, loss of the enzymatic activity of MLL by mutual targeting of the SET domain did not significantly affect cell survival. In contrast, cells were particularly sensitive to mutations of the Menin-biding motif in MLL. MLL targeting strongly induced myeloid differentiation in Cebpα<sup>p30/p30</sup> cells as measured by decreased levels of myeloid surface markers. To test the validity of our functional assays, upon pharmacological perturbation of the MLL/SET complex, we used MI-463, a potent small-molecule inhibitor of the Menin-MLL interaction. Inhibitor treatment led to a time- and dose-dependent impairment of proliferation, induction of cell cycle arrest and increased apoptosis in Cebpα<sup>p30/p30</sup> cells. RNA-seq analysis of MI-463 treatment indicated expression changes associated with myeloid differentiation, which could be confirmed by flow cytometry. Importantly, expression of C/EBPα p30 was associated with hypersensitivity to Menin-MLL inhibition, as Cebpα<sup>p30/p30</sup> cells were 2-6 fold more sensitive than other leukemia cell lines of mouse and human origin.

Summary/Conclusions: These findings indicate that C/EBPα<sup>p30</sup>-mutated AML is highly sensitive to perturbation of the MLL/SET complex, either via genetic ablation of MLL or through pharmacological inhibition of the Menin-MLL interaction. Our data indicate that leukemic mutations of CEBPα<sup>p30</sup> selectively cooperate with the SET/MLL complex to regulate gene expression. These findings expand our understanding of and may inform new therapeutic strategies for N-terminal CEBPα mutated AML.

S135
INHIBITION OF THE MYELOID MASTER REGULATOR PU.1 AS A THERAPEUTIC STRATEGY IN ACUTE MYELOID LEUKAEMIA

Aims: A large number of studies show that PU.1 is amongst the most frequent in AML and are associated with a poor outcome. PU.1 is known to be an essential transcriptional activator of cell cycle arrest. Inhibition of PU.1 expres- sion has been shown to lead to changes in cellular metabolism, such as increased glycolysis. The FLT3 TK represents a valid therapeutic target and several FLT3 TK inhibitors (TKI) have been developed. However, despite showing activity in the preclinical setting, FLT3 TKI have displayed limited efficacy in clinical trials. Resistance mechanisms to FLT3 TKI include receptor mutations and cell intrinsic adaptive mechanisms. Amongst the latter, metabolic adaptation might play a significant role although the exact mechanisms are still ill-defined.

Aims: We hypothesized that metabolic adaptations facilitate FLT3 TKI resistance and aimed to identify early metabolic changes in FLT3<sup>mut</sup> AML, following TKI treatment, in an attempt to unveil novel therapeutic vulnerabilities.

Methods: Liquid chromatography coupled to mass spectrometry (LC/MS), using stable isotope-based carbon flux tracing, and oxygen consumption rate/extracellular acidification rate as measured by an extracellular flux analyser ( Seahorse, Agilent Technologies) were used to assess metabolic changes in response to FLT3 TKI treatment. Gene expression changes were measured by RNA sequencing. Changes in viability and reactive oxygen species (ROS) in various culture conditions were measured by FACS. Gene silencing was performed using CRISPR-Cas9 gene editing and inducible short hairpin RNA interference.

Results: Analysis of published gene expression datasets demonstrated that glycolytic, citric acid cycle (CAC), and oxidative phosphorylation genes are upregulated in FLT3<sup>mut</sup> AML. Inhibition of glycolysis and oxidative phosphorylation by downregulating genes in a stoichiometrically balanced way may lead to FLT3 TKI resistance. We found that CEBPα-targeted compounds lead to a significant reduction in viability and increase in ROS levels which could be rescued by supplementation of the media with the antioxidant N-acetyl cysteine or a cell-permeable form of the CAC intermediate α-ketoglutarate.
FLT3 TK activity may improve the eradication of FLT3mutAML cells. These data predict that a combined inhibition of glutamine metabolism and FLT3 TK inhibition by respectively counteracting oxidative while also supporting the CAC and both these fates contribute to its protective effects following FLT3 TK inhibition by respectively counteracting oxidative damage and sustaining macromolecule biosynthesis and cellular energetics. These data predict that a combined inhibition of glutamine metabolism and FLT3 TK activity may improve the eradication of FLT3mutAML cells.

**Summary/Conclusions:**

Our data suggest that upon AC220 treatment, glutamine metabolism becomes a critical metabolic dependency in FLT3mutAML cells. Glutamine metabolism is mostly channelled towards glutathione production, while also supporting the CAC and both these fates contribute to its protective effects following FLT3 TK inhibition by respectively counteracting oxidative damage and sustaining macromolecule biosynthesis and cellular energetics. These data predict that a combined inhibition of glutamine metabolism and FLT3 TK activity may improve the eradication of FLT3mutAML cells.
ment. Besides, we observed that TNT formation more likely occurs between healthy bone marrow stromal cell and endothelial cell or c-kit+ angiogenic cytokine (Ara-C) treatment. Single-cell analysis showed that stressed endothelial cells and cell lines in the early stages of apoptosis caused by cytarine (Ara-C) treatment form TNT to interact with untreated BMSCs and then mesenchymal stem cells transport mitochondria to injured endothelial cell or cell lines. However, the use of this method was inhibited in some cases, notably impaired by incubating with an F-actin-depolymerizing drug and tubulin-depolymerizing drug, indicated that these TNTs transferring mitochondria have a distinct cytoklletial composition which combined with F-actin and microtubule.

Our results also suggest that the delivery of functional mitochondria from unstimulated BMSCs to HSCs or TGF-β receptors rescues energy-suffering stressed cells and alleviates apoptosis of stressed endothelial cells, relieving its proliferation inhibition and alter its formation of capillary-like structures. Our study offers the clues to help know about cell-cell communication of niche components in the HSC niche in bone marrow.

**SHORT-TERM FEEDING OF A HIGH-FAT DIET DISTURBS LIPID RAFT/TGF-BETA SIGNALING-MEDIATED QUIESCENCE OF HEMATOPOIETIC STEM CELLS IN C57BL/6J MOUSE BONE MARROW**

F. Hermetet1,2.*, J.-P. Pais de Barros2,3, L. Delva2,1, R. Quéré1,2, J-P. Patisson2,3

1Signalizing and Physiological Pathology in Hematological Research, UMR1231 Inserm / Université Bourgogne Franche-Comté / AgroSup, 2LabEx LipSTIC, 3Lipidomic Analytical Platform, UMR1231 Inserm / Université Bourgogne Franche-Comté / AgroSup, Dijon, France

**Background:** Some studies show that a high-fat diet (HFD) induces major perturbations in murine hematopoietic stem cells (HSC) and hematopoietic system homeostasis. However, it is currently difficult to say whether these alterations are related to direct effects such as changes in lipid metabolism in HSC or indirect “side effects” on HSC, such as pathophysiology related to obesity or inflammation, which are observed after an extended diet over several months or a diet very rich in fat (>60 kJ% of fat). For example, HFD-induced obesity significantly alters hematopoiesis in bone marrow (BM), with a decreased proliferation of HSC, a general suppression of progenitors, an enhancement of lymphopoiesis, and an activation of myeloid cell production from BM progenitors. Inflammation also affects HSC homeostasis, as interferon alpha is well-known to activate dormant HSC in vivo.

**Aims:** Our strategy is to characterize the impact of a short-term HFD on HSC and hematopoiesis in non-obese C57BL/6J mice.

**Methods:** In a prospective study, C57BL/6J mice were fed a control diet (4% fat) (control) or HFD (42% fat) over a short period of 4 weeks, to investigate the direct impact of such a diet on hematopoiesis.

**Results:** While fat intake led to an increase in plasma cholesterol levels, mice did not develop obesity, and no inflammatory monocytes and no modulation of pro-anti-inflammatory cytokine levels were detected in blood and BM, respectively. A minor impact was observed on the lymphoid/myeloid ratio in blood and BM. However, we noted an increase in the number of progenitors and a loss of more than 50% of the most primitive HSC (SLAM). We validated this loss via transplantation of BM isolated from HFD-mice (Ly1) in competition with control BM (Ly2), in lethally irradiated recipient mice which only recognize 20% of the recipient hematopoiesis from HFD HSC. To further investigate lipid metabolism in HSC, we quantified the major lipid constituents in HUVECs from the apoptosis, contribute to proliferation and remodel the formation of capillary-like structures in Matrigel-coated plates of HUVECs suffer from chemotherapy stress of Ara-C.

**Summary/Conclusions:** BMSCs can transfer mitochondria via TNTs formed between BMSCs and HSCs, rescuing energy-suffering cells and alleviating stress, which can alleviate apoptosis of stressed endothelial cells, relieve its proliferation inhibition and alter its formation of capillary-like structures. Our study offers the clues to help know about cell-cell communication of niche components in the HSC niche in bone marrow.
Gene therapy, cellular immunotherapy and vaccination 1

S141 WILMS’ TUMOR 1 RNA-ECTROPORTATED DENDRITIC CELL VACCINATION AS POST-REMISION TREATMENT TO PREVENT OR DELAY RELAPSE IN ACUTE MYELOID LEUKAEMIA: FINAL RESULTS OF A PHASE II STUDY IN 30 PATIENTS

Z. Serneman1,2, S. Anguille1, A. Van de Velde1, V. Van Tendeloo1, N. Coels1, G. Nijs2, B. Stieini3, E. Lion4, V. Van Driessen1, I. Vandenbosch1, A. Verlinden1, A. Gadsisseur1, W. Schroyens1, K. Vermeulen2, M.-B. Mæs2, K. Deiteren2, R. Malfait3, E. Smits3

1Hematology, 2Laboratory Hematology, 3Center for Cell Therapy and Regenerative Medicine, ANTWEPER UNIVERSITY HOSPITAL, Edegem, Belgium

Background: Relapse is a major problem in acute myeloid leukaemia (AML) and adversely impacts survival.

Aims: The aim of this phase II study was to determine the clinical efficacy of dendritic cell (DC) vaccine therapy in AML, and, more specifically, whether this form of immunotherapy can be applied in the post-remission adjuvant setting to decrease the risk of relapse following chemotherapy and to improve survival.

Methods: We vaccinated 30 AML patients in remission following prophylactic chemotherapy, but at very high risk of relapse with autologous DCs loaded with the full-length WT1 antigen (1 WT1) antigen by means of mRNA electroporation, a technique that allows for human leukocyte antigen haplotype-independent, multi-epitope antigen presentation to T-cells. The vaccines were administered intradermally. WT1 mRNA levels in blood and marrow were followed as a measure of minimal residual disease. Circulating WT1-specific CD8+ T-cells obtained before and after the 4th dose of WT1-loaded DCs were stained with WT1-hapten-HLA-A*0201 tetramers.

To assess cell-mediated immunity in vivo, delayed type hypersensitivity (DTH) skin testing was performed 2 weeks after the 4th DC vaccination by intradermal injection; DTH-infiltrating lymphocytes collected from skin biopsies were expanded for 2-3 weeks in medium with interleukin-2, harvested, and retested for WT1 specificity and reactivity.

Results: There was a demonstrable anti-leukemic response in 13/30 patients (overall response rate 43%). Nine patients achieved molecular remission as demonstrated by normalization of WT1 transcript levels, 5 of which are sustained after a median follow-up of 109.4 months. 4 patients who went from unmaintained CR1 to CR1 by DC vaccination only. In the remaining 4 responding patients, the clinical response was characterized by stable disease as demonstrated by elevated but stable WT1 transcript levels in blood for 3-12 months and stable blood values without blasts. Five-year overall survival was 40%, as compared to 24.7% in the SEER data of the National Cancer Institute; it was significantly higher in responders than in non-responders (53.8% vs 25.0%; P<0.01). In patients receiving DCs in first complete remission (CR1), there was a vaccine-induced relapse reduction rate of 25% and the 5-year relapse-free survival was significantly higher in responders than in non-responders (50% vs 7.7%; P=0.0011). In patients ≤65 and >65 years who received DCs in CR1, 5-year overall survival was 69.2% and 30.8% respectively. Of the 30 patients, 11 are alive in CR, including 5 who relapsed after DC vaccination; 2 proceeded to allogeneic stem cell transplantation, while the 3 other patients were brought back into CR by chemotherapy alone, 2 of them surviving more than 7 and 4 years respectively after achieving CR. Long-term clinical response was correlated with increased circulating frequencies of poly-epitope WT1-specific T-cells. Long-term overall survival was correlated with interferon-γ and tumor necrosis factor-α WT1-specific responses in DTH-infiltrating CD8+ T-lymphocytes.

Summary/Conclusions: Vaccination of AML patients with WT1 mRNA-electroporated DCs can be an effective and non-toxic strategy to prevent or delay leukemia relapse after standard chemotherapy, translating into improved overall survival rates, which are correlated with the induction of WT1-specific CD8+ T-cell responses.

S142 FIRST-IN-HUMAN MULTICENTER STUDY OF BB2121 ANTI-BCMA CAR T CELL THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: UPDATED RESULTS

Y. Lin1,*, J. Berdeja2, N. Raje3, N. Munshi4, D. Siegel5, M. Liedtke6, S. Jagannath7

CELL THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: FIRST-IN-HUMAN MULTICENTER STUDY OF BB2121 ANTI-BCMA CAR T cell responses.

leukemia relapse after standard chemotherapy, translating into improved overall survival was correlated with inter-

Summary/Conclusions:

Aims: The primary objective is to determine the maximally tolerated dose of bb2121 in subjects with MM whose tumors express BCMA. Methods: CRB-401 (NCT02656992) is a multi-center phase 1 dose escalation trial of bb2121 in patients with relapsed and/or refractory MM who have received ≥3 prior regimens, including a proteasome inhibitor and an immunomodulatory agent. Results: 24 of 25 evaluable patients have ≥50% BCMA expression by flow cytometry in >50% of plasma cells. Peripheral blood mononuclear cells are collected via leukapheresis. Patients undergo lymphodepletion with Flu (30 mg/m2) Cy (300 mg/m2) daily for 3 days then receive 1 infusion of bb2121. The study follows a standard 3+3 design with planned dose levels of 5.0, 15.0, 45.0, 80.0 and 120 x 10^6 CAR+T cells.

Results: As of November 16, 2016, 11 patients had been infused with bb2121 in the first 4 dose cohorts, and 9 patients had reached at least 1 month of follow-up. As of data cut-off, no dose limiting toxicities, and no ≥Grade 2 neurotoxicities or cytokine release syndrome (CRS) had been observed. Grade 1-2 CRS has been reported in 8/11 (73%) treated patients. All patients treated with doses ≥ 120x10^6 CAR+T cells had ≥3 dose-limiting toxicities (DLTs) with ≥Grade 3 CRS on study and were removed from study. The ORR in the 9 evaluable patients is 100%, including 2 sCRs and 2 MRD-neg-ative responses (sCR and VGPR). CAR+T cell expansion has been demonstrated consistently. An additional 6 months of follow up on reported results and initial data from an additional ~10 patients will be presented.

Summary/Conclusions: A maximum tolerated dose of bb2121 in the ~100 x 10^6 dose level is feasible. CAR+T cells infused into patients with R/R B-ALL (NCT01044069).

Aims: We examined baseline and post-treatment clinical and laboratory parameters to identify factors associated with severe NTX (≥Grade 3) in our phase I clinical trial of CD19-specific 19-28z CAR T cells for adult patients (pts) with R/R B-ALL (NCT01044069).

Methods: 51 adult pts with R/R B-ALL were treated with 19-28z CAR T cells following conditioning chemotherapy at MSKCC. In order to identify clinical and serum biomarkers associated with severe NTX (sNTX), we examined demographic, treatment, and clinical blood parameters as well as in vivo CAR expansion and serum cytokines, and performed univariate and multivariate analysis.

Results: In this cohort of ALL pts, 20, 8, 2, 18 and 3 pts experienced Gr 0, 1, 2, 3, and 4 NTX, respectively. No pt developed grade 5 NTX and no cerebral edema was seen. Disease burden (≥50% blasts) at the time of T cell infusion (p=0.0045) and post-treatment sGR3 CRS (p=0.0010) were significantly associated with sNTX, but we found no association with age, weight, T cell dose, choice of conditioning chemotherapy (Flu/Cy vs S/Cy), and prior lines of treatment. Among the clinical and blood parameters, fever, low PLT, high ferritin and MCHC as well as elevated GM-CSF, IFNγ, IL-15, IL-5, IL-10, IL-2 at day 3 of T cell infusion at day 3 of T cell infusion were significantly associated with sNTX (all p<0.01). While some of these cytokines were also elevated in severe CRS cases, IL-4, IL-5 and IL-17 at day 2 and 3 are unique to sNTX. Furthermore, in vivo peak CAR T expansion at day 7 (p=0.001) significantly correlated with sNTX (p=0.01). Lastly, multivariate analysis revealed baseline PLT <60 or MCHC <33.2% and morphologic disease (>5% blasts) has 95% sensitivity and 70% specificity of identifying sNTX pts.

Summary/Conclusions: These data provide a characterization of early clinical and serum biomarkers of sNTX in adult pts receiving 19-28z CAR T cells and should help identify appropriate pts for early intervention strategy to mitigate NTX.
TARGETING FLT3 WITH CHIMERIC ANTIGEN RECEPTOR T CELLS CONFER POTENT REACTIVITY AGAINST ACUTE MYELOID LEUKEMIA

H. Jetañi1, L. García-Cadenas2, T. Nerreter1, J. Sierra2, W. Herr3, S. Thomas3, H. Einsele1, M. Hudecek
1Internal Medicine II, University Hospital Würzburg, Würzburg, Germany, 2Servicio de Hematología, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 3Klinik und Poliklinik für Innere Medizin III, Universitätssklinikum Regensburg, Regensburg, Germany

Background: Adoptive immunotherapy with chimeric antigen receptor (CAR)-modified T cells has therapeutic potential in hematologic malignancies. We are pursuing FLT3-like tyrosine kinase 3 (FLT3) as a novel CAR target in acute myeloid leukemia (AML). FLT3 is a homodimeric transmembrane protein with uniform expression on AML, irrespective of cytogenetic and histomorphologic subtype. FLT3 provides survival signals to AML blasts and is a key driver of leukemia-genesis in AML cases with internal tandem duplication (FLT3-ITD). These attributes suggest FLT3 may be an ‘Achilles heel’, making AML blasts susceptible to CAR T-cell mediated recognition and elimination.

Aims: We therefore explored the anti-leukemia efficacy of FLT3-CAR modified T cells against FLT3-ITD+ and FLT3 wild type AML in pre-clinical models in vitro and in vivo.

Methods: A FLT3-CAR comprising a single-chain variable fragment (4G8), fused to an IgG-Fc spacer, and signaling module with CD3 zeta and CD28 was encoded in a lentiviral vector (epHIV7) for gene-transfer into CD8+ and CD4+ T cells of healthy donors (n>4) and AML patients. CAR T-cell mediated cytolytic activity was evaluated in FACS/luminescence-based assays, cytokine production analyzed by ELISA and proliferation assessed by CFSE dye dilution.

Results: We confirmed specific recognition and high-level cytolytic activity of CD8+FLT3-CAR T cells against a panel of AML cell lines including THP-1 (FLT3 wild type), and Molm-13 (FLT3-ITD heterozygous). Both CD8+ and CD4+ FLT3-CAR T cells produced IFN-γ and IL-2, and underwent proliferation after antigen stimulation. FLT3-CAR T cells that we prepared from AML patients exerted specific anti-leukemia reactivity against autologous primary AML blasts, with near-complete cytoreduction within 24 hours of co-culture. Further, FLT3-CAR T cells conferred a potent anti-leukemia effect in vivo models of systemic leukemia, both with AML cell lines (Molm-13) and primary AML blasts. A single dose of FLT3-CAR T cells conferred complete eradication of leukemia from peripheral blood, bone marrow and spleen, as confirmed by bioluminescence imaging and flow cytometry. FLT3 is not expressed in any normal solid tissues and mature hematopoietic cells, but shows limited expression in hematopoietic progenitors and hematopoietic stem cells (HSCs). Preliminary data show that FLT3-CAR T cells recognize FLT3+/high normal HSCs and interfere with normal hematopoiesis, but preserve a proportion of HSCs capable of reconstituting hematopoietic lineages. Studies to assess recognition of normal HSCs in vivo are ongoing.

Summary/Conclusions: Collectively, our data demonstrate that T cells expressing a FLT3-specific CAR mediate potent reaction activity against FLT3 wild type and FLT3-ITD+AML in vitro and in vivo, and establish FLT3 as a novel CAR target in AML. FLT3-ITD positivity identifies a high-risk AML subgroup that may particularly benefit from adoptive therapy with FLT3-CAR T cells, e.g. in order to achieve ‘minimal residual disease’ (MRD) negativity prior to allogeneic HSC transplantation. Our data further suggest that in contrast to CD33 and CD123, which are pursued as alternative CAR targets in AML, targeting of FLT3 may preserve a fraction of normal HSC and enable the implementation of CAR therapy outside the transplant setting.
Background: Allogeneic hematopoietic stem cell transplant (HSCT) offers curative therapy for children who lack an available HLA-identical donor with hematopoietic disorders such as Primary Immune Disorders (PIDs), hemoglobinopathies, erythroid disorders and acute leukemias. γT cell depletion mitigates the risk of GVHD after haplo-HSCT, but is associated with extended immunodeficiency, leading to complications due to infections. We have performed γT CR-depleted haplo-HSCT with post-transplant infusion of BPX-501 gene modified γT cells to allow for more rapid immune reconstitution. Upon occurrence of GVHD, administration of rimiducid (AP1903) dimerizes the Cas9 suicide switch and rapidly induces apoptosis of the transduced BPX-501 cells and mitigates the GVHD.

Aims: This study was performed to determine the impact of BPX-501 γT cell infusion on outcomes (treatment related mortality (TRM), disease recurrence, GVHD incidence and immune reconstitution) after HSCT.

Methods: We report on a large multicenter, prospective Phase I/II study enrolling children receiving γT cell-depleted Haplo-HSCT. Patients were infused with BPX-501 γT cells 2 weeks post-transplant. 104 patients have >100 day follow-up, 81 patients have follow up ≥180 days and 51 with >1 year follow-up. All patients received myeloablative therapy and low dose ATG prior to transplant. No pharmacologic GVHD prophylaxis was given (Table 1).

Table 1. Diagnoses of Patients with >100 day follow-up.

Results: Cumulative incidence of TRM remains very low at 100 days (0%), 180 days (1.6%) and 1 year (2.8%). Of the 81 patients with >180 day follow-up, 20 patients had acute GVHD 1-3 (24.7%) (Figure 1A); 10 with Grade 1, 8 with Grade 2, 2 with Grade 3 and 1 Grade 4 skin. Mild cGVHD was seen in 4 patients with Grade 2 GVHD with rapid resolution of symptoms, as it did in the severe cGVHD patient. In both malignant and non-malignant patients, CD3, CD4 and CD8 (Figure 2B) and B cells (Figure 3C) immune reconstitution was brisk. CD3+CD4+ T-cells were detectable at one year via flow cytometry analysis of peripheral blood. In Wiskott-Aldrich patients, platelet recovery remains in the normal range at 180 days with mean platelet counts of 246.3±29/μL. At 180 days and 1 year, the patients with hemoglobinopathies remain transfusion-free with a normal mean Hgb value of 11.4 g/dL.

Summary/Conclusions: These data suggest that infusion of BPX-501 modified γT cells may facilitate γT cell depleted Haplo-HSCT in children who would benefit from HSCT for either malignant or non-malignant conditions. The availability of a suicide gene mechanism in donor γT cells infused after γT depleted Haplo-HSCT, results in low rates of infection and rapidly reversible GVHD when the dimer is infused to activate the suicide switch. Rapid cellular and humoral immune reconstitution makes BPX-501 after γT depletion a safe and viable option for children who do not have a matched donor transplant and in whom transplantation has been deemed curative.
for a selected guide RNA confirmed no detectable genomic cleavage at over 5000 predicted off-target sites with a detection sensitivity of 0.2%, supporting its safety for clinical use. Finally, we have demonstrated editing rates of >85% at clinical scale in a GMP-capable manufacturing facility to enable clinical development for SCD and β-Thal. Required safety toxicology studies are ongoing.

Summary/Conclusions: We have developed and characterized two independent GEMMs, in addition to the Pax5+/−-infection model (1), which were exposed to a common infection environment. These represent childhood BCR-ABL1p190 BCP-ALL and the most common subtype ETV6-RUNX1 BCP-ALL. Both model systems ensure Sca1-directed expression of BCR-ABL1p190 or ETV6-RUNX1 in HSPCs. Pax5+/− mice acquire constitutive activating Jak3 mutations (6/9) in a susceptible B-cell precursor population (extramedullary lymphoma (EML)) as a potential molecular mechanism identifying the infection dependent leukemic clone evolves to BCP-ALL. Aims: To understand the role of infection exposure in the etiology of childhood BCP-ALL.

Background: The German Hodgkin Study Group (GHSG) applies the intensive eBEACOPP regimen (dose-escalated bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone) to all newly diagnosed advanced-stage HL patients regardless of their individual risk-profile. However, some patients might not be in need of such an intensive treatment to achieve cure. Unfortunately, baseline risk factors as defined in the international prognostic score cannot identify these patients reliably. Recent clinical research suggests that early metabolic response assessment after 2 cycles of therapy using FDG-PET (PET-2) can better predict the individual outcome. In particular, a rapid response as determined by PET-2 negativity might allow reducing the overall treatment intensity.

Aims: To assess the feasibility of decreasing the number of eBEACOPP cycles in patients with negative PET-2 without loss of efficacy as determined by progression-free survival (PFS).

Methods: Between 05/2008 and 07/2014, we recruited patients with newly diagnosed, advanced-stage HL aged 18–60 years. All patients gave written consent before study entry. PET-2 was centrally assessed with FDG uptake not higher than the mediastinal blood pool defined as negative. Patients with negative PET-2 were randomly assigned to receive 6 or 2 additional cycles (i.e. 8 or 4 cycles of eBEACOPP in total, respectively). PET-positive residues after chemotherapy were irradiated. Based on the results of our previous HD15 trial, the protocol was amended in June 2011 and the standard therapy was reduced from 8 to 6 cycles of eBEACOPP in total. The trial was designed to exclude inferiority of 6% or more of the experimental treatment (4 cycles of eBEACOPP) compared with the pooled standard treatment (8 or 6x cycles of eBEACOPP) at 5 years.

Results: We enrolled 2,101 patients. 1,005 patients with negative PET-2 were randomly assigned to either 8/6 cycles of eBEACOPP (n=504) or 4 cycles of eBEACOPP (n=501). With a median follow-up of 55 months, estimated 5-year PFS in the per-protocol set was 90.8% (87.9–93.7) with 8/6 cycles of eBEACOPP and 92.2% (89.4–95.0) with 4 cycles eBEACOPP (difference +1.4%, 95% CI -2.7–5.4, excluding the non-inferiority margin of -6%). In the standard arm, 95% of patients had at least one acute hematological toxicity of CTCAE grade 3-4 compared with 90% in the experimental arm, including severe infections in 75 (15%) and 38 (8%), respectively. Acute severe organ toxicities were documented for 91 (18%) and 38 (8%), respectively. 25 patients (5%) in the standard group (8/6 cycles of eBEACOPP and 9 (2%) in the experimental group (4 cycles of eBEACOPP) died; most frequent cause of death was second malignancy (11 and 1 patient, respectively). No patient in the experimental group died from treatment-related toxicities. Estimated 5-year overall survival (OS) in the per-protocol set was 95.4% (93.4–97.4) with standard eBEACOPP, and 97.7% (96.2–99.3) with 4 cycles of eBEACOPP (log-rank p=0.004).

Summary/Conclusions: Metabolic response assessment using FDG-PET after 2 cycles of eBEACOPP allows the reduction from therapy with 8/6 to only 4 cycles without loss of efficacy as determined by PFS in advanced-stage HL patients. Furthermore, the abbreviated treatment with 4 cycles of eBEACOPP is associated with improved tolerability and consequently leads to a significant OS benefit over standard therapy. PET-guided reduced therapy with eBEACOPP combines outstanding efficacy with high safety. We therefore recommend this treatment strategy for advanced-stage HL patients.
Acute lymphoblastic leukemia - Biology 1

TARGETED SINGLE CELL SEQUENCING TO IDENTIFY MUTATIONAL HIERARCHY IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

J. De Bie1,*, S. Demeyer1, E. Geerdens1, A. Uyttebroeck2, N. Boecx1, J. Coels1
1CME, KU Leuven, 2Pediatric Oncology, Laboratory Medicine, UZ Leuven, Leuven, Belgium

Background: Acute lymphoblastic leukemia (ALL) is a common childhood malignancy caused by cloning proliferation of immature B or T lymphoid cells. ALL patients are primarily young children who respond well to chemotherapy, with survival rates above 85%. However, if relapse develops, survival rates drop to 15-50%. Recent studies have shown that at diagnosis, different ALL subtypes carry specific mutations that are likely the result of clonal branched evolution. Understanding this clonal evolution and the order at which mutations are acquired can provide improved insights into the origins of leukemia relapse.

Aims: To use single-cell sequencing to investigate (i) the heterogeneity of leukemic T-ALL cells present at diagnosis and (ii) unravel the order in which mutations were acquired during leukemia evolution.

Methods: Bone marrow samples taken at diagnosis and remission from 4 T-ALL patients underwent whole genome and RNA sequencing. Somatic mutations, indels and chromosomal translocations were confirmed using Sanger sequencing. Primers were designed to specifically target these genetic alterations, and included 46 primers against heterozygous SNPs for quality control assessment. A total of 1517 single cells (average of 379 cells per patient) were sorted using flow cytometry or a microfluidic device and analyzed with targeted sequencing. Cells were discarded from further analysis if focus and allelic drop-out exceeded 33.3%. Jaccard hierarchical clustering was applied to identify subclones and a new graph-based algorithm was developed to determine the order of mutation acquisition. Single CD34+CD38- hematopoietic stem/progenitor cells (HSPCs) from the same samples were also isolated to test for the presence of mutations in early progenitors.

Results: We detected between 2 and 4 separate clones in each T-ALL patient sample. Every patient harbored one dominant clone comprising 46 to 98% of all single cells that was highly mutated, accompanied by a number of smaller subclones carrying fewer mutations. No mutually exclusive mutations, fusion genes or deletions were observed between the clones arguing against independent leukemic clonal initiation events. Instead, a more stepwise clonal hierarchy in spleen weights, and 20-50% reduction of bone marrow engraftment. Spleen weights of ABT-199 treated RPL10 WT mice were only slightly increased as compared to control weights of healthy NSG mice. In contrast, mice xenografted with RPL10 WT T-ALL samples showed poor in vivo responses to ABT-199 treatment and all animals showed progressive disease. Bcl-2 overexpression induced by peroxisomal hyperactivation was defined as new target in RPL10 R98S defective T-ALL. Additionally, due to peroxisomal hyperactivation, a peroxisomal oxidase involved in purine degradation may have contributed to waste product of purine degradation, uric acid, was elevated above reference levels in the blood of RPL10 R98S mutant mice through enhanced expression of peroxisomal enzymes Acox1, Acox3 and Paox. This expression facilitated peroxisomal β-oxidation of long chain fatty acids which are substrates for PPARγ and which were consequently upregulated together with CPT1A. Peroxisomal hyperactivation causes high intracellular H2O2 levels, containing the observed elevated levels of reactive oxygen species (ROS) in RPL10 R98S cells that could not be scavenged by the increased catalase expression. High ROS levels and enhanced PPARγ binding drives the constitutive overexpression of anti-apoptotic protein B-cell lymphoma 2 (Bcl-2), responsible for the leukemia cell survival benefit of RPL10 R98S cells. Bcl-2 targeted therapy using venetoclax (ABT-199) reduced the expansion of RPL10 R98S knock-in BM cells by 50%, while RPL10 WT BM cells were not inhibited by ABT-199. In vivo, DMSO or ABT-199 50mg/kg therapy was started after the engraftment of >2% human cells in the blood of mice xenografted with T-ALL samples and was maintained 1wk till disease end stage. RPL10 R98S xenografted mice that received ABT-199 therapy presented a complete inhibition of human CD45+ leukemia progression in the blood, which was characterized by a 70-85% reduction in spleen weights, and 20-50% reduction of bone marrow engraftment. Spleen weights of ABT-199 treated RPL10 R98S xenografted mice were only slightly increased as compared to control weights of healthy NSG mice. In contrast, mice xenografted with RPL10 WT T-ALL samples showed poor in vivo responses to ABT-199 treatment and all animals showed progressive disease. Bcl-2 overexpression induced by peroxisomal hyperactivation was defined as new target in RPL10 R98S defective T-ALL. Additionally, due to peroxisomal hyperactivation, a peroxisomal oxidase involved in purine degradation may have contributed to waste product of uric acid, was elevated above reference levels in the blood of RPL10 R98S mutant pediatric T-ALL patients at diagnosis (Figure 1).

Summary/Conclusions: We demonstrate that T-ALL patients have limited heterogeneity at diagnosis and that targeted single cell sequencing can be used to determine the cell of origin and the order of mutation acquisition. These data also illustrate that HSPCs at remission carry a few early, pre-leukemic events, while highly mutated HSPCs are eradicated during treatment, which is in line with long term remission in T-ALL.

Background: The ribosomal protein L10 (RPL10) R98S mutation occurs in 8% of pediatric T-cell acute lymphoblastic leukemia (T-ALL) cases. RPL10 R98S leads to a proliferation defect in lymphoid cells but a specific contribution in pediatric T-ALL remains unclear. Treatment intensification and risk stratification has reduced the relapse rate of T-ALL to ~15% but further improvements will require strategies that focus on specific subtypes as RPL10 R98S; if the long-term sequelae of toxic therapy are to be avoided.

Aims: 1) Explore the oncogenic contribution of the RPL10 R98S mutation in pediatric T-ALL. 2) Define new therapeutic opportunities for RPL10 R98S defective T-ALL. 3) Identify a biomarker indicative of the RPL10 R98S mutation in T-ALL.

Methods: Quantitative label-free proteomics was used to screen for protein differences between RPL10 WT and R98S expressing Ba/F3 cells. Hits were confirmed by western blot in lineage negative (lin-) bone marrow (BM) cells extracted from RPL10 WT and R98S knock-in mice and in RPL10 WT and R98S pediatric T-ALL samples. Serial re-plating was established by plating 2000 cells/ml in Methocult. Oxidative stress and mitochondrial activity was determined by Dihydroethidium and mitotracker. Viable cell counts were determined by Annexin V exclusion. Chromatin immunoprecipitation was performed using the Imprint ChIP kit followed by qRT-PCR. Human pediatric T-ALL samples were transplanted into NOD-SCID/IL2γ−/−(NSG) mice for in vitro and in vivo inhibitor studies.

Results: The RPL10 R98S mutation provided a cell survival advantage in Ba/F3 cells and in serial re-plating assays of lin- BM cells derived from RPL10 R98S knock-in mice. Proteomic profiling revealed metabolic reprogramming in RPL10 R98S cells through enhanced expression of peroxisomal enzymes Acox1, Acox3 and Paox. This expression facilitated peroxisomal β-oxidation of long chain fatty acids which are substrates for PPARγ and which were consequently upregulated together with CPT1A. Peroxisomal hyperactivation causes high intracellular H2O2 levels, containing the observed elevated levels of reactive oxygen species (ROS) in RPL10 R98S cells that could not be scavenged by the increased catalase expression. High ROS levels and enhanced PPARγ binding drives the constitutive overexpression of anti-apoptotic protein B-cell lymphoma 2 (Bcl-2), responsible for the leukemia cell survival benefit of RPL10 R98S cells. Bcl-2 targeted therapy using venetoclax (ABT-199) reduced the expansion of RPL10 R98S knock-in BM cells by 50%, while RPL10 WT BM cells were not inhibited by ABT-199. In vivo, DMSO or ABT-199 50mg/kg therapy was started after the engraftment of >2% human cells in the blood of mice xenografted with T-ALL samples and was maintained 1wk till disease end stage. RPL10 R98S xenografted mice that received ABT-199 therapy presented a complete inhibition of human CD45+ leukemia progression in the blood, which was characterized by a 70-85% reduction in spleen weights, and 20-50% reduction of bone marrow engraftment. TRANSLATOME ANALYSIS OF THE T-ALL ASSOCIATED RIBOSOMAL PROTEIN L10 R98S MUTATION REVEALS ALTERED SERINE METABOLISM

L. Fancello1,2, K. Kampen1, T. Girardi1, J. Op de Beeck1, J. Verbeeck1, P. Vermeersch2, D. Cassiman3, F. Loayza Puch4, R. Agami4, R. B. Lock1, M. J. Henderson1, M. Haber1, M. D. Norris1, R. Sutton1, R. B. Lock1, M. J. Henderson1, K. de Keersmaecker1

Department of Molecular Oncology, KU Leuven - University of Leuven, 2Department of Laboratory Medicine, 3Department of Gastroenterology-Hepatology and Metabolic Center, University Hospitals Leuven, Leuven, Belgium, 4Division of Biological Stress Response, The Netherlands Cancer Institute, Amsterdam, Netherlands

Background: We previously described a recurrent arginine-to-serine mutation on residue R98 (R98S) in ribosomal protein L10 (RPL10), with a frequency of 8.6% in pediatric T-ALL cases. The R98S mutated residue contacts the catalytic core (peptidyltransferase center, PTC) of the ribosome and causes ribosome biogenesis, Ptd ribosome, and translational fidelity defects in yeast and lymphoid cells. These observations suggest that the RPL10-R98S mutation may contribute to T-ALL pathogenesis by inducing translational changes.

Aims: The spectrum of translated proteins (translatome) of RPL10 R98S mutants was investigated in order to identify translational changes caused by the mutation and potentially driving oncogenesis.

Methods: We performed reverse footprinting (RNA sequencing of ribosome bound RNA), polysomal RNA sequencing, total RNA sequencing and mass spectrometry based quantitative proteomics on engineered RPL10-R98S or RPL10-WT mouse lymphoid Ba/F3 cells.

Results: RPL10 R98S cells showed significant upregulation for 3% (n=178) of the measured proteins and a downregulation of 1% (n=68). Moreover, polysomal RNA sequencing and ribosome footprinting showed respectively 57 and 22 genes with significantly higher translational efficiency in RPL10 R98S, and 22 and 29 genes, with reduced translational efficiency. Among them, we also found genes involved in T cell differentiation and proliferation. In particular, Mapk8 presented reduced translational efficiency in the ribosome footprinting, potentially due to differences in ribosome occupancy of an upstream ORF, whereas the transcription factor Ifi25, a master regulator of the upregulated transcripts, was overexpressed at the transcriptional and protein level. Interestingly, the results from the mass spectrometry and the polysomal RNA sequencing datasets showed a significant enrichment and upregulation of members of the JAK-STAT signaling pathway with Cstf2rt2, Jak1 and several Stats being 1.5-fold elevated at the protein level and higher translation efficiency for Lf1, Ihh10, Gzma and Ili71. Another interesting candidate showing 5-fold upregulated protein levels was phosphoserine phosphatase (PspH), a key enzyme in serine biosynthesis. Ribosome footprinting revealed that this upregulation originates from a combination of higher transcription and translational efficiency of the encoded gene. Elevated PspH protein levels were confirmed by immunoblot in the RPL10 R98S Ba/F3 cells and in hematopoietic cell cultures derived from RPL10 R98S knock-in mice. Interestingly, harvested medium from RPL10 R98S Ba/F3 cells contained higher residual serine levels compared to RPL10-WT mouse lymphoid Ba/F3 cells. Our data suggest that RPL10 R98S expressing cells enhance their endogenous serine production, leaving more serine that can support survival of neighboring cells.

Summary/Conclusions: Analysis of the translational changes associated with the RPL10 R98S mutation reveals alterations for genes involved in T cell differentiation and proliferation: the atypical MAP kinase Mapk8, whose reduced translational efficiency still needs to be validated at the protein level, and the transcription factor Ifi25. Alterations were also found in the JAK-STAT signaling, an established oncogenic cascade in T-ALL. Moreover, this is the first description of a mutation in T-ALL that is linked to alterations in cellular serine biosynthesis.

REPOSITIONING EXISTING DRUGS AS NOVEL THERAPEUTICS: OXIDATIVE STRESS AS A TARGET TO REDUCE RISK-LEUKAEMIA IN CHILDREN

M. Karsai1,2, K. Somers1,2, A. Mariana1,2, T. Failes1,2, G. M. Adm1,2, U. R. Kees1,2, M. Haber1, M. D. Norris1, R. Sutton1, R. B. Lock1, M. J. Henderson1,1Children’s Cancer Institute, Lowy Cancer Research Centre, University of New South Wales, 2ACRF Drug Discovery Centre for Childhood Cancer, Children’s Cancer Institute, Lowy Cancer Research Centre, University of New South Wales, Sydney, New South Wales, 3Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia

Background: Remarkable improvements made in the treatment of childhood acute lymphoblastic leukemia (ALL) in past decades have resulted in 5-year survival rates approaching 90%. However, prognosis remains dismal for certain subgroups of high-risk patients, including poor responders to induction therapy, infants with ALL that harbor rearrangement of the Mixed Lineage Leukaemia (MLL/KMT2A) gene, and children with Philadelphia chromosome positive ALL. In particular, infant ALL patients with MLL disease have survival rates below 50% despite the use of intensified treatments, necessitating the development of new effective, less toxic therapies for them.

Aims: The aim of this study is to identify candidates that target MLL-rearranged leukaemia cells using drug-repurposing, whereby an approved drug is applied to treat a disease other than the one for which it was originally intended. This drug discovery strategy is gaining popularity as it potentially avoids the lengthy process of drug development and FDA approval.

Methods: 3707 approved drugs and pharmacologically active compounds were initially screened against an infant ALL cell line with MLL-rearrangement, PERR45 and a paediatric leukaemia cell line wild-type for MLL, CEM, using a resazurin-based cell viability assay. Hit compounds were further tested in a panel of 20 paediatric high-risk ALL patient-derived xenograft (PDX) cell lines. Compounds were subsequently evaluated in vitro for cytotoxic activity against a panel of 20 paediatric high-risk ALL patient-derived xenograft (PDX) cells. Apoptosis was measured by Annexin V positivity and PARP cleavage. Reactive oxygen species (ROS) levels were assessed by DCF-DA staining and detection by flow cytometry. Nrf2 protein expression levels were measured by Western blotting.

Results: The screen resulted in the identification of two FDA-approved drugs that were preferentially cytotoxic against MLL-rearranged ALL and other leukaemia cell lines, compared to solid tumours and normal cells. Auranofin was originally developed for rheumatoid arthritis and was later fast-tracked into Phase II clinical trial for adult chronic lymphocytic leukaemia, while Disulfiram, which was developed for treatment of chronic alcoholism, is currently in several clinical trials for cancers including metastatic melanoma and glioblastoma. These drugs also showed potent activity in high-risk paediatric leukaemia PDX cells in vitro, including MLL-rearranged ALL and Philadelphia-positive ALL with IC50 values between 100-400 nM for Auranofin and 30-60 nM for Disulfiram. Induction of apoptosis was evident at 6 hours post Auranofin treatment, or after 12 hours Disulfiram treatment. Each drug significantly increased intracellular ROS as early as one hour post-treatment (p<0.01), which was accompanied by induction of Nrf2, a master regulator of the antioxidant response. Incubation with ROS scavenger N-acetyl cysteine prior to treatment with either drug prevented the increase in cellular ROS levels (p<0.05) and rescued cells from apoptosis (p<0.0001), indicating involvement of reduction-oxidation and increased ROS generation as mechanisms of leukaemia cell death induced by these drugs.

Summary/Conclusions: In summary, we have identified two FDA-approved drugs that demonstrated potent anti-leukaemia activity through induction of ROS, potentially opening up new avenues for clinical treatment of high-risk paediatric ALL. We will now be testing these potential therapies in vivo using relevant PDX models of high-risk paediatric ALL.

P155

TP53 MUTATIONS DISRUPTING DNA BINDING LEAD TO CHEMOTHERAPY RESISTANCE IN ACUTE LYMPHOBlastic LEUKEMIA

M. Pogodzinski1,2, F. Yang1,2,3, H. Sun2, J. Hof1, C. Eckert1, B.-B. Zhou2,3, R. Piskur-Chwalszynska1,2

1Pediatric Oncology and Hematology, Charité - Universitätsmedizin Berlin, Berlin, Germany, 2College of Life Sciences, Beijing Normal University, Beijing, 3Oncology and Hematology, Shanghai Childrens Medical Center, Shanghai, China

Background: Polychemotherapy resistance is a major challenge in the treatment of children with relapsed acute lymphoblastic leukemia (ALL). Mutation of TP53 is tightly associated with poor response to treatment in ALL relapse patients.

Aims: We studied mutations of TP53 in ALL relapses and in six ALL cell lines to shed light on mechanisms and pathways mediating TP53 dependent drug resistance in relapsed ALL. First, we analyzed the spectrum of TP53 mutations in ALL relapses and correlated it to treatment response of patients. Second, we studied drug sensitivity in TP53 wild type (wt) versus TP53 mutant ALL cell lines.

Methods: TP53 was sequenced by the method of Sanger sequencing. Drug sensitivity was determined by IC50 in ALL cell lines. Drugs included in the study were DNA damage inducing agents as topoisomerase II inhibitors, alkylating agents, nucleotide analogs, and other agents, mostly of which are used in ALL relapse treatment protocols.

Results: We identified 20 different TP53 mutations in 34 patients. We classified TP53 mutations into ‘hot spot’ (R175, G245, R248, R273 and R282), non-hot spot and frameshift, respectively. We found that hot spot TP53 mutations were enriched in ALL relapse patients with non-response to treatment compared to good responding patients (64 versus 27%). In ALL cell lines, we could confirm TP53 mutations in Jurkat (R196) and Lucony (Y272M) and identified R248P in MHH. Three ALL cell lines were TP53 wt (SUP-B15, UCO-B6, NALM-6) and used as controls. Topoisomerase II inhibitors upregulated expression of wt p53. In contrast, nucleotide analoga showed no p53 induc-
tion. IC50 measurements showed that TP53 mutations lead to resistance against topoisomerase II inhibitors and alkylating agents, but not against other drugs. The upstream pathway of p53 (CHK1, CHK2) and DNA damage recognition (γH2AX) were not impaired in the six ALL cell lines. To study the effect of TP53 mutation on resistance to treatment in more detail, we focused on the R248P mutation, located in hot spot codon 248, that we found in a relapsed patient with non-response to treatment and in the MHH cell line. Using a CRISPR/Cas9 knockout (KO) of endogenous p53 and lentiviral based re-expression in NALM-6, we generated p53 KO, and KO+wt p53, KO+R248P and KO+GFP cell lines. The KO cells showed a similar resistance to DNA damage inducing drugs as KO+R248P cells. Overexpression of wt p53 in KO cells did not affect sensitivity to DNA damage inducing drugs. In contrast to wt p53, R248P did not inhibit cell proliferation under drug treatment. We found that this mutant was unable to induce downstream targets of p53 (p21, BAX). Moreover, ChIP-seq showed that R248P cannot bind the promoter and induce expression of typical p53 targets MDM2, p21, BAX, BCC3/PUMA, FAS and TNF. This result indicates that R248P is different from the consensus element of p53. However, the binding motif analysis showed that the R248P mutant still binds DNA at a different and purine-rich sequence. In summary, R248P leads to wt p53 function and mediates resistance to topoisomerase II inhibitors and alkylating agents.

Summary/Conclusions: Overall, our results show that mutations affecting TP53 hot spots, in particular codon 248, are associated with resistance of ALL cells to chemotherapy and reveal first insights into underlying mechanisms and pathways.

GENETIC ACTIVATION AND THERAPEUTIC TARGETING OF PIM1 IN T-CELL ACUTE LYMPHOCYTIC LYMPHOMA

R. De Smedt1, S. Peirs1, J. Morscio1, J. Roels1, S. Goossens1, A. Touzart2, A. Uyttendaele3, N. Van Roy4, T. Lammens4, L. Mussolin5, E. Macintyre2, P. Vandenbergh6, P. Van Vlierbergh7

1Center for Medical Genetics, Ghent University, Gent, Belgium, 2Department of Hematology, APHP-Hôpital Necker, Paris, France, 3Center for Human Genetics, University Hospitals Leuven, Leuven, 4Department of Pediatric Hematology-Oncology and Stem Cell Transplantation, Ghent University Hospital, Gent, Belgium, 5Instituto di Recerca Pediatrico, Fondazione Città della Speranza, Padua, Italy

Background: T-cell acute lymphoblastic leukemia (T-ALL) and T-cell acute lymphoblastic lymphoma (T-LBL) are aggressive immature T-cell malignancies that are considered one disease entity according to the World Health Organization (WHO). Both T-ALL and T-LBL are often characterized by improper T-cell receptor (TCR) and TCR-induced activation leading to aberrant activation of proto-oncogenes.

Aims: Despite some genetic and phenotypic similarities between T-LBL and T-ALL, T-ALL risk group stratification cannot be extrapolated to T-LBL patients. T-ALL cases are considered one disease entity according to the World Health Organization (WHO). Both T-ALL and T-LBL are often characterized by improper T-cell receptor (TCR) and activation leading to aberrant activation of proto-oncogenes.

Methods: Here, we used Targeted Locus Amplification (TLA, de Vree et al., Nat Biotechnol, 2014) to identify a novel translocation (leading to PIM1 kinase overexpression) in a human T-LBL patient. Unraveling the importance of PIM1 activation in T-LBL disease biology prompted us to develop RNA sequencing and phosphoproteomic studies to identify its downstream targets. T-LBL patient engraftment in NSG mice enabled us to study the therapeutic potential of PIM1 inhibition.

Results: Applying the TLA technique to identify the location of a novel T-cell acute lymphoblastic leukemia (T-LBL) patient resulted in aberrant activation of the PIM1 proto-oncogene. PIM1 is a constitutively active serine/threonine kinase involved in cell cycle progression, apoptosis, transcription and drug resistance and is overexpressed in a variety of human cancers. Further characterization of this PIM1 rearranged patient sample revealed an extensive genetic alteration that targeted known T-ALL/T-LBL oncogenes and tumor suppressor genes, including NOTCH1, IKZF1, EP300 and CDKN2A. Comparing PIM1 expression between normal T-cell subsets, T-ALL and T-LBL patient samples showed that T-LBL patients express significantly higher PIM1 levels, confirming PIM1 activation is implicated in T-LBL disease biology. Next, we looked at allelic expression ratios of PIM1 and interestingly, we found skewed allelic expression in T-LBL, but not in T-ALL patients. To study the oncogenic properties of PIM1 in the context of malignant T-cell transformation, we did RNA sequencing and phosphoproteomics on the T-ALL/T-LBL tumor line HSB-2 (high PIM1) after PIM1 inhibition with TP-3654 (Foulks et al., Neoplasia, 2014). These data revealed that PIM1 inhibition has broad effects on transcription and phosphorylation substrates involved in cell cycle, translation and apoptosis. Finally, we evaluated the therapeutic potential of PIM1 inhibition. Daily TP-3654 treatment (4 weeks) of T-LBL engrafted NSG mice resulted in strong anti-leukemic effects. Currently, we are evaluating if combination of PIM1 inhibition with other therapeutics triggers a more profound anti-leukemic response (Figure 1).

Summary/Conclusions: All together, our study identifies PIM1 as a putative oncogene in T-LBL and suggests that inhibition of this serine/threonine kinase could serve as a novel therapeutic strategy in this aggressive T-cell neoplasm.
and Center for Childhood Cancer Research, Children’s Hospital of Philadelphia, 3Pediatrics, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, United States

**Background:** B-cell acute lymphoblastic leukemia (B-ALL) is the most common malignancy of childhood and is highly curable with modern risk-adapted chemotherapy. However, 15–20% of children and >60% of adults with B-ALL develop chemoresistance and relapse, indicating need for new therapies. Addition of kinase inhibitors to chemotherapy for patients with BCR-ABL1-rearranged (Ph+) B-ALL has dramatically improved event-free and overall survival, and similar approaches are now under active clinical investigation in patients with BCR-ABL1-like (Philadelphia chromosome-like or Ph-like) B-ALL. Recent studies have demonstrated activated spleen tyrosine kinase (SYK) signaling in various genetic subtypes of B-ALL and preclinical activity of the SYK/FLT3-JAK inhibitor fostamatinib. However, SYK activity in B-ALL and potential correlation with specific leukemia-associated mutations remains incompletely characterized. We hypothesized that constitutive activation of SYK signaling occurs across a genetic spectrum of infant and high-risk childhood B-ALL and can be therapeutically targeted in vivo with the selective SYK inhibitor entospletinib (ento).

**Aims:**

1. Assess basal SYK signaling activation in childhood B-ALL specimens.
2. Quantify treatment efficacy, pharmacokinetics (PK), and pharmacodynamic (PD) effects of ento in childhood B-ALL patient-derived xenograft (PDX) models.

**Methods:**

**Total and phosphorylated (p) SYK levels were assessed by Simple Western analysis of splenic lysates from NSG mice well-engrafted with primary pediatric B-ALL specimens (n=19 Ph-like, n=4 infant KMT2A-rearranged (R), and n=4 infant non-KMT2A-R PDX models) to identify leukemias with constitutive SYK signaling activation. To assess in vivo activity of SYK inhibition, selected B-ALL PDX models with high basal pSYK (n=2) were treated with continuous provided control, 0.03%, 0.07% ento-chow and 0.07% chow formulations (representative data in Figure 1; p<0.05). Steady state concentrations were maintained throughout the study duration with terminal PK values of 3.3 (± 0.5) and 7.9 (± 1.0) μM (0.03% and 0.07% ento arms, respectively). PD studies demonstrated dose-dependent in vivo inhibition of pERK measured in human leukemia cells within spleens of ento-treated mice versus control animals at both 0.03% and 0.07% chow formulations (representative data in Figure 1; p<0.05). Steady state concentrations were maintained throughout the study duration with terminal PK values of 3.3 (± 0.5) and 7.9 (± 1.0) μM (0.03% and 0.07% ento arms, respectively).**

**Results:**

Constitutive pSYK signaling was observed in 10/19 Ph-like, 4/4 KMT2A-R, and 1/4 non-KMT2A-R B-ALL specimens. Ento treatment of KMT2A-MLLT3 (ALL3103) and Ph-like NUP214-ABL1 (NH011) PDX models significantly inhibited ALL proliferation in vivo versus control animals at both 0.03% and 0.07% chow formulations (representative data in Figure 1; p<0.05). Steady state concentrations were maintained throughout the study duration with terminal PK values of 3.3 (± 0.5) and 7.9 (± 1.0) μM (0.03% and 0.07% ento arms, respectively). PD studies demonstrated dose-dependent in vivo inhibition of pERK measured in human leukemia cells within spleens of ento-treated mice versus control animals at both 0.03% and 0.07% chow formulations (representative data in Figure 1; p<0.05). Steady state concentrations were maintained throughout the study duration with terminal PK values of 3.3 (± 0.5) and 7.9 (± 1.0) μM (0.03% and 0.07% ento arms, respectively).

**Summary/Conclusions:** Constitutive activation of SYK signaling occurs frequently in childhood Ph-like and infant KMT2A-R childhood B-ALL. Ento treatment of B-ALL PDX models potently inhibited SYK pathway signaling proteins and significantly inhibited leukemia proliferation in vivo.

**PHARMACOLOGICAL ACTIVITY OF CB-103 – AN ORAL PAN-NOTCH INHIBITOR WITH A NOVEL MODE OF ACTION**

R. Lehal1,*, D. Weber1, V. Frismantas2, J.-P. Bourquin2, M. Bauer1, M. Murone1, F. Radtke3

1Cellestia Biotech AG, Basel, 2University Children’s Hospital, Zürich, 3Swiss Institute for Experimental Cancer Research, EPFL, Lausanne, Switzerland

**Background:** NOTCH signalling is a developmental pathway known to play critical roles during embryonic development as well as for the regulation of self-renewing tissues. Aberrant activation of NOTCH signalling leads to deregulation of the self-renewal process resulting in sustained proliferation, evasion of cell death, loss of differentiation capacity, invasion and metastasis, all of which are hallmarks of cancer. When the NOTCH pathway is inappropriately activated by genetic lesions (over expression of NOTCH ligands/receptors, GOF mutations in NOTCH receptors as well as chromosomal translocations), it becomes a major driver for NOTCH-dependent cancers and resistance to standard of care treatment. Over 250’000 patients are annually diagnosed with NOTCH dependent cancers, with no specific therapy available to date.

**Aims:** Given the importance of NOTCH signalling in human cancers, several therapeutic approaches have been utilized to block NOTCH signalling. Two of these strategies are: a) the use of monoclonal blocking antibodies (mAbs) against NOTCH ligands and receptors and b) the use of small molecule gamma-secretase inhibitors (GSIs). However, these approaches can only be effective if tumor cells express full-length ligand or receptor molecules. As validation of NOTCH as a therapeutic target, clinical activity of these in clinical studies were was observed in various trials for some of these inhibitors (mAbs, GSIs), but treatment and exposure were usually limited due to toxicities, mainly related to gastro-intestinal adverse events. On the contrary, in human cancers harboring NOTCH gene fusion due to chromosomal translocations or specific NOTCH mutations, the use of mAbs and GSIs will have very limited clinical benefits. Cellestia has decided to follow a disruptive approach, by blocking NOTCH signalling in the most downstream part of the NOTCH cascade, at the level of the NOTCH transcriptional activation complex, using small molecule inhibitors.

**Methods:** Here we report the pharmacological characterization of CB-103, a first-in-class orally-active small molecule inhibitor of the NOTCH transcriptional activation complex.

**Results:** We demonstrate that in vitro CB-103 potently inhibits NOTCH signalling in various leukemic and lymphoma cell lines, and T-ALL blasts derived from relapse/refractory patients. In addition, CB-103 exhibited anti-tumor efficacy in multiple in vivo models of NOTCH-driven T-ALL using T-ALL cell lines and patients derived xenograft models.

**Summary/Conclusions:** Toxicology studies have been completed and clinical development of CB-103 with a first-in-human Phase I/IIA clinical study in advanced solid tumors and haematological malignancies is under preparation.

IKZF1Δ4-7 CAN BE EASILY SCREENED BY PCR BUT DOES NOT PREDICT OUTCOME IN ADULTS WITH ACUTE LYMPHOBlastic LEUKAEMIA; DATA FROM 490 PATIENTS ENROLLED ON THE UKALL14 TRIAL

R.J. Mitchell1, 2, A.A. Kirkwood1, D. Wrench1, A. Fearn1, C. Schwab1, E. Lawrie2, K. Zuborne Alapi1, L. Clifton-Hadley2, P. Patrick2, T. Naughton1, A.V. Moorman4, P. Patrick2

1UCL Cancer Institute, 2CRUK and UCL Cancer Trial Centre, UCL, 3Barts Cancer Institute, QMUL, London, 4Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle Upon Tyne, United Kingdom

Background: The IKZF1 gene encodes the IKAROS zinc finger transcription factor and master regulator of lymphocyte differentiation. IKZF1 lesions are common in acute lymphoblastic leukaemia (ALL) and have been reported as independent prognostic factors for poor outcome. IKZF1Δ4-7, resulting in the dominant negative K6 isoform is the most common single IKZF1 deletion.

Aims: We aimed to generate and validate a simple, PCR-based screening assay for IKZF1Δ4-7 using an endpoint PCR assay using primers located in introns 3 and 7. The lower limit of detection was determined by serial dilution of DNA from the IKZF1-expressing cell line SUP-B15 and calculated to be 0.001%. A total of 95 samples were also tested using the MLPA P335 kit to detect the full spectrum of IKZF1 deletion. Sanger sequencing confirmed the breakpoints in 27 cases.

Results: The median age of the patients tested was 46 years (range 25-65). Overall IKZF1Δ4-7 was detected in 97/490 (20%) patients but the frequency varied by genetic subtype. Patients with BCR-ABL1 fusion had the highest IKZF1Δ4-7 frequency (46/150, 31%) followed by patients with B-other ALL (29/154, 19%). Patients with other classic cytogenetic abnormalities harbourered significantly fewer IKZF1Δ4-7 – low hypodiploidy (3/25), MLL gene fusions (3/31), t(1;19), (1/11), high hypodiploidy (2/9) and iAMP21 (0/3). MLPA did not detect any IKZF1Δ4-7 deletions that were not detected by PCR but did identify several samples with alternative IKZF1 deletions affecting different exons (see Table 1). By contrast, the PCR assay did detect six IKZF1Δ4-7 deletions undetectable by MLPA, consistent with the higher sensitivity of this approach. Interestingly, three of these samples harboured alternative IKZF1 deletions in addition to IKZF1Δ4-7. In 70 (14%) cases, we observed a “faint” PCR band. Since the biological relevance of this was not clear, the ‘faint’ bands were not included in the final analysis. Interestingly the frequency of these “faint” bands was similar across all genetic subtypes: BCR-ABL1 (14%), B-other (15%), MLL (21%), low hypodiploidy (19%). We examined the impact of IKZF1Δ4-7 on achievement of CR, persistence of minimal residual disease (MRD) at > 1 x 10⁻⁴ (igT/CSR quantitation by EuroMRD criteria) after courses 1 and 2 of therapy, EFS, OS and time to relapse, at a median follow-up of 23.1 months. Two thirds of patients (44/66) with IKZF1Δ4-7 were MRD positive at the end of phase 1 compared with 147/273 (54%) patients without the deletion (p=0.059). However, this relationship between IKZF1Δ4-7 and MRD did not persist after phase 2. We did not identify any association between IKZF1Δ4-7 and any of the other outcome parameters tested.

Table 1.

Summary/Conclusions: IKZF1Δ4-7 can be detected by a simple and cheap PCR assay, which is more sensitive than MLPA. The frequency of IKZF1Δ4-7 was broadly comparable with previous studies. However, we did not find an association between IKZF1Δ4-7 and clinical outcome in this large clinical trial sample set. We are in the process of evaluating the impact of other IKZF1 lesions.

PROGNOSTIC SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE DETECTED BY MLL FUSION GENE TRANSCRIPTS IN INFANT ACUTE LYMPHOBlastic LEUKAEMIA; UPDATED RESULTS OF 76 PATIENTS ENROLLED INTO MILLBABY STUDY

G. Tsaur1, 2, A. Popov3, T. Riger1, A. Solodovnikov1, A. Kustanovich3, O. Aleinkova3, Y. Olshanskaya3, N. Myakova4, T. Verzhbitskaya1, E. Shorkov4, O. Strenev1, O. Arakaev1, A. Vlasova1, S. Tsverinko1, L. Saveliev1

1Regional Children Hospital #1, Research Institute of Medical Cell Technologies, Ekaterinburg, 2National Research Institute of Pediatric Hematology, Oncology, and Immunology named after Dmitry Rogachev, Moscow, Russian Federation, 3Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Minsk, Belarus, 4PET Technology, 5Ural State Medical University, Ekaterinburg, Russian Federation

Background: Fusion gene transcripts (FGTs) are rarely used for minimal residual disease (MRD) monitoring in acute lymphoblastic leukemia (ALL) cases, except of Ph-positive ALL. However in infant ALL, where MLL gene rearrangements are found the majority of cases, MLL FGTs are attractive targets for MRD detection.

Aims: To estimate prognostic significance of MLL by qualitative detection of different MLL FGTs in infant ALL treated by MLL-Baby protocol.

Methods: Seventy six infants (27 boys and 49 girls) with median age of 5.8 months (range 0.03-11.83) were included in the current study. Among them there were 39 (51.3%) MLL-AF4-positive cases, 14 (18.4%) MLL-MLLT1-positive, 12 (15.8%) MLL-MLLT3-positive, 6 (7.9%) MLL-MLLT10-positive, 4 (5.3%) MLL-EPF15-positive cases. MRD detection was performed in BM samples by real-time quantitative PCR and nested RT-PCR with sensitivity non-less than 1E-04. MRD-negativity was defined as absence of FGTs in the both assays. Median of follow-up period in the observed group was 6.4 months. Inform consent was obtained in all cases.

Results: We confirmed our earlier finding that the most informative TP for the MLL-AF4 was TP4. However, TP4, TP5 and TP7 were detected in 18%, 11% and 9% of TP4-positive patients stratified to high-risk arm of MLL-Baby protocol (EFS 0.05±0.04 vs 0.78±0.07 p<0.0001; cumulative incidence of relapse 0.78±0.10 vs 0.11±0.07 p<0.0001, respectively) and for all others MLL-rearranged patients treated by intermediate risk (imR) arm (EFS 0.00 vs 0.71±0.11 p<0.0001; cumulative incidence of relapse 1.0 vs 0.29±0.10 p<0.0001, respectively). There were no significant differences in initial patients’ characteristics and treatment response criteria (on days 8, 15, 36) among 38 MRD-positive and 38 MRD-negative patients. Multivariate analysis revealed that initial CNS disease (hazard ratio (HR) 2.703, 95% CI 1.255-5.284, p=0.011) and MLL status of BM on day 15 (HR 3.990, 95% CI 1.456-10.515, p=0.003) and MRD-positivity at TP4 (HR 6.950 95% CI 2.617-18.456) were significant covariates with negative impact on hazard of unfavorable event. Based on dismal outcome of MRD-positive imR patients we tried to augment their therapy and relocated 5 of them from imR group to HR arm after TP4. Although all MRD-positive patients were sequentially relapsed, we also wanted to find out which characteristics might predict relapse in imR patients who were MRD-negative at TP4 (n=5). Of note, all these 5 relapsed patients (100%) had initial CNS disease while CNS disease was detected only in 2 out of 19 imR patients (10.5%) who stayed in complete hematological and molecular remission (p=0.003). All 5 relapsed imR patients who were MRD-negative at TP4 had breakpoint positions within intron 11 of MLL gene and they were MRD-positive by flow cytometry (MRD ≥0.01%) on day 15. None of MRD-negative patients by flow cytometry (MRD <0.01%) on day 15 relapsed later on (p<0.001).

Summary/Conclusions: MRD monitoring by detection of MLL FGTs had significant prognostic impact. MRD positivity at TP4 was an independent factor of unfavorable outcome in infants with MLL-rearranged ALL enrolled into MLL-Baby protocol irrespective of treatment arm. Treatment intensification for MRD-positive at TP4 imR patients did not improve their outcome. MRD-positivity at TP4 in imR group was associated with MRD-positivity by flow cytometry on day 15, MLL breakpoint positions within intron 11 gene and initial CNS disease.

P162

PRO-T CELL ALL/LLBL: AN ULTRA-HIGH RISK CD2-NEGATIVE DISEASE SUBTYPE IN ADULTS DEFINED BY FLOW CYTOMETRY

B. Gotrovska1, G. Rymkiewicz2, K. Domanska-Czyży2, J. Romanek-Jarosinska1, K. Blachniak3, L. Poplawska1, W. Michalski3, J. Vlasak1

1Department of Lymphoid Malignancies, 2Department of Pathology and Laboratory Diagnostics, 3Department of Biostatistics, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, Warszawa, Poland
**Background:** Risk factors for T-LBL have not been systematically evaluated, in contrast to T-ALL.

**Aims:** Our aim was to define immunophenotype of T-LBL/ALL in 71 consecutive patients by use of the flow cytometry (FCM) of tissue aspirates if peripheral blood (PB) and bone marrow (BM) were uninvolved. We also evaluated prognostic value of immunophenotype according to WHO 2008 subtype and ETP (Early T-cell Phenotype) definition in adult patients with T-LBL/ALL treated on uniform ALL protocol.

**Methods:** Between 1997 and 2015, 71 adult patients with T-LBL/ALL were treated according to the GMLL 05/93 and T-LBL/2004 protocols. Immunophenotype was determined by immunohistochemical staining and by FCM of cellular suspension obtained from lymph nodes (n=31), mediastinal mass (n=12) or nasopharyngeal/perimandibular infiltration (n=2) by fine needle aspiration biopsy (FNAB), as well as BM (n=10), PB (n=7) and pleural fluid (n=9). Disease subtype was defined according to WHO 2008 classification: pre-B (CD2-), pro-B (CD10+), common (CD10+), null (CD10-), null/precursor-B and pro-B (CD10-)/null/precursor-B. ETP phenotype was defined as follows: absent (up to 5% positive cells) CD1a and CD8 expression, absent or dim (75% positive cells) CD11c expression, expression (25% positive cells) of 1 or more myeloid (CD13,CD33,CD15) or cell (CD34, HLA-DR) markers.

**Summary/Conclusions:** Survival of T-LBL/ALL pts depends on CD1a and CD2 expression as well as WHO subtype. ETP is a non-uniform category with the following immunophenotypic features: pro-B (CD10+), pro-B (CD10-)/null/precursor-B, null (CD10-), common (CD10+), and precursor-B (CD10-). ETP phenotype was defined as follows: absent (up to 5% positive cells) CD1a and CD8 expression, absent or dim (75% positive cells) CD11c expression, expression (25% positive cells) of 1 or more myeloid (CD13,CD33,CD15) or cell (CD34, HLA-DR) markers.

**Background:** In pediatric ALL end of induction minimal residual disease (EOI MRD) evaluated at day 29-33 after the first chemotherapy course is a primary determinant of outcome. The significance of EOI MRD in adult ALL is less clear.

**Aims:** To assess EOI MRD and its impact on survival and relapse risk in adult patients with Philadelphia-negative (Ph-) ALL in complete remission (CR) with a single chemotherapy course.

**Methods:** Induction chemotherapy for patients in the Northern Italy Leukemia Group 10/07 trial (ClinicalTrials.gov NCT-00795756). Blood (PB) and bone marrow (BM) were uninvolved. We also evaluated prognostic value of immunophenotype according to WHO 2008 subtype and ETP phenomenon. BM +<20% involvement (LBL): 27%, age<35 yrs: 72%, males: 67%, mediastinal mass (MM): 92%, primary CNS: 8%. Immunophenotype: pro-T: 21%, pre-T:17%, null:55%, null/null:44%, lymphoid/leukocytosis (n=3): 0-3% (n=25/36%) or 4-7% (n=45/64%) of pts. Most frequently expressed pTag were: CD5, CD7, CD10, CD13, CD15, CD19, CD20, CD22, CD34, CD54, CD56, CD69, CD80, CD117, CD123, CD126, CD138, CD134, CD135 (CD133) and DR/13/33/15 expressed in 100%/50%/50%/50% of ETP pts. 4 pts (31%) with EOI MRD were categorized as pre-T and 9 (69%) as pro-T. With a median (95%CI) follow up of 137 (0.99, 1.733) months, 5-yr OS (95%CI) was 59% (0.72, 0.559) and 64% (0.5, 0.782) compared to 11% (0.034, 0.256), 32% (0.152, 0.494) and 27% (0.097, 0.452) for pts without EOI MRD, CD1a and 3 or less pTag, respectively. In pts with BM involvement, MRD was ≥10-4 in 62.5% (n=14) of pts, ≥10-3 in 22.5% (n=5) of pts and <10-4 in 15% (n=3) of pts. EOI MRD did not correlate with patient age and adverse phenotype or cytogenetics were not significant.

**Summary/Conclusions:** Survival of T-LBL/ALL pts depends on CD1a and CD2 expression as well as WHO subtype. ETP is a non-uniform category with the following immunophenotypic features: pro-B (CD10+), pro-B (CD10-)/null/precursor-B, null (CD10-), common (CD10+), and precursor-B (CD10-). ETP phenotype was defined as follows: absent (up to 5% positive cells) CD1a and CD8 expression, absent or dim (75% positive cells) CD11c expression, expression (25% positive cells) of 1 or more myeloid (CD13,CD33,CD15) or cell (CD34, HLA-DR) markers.

**Background:** Risk factors for T-LBL have not been systematically evaluated, in contrast to T-ALL.

**Aims:** To assess EOI MRD and its impact on survival and relapse risk in adult patients with Philadelphia-negative (Ph-) ALL in complete remission (CR) with a single chemotherapy course.

**Methods:** Induction chemotherapy for patients in the Northern Italy Leukemia Group 10/07 trial (ClinicalTrials.gov NCT-00795756). Blood (PB) and bone marrow (BM) were uninvolved. We also evaluated prognostic value of immunophenotype according to WHO 2008 subtype and ETP phenomenon. BM +<20% involvement (LBL): 27%, age<35 yrs: 72%, males: 67%, mediastinal mass (MM): 92%, primary CNS: 8%. Immunophenotype: pro-T: 21%, pre-T:17%, null:55%, null/null:44%, lymphoid/leukocytosis (n=3): 0-3% (n=25/36%) or 4-7% (n=45/64%) of pts. Most frequently expressed pTag were: CD5, CD7, CD10, CD13, CD15, CD19, CD20, CD22, CD34, CD54, CD56, CD69, CD117, CD123, CD126, CD138, CD134, CD135 (CD133) and DR/13/33/15 expressed in 100%/50%/50%/50% of ETP pts. 4 pts (31%) with EOI MRD were categorized as pre-T and 9 (69%) as pro-T. With a median (95%CI) follow up of 137 (0.99, 1.733) months, 5-yr OS (95%CI) was 59% (0.72, 0.559) and 64% (0.5, 0.782) compared to 11% (0.034, 0.256), 32% (0.152, 0.494) and 27% (0.097, 0.452) for pts without EOI MRD, CD1a and 3 or less pTag, respectively. In pts with BM involvement, MRD was ≥10-4 in 62.5% (n=14) of pts, ≥10-3 in 22.5% (n=5) of pts and <10-4 in 15% (n=3) of pts. EOI MRD did not correlate with patient age and adverse phenotype or cytogenetics were not significant.
Background: The outcome for older adults with acute lymphoblastic leukaemia (ALL) is unsatisfactory. The UKALL12/ECOG2993 study showed that high risk cytogenetic abnormalities, were common, as well as lower rates of complete remission (CR) and 5 year overall survival (OS) in those aged 55–65 years of age as compared to younger persons. There are few studies which focus on older patients with ALL, despite an increasing incidence with age.

Aims: A trial to establish a age-appropriate baseline chemotherapy from which to design widely-applicable studies of novel agents in older people with ALL.

Methods: UKALL60+ offers five ‘Arms’ to be decided by investigator and patient choice; Arm A= Philadelphia chromosome positive (Ph+), Arm B= Non-intensive (designed to be delivered primarily out of hospital), Arm C= Intensive, Arm D= Intensive+, and Arm E= Registration only (in which treatment is at investigators discretion, including no active therapy). Any elderly patient with newly diagnosed ALL is eligible. There are no exclusions for co-morbidities, including prior malignancies. Baseline characteristics of each group including Charlson index, ECOG, Karnofsky and CRASH scores are being collected. The primary endpoint is the rate of complete remission (CR) after 2 phases of induction. Secondary objectives include determination of MRD status at 3 time points, EFS and OS at 1 year, treatment related mortality and quality of life.

Results: Since December 2012 85 patients have been recruited (4 excluded due to misdiagnosis) with a median age of 67 years (Range 55 – 83). Median follow up is 18.1 months. ECOG performance status was 0 in 33 (41%), 1 in 37 (46%), 2 in 8 (10%) and ≥3 in 4 (4%). Treatment allocation has been Ph+ n=18, Intensive n=34, non-Intensive n=11, Intensive+ n=7, and Registration only n=11 patients. It is too early to perform a full analysis of the reasons given for choosing each regimen but age appears to be a major factor for Ph−ve patients, with a median age of 74 years (Range 64-82) in the non-Intensive arm compared with 66 years (Range 56 -76) in the Intensive and Intensive+ arms. A total of 36/61 (57%) patients had high risk cytogenetics including BCR-ABL1 (n=21), low hypodiploidy (n=10), complex karyotype (n=1) and KMT2A-AFF1 (aka MLL-AF4) (n=4). Charlson index and CRASH score data is awaited. At the end of 2 phases of treatment on Arm A (Ph+ve) 17/18 (94%) patients achieved CR. On Arms B-D 27/52 (52%) patients achieved CR. Grade 3/4 AEs were seen in the majority of patients. The most common toxicities were haematological and infections. So far 30 relapses have been reported. 25 are isolated mediulary relapses, 4 isolated CNS and combined in 1 patient. To date, 41 deaths have been reported; 32 patients died of ALL, 7 of infection, 1 cardiac and 1 multi-organ failure. Fifty one patients have had a PFS event. The median PFS is 13.2 months in Arm A (Philadelphia +ve) and 11.3 months Arm B-D. The median OS is 19.5 months in Arm A (Philadelphia +ve) and 15.5 months in Arms B-D (Figure 1).

Figure 1.

Summary/Conclusions: ALL in older patients is challenging to treat, with a difficult balance between efficacy and toxicity. We observed a high rate of high risk cytogenetics, especially notable being the rate of low hypodiploidy. Initial high CR rates are seen in those with Ph+ve disease, this does not appear to translate into improved PFS and OS when compared with Philadelphia negative disease. The commonest cause of death in this group is ALL. We will use our baseline data to develop appropriate regimens for future studies of novel agents.

P165

CLINICAL OUTCOMES OF ELDERLY ACUTE LYMPHOBLASTIC LEUKEMIA/LYMPHOMA – A SINGLE INSTITUTION EXPERIENCE

K. Miller1, A. Al-Kali1, W. Hogan1, M. Elliott1, K. Begna1, N. Gangat1, M. Patnaik1, M. Litzow1, H. Alkhateeb1

1Division of Hematology, Mayo Clinic, Rochester, United States

Background: Elderly acute lymphoblastic leukemia/lymphoma (ALL) is a rare disease with a poor prognosis and is underrepresented in clinical trials. This could be due to comorbidities, early death during induction, lower rates of complete remission, and higher risk of relapse with poor biological features (Gokbuget, Blood, 2013).

Aims: Describe clinical outcomes and prognostic factors of elderly ALL.

Methods: After IRB approval, we performed a retrospective study of patients (pts) aged ≥60 diagnosed with ALL from 2000 to 2016 at Mayo Clinic Rochester. Statistical analysis was performed using JMP 10.0 software.

Results: Out of 210 adult ALL pts, we identified 63 (30%) consecutive pts with elderly ALL. The average age at time of diagnosis was 67 (60-82), & 38 (60%) were males. Median follow up was 16.1 months (0.2-126), during which time 49 (63%) deaths occurred; 25 (63%) related to the disease, & 15 (37%) secondary to infection or other causes. Baseline characteristics at time of diagnosis: 54 (86%) pts had B-cell phenotype, 19 (35%) were Ph+. Only 9 (14%) pts had T-cell phenotype. 20 (31%) pts had a Charlson Comorbidity Index ≥2 & 17 (27%) presented with ECOG PS ≥2. Median Hgb was 10.6 g/dl (4.9-18.5), WBC 6.2 x 109/l(0.5-160.8), PLT 51 x 109/l(4-750), peripheral blast 30% (0-95), marrow blast 87.5% (0-100), & LDH 381.5 U/L (141-8440). Lymphoblastic lymphoma was only evident in 3 (5%) pts. Among pts with available data, 34/58 (59%) had B symptoms, 16/57 (28%) lymphadenopathy, 7/57 (12%) splenomegaly, 6/60 (10%) pleural effusions & 10/65 (22%) of pts had CNS leukemia. Cytogenetics at time of diagnosis: Of 48 pts with available data, 20 (41%) had complex cytogenetics (≥5 abnormalities), 18 (38%) had a monosomal karyotype, 8 (17%) were hypodiploid, 4 (8%) were hyperdiploid, & 2 (4%) were a mix of hypo- & hyper-diploid. FISH studies were available for 50 pts: 10 (20%) had CDKN2A del, 3 (6%) (4;11) MLL-AF4, 2 (4%) (11;19) E2A-PBX1, 1 (2%) KIT/kit deletion. Treatment and Outcomes: 10 (16%) pts received palliative therapy only, which included TKIs, chemotherapy, or hospice. The other 53 (84%) received induction chemotherapy. Only 12 (23%) had an up-front dose reduction due to comorbidities. 32 (60%) received Hyper-CVAD, concomitantly with rituximab in 11 (34%) pts. & TKIs in 9 (28%) pts. 21 (40%) pts received other regimens, of which 14 (67%) had asparaginase-based chemotherapy. Only 2 (4%) pts who received induction chemotherapy died within the first 60 days; both received Hyper-CVAD. Median number of cycles to achieve CR was 1 (1-8) with CR/CR rate of 93%, & median time to CR1 was 34 days (19-459). 3 pts who underwent palliative chemotherapy achieved CR (all had Ph−ve disease & received TKIs). 7 pts (13%) had primary induction failure. 50% of pts relapsed within a median time of 12.6 (3.6-72.8) months. Only 10 pts under- went autologous hematopoietic stem cell transplantation (HSCT), of which 2 (20%) relapsed in less than 180 days. Median survival after HSCT was not reached. Predictors of survival: Elderly ALL has worse mOS compared to our adult ALL cohort, 17.2 (IQR: 11.7-32.9) vs 52.1 (IQR: 27.6-169.9) mon (p=0.0016). In a univariate analysis model which included multiple variables, only ECOG PS ≥2, WBC>30,000, CDKN2A del, & CNS leukemia were statistically significant, however only CNS leukemia (p=0.0009) & WBC (p=0.0018) retained independent statistical significance in multivariate mode, with a trend in CDKN2A del (p=0.06) (Figure 1).

Figure 1.

Summary/Conclusions: Elderly pts with ALL have worse survival compared to younger adults. However, this was not reflected by a low CR rate, or a high rate of mortality during induction, but by grim disease overall. We report for the first time the incidence of 20% for CDKN2A del in this disease group. Further studies are needed to confirm this finding, as it could be a target for novel therapies.

MANAGEMENT AND OUTCOME OF ADULT PH+ ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED AT THE “SAPIENZA” UNIVERSITY BETWEEN 1996 AND 2016

S. Chiaretti1, V. Gianfelici1, R. Agrippino1, L. Elia1, F. Paoloni2, S. Capria1

1Department of Hematology, Sapienza Università di Roma, Rome, Italy

Background: Adult patients with Ph+ ALL have a poor outcome with standard therapy. The outcome for older adults with ALL is challenging to treat, with a difficult balance between efficacy and toxicity. We observed a high rate of high risk cytogenetics, especially notable being the rate of low hypodiploidy.
Analysis of 28 cases of children younger than 18 years with Ph+ ALL treated at our institution from 1996 to 2005 was performed. Patients were initially classified in high-risk disease entity unless selected for pre-B leukemia (14 cases). Induction chemotherapy was then performed according to the Spanish Hemato-Oncology Cooperative Group protocols in a pediatric setting. Consolidation chemotherapy was administered in a similar manner, with the addition of TKI for 22 patients (14 imatinib and 8 dasatinib). All cases received TKI during consolidation/maintenance when it became available. Elderly patients (42 years) and young adults (20-38 years) were analyzed separately.

Results: In the older group, 79 patients achieved a CR (71.8%); 8 were refractory and 3 died in CR; 35 patients had the p190 fusion protein, 28 had p210, and 4 had both fusions. In the pediatric group, 21 patients achieved a CR (66.7%); 7 were refractory and 2 died in CR; 18 patients had the p190 fusion, 9 had p210, and 1 had both fusions. Differences are statistically significant (\(p<0.05\)). CD9 was more frequent in pediatric cases (40% vs. 30%) and in cases treated with TKI alone. However, none of these differences remained significant after adjustments were performed using Cox regression models.

Conclusions: CD9 expression is significantly associated with outcome in patients with Ph+ ALL. However, the observed differences in CD9 expression do not seem to be due to differences in the TKI used or the chemotherapy regimen. Further studies are needed to investigate the potential role of CD9 expression in predicting survival outcomes in pediatric B-ALL patients.
Results: Our series included 69 boys and 57 girls diagnosed with acute leukemia, with a median age of 6.1 years (range 0-17.4 years). We included 12 infant patients (<1 year old). Eighty-two (65%) patients had B-cell precursor acute lymphoblastic leukemia (BCP-ALL), 24 patients T-cell ALL and 20 patients had acute myeloblastic leukemia (AML). Globally, we found higher expression levels of class I HDAC isozymes (HDAC 1, 2, 3 & 8) in leukemic samples as compared to non-neoplastic samples, as previously reported. Interestingly, some HDAC isozymes associated with specific genetic aberrations. Those patients with rearrangement of ALL (KMT2A) gene (n=18, including 9 BCP-ALL and 9 AML; 7 infants and 11 pediatric) showed a significantly higher expression of HDAC9 (p=0.0001) and a statistically significant underexpression of HDAC1 and HDAC3 (p=0.003 & p=0.02, respectively, see Figure 1). Infants (n=12) also had a significantly lower expression of HDAC7 (p=0.043). In the same line, all pediatric patients with pro-B phenotype (CD10 negative) had low levels of HDAC7, but differences did not reach a statistical significance. After a median follow-up of 5.9 years, 15 patients died, with an overall survival (OS) of 62±9% for BCP-ALL, 83±6% for T-ALL and 55±13% for AML patients (p=0.0001). In the BCP-ALL subgroup, the expression of HDACs did not predict outcome, and only CNS infiltration and leukocytosis were unfavorable risk factors for OS. Again, CNS+, high WBC count and presence of minimal residual disease (MRD) post-induction were predictive for worse event free survival (EFS). Although the number of cases is low and these results must be taken with caution, T-ALL patients with the highest expression of HDAC3 (upper quartile) significantly correlated with worse OS (94% vs 25%, p=0.001) and a trend towards worse EFS (89% vs 53%, p=0.06). The only significant risk factor for EFS in this subgroup was the presence of MRD after induction (p=0.003).

P169 MINIMAL DISSEMINATED DISEASE DETECTION BY FLOWCYTOMETRIC IMMUNOPHENOTYPING IN T-CELL ACUTE LYMPHOBLASTIC LYMPHOMA G.K. Viswanathan1,*, P. Tembhare1, N. Patkar1, S. Gujral1, P.G. Subramanian1, K. Sasaki1, N. Pemmaraju1, Y. Alvarado1, J. Jacob1, R. Garris1, P. Thompson1, J. Cortes1, E. Jabbour1 1Hematopathology Laboratory, Advanced Centre for Treatment, Research and Education in Cancer (ACTREC) - Tata Memorial Centre (TMC), Mumbai, India

Background: T-cell acute lymphoblastic lymphoma (T-LBL) with minimal disseminated disease (MDD) is defined as the presence of T-LBL with <25% blasts in the peripheral blood (PB) and/or bone marrow (BM) by morphology and the absence of immunophenotypically abnormal T-lymphoblasts in bone marrow by flowcytometry. Published literature regarding the prevalence and clinical significance of this rare subgroup is sparse. In this study we analysed the prevalence of minimal disseminated disease in cases of T-LBL with <25% blasts in PB and BM using 8-10 colour flowcytometric immunophenotyping and evaluate the clinical and immunophenotypic features. Aim: To evaluate the prevalence of minimal disseminated disease in bone marrow in cases of T-cell acute lymphoblastic lymphoma with <25% blasts in PB and BM using 8-10 colour flowcytometric immunophenotyping and evaluate the clinical and immunophenotypic features.

Methods: This is a retrospective analysis of 42 patients of T-LBL with predominantly lymphomatous presentation with <25% blasts in peripheral and bone marrow. The following parameters were taken into account including complete hemogram, peripheral blood examination, bone marrow morphology and immunophenotyping, CSF analysis, pleural fluid morphology and immunophenotyping, tissue biopsy (lymph node or mediastinal mass), PET-CT findings and LDH levels. Flowcytometric immunophenotyping on bone marrow was performed on a 3 laser 10 color Beckman-Coulter Navios® platform and analysed using Kaluza® software. A minimum of 1,00,000 events were acquired and the presence of minimal disseminated disease was noted.

Results: A retrospective analysis of 42 cases of T-LBL with <25% blasts in PB and BM with predominantly lymphomatous presentation with <25% blasts in peripheral and bone marrow was done. The mean age was 12.2 years (Range:2-48 years). M:F ratio was 1:1.7. Nearly all patients had normal haemoglobin, total leucocyte count and platelet counts. LDH was raised in majority of the patients (Mean 674±L; N=190±UL). CSF examination was negative in all cases indicating that it is unlikely to have CNS involvement in patients with <25% blasts in PB and BM. Minimal disseminated disease was seen in 12 cases (12/42=28.6%) of cases. Of the 12 cases with minimal disseminated disease two cases were near early T-cell precursor acute lymphoblastic leukemia (near ETP-ALL) type and none were of ETP-ALL type. None of the cases showed circulating blasts in PB. The mean (range) bone marrow blast count in the group without MDD was 2.4% (0-4%) and in the group with MDD was 5.1% (0-15%). In the group with MDD (12 cases), only 5 cases showed >5% blasts/hematogones identifiable by morphology. This indicates flowcytometry is necessary in cases with <5% blasts to pick up cases of MDD. PET-CT was not sensitive to pick-up MDD as increased FDG uptake was seen in only a single case of MDD; it was negative in all cases without MDD. MDD by flowcytometry ranged from 0.007% to 18.5% (mean: 3.6%; median: 4%) (Figure 1).

Figure 1.

Summary/Conclusions: Our study shows that minimal disseminated disease is seen in more than one-fourth of cases (28.6%) of T-LBL with <25% blasts in PB and BM. This underlines the importance of flowcytometric evaluation of bone marrow in cases with <25% blasts identified by morphology. The identification of minimal disseminated disease in T-LBL is important as studies have shown inferior event free survival in T-LBL with minimal disseminated disease as compared to patients without minimal disseminated disease.

P170 INOTUZUMAB OZOGAMICIN IN COMBINATION WITH LOW-INTENSITY CHEMOTHERAPY (MINI-HYPER-CVD) AS FRONTLINE THERAPY FOR OLDER PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA: UPDATED RESULTS FROM A PHASE III STUDY N. Short1, H. Kantarjian1, S. O’Brien1, F. Ravandi1, D. Thomas1, G. Garcia-Manero1, N. Daver1, G. Borthakur1, N. Jain1, M. Konopleva1, K. Sasaki1, N. Pennmaraju1, Y. Alvarado1, J. Jacob1, R. Garris1, P. Thompson1, J. Cortes1, E. Jabbour1 1The University of Texas MD Anderson Cancer Center, Houston, 2The University of California - Irvine, Orange, United States

Background: Older patients (pts) with acute lymphoblastic leukemia (ALL) have poor tolerance of intensive chemotherapy, and novel strategies are needed in this population. In pts with relapsed/refractory ALL, inotuzumab ozogamicin (InO), an anti-CD22 antibody-drug conjugate, has been shown to improve survival compared to salvage chemotherapy.

Aims: We designed a phase III trial to evaluate the safety and efficacy of low-intensity chemotherapy (mini-Hyper-CVD) plus InO as frontline treatment for older pts with newly diagnosed ALL.

Methods: Pts ≥60 years of age with newly diagnosed Philadelphia chromo- some-negative pre-B received mini-Hyper-CVD (composed to hyper-CVAD: no anthracycline, 50% dose reductions of cyclophosphamide and dexamethasone, 75% dose reduction of methotrexate, 85% dose reduction of cytarabine). InO was given on day 3 of the first 4 cycles. The first 6 pts received InO at a dose of 1.3 mg/m2 for cycle 1 followed by 0.8 mg/m2 for cycles 2-4; pts 7-34 received 1.8 mg/m2 for cycle 1 followed by 1.3 mg/m2 for cycles 2-4. Due to concern for veno-occlusive disease (VOD), the protocol was amended so that pts 35+ received InO at a dose of 1.3 mg/m2 for cycle 1 followed by 1.0 mg/m2 for cycles 2-4. Rituximab was given during the first 4 cycles in pts with CD20 expression ≥20%; all pts received IT chemotherapy prophylaxis with the first 4 cycles. Pts in CR after 8 cycles then received POMP maintenance for up to 3 years.
**Results:** Between 4/2012 and 12/2016, 47 pts have been treated, 4 of whom had received 1 cycle of prior therapy and were in CR at the time of enrollment. The median age was 68 years (range, 60-81), and median CD22 expression was 97% (range, 72-100%). Of 43 pts evaluable for response, 42 responded (ORR=96%). Best response was CR in 36 pts (84%), CRp in 5 (12%) and CRi in 1 (2%). MRD negativity by 6-color multiparameter flow cytometry was achieved in 31 of 41 evaluable pts (76%) on day 21 and in 44 of 46 evaluable pts (96%) within 12 weeks of treatment. The median follow-up was 24 months (range, 1-55 months), 3 pts (6%) underwent allogeneic stem cell transplantation (ASCT) in first remission. Of the 46 responders, 6 pts (13%) have relapsed. 16 pts have died, 1 due to resistant disease, 4 after relapse, 1 after ASCT and 10 in CR/CRp. 21 pts remain on treatment (consolidation, n=3; POMP maintenance, n=19), and 5 pts have completed all therapy. The 3-year continuous CR and OS rates were 72% and 54%, respectively. Compared to a historical cohort of 79 pts older treated at our institution with hyper-CVAD ± rituximab, mini-hyper-CVD+InO resulted in significantly improved OS (3-year OS rate: 54% vs 31%; median OS not reached versus 16 months; P=0.007).

**Summary/Conclusions:** The combination of InO with mini-hyper-CVD is safe and effective in older pts with newly diagnosed ALL, resulting in a promising 3-year OS rate of 54%. This results appear superior to the outcomes of older pts treated with hyper-CVAD.

1Department of Pediatrics, Nagoya University Graduate School of Medicine, 2Center for Advanced Medicine and Clinical Research, 3Department of Pathology, Nagoya University Hospital, 4Department of Pathology, Japanese Red Cross Nagoya First Hospital, Nagoya, 5Department of Pediatrics, Shizuoka University School of Medicine, Matsumoto, 6Department of Pathology, Department of Hematology and Oncology, Shizuoka Children’s Hospital, Shizuoka, Japan

**Background:** Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare hematological malignancy that is derived from plasmacytoid dendritic cell precursors. BPDCN tends to occur in elderly people with frequent skin involvement and is associated with an aggressive clinical course and a poor prognosis. Although optimized diagnostics and therapies should improve patient outcomes, the pathobiological and genetic aspects of BPDCN remain unclear.

**Aims:** We planned this study to identify a critical genetic event in BPDCN, which could provide better understanding of BPDCN pathogenesis.

**Methods:** We enrolled fourteen patients (five children and nine adults) with BPDCN who were treated in our institutions. We primarily performed RNA sequencing-based comprehensive transcriptome analysis with their samples at the onset to detect gene fusions. These results were then used as the basis for genetic validation studies and functional analyses with an exogenous expression model.

**Results:** We identified a recurring gene rearrangement that involved the MYB proto-oncogene in all five pediatric patients (100%) and four of nine adult patients (44%) with BPDCN. The resulting fusion genes included MYB-ZAP7 (four patients), MYB-PLEKHO1 (three patients), MYB-DCPS (one patient) and MYB-MIR2134 (one patient), none of which have been previously reported to our knowledge. The translocations corresponding to these fusions were not detected by the metaphase analysis except in one patient with t(1;15), who harbored MYB-PLEKHO1. These fusion genes were detectable at diagnosis and relapse but not at remission. Fluorescence in situ hybridization (FISH) analysis efficiently detected the breaking apart of MYB in formalin-fixed, paraffin-embedded sections. Consequent to the rearrangement, the negative regulatory domain of MYB was truncated, leading to constitutive MYB transcriptional activation, as described in other malignancies. Exogenous MYB-PLEKHO1 expression in HEK293T cells led to the upregulation of several known downstream MYB targets. Gene set enrichment analysis also confirmed the activation of MYB target gene sets. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, SIRPα, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed whole-exome sequencing of paired tumor–germline samples. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, SIRPα, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed whole-exome sequencing of paired tumor–germline samples. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, SIRPα, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed whole-exome sequencing of paired tumor–germline samples. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, SIRPα, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed whole-exome sequencing of paired tumor–germline samples. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, SIRPα, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed whole-exome sequencing of paired tumor–germline samples. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, SIRPα, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed whole-exome sequencing of paired tumor–germline samples. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, SIRPα, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies.

**Summary/Conclusions:** We identified a high frequency of MYB rearrangements that promoted the MYB transcriptional activity in BPDCN. MYB split FISH analysis can constitute a valuable diagnostic tool for detecting MYB rearrangements. We expect that our findings provide critical insights regarding BPDCN pathogenesis and contribute to molecular biology-oriented diagnostic techniques and molecular-targeted therapies for this intractable malignancy.

**BRANCHED CHAIN ACID METABOLISM REGULATES ALPHA-KETOGLUTARATE HOMEOSTASIS RESEMBLING MUTANT-IDH DRIVEN DNA HYPERMETYLATION IN AML**

S. Raffe1,2,3, M. Falcone1, N. Kneisel4, H. Hansson5, W. Wang6, C. Lutz3, L. Bullinger7, S. Cacciardelli8, P. Wuchter4, J. Steidle5, A. Höfling8, J. Westermann9, G. Ehniger7, C. Herrmann7, A. D. Ho1, J. Krijgsveld5, B. Radlweg7, A. Trumpf1,2

1Division of Stem Cells and Cancer, German Cancer Research Center, 2Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HIT), 3Heidelberg University Hospital, 4Mannheim University Hospital, 5Department of Internal Medicine, 6Heidelberg University Hospital, 7Division of Hematology and Oncology, 8Heidelberg University Hospital, 9Department of Pathology, University Hospital, Mannheim, Germany

**Background:** Acute myeloid leukemia (AML) is a heterogeneous disease characterized by impaired differentiation and dysregulated pathways that contribute to hematopoietic cell growth and survival. In particular, mutations in the isocitrate dehydrogenase 1 (IDH1) and IDH2 genes result in the production of the oncometabolite 2-hydroxyglutarate (2-HG), which inhibits the α-ketoglutarate (α-KG) domain of 2-oxoglutarate-dependent dioxygenases (2-ODDs), leading to hypermethylation of DNA. This process, termed “oncomethylation,” contributes to the development and progression of AML.

**Aims:** The aim of this study was to investigate the role of branched chain amino acid (BCAA) metabolism in AML, particularly in the context of mutant-IDH-driven DNA hypermethylation.

**Methods:** We used a combination of metabolic and transcriptional profiling approaches to examine the impact of BCAA metabolism on α-KG homeostasis in AML. We assessed the expression levels of enzymes involved in BCAA metabolism and the activity of 2-ODDs in AML cell lines and primary patient samples. In addition, we performed in vitro and in vivo experiments to determine the effects of interventions targeting BCAA metabolism on α-KG availability and DNA methylation.

**Results:** We found that the expression of enzymes involved in BCAA metabolism, such as branched chain aminotransferase 1 (BCAT1) and branched chain alpha-ketoacid dehydrogenase complex (BCKD), was upregulated in AML cells compared to normal hematopoietic progenitors. Furthermore, we observed a significant correlation between the expression of BCAA metabolism genes and the levels of α-KG in AML samples. Inhibition of BCAA metabolism by small-molecule inhibitors led to a decrease in α-KG levels and an increase in DNA methylation, indicating that BCAA metabolism regulates α-KG homeostasis and contributes to oncomethylation in AML.

**Summary/Conclusions:** Our findings suggest that BCAA metabolism is an important regulator of α-KG homeostasis in AML, and that interventions targeting this pathway may offer new therapeutic strategies for the treatment of this devastating disease.
Background: The branched chain amino acids (BCAAs) valine, leucine, and isoleucine are essential AAs for the human body. The activity of BCAA metabolism is a hallmark of the disease phenotype. Both increased and decreased levels of the enzyme BCAA Transaminase 1 (BCAT1) have recently been associated with aggressiveness in several cancer entities. However, the mechanistic role of BCAT1 in this process remains uncertain.

Aims: To elucidate the mechanistic link between BCAT1 function and epigenetic deregulation in leukemia stem cells (LSCs) and consequences on clinical outcomes.

Methods: High-resolution proteomics of LSCs, Knockdown and overexpression of BCAT1 in AML patient samples and AML cell lines, Gene set enrichment analysis, BCAA tracking experiments, Xenotransplantations, Metabolomics, DNA methylation arrays, correlative and mechanistic link to clinical data sets.

Results: We performed high-resolution proteomic analysis of human acute myeloid leukemia (AML) stem cell (LSC) and non-LSC populations, which have been functionally validated by xenotransplantation into NSG mice, and we found the BCAA pathway enriched and BCAT1 overexpressed in LSCs. We show that BCAT1, which transfers α-amino groups from BCAAs to α-ketoglutarate (αKG), is a cell-autonomous repressor of leukemia at its role in the branched chain amino acid (BCAA) cycle cαKG is an essential co-factor for αKG-dependent dioxygenases such as EGLN1 and the TET family of DNA demethylases. Knockdown (KD) of BCAT1 in leukemia cells caused accumulation of αKG resulting in HIF1 protein degradation mediated by EGLN1. This resulted in a growth and survival defect and abrogated leukemia-initiating potential. In contrast, overexpression (OE) of BCAT1 in leukemia cells decreased intracellular αKG levels and caused DNA hypermethylation. BCAT1-high AML samples displayed a DNA hypermethylation phenotype similar to IDHmut cases, in which HIF2 is inhibited by the oncometabolite 2-Hydoxyglutarate. High levels of BCAT1 were strongly correlated with IDHmut, but not IDHwt or TET2mut AMLs. Gene sets characteristic for IDHmut AMLs were enriched both in IDHmut and BCAT1-high patient samples and in BCAT1-OE leukemia cells. BCAT1-high samples showed reduced enrichment for LSC signatures and paired sample analysis revealed a significant increase of BCAT1 levels upon relapse of the disease.

Summary: In summary, BCAT1 reduces dioxygenase activity by limiting intracellular αKG, thus linking BCAA catabolism to HIF1a stability and DNA hypermethylation. Our results suggest the BCAA-BCAT1-αKG pathway as a therapeutic target to compromise LSC function in IDHmut and TET2mut AML patients.

THE LONG NON-CODING RNA HOXB-AS3 REGULATES RIBOSOMAL BIOGENESIS IN NPM1-MUTATED ACUTE MYELOID LEUKEMIA

D. Papaiouannou1,2, A. Petri2, S. Terreni3, C. Thue4, S. Volinia4, P. Yan1, R. Bundshuh5, G. Singh6, S. Kauppinen2, C. Bloomfield1, D. Adrienne1, R. Garzon1

Background: The prognostic significance of long non-coding RNA expression (lncRNAs) in older (>60 years) patients (pts) with cytogenetically normal acute myeloid leukemia (CN-AML) was recently reported (Garzon et al., 2014). The IncRNA HOXB-AS3, which is embedded in the HOXB locus,HOXB-AS3, was previously identified among the lncRNAs that associated with mutated NPM1 (NPM1mut) in CN-AML.

Aims: Our aims were to evaluate the biologic significance of HOXB-AS3 expression in NPM1mut AML. Methods: Methods: HOXB-AS3 expression profiling was performed by real-time PCR. Knock-down (KD) of HOXB-AS3 was performed in vitro and in vivo [in a pt-derived xenograft (PDX) model] with locked nucleic acid-modified gapmers. Comparative proteomic analysis was conducted with a modified version of the RNA antisense purification (RAP) protocol (McHugh et al., 2015). Direct visualization of the HOXB-AS3 was performed using custom-designed Basecoveolysis Kit (Advanced Cell Diagnostics, Newark, CA) according to the manufacturer’s instructions.

Results: Of 6 AML cell lines that were tested, only OCI-AML3 cells, which harbor NPM1mut, showed detectable levels of HOXB-AS3 expression. Five- and 3-prime Rapid Amplification of cDNA Ends (RACE) assays in OCI-AML3 identified a novel HOXB-AS3 transcript previously annotated (NR_033201/NR_033203/ENST0000491264) and 1 novel variant of HOXB-AS3. NPM1mut pt samples exhibited higher expression of HOXB-AS3 compared to those with wild-type (WT) NPM1 (P<0.01) and healthy donors (P=0.01). In vitro KD of HOXB-AS3 led to decreased proliferation of OCI-AML3 cells, as measured by BrdU-based cell cycle analysis (S-phase average% in control vs KD: 24% vs 16% P=0.02). HOXB-AS3 KD also led to a reduction in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P<0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies (P<0.001). To evaluate the effect of HOXB-AS3 KD in vivo we generated immunodeficient NOD-SCID mice with blasts of a NPM1mut pt. Treatment of the engrafted mice with nanoparticle-formulated anti-HOXB-AS3 gapmers led to significant prolongation of survival compared to treatment with non-targeting control gapmers in 2 independent experiments (P=0.01 and P=0.005). Mass spectrometry and comparative proteomic analysis of HOXB-AS3- and U1-specific RNA-protein complexes identified EB1 and NPM1 as candidate HOXB-AS3-binding proteins. RNA-immunoprecipitation experiments validated the interaction of HOXB-AS3 with EB1 (20-fold increase of HOXB-AS3 abundance in EB1-precipitate compared to normal IgG control, P<0.001). Direct visualization of HOXB-AS3 showed co-localization of the IncRNA and WT NPM1 in the nucleolus. HOXB-AS3 has been previously shown to interact with NPM1 and to regulate ribosomal biogenesis and growth of AML cells (Nguyen et al., 2016). We hypothesized that HOXB-AS3 could affect the EB1-NPM1 interaction and impact on the ribosomal biogenesis process. In consistency with this hypothesis, HOXB-AS3 KD led to a decrease in the transcription of rRNA species in OCI-AML3 cells (P<0.001) and in vitro-treated blasts of 2 NPM1mut pts (P<0.001). HOXB-AS3 KD also led to a reduction of protein synthesis in the AML cells, as measured by incorporation of fluorochrome-tagged tracers in newly translated polyribosomes.
Summary/Conclusions: Conclusions: HOXB-A53 is strongly associated with NPM1 mutations in AML. HOXB-A53 interacts with EBPl and NPM1 and regulates ribosomal biogenesis in the leukemic blasts. From a therapeutic standpoint, HOXB-A53 constitutes a promising target, as in vivo anti-HOXB-A53 treatment prolonged survival in a murine PDX model.

A DUAL BH3-MIMETIC APPROACH TARGETING BOTH BCL-2 AND MCL1 IS HIGHLY EFFICACIOUS AND WELL-TOLERATED IN ACUTE MYELOID LEUKEMIA

D. Moujalled1,2, G. Pomilio1,2, C. Ghiauro2, D. Segal1, T.-C. Teh1,2, J. Salmon1,2, S. Rijal1, P. Lan2, L. Kraus-Berthier3, A. Roberts4, D. Huang4, A.L. Maragno3, G. Lessene5, O. Geneste5, A. Wei6
1Australian Centre for Blood Diseases, Monash University, 2Department of Clinical Haematology, The Alfred Hospital, Melbourne, Australia, 3Oncology R&D Unit, Institut de Recherches Servier, Croissy Sur Seine, France, 4The Walter and Eliza Hall Institute, Melbourne, Australia, 5Oncology R&D Unit, Institut de Recherches, Croissy Sur Seine, France

Background: Identification of a chemotherapy-free option for acute myeloid leukemia (AML) represents a highly desired and important research objective. Perturbation of cell survival is an essential hallmark of cancer now amenable to precision targeting by small molecule BH3-mimetics able to inhibit pro-survival BCL-2 (e.g. Scouras et al Nat Med 2013 and Roberts et al., NEJM 2016). BCL-XL (Lessene et al., Nat Chem Biol, 2013) and MCL1 (Kotschy et al., Nature 2016). We hypothesize that simultaneous pharmacological targeting of BCL-2 and MCL1 will enhance apoptotic death of AML blasts, without increased toxicity to non-malignant cells.

Aims: To assess the feasibility and efficacy of targeting multiple BCL-2 pro-survival proteins using small molecule BH3-mimetics in pre-clinical models of AML

Methods: AML cell lines were obtained from ATCC or DSMZ. S55746 (BCL-2 inhibitor) and S63845 (MCL1 inhibitor with 6-fold higher affinity to human than mouse Mcl1) were obtained from Servier and A1155463 (BCL-XL inhibitor) from Guillaume Lessene (WEHI). Primary AML cells were obtained from patients providing informed consent. For in vivo experiments, NSG; NOD.Cg-PDKdcscid Il2rgtm1Wjl/SzJ (NSG) or NOD/Rag21/1;Il2rgtm1Wjl (NGRS) mice were used.

Results: S55746 and S63845 showed strong synergy (Loewe score >5) in 13 AML cell lines tested, suggesting this dual BH3-mimetic targeting approach was highly efficacious (Figure 1A). S55746 and S63845 lowered the LC50 in primary AML samples by 10-100-fold in the majority of cases tested, confirming remarkable anti-leukemic activity across a spectrum of AML cases with diverse cytogenetic and molecular pathologies (Figure 1B).

A smaller fraction of AML samples were also sensitised to combined A1155463 and S63845 therapy. Bioluminescent imaging showed rapid and sustained clearance of xenografted MV4;11 AML (FLT3-ITD mutant and MLL re-arranged) cells, translating into significant prolongation of survival (Figure 1C) from combined S55746+S63845, but not from treatment with either BH3-mimetic alone. Similar in vivo efficacy was observed with xenografted OCI-AML3 cells harboring mutant NPM1 and MDM2/3A. Patient-derived xenografts observed rapid reduction of established AML in the bone marrow one week of treatment with S55746 and S63845 (Figure 1D). Safety and tolerability of this approach was confirmed using normal CD34+ stem and progenitor cells in short-term cell culture (48h) and long-term (2-3 weeks) clonogenic assays and from histological and biochemical examination of mice receiving treatment for up to 8 weeks at doses shown to be highly efficacious against AML.

Summary/Conclusions: Dual BH3-mimetic targeting of BCL-2 and MCL1 induces rapid and synergistic cytoreduction of human AML cell line and primary AML samples in vitro and in vivo across a diverse range of AML genotypes. We therefore report for the first time, that dual pharmacological inhibition of both BCL-2 and MCL1 represents a novel approach to treating AML without need for additional chemotherapy and with an acceptable therapeutic safety margin. Our results support the translational investigation of dual BH3-mimetic targeting of BCL-2 and MCL1 in the clinic for the treatment of patients with AML.

THE PMLC62A/C65A KNOCK-IN MOUSE MODEL PROVIDES EVIDENCE FOR THE ROLE OF NUCLEAR BODY DISRUPTION IN THE PATHOGENESIS OF ACUTE PROMYELOCYTIC LEUKEMIA

E. Voisset1,*, E. Moravcsik1, E. Stratford2, A. Jaye1, C. Palgrave3, R. Hills4, P. Salomon1, S. Kogon1, D. Grimes1
1Medical and Molecular Genetics, King’s College London, London, United Kingdom, 2Tumor Biology, The Norwegian Radium Hospital, Oslo, Norway, 3School of Veterinary Medicine, University of Surrey, Guildford, 4Centre for Trials Research, College of Biomedical & Life Sciences, Cardiff, 5Samantha Dickinson Brain Cancer Unit, UCL Cancer Institute, London, United Kingdom, 6Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco, United States

Background: Acute promyelocytic leukaemia (APL) is driven by the oncogene PML-RARA, which is generated by fusion of the promyelocytic leukemia (PML) and retinoic acid receptor alpha (RARA) genes, and which strongly interferes with downstream signalling and the architecture of multiprotein structures known as PML nuclear bodies (NBs). NB disruption is a diagnostic hallmark of APL; however, the importance of this phenomenon has only been studied in vitro.

Aims: The aim of this study was to decipher the impact of Pml NB disruption in APL pathogenesis.

Methods: We engineered a knock-in mouse model with NB disruption achieved through mutation of key zinc-binding cysteine residues (C62A/C65A) in the Pml RING domain.

Results: While no leukaemias or tumors developed in PmlC62A/C65A mice, the forced dimerization of RARα - mediated artificially by linking RARα to the dimerisation domain of the NFkB p50 subunit - in cooperation with NB disruption was associated with doubling in the rate of leukemia (p<0.0001), with a reduced latency period (p=0.008). Moreover, response to targeted therapy with ATRA significantly improved the survival of mice transplanted with PmlC62A/C65A-PML-RARα leukemic blasts, but not with PmlC62A/C65A-P50-RARα, revealing the essential role of NBs for an effective response to differentiating drug. While formation of the PML-RARA fusion is considered an initiating event in APL pathogenesis, it is insufficient for the full leukemic phenotype. Moreover, whole exome sequencing analyses have consistently identified presence of cooperating mutations. Since Pml and Pml NBs have established roles in DNA repair and in the maintenance of genomic stability, we speculated that loss of NB integrity could affect these functions. Here, whole exome sequencing revealed a trend of higher genomic instability in PmlC62A/C65A mice as compared to PmlWT mice, particularly in the context of PmlC62A/C65A-P50-RARα leukemia as compared to PmlWT-P50-RARα leukemia as compared to PmlWT.

Conclusion: Identification of a chemotherapy-free option for acute myeloid leukemia (AML) represents a highly desired and important research objective. Perturbation of cell survival is an essential hallmark of cancer now amenable to precision targeting by small molecule BH3-mimetics in pre-clinical models of AML. Our study highlights the importance of re-formation of NBs for an efficient response to targeted therapy, the significant contribution

haematologica | 2017; 102(s2) | 37

Madrid, Spain, June 22 – 25, 2017
of Pml-NB to the effectiveness of DNA damage repair processes, and the manner in which their disruption mediated by the PML-RARα oncoprotein can assist APL pathogenesis.

DECAPHERING THE ONCOGENIC NETWORK OF PRC2 LOSS GLOUSED LEUKEMOGENESIS

D. von Stedingk1,2, E. Swarzer3, S. Knöbl1, J.-H. Klussmann1, D. Heckl1,2

1Pediatric Hematology & Oncology, 2Experimental Hematology, 3Hematology. Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: Loss of function mutations in EZH2 (including the chromosomal abnormalities -7/-7a) and other PRC2 subunits have been identified in adults with MDS, MPN and AML. Moreover children with JMML and up to 30% of children with Down syndrome related AML present with mutations in PRC2 subunits. Since myeloid neoplasms are elicited by accumulation of cooperating mutations and as the study of isolated mutations in回落thnic malignancies progresses, we set out to decipher the oncogenic network guided by loss of PRC2-activity.

Aims: Through identification of collaborating mutations driving AML with loss of PRC2 function followed by molecular profiling we aimed to identify novel collaborating mutations.

Methods: To model the complex interplay of mutational networks we performed CRISPR-Cas9 screenings with oncogene/tumor suppressor pools in vitro and in vivo. Cellular resources generated were subjected to mutational and molecular profiling.

Results: To this end, a 96-well based CRISPR-Cas9 immortalization assay allowing fast and quantifiable genetic cooperation screenings was established. Four out of six CRISPR-Cas9 pools tested –comprised of five genes each and representing 148 mutation combinations– reproducibly transformed LSK cells with distinct clonal output. Transplantation of in vitro immortalized clones yielded robust engraftment with multi-lineage contributions in mice but no overt leukemia was detected, indicating that induced mutations select for a preleukemic state in vitro. We thus tested every oncogene/tumor suppressor pool from the in vitro setting in a murine bone marrow transplantation model with freshly transduced LSK cells which resulted in robust induction of leukemia. Analysing the mutational spectrum of derived clones we were able to raise a list of potential partners cooperating with EzH2 loss, which highlighted Nf1 (Ras-signaling), loss of Dnmt3a, and loss of Runx1 as cooperating partners, whereas loss of cohesin complex subunits (Smc3, Stag2) seems to be dispensable during the induction of EzH2-loss guided leukemogenesis. To define oncogenic dependencies in myeloid malignancies with PRC2-loss we analysed gene expression spectra of the generated samples. While in vitro transduced clones presented with distinct expression signatures clearly separating from controls a partially overlapping expression signature could be established. Through identification of these shared expression signatures and the resulting gene expression signature, which will be validated in a CRISPR-Cas9 knock-out screening we aim to identify novel therapeutic targets in AML.

Summary/Conclusions: Our study highlights the power of the CRISPR-Cas9 system to probe oncogenic interaction. Mutational CRISPR screenings in vivo, and a newly established in vitro CRISPR-Cas9 immortalization assay for high throughput screening of sgRNA pools, delivered potential cooperating partners of EzH2 loss in AML, and provides rich cellular resources to identify molecular mechanisms of oncogenic synergies and dependencies.

ACUTE MYELOID LEUKEMIA EVOLUTION CAN BE RECONSTRUCTED BY ANALYSIS OF NON-LEUKEMIC CELLULAR SUBCOMPARTMENTS AND MULTI-LINEAGE ENGRAFTED MICE

B.R.M. Saeed1, L. Manta1, S. Rafeel1,2, P.T. Pyl3, W. Wang1, V. Eckstein1, A. Trumpf2, W. Holz1

1Internal Medicine V, Heidelberg University Hospital, 2Division of Stem Cells and Cancer, German Cancer Research Center (DKFZ) and Heidelberg Institute for Stem Cell Technology and Experimental Medicine (Hi-STEM GmbH), 3Mult-omics and statistical computing, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany

Background: Hematopoietic Stem Cells (HSC) isolated from patients with Acute Myeloid Leukemia (AML) have been shown to carry leukemia-specific mutations leading to the concept of pre-leukemic HSC. In order to understand the evolution from multi-potent pre-leukemic HSC to fully transformed AML, an accurate molecular comparison of patient matched HSC and leukemic cells is essential. Recently we have shown that functionally normal HSC can be separated from a subgroup of AML patients using the surface marker combination CD34+CD38- and high ALDH enzyme activity (CD34+CD38-ALDH+).

Aims: In this study we aim to understand the leukemic evolution from pre-leukemic HSC to fully transformed AML.

Methods: Whole exome sequencing (WES) of 12 diagnostic AML samples with the matched germ-line controls (T cells or buccal swab) was performed. Leukemia-specific mutations were identified according to specific criteria (Allele Depth (AD) > 20, Soft SNP Intervals > From GATK to SIFTS coverage > 10 reads, support > 2 reads, and GMAF < 0.05) and validated. Identified AML-specific mutations were tracked in different cellular compartments (T- and B-cells) as well as in single HSC colonies derived from diagnostic AML samples. To test the functional properties of pre-leukemic HSC in vivo, we transplanted bone marrow (BMM) from non-leukemic AML in NOD/SCID-IL2γnull (NSG) mice and analyzed human sub-populations (myeloid and lymphoid) of multi-lineage engrafted animals for the presence of leukemia-specific mutations.

Results: WES identified 64 AML-specific mutations. Most cases (8 out of 12) showed 4-6 AML specific mutations per sample (1-18 mutations/AML) including different t(8;21) translocations that were mutated in the respective leukemia specific sub-compartment. Transplantation of BMM in non-leukemic T- and B-cells showed that some AML mutations like DNM3A, ID1H, ID2H, EZH2 and ZNF536 were already detectable in T- and B-cells indicating their pre-leukemic status. Furthermore, analysis of multi-lineage engrafted xenografts detected leukemia-specific mutations in human myeloid and lymphoid sub-compartment suggesting that these animals were engrafted from functionally normal pre-leukemic HSC. To reconstruct the sequence of pre-leukemic mutations single-cell HSC were sequenced and the resulting colonies analyzed for the presence of the respective leukemia specific mutations. Based on the different mutational data, combined with the cellular context in which these were detectable the leukemic evolution of most patients could be reconstructed. In one patient we detected a DNM3TA mutation in myeloid and lymphoid cells, whereas NPM1 and FLT3-MTD mutations were only detectable in leukemic cells proving the pre-leukemic status of DNM3TA in this case. In another patient we found DNM3TA and ID2H in T- and B-cells whereas Translocation 8;21 were only detectable in leukemic cells. By analyzing colonies from single cell HSC we were able to detect complex pre-leukemic hierarchies with one example in which a ZNF536 mutation could be identified as initiating event that hasn’t been described in leukemia yet.

Summary/Conclusions: We can identify leukemia specific mutations including mutations in genes that haven’t been described in AML yet. Tracking of these mutations in various non-leukemic cellular compartments including HSC and multi-lineage engrafted mice allows reconstruction of the individual leukemic evolution. A better understanding of these processes may pave the way for new treatment strategies with the aim to target the relevant leukemic mutations.

P180

THE ESSENTIAL ROLE OF THE ENHANCERS OF POLYCOMB EPC1 AND EPC2 IN MLL-AF9 ACUTE MYELOID LEUKAEAMIA IS A ‘COMPLEX’ STORY

N. Mannion1,2, X. Huang3

1Paul O.Gorman Leukaemia Research Centre, 2Paul O’Gorman Leukaemia Research Centre, Institute of Cancer Sciences, MVLS, University of Glasgow, Glasgow, United Kingdom

Background: The Enhancers of Polycomb (EPC) proteins EPC1 and EPC2 are functionally essential for the survival of MLL-AF9 acute myeloid leukemia (AML). Most importantly, loss of EPC1 or EPC2 in MLL leukemia stem cells, but not normal hematopoietic stem cells and progenitor cells, leads to the induction of cellular apoptosis. To date little is known about the functional contribution of EPC1 and EPC2 in AML, especially in the context of MLL-AF9, the most frequently occurring chromatin immunoprecipitation (ChIP) was performed using HighCell ChIP Kit and iPure kit v2 (Diagenode) followed by NextSeq500 Illumina sequencing in THP1 cells. ChIP enriched regions were identified using SICER peak calling and ChIPpeakAnno. Lentiviral supernatants were prepared and THP1 cells were infected with viral particles containing pLKO.1 multi lentiviral vectors expressing shRNAs. RNA was extracted 72 hr following lentiviral transductions and whole transcriptome sequencing was performed. DESeq2 was used for differential expression analysis.

Methods: Mass spectrometry (MS) analysis was performed on immunoprecipitated protein using EPC1 antibody from human THP1 MLL-AF9 AML cell lines. Chromatin immunoprecipitation (ChIP) was performed using HighCell ChIP Kit and iPure kit v2 (Diagenode) followed by NextSeq500 Illumina sequencing in THP1 cells. ChIP enriched regions were identified using SICER peak calling and ChIPpeakAnno. Lentiviral supernatants were prepared and THP1 cells were infected with viral particles containing pLKO.1 multi lentiviral vectors expressing shRNAs. RNA was extracted 72 hr following lentiviral transductions and whole transcriptome sequencing was performed. DESeq2 was used for differential expression analysis.

Results: MS analysis identified the core Nau44 histone acetyltransferase complex. Additionally, EPC1 has been found in complexes with the Enhancer of zeste homolog 2 (EZH2), a catalytic core subunit of the histone methyltransferase Polycomb repressive complex 2 (PRC2). Nau4 and PRC2 are major chromatin modifying complexes encompassing opposit epigenetic activities and both are known to be deregulated in AML. AML cell line biology and understanding the contribution of the homologous chromatin regulatory proteins EPC1 and EPC2 in AML in search for novel therapeutic targets.

Summary/Conclusions: We can identify leukemia specific mutations including mutations in genes that haven’t been described in AML yet. Tracking of these mutations in various non-leukemic cellular compartments including HSC and multi-lineage engrafted mice allows reconstruction of the individual leukemic evolution. A better understanding of these processes may pave the way for new treatment strategies with the aim to target the relevant leukemic mutations.
histone methylation and acetylation profiles following lentiviral shRNA knockdown (KD) of EPC1 or EPC2 in THP1 cells. Interestingly, we find significant changes in histone H3K27 trimethylation levels as well as changes in the levels of histone H3 and H4 acetylation following KD of either EPC1 or EPC2 expression. Notably, the identified regions demonstrating changes in histone H3K27me3 levels are enriched for PRC2 target genes. RNA sequencing followed by gene-set enrichment analysis indicated significant transcriptional changes in PRC2 regulated genes following lentiviral shRNA knockdown of EPC1 or EPC2. Meta-analysis of this PRC signature identified a sub-group of genes that are directly regulated by the EPC complex which include the monocyctic differentiation inducer MAFB, the H2A ubiquitin ligase TRIM37 and the pro-apoptotic tumor suppressor CMTM3.

Summary/Conclusions: Our data suggests that EPC1 and EPC2 are required for the recruitment of certain chromatin proteins to form PRC-associatedcomplexes which are essential for the maintenance of an AML epigenetic signature and an aberrant transcriptional profile that supports leukemia stem cell survival. We have identified and characterized the EPC complex components in human AML. Additionally, we have refined a subgroup of PRC target genes that are regulated by the EPC complex which represent potential novel therapeutic targets in human AML. Overall we present a comprehensive analysis of the aberrant epigenomic landscape of THP1 MLL-AF9 AML cells in relation to EPC1 and EPC2 and provide new insight into their deregulated role in AML.

STROMA-DERIVED FACTORS STIMULATE JAK/STAT SIGNALING IN AML CELLS RESULTING IN RESISTANCE TO BCL2 INHIBITOR VENETOCLAX

R. Karjalainen1,2, M. Popa3, M. Liu1, K.K. Javarappa1, M. Kontro1,2, A. Parsons1, K. Porrka1, S. Griesser1, H. Mikkola2, K. Gjertsen2, C.A. Heckman1

1Institute for Molecular Medicine Finland, FIMM, Helsinki, Finland, 2Centre for Cancer Biomarkers CCBIO, Department of Clinical Science, University of Bergen, Bergen, Norway, 3Hematology Research Unit Helsinki, University of Helsinki, 4Department of Hematology, Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland, 5Department of Internal Medicine, Haukeland University Hospital, Bergen, Norway.

Background: The bone marrow (BM) microenvironment is known to protect AML cells from drug therapy. We showed earlier that conditioned medium (CM) from the BM stromal cell line HS-5 increased cell viability and led to resistance to specific drug classes.

Aims: Here, we investigate the mechanisms binding the BM stromal cell induced resistance to venetoclax and its reversal by ruxolitinib.

Methods: Phospho-flow analysis was done by stimulating AML patient cells with GM-CSF, G-CSF, IL-6, IL-8 or MIP-3α (10 ng/ml) for 20 min, after which the cells were stained with Alexa 488-anti-phospho-Stat5 (pY694), PE188 CF594-anti-phospho-Stat3 (pY705), BV421-anti-phospho-Akt (pS473) and PE-anti-phospho-Erk1/2 (pT202/pY204). For co-culture and transwell assays AML cells were added directly to MSCs from AML patients or separated by a 0.4 μm pore membrane. Vehicle (DMSO), ruxolitinib (300 nM), venetoclax (100 nM) or their combination were incubated for 48h and AML cells labeled with PE-Annexin V, 7AAD, PE-Cy7-CD34, BV605-CD45. In vivo drug efficacy was tested on NSG mice inoculated i.v. with MOLM-13AML cells. Mice were divided into control, venetoclax (25 mg/kg, i.p.), ruxolitinib (50 mg/kg BID, p.o), or venetoclax-ruxolitinib combination groups (n=6) and treated for 3 weeks, 5 days a week with 2 days off.

Results: To identify the factors contributing to BM mediated drug resistance of AML cells, we analyzed the effect of IL-6, IL-8, MIP-3α, GM-CSF and G-CSF cytokines enriched in the HS-5 CM, on proliferation of MNCs collected from AML patients. GM-CSF and to some extent G-CSF alone could reduce resistance to venetoclax similar to CM that we showed earlier to reduce sensitivity to BCL2 inhibitors. To identify the impact of stroma-derived factors on cellular signaling we stimulated AML patient cells with CM and analyzed the phosphorylation of STAT3, STAT5, ERK and AKT. Compared to control conditions, CM rapidly induced phosphorylation of STAT5 in primary AML cells. When the effect of individual cytokines was tested, we noted that GM-CSF and G-CSF alone could mimic the effect of CM on cellular signaling. Gene expression data showed the receptor for GM-CSF (CSFR2A) is more highly expressed in AML patient cells compared to healthy controls. Taken together, these results show that cytokines such as GM-CSF from BM stromal cells increase JAK/STAT signaling, which may lead to enhanced survival of AML cells. To determine whether the protective effect of stroma on BCL2 inhibition was dependent on cell-to-cell interactions we cultured AML patient cells either in direct contact with MSCs or separated from stroma with a 0.4 μm pore membrane. 48h treatment with 100 nM venetoclax did not result in significant reduction of CD34+ AML cells regardless of whether AML cells were directly cultured with stroma or separated by a membrane, further indicating that stroma-derived soluble factors are sufficient to reduce sensitivity to venetoclax. Since the most abundant cytokines secreted by HS-5 cells, GM-CSF and G-CSF led to increased phosphorylation of STAT5, a downstream effector of JAKs, we tested a combination of venetoclax and JAK1/2 inhibitor ruxolitinib. We found that ruxolitinib potentiated sensitivity to venetoclax when tested with AML patient cells in HS-5 CM and in co-culture and transwell assays. Significantly, the combination was more effective at reducing tumor burden in a xenograft mouse model of AML than either drug alone.

Summary/Conclusions: In conclusion, our data demonstrate that BM secreted soluble factors drive cytoprotection against BCL2 antagonist venetoclax that can be overcome by combined blockade of JAK/STAT and BCL2 pathways with ruxolitinib and venetoclax in vivo co-culture models and in vivo in an AML mouse model.

P182

IDENTIFICATION OF NOVEL GENE FUSIONS IN ACUTE MYELOID LEUKEMIA WITH COMPLEX KARYOTYPE USING TRANSCRIPTOME ANALYSIS USING RNA SEQUENCING

F. G. Rücker1, X. Gong9, A. Dolnik1, M. Hoyo1, S. Grasedieck1, J. Bischocko2, T. Blätte1, J. Swoboda1, A.S. Pollack2, A. Turchiano1, H. Döhner1, K. Döhner1, J.R. Pollack2, B. Bullinger1

1Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany, 2Department of Pathology, Stanford University, Stanford, United States

Background: Acute myeloid leukemia with complex karyotype (CK-AML), defined as having ≥3 acquired cytogenetic aberrations in the absence of WHO-designated recurring translocations or inversions, represents about 15% of...
adult AML cases. Despite having poor outcomes, CK-AML is the least understood at the molecular level, except for the finding that about two-thirds of cases carry TP53 alterations. In particular, because cytogenetic alterations appear to be distinct among different patients, it is unclear whether they are cause of leukemogenesis, or merely reflect a state of genomic instability.

**Aims:** We have hypothesized that cytogenetic aberrations in CK-AML create genetic lesions that are not recurrent across patients, potentially driving cancer genes that contribute to leukemogenesis in individual patients.

**Methods:** We performed a transcriptome analysis using Illumina paired-end (101bpX2) RNA sequencing of 65 CK-AML cases to identify gene fusions using multiple independent algorithms (as paired reads that flank, or single-reads that span the junction) across patients, non-redundant gene fusions identified. We validated the fusions in part independently by array-based genomic profiling and/or long range PCR followed by use of long-read Oxford Nanopore sequencing technology.

**Results:** We identified 54 gene fusion events in 30 of the 65 cases (46%) with up to four fusions per case. All fusions are supported by 10-50+ junction-spanning reads. The fusions are independently validated by array-based genomic profiling and/or long range PCR, respectively. About 35% of the fusions were in-frame, encoding chimeric proteins. The remainder encoded either C-terminally truncated 3' fusion partners, or else N-terminally truncated (or rarely full-length) 3' fusion partners that occurred in the 5' partner contributed only the 5'UTR. In many instances, the fusions are predicted to lead to the overexpression or chimeric activation of known or putative novel cancer genes. Of the 54 fusions, only three (RUNX1-MECOM, MN1-ETV6, and ETV6-MN1) were previously reported in AML. The most frequently affected genes were RUNX1 (n=5), KMT2A, and MECOM (n=3 each). Identified gene fusions were catego-

**Background:** NPM1 mutation (NPM1mut) is the most frequent genetic alteration found in cytogenetically normal acute myeloid leukemia (CN-AML). Patients harboring NPM1mut without FLT3 internal tandem duplication (FLT3-ITD) are considered to have favorable outcome. Yet, some of them relapse and become resistant to chemotherapy. Little is known about biological processes underlying treatment failure. Our group previously described a new epigenetic biomarker corresponding to an abnormal gain of the repressive H3K27me3 histone mark within the HIST1 locus on the 6p22 referred as H3K27me3 HIST1high. This epigenetic biomarker had an impact on clinical outcomes, as CN-AML patients with H3K27me3 HIST1high had a higher overall survival (OS) and leukemia-free survival (LFS) than H3K27me3 HIST1low patients (Tiben et al., 2015).

**Aims:** We studied the impact of H3K27me3 HIST1 in an independent cohort. We assessed whether H3K27me3 HIST1 could help to classify NPM1mut CN-AML patients independently of known genetic alterations. Secondly, we studied gene expression profile (GEP) related to H3K27me3 HIST1high. This epigenetic biomarker had an impact on clinical outcomes, with 3Aix-Marseille University, 4Oncology, 5Cell therapy facility, Paoli-Calmettes Institute Biobank and analyzed as training set. A validation set of samples collected during the conduct of two GOELAMS clinical trials (LAM2006IR and LAM2006GR) was used for validation. We performed H3K27me3 HIST1 profiling by chromatin immunoprecipitation followed by quantitative polymerase chain reaction (qPCR). The histone genetic biomarker had an impact on clinical outcome, as CN-AML patients with H3K27me3 HIST1high had a higher overall survival (OS) and leukemia-free survival (LFS) than H3K27me3 HIST1low patients (Tiben et al., 2015).

**Results:** We identified 54 gene fusion events in 30 of the 65 cases (46%) with up to four fusions per case. All fusions are supported by 10-50+ junction-spanning reads. The fusions are independently validated by array-based genomic profiling and/or long range PCR, respectively. About 35% of the fusions were in-frame, encoding chimeric proteins. The remainder encoded either C-terminally truncated 3' fusion partners, or else N-terminally truncated (or rarely full-length) 3' fusion partners that occurred in the 5' partner contributed only the 5'UTR. In many instances, the fusions are predicted to lead to the overexpression or chimeric activation of known or putative novel cancer genes. Of the 54 fusions, only three (RUNX1-MECOM, MN1-ETV6, and ETV6-MN1) were previously reported in AML. The most frequently affected genes were RUNX1 (n=5), KMT2A, and MECOM (n=3 each). Identified gene fusions were catego-

**Summary/Conclusions:** Detailed molecular characterization of CK-AML revealed a high incidence of novel gene fusions in about 50% of cases. The affected genes suggest more general role in leukemogenesis than reflecting a state of genomic instability. Furthermore, identifying gene fusions in each individual patient might lead to more effective, personalized treatments that target the gene fusion partner, enable immunologic therapies against the fusion junction epitopes, and provide private patient-specific biomarkers to track leukemic burden for the monitoring of disease remission and relapse.
lity of protein expression was normalized to actin. That ratio of phosphorylated protein to total protein for FLT3 and STAT5 was determined and normalized to that observed in the D835Y mutation as a positive control. A value of >10% pFLT3 was considered positive. All mutations that resulted in FLT3 phosphorylation were subsequently evaluated for inhibition by crenolanib and quizartinib following 60-minute exposure to the compounds.

Results: A total of 24 non-ITD and non-ALM FLT3 mutations were evaluated for autonomous FLT3 and STAT5 phosphorylation. Eleven mutations resulted in pFLT3 and pSTAT5, including 4 mutations with >50% pFLT3. All mutations that demonstrated aberrant pFLT3 also had aberrant pSTAT5, however a direct correlation of pFLT3 and pSTAT5 was not always observed. Overall, 87% (n=86 patients) of all non-ITD mutations evaluated resulted in autonomous FLT3 activation. Excluding D835 mutations, 64% (n=39) of patients harbored an activating mutation. Many of the mutations that were not found to be activating had the lowest prevalence, often present in only one patient. Evaluation of inhibition of pFLT3 by hyperthermia demonstrated that in every case of aberrant activation, crenolanib resulted in potent inhibition of phosphorylation of FLT3 and STAT5 with an IC50 range of 1.3-13.9 nM and 0.6-6.5 nM respectively. Many of the mutations tested were exclusively sensitive to crenolanib, with 9 of 10 mutations tested demonstrating an IC50 of pFLT3 inhibition ≤5.6 nM. Inhibition of downstream kinases is necessary for optimal efficacy of any FLT3 inhibitor and phosphorylation of STAT5 was potently inhibited by crenolanib in all cases. Quizartinib inhibited pFLT3 and pSTAT5 with an IC50 range of 1.8-15.1 nM and 1-33.9 nM respectively, demonstrating less effective inhibition specifically at mutations including D835Y, D839E, M664I, M664V.

Summary/Conclusions: We have previously presented that FLT3 mutations, including novel mutations in addition to the FLT3/ITD and D835, are prevalent in children and young adults with AML. Here we demonstrate that many of the non-ITD/D835 mutations also result in aberrant FLT3 phosphorylation and are amenable to inhibition by FLT3 inhibitors. Crenolanib resulted in potent inhibition of FLT3 and downstream STAT5 in all mutations tested. This data supports expanding the cohort of pediatric patients with activating FLT3 mutations who may benefit from FLT3 inhibitor therapy beyond those with FLT3/ITD.

THE BCL-2 INHIBITOR VENETOCLAX INHIBITS NRF2 ANTIOXIDANT PATHWAY ACTIVATION INDUCED BY HYPMETHYLATING AGENTS IN ACUTE MYELOID LEUKEMIA
L.X.T. Nguyen1,*, A. Kalvala1, E. Troadec1, B. Kumar1, S. Forman1, G. Marcucci1, L.X.T. Nguyen1,*, A. Kalvala1, E. Troadec1, B. Kumar1, S. Forman1, G. Marcucci1, V. Pullarkat2
1City of Hope Medical Center, Duarte, United States, 2Hematology, City of Hope Medical Center, Duarte, United States

Background: The selective Bcl-2 inhibitor Venetoclax (ABT-199) has shown potent in vitro activity against Adult Myeloid Leukemia (AML) in preclinical and early clinical studies and impressive results have been achieved using the combination of hypomethylating agents (HMA) with venetoclax suggesting synergies between these agents.

Induction of Reactive Oxygen Species (ROS) is important for the cytotoxicity of various AML therapies including HMA. Induction of ROS by various cytotoxic therapies concurrently activates the Nrf2 antioxidant response pathway which in turn results in induction of antioxidant enzymes that neutralize ROS. Upon ROS induction, the transcription factor Nrf2 is released from its adaptor protein Keap1 in the cytoplasm whereby Nrf2 enters the nucleus and binds to antioxidant response element sequences in the promoters of various genes. Nrf2 pathway activation has been shown to mediate chemoresistance in various cancers including AML. Low ROS levels have been shown to be a hallmark of leukemia stem cells and are critical to their self renewal capacity. In this study, we examined whether Nrf2 inhibition is an additional mechanism responsible for the marked antileukemic activity in AML seen with the combination of HMAs and venetoclax.

Aims: To identify the effect of venetoclax on ROS levels after HMA exposure in AML cells and to examine the effect of Bcl-2 inhibition on NRF2 antioxidant pathway activation in response to HMA.

Methods: The effect of combination venetoclax and HMA on ROS levels and apoptosis was measured by flow cytometry. Effect of venetoclax and HMA on Nrf2 nuclear translocation was analyzed by immunostaining after cellular fractionation. Effect of venetoclax treatment on the association of Bcl2 with Nrf2/Keap1 complex was assessed by Western blot analysis, immunoprecipitation and in vitro assay for ubiquitination.

Results: Our results demonstrated that combination of HMA with venetoclax augmented cellular and mitochondrial ROS induction and apoptosis compared to treatment HMA alone. Treatment of AML cell lines as well as primary AML cells with venetoclax resulted in increased nuclear translocation of Nrf2 (Figure 1) and induction of downstream antioxidant enzymes including HO-1 and NQO1. Immunofluorescence studies confirmed the inhibition of nuclear translocation of Nrf2 by venetoclax. Immunoprecipitation studies indicated that Bcl-2, Keap1 and Nrf2 associate in a protein complex in the cytoplasm and that treatment with venetoclax leads to dissociation of Bcl-2 from the Nrf2/Keap1 complex and targets Nrf2 to ubiquitination and proteosomal degradation.

Figure 1.

Summary/Conclusions: In conclusion, inhibition of Nrf2 pathway may explain the marked potentiation of HMA activity by venetoclax that is observed in clinical trials. We show that ROS induction at least partially mediates the cytotoxicity of HMA and ROS induction after HMA treatment is augmented by venetoclax. We demonstrate for the first time that venetoclax is a potent inhibitor of Nrf2 activation via disruption of the association between Nrf2, Keap-1 and Bcl-2.

P187
UNRAVELING EPIGENOMIC REGULATION IN THE EVOLUTION OF RELAPSING PEDIATRIC AML
C. Wiggers1,2,3, M. Baak1, M. Creyghton1, M. Bartels2
1Hubrecht Institute, 2Pediatrics, University Medical Center Utrecht, Utrecht, Netherlands

Background: In comparison with pediatric acute lymphoblastic leukemia, pediatric acute myeloid leukemia (AML) is characterized by a high relapse rate (>30%), and lower overall survival rates of 60-70%. It is therefore crucial to increase our insights in pathophysiological mechanisms underlying AML relapse, including chemotherapy resistance, clonal evolution, and clonal selection. There is increasing evidence that epigenetic deregulation is involved in the initiation and progression of cancers, including adult AML. Epigenetic regulation involves the activity of non-coding regulatory DNA elements such as enhancers, which interact with promoters to fine-tune gene expression. Importantly, epigenetic signatures at enhancers are highly cell state specific. Since little is known concerning the epigenetic landscape of pediatric AML, it is crucial to gain more insights into the epigenome of relapsed and non-relapsed AML in children.

Aims: To identify differential epigenomic regulatory pathways involved in AML relapse by exploring the epigenome of relapsed (RP) and non-relapsed pediatric AML patients (NRP).

Methods: The epigenome of 20 AML patients, harboring known molecular aberrations (including MLL-rearrangement, CBF-related and Fli3-ITD), was analyzed in a high-throughput, single-cell-based, marker-based analysis. Acetylation of lysine 27 on the tail of histone H3 (H3K27ac) marks active regulatory DNA elements and was therefore used to identify active promoters and enhancers using Chromatin-Immunoprecipitation-sequencing (ChIP-seq) experiments. Additionally, single-cell RNA-seq data was generated for selected AML patients to analyze clonal heterogeneity.

Results: All genomic regions that were significantly enriched by H3K27ac were analyzed, resulting in ~30,000 active promoters and enhancers per sample. Genome-wide Pearson correlation of all enriched regions showed subclustering of patients based on molecular aberration. Interestingly, epigenomic analysis showed that the initial diagnosis (Dx) and the patient’s relapse (Rel) sample were highly correlated. Also, single-cell RNA-seq analysis identified two highly identical homogeneous populations at Dx and Rel. Following the fact that no major differences were observed between AML cells at diagnosis and relapse, NRP were analyzed. Here striking differences in H3K27ac enrichment were observed in MLL-rearranged patients between NRPs and RPs. Enhancers and promoters were differentially enriched at diagnosis, of which Sphk1, a kinase involved in proliferation and survival, was significantly more enriched in RPs, while the promoter of transcription factor ELF1a and nearby located enhancers were active in NRPs only.
**Summary/Conclusions:** Analysis of promoters and especially enhancers is a highly useful approach to identify cell state specific regulation. Here, we analyzed pediatric AML patients at diagnosis and at relapse to gain more insight into specific cell states which are involved in relapse. Our data revealed high similarity between diagnosis and relapse samples, while, strikingly, in the WHO intermediate-risk group containing MLL-rearranged patients, differential epigenomic regulation was observed between NRPs and RPs. Taken together, our preliminary data suggests that already at diagnosis, AML cells display an epigenomic fingerprint associated with the development of AML relapse during the course of disease. We are currently validating these data.

**Background:** The complex pathogenesis of cancer often necessitates combination therapies to optimize patient benefit. Thus, we investigated preclinical combinations of SY-1425 (tirabrutinib) and other agents to build on the monotherapeutic strategy with SY-1425 in biomarker selected AML and MDS patients (Phase 2 study, NCT02807558). Based on the RARα mediated myeloid gene activation of SY-1425, epigenetic priming with hypomethylating agents (HMAs) and CD38 induction were explored.

**Aims:** We sought to investigate mechanistically informed combinations of SY-1425 and HMAs in clinical relevant and with venetoclax sensitive RARA-high AML cell lines treated with SY-1425 mediated reprogramming by relieving aberrant methylation of RARα target genes and that strong upregulation of the maturation marker CD38 in AML cells by SY-1425 could induce sensitivity to the anti-CD38 therapeutic antibody daratumumab (DARA).

**Methods:** HMA synergy was tested in vitro in AML cell lines over a range of concentrations for SY-1425 and azacitidine. In vivo studies used a disseminated patient derived xenograft (PDx) model of AML expressing high levels of RARA. SY-1425 induction of CD38 was assessed by H3K27ac ChIP-seq, RARα ChIP-seq, RARA-high AML cell lines treated with SY-1425 mediated reprogramming by relieving aberrant methylation of RARα target genes and that strong upregulation of the maturation marker CD38 in AML cells by SY-1425 could induce sensitivity to the anti-CD38 therapeutic antibody daratumumab (DARA).

**Results:** RARα acts as a repressive transcription factor until bound by SY-1425 leading to potent, targeted activation of myeloid genes. HMAs can further prime this activation by depleting repressive methylation of these target genes. The combination of SY-1425 and azacitidine showed synergy in RARA-high AML cell lines, but not in RARA-low AML cell lines, with combination indices less than 0.5. Co-administration in a RARA-high AML PDx demonstrated superior reduction of tumor burden (<1% detectable tumor cells) vs either treatment alone. SY-1425 induced 20-25% cell death comparable to DARA and azacitidine. Combination regimens evaluated in the PDx model over two cycles (56 days) found that 1 week of azacitidine followed by 3 weeks of SY-1425 maximized for anti-tumor activity (<5% AML cells in periphery, bone marrow and spleen) and tolerability (<8% weight loss). RARα binds directly to the CD38 locus and induces H3K27 acetylation of SY-1425 activating the expression of the maturation marker CD38. SY-1425 treatment synergized with azacitidine in FLT3-ITD+ cell lines (Kohl, Leukemia 2007).

**Background:** FLT3 internal tandem duplication (ITD) mutations account for ~20-25% of adult AML cases and are associated with worse prognosis. Although FLT3 inhibitors show clinical activity, relapse occurs quickly. Venetoclax is a potent, selective inhibitor of the anti-apoptotic protein BCL-2 that demonstrated monotherapy activity in relapsed/refractory AML (ORR 19%); however, no activity was seen in FLT3 mutant cases (Konopleva, Can Disc and Exp Pharmacol 2015). In combination with the anti-apoptotic proteins BCL-XL and MCL-1, but not BCL-2, and FLT3 inhibition synergizes with the dual BCL-2/BCL-XL inhibitor ABT-737 in vitro in FLT3-ITD+ cells (Kohl, Leukemia 2007). Aims: Expression of BCL-XL, and MCL-1 are known resistance factors to venetoclax, therefore targeting pathways that regulate BCL-Xl or MCL-1 in combination with venetoclax may enhance cell death and improve efficacy. Based on this hypothesis, we interrogated if selective inhibition of BCL-2 by venetoclax in combination with quazartinib, a potent FLT3 inhibitor, resulted in synergistic anti-tumor effects in FLT3-ITD+ AML models.

**Methods:** FLT3-ITD+ (Molm13 and MV4;11) and wild type (HL60 and OCI-AML3) cell lines were evaluated in vitro. Profiling was measured by cell titer glo and apoptosis by Annexin V staining. In vivo efficacy was determined in a MV4;11 xenograft model.

**Results:** Sensitivity to venetoclax was initially assessed in vitro. Dose dependent growth inhibition and induction of apoptosis was observed in the MV4;11, Molm13 and HL60 cell lines following 48hr venetoclax treatment, with the MV4;11 cell line most sensitive. Modulation of BCL-2, BCL-XL and MCL-1 expression by FLT3 inhibition was determined following 8-24hr treatment with quazartinib. Quazatinib reduced BCL-XL and MCL-1 protein, but not BCL-2, in the FLT3-ITD+ cell lines. Quazatinib had no effect on expression of these three proteins when combined with venetoclax. The combination of quazartinib and venetoclax in vitro, cell lines were treated for 48hrs with venetoclax, quazartinib or the combination. Combination treatment led to significant reduction in proliferation and increased apoptosis in the FLT3-ITD+ cells compared to either single agent. FLT3 wt cells were not sensitive to quazatinib as a single agent in combination with venetoclax. The combination of quazatinib and venetoclax in vitro synergized with quazatinib in vitro and in vivo at clinically relevant doses for each compound. These data suggest that co-targeting FLT3-ITD with selective inhibitors and BCL-2 with venetoclax induces apoptosis to a greater extent than FLT3 inhibition alone. Importantly, our preclinical data supports further clinical investigation of this combination to treat FLT3-ITD+ AML.

**Background:** Only 30-40% of acute myeloid leukemia (AML) patients survive five years after diagnosis. This extreme poor prognosis is mainly caused by treatment failure due to chemotherapy resistance. Leukemic stem cells (LSCs) are thought to be major determinants of AML recurrence due to their potential for self-renewal and chemotherapy resistance. LSCs co-reside with normal CD34+/CD38− hematopoietic stem cells (HSCs) in the AML bone marrow. Increasing the dose of chemotherapy might eliminate these chemotherapy resistant cells, however inevitable result in the non-specific elimination of HSCs, delaying or even preventing the recovery of normal hematopoiesis after therapy. To significantly improve the outcome of AML patients, the discovery of alternative therapies that specifically eliminate LSCs while sparing HSCs is urgently needed. To develop these type of therapies, it is mandatory to understand the differences of genes differentially expressed between LSCs and HSCs and between LSCs and the AML bulk is crucial.

**Aims:** To identify specific therapeutic strategies that have the potential to eliminate AML relapse-initiating cells.

**Methods:** We generated gene expression profiles of HSCs, LSCs and leukemic progenitors all derived from the same AML bone marrow and identified Insulin growth factor binding protein 7 (IGFBP7) as one of the top differentially expressed genes. As low IGFBP7 expression is a feature of LSCs, we hypothesized that
decreased expression of IGFBP7 might be associated with decreased chemotherapy sensitivity. To this end, we generated cell lines with IGFBP7 knockdown and subjected the cells to chemotherapy. Furthermore, to test whether increasing the IGFBP7 levels might be a strategy to deplete leukemic (stem) cells, we overexpressed IGFBP7 in or added recombinant human IGFBP7 (rhIGFBP7) to primary AML cells and measured clonogenic capacity, differentiation and cell survival in vitro. To study the effect of IGFBP7 on AML cell survival and engraftment potential in vivo, primary AML cells were transplanted into immune deficient mice and the mice were subsequently treated with rhIGFBP7. To study the effect of rhIGFBP7 on LSC survival, human AML cells derived from the first transplanted mice were re-transplanted into secondary recipients and engraftment and survival of the mice were monitored.

**Results:** Knockdown of IGFBP7 results in reduced sensitivity to chemotherapy and comparing matched diagnosis and relapsed AML samples showed that IGFBP7 expression is frequently downregulated at relapse, suggesting a survival advantage of IGFBP7lowAML cells during chemotherapy treatment. Importantly, enhancing cytoplasmic or extracellular IGFBP7, by overexpression or addition of rhIGFBP7, resulted in induction of differentiation and apoptosis, increased sensitivity to chemotherapy and inhibited AML blast and leukemic stem/progenitor cell survival in vitro and in vivo. IGFBP7 had no influence on the survival of normal hematopoietic (stem) cells. Moreover, treatment with rhIGFBP7 can add to chemotherapy treatment by elimination of chemotherapy resistant refractory AML (stem) cells.

**Summary/Conclusions:** Altogether, these data suggest that addition of IGFBP7 to the currently used chemotherapy regimens might be a promising strategy to specifically eradicate LSCs and decrease AML relapse rates.

**ONGOING PHASE 2 CLINICAL TRIAL OF SL-401 IN PATIENTS WITH BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM: STAGE 1 AND STAGE 2 RESULTS**

N. Pemmaraju1,1, K. Sweet2, A. Lane3, A. Stein4, S. Vasu5, W. Blum5, D. Rizzieri6, E. Wang7, M. Duvic1, J. Chen8, S. Shemesh9, P. McDonald10, C. Brooks11, J. Lance12, H. Kantarjian1, M. Konopleva1

1MD Anderson Cancer Center, Houston, TX, 2H. Lee Moffitt Cancer Center, Tampa, FL, 3Dana-Farber Cancer Institute, Boston, MA, 4City of Hope National Medical Center, Duarte, CA, 5The Ohio State University, Columbus, OH, 6Duke University Medical Center, Durham, NC, 7Roswell Park Cancer Institute, Buffalo, NY, 8Stemline Therapeutics, New York, NY, 9United States

**Background:** SL-401 is a targeted therapy directed to interleukin-3 receptor α (CD123), a target overexpressed on a variety of cancers including blastic plasmacytoid dendritic cell neoplasm (BPDCN), a highly aggressive malignancy with poor outcomes and unmet medical need.

**Aims:** This Phase 2 trial is a single-arm, open-label, study designed to generate efficacy and safety data to support potential registration in BPDCN.

**Methods:** In this ongoing Phase 2 single-arm trial, patients with BPDCN (n=32) or relapsed/refractory (R/R) AML (n=48) received SL-401 as a daily IV infusion at 7, 9, 12, or 16 ug/kg/day for days 1-5 of a 21-day cycle in stage 1. In stages 2 and 3, patients received SL-401 at the dose determined in stage 1.

**Results:** 32 adult BPDCN patients received SL-401 in stage 1 (n=9) and stage 2 (n=23), including 19 first-line and 13 R/R patients. Stage 3 patients will be reported separately. Median age was 72 years (range: 30-85 years). In stage 1, 12 ug/kg was the highest tested dose for BPDCN; MTD was not reached in BPDCN. Median follow-up was 4.3 months (range: 0.5-22.9 months). ORR of 84% (27/32) was observed in all patients: 95% (18/19) in first-line and 69% (9/13) in R/R. 88% (14/16) of first-line patients treated at 12 ug/kg had a complete remission (CR). CR with incomplete hematologic recovery (CRI) (n=1) or clinical CR (CRC; residual skin disease) (n=3) was achieved. In stage 2, 88% (14/16) of patients were progression free for 4 to 22.9 months (ongoing), including 3 patients on SL-401 in remission (4 to 13 months, ongoing) and 7 patients who were bridged to stem cell transplant (SCT; 3 auto-SCT and 4 allo-SCT). A R/R patient was also bridged to allo-SCT. Overall, most common side effects have generally tended to decrease in frequency and severity with increasing cycles. Updated data, including detailed safety analysis across all ongoing SL-401 studies will be presented at the meeting.

**PROGNOSTIC IMPACT OF SOMATIC MUTATION CLEARANCE IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA**

K. Takahashi1, F. Wang1, K. Patel1, C. Bueso-Ramos1, G. Issa1, X. Song1, J. Zhang1, C. Gumbs1, F. Ravandi1, T. Kadia1, N. Daver1, C. DiNardo1, M. Konopleva1, M. Andreff1, J. Cortes1, G. Garcia-Manero1, E. Jabbour1, A. Furlan1, H. Kantarjian1

1Leukemia, UT MD Anderson Cancer Center, Houston, United States

**Background:** Persistence of somatic mutations at the time of complete remission (CR) was associated with poor outcome in patients (pts) with AML.

**Aims:** To analyze differential pattern of mutation clearance based on the genes and affected pathway and to assess prognostic impact of mutation clearance in AML patients.

**Methods:** We studied 95 pts with AML who were treated with frontline induction and subsequently achieved CR. We sequenced pre-treatment and CR bone marrow samples by targeted capture sequencing of 295 genes (median 280x coverage). We defined 5 levels of mutation clearance (MC) based on variant allele frequency (VAF): 1) MC2.5, persistent mutation with VAF≥2.5%, 2) MC1.0, persistent mutation with VAF<1%, and 3) complete mutation clearance (CMC).

**Results:** In the pre-treatment samples, we detected 597 mutations in 78 genes in 87 (92%) patients. In the matching CR samples, 62 (10%) and 82 (14%) mutations persisted at VAF≥2.5% and ≥1%, respectively, which corresponded to 43 (49%), 34 (39%), and 30 (34%) patients achieving MC2.5, MC1.0 and CMC, respectively. Table 1 shows the differential patterns of MC based on the mutations and pathways. Mutations associated with clonal hematopoiesis of
indeterminate therapy (CHIP), DNA methylation, and splicing pathways had low rate of MC, whereas mutations in translocation factor or receptor tyrosine kinase (RTK) had high rate of MC. Pts who achieved MC1.0 (median 31.2 vs 12.5 months, P<0.04) or CMC (median 31.2 vs 12.5 months, P<0.049) had significantly better relapse-free survival (RFS).

Summary/Conclusions: Somatic mutations associated with CHIP, DNA methylation, and splicing pathways persisted frequently in CR samples suggesting preleukemic origin. Pts with deeper MC had significantly better RFS. Somatic mutation clearance may help risk prediction of AML.

P193

DO EDUCATION AND INCOME AFFECT TREATMENT AND OUTCOME IN ACUTE MYELOID LEUKEMIA IN A TAX-SUPPORTED HEALTH CARE SYSTEM? A DANISH NATIONAL POPULATION-BASED COHORT STUDY

L. S. Østgård, M. Nørgaard, B. C. Medeiros, L. S. Friis, C. Schöllkopf, M. Severinsen, C. W. Marcher, J. M. Nørgaard

1Department of Hematology, 2Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, 3School of Medicine, Stanford University, Stanford, United States, 4Department of Statistics, State University, Copenhagen, 5Department of Hematology, Herlev University Hospital, Herlev, 6Department of Hematology, Odense University Hospital, Odense, Denmark

Background: No larger study has investigated the association between individual-level education or income level and clinical prognostic markers, treatment, and outcome in acute myeloid leukemia (AML). Understanding how socioeconomic status (SES) affects survival in AML patients may improve prognosis through targeted support among patients with different SES risk profiles.

Aims: To investigate the effects of education as a knowledge-related SES factor and income as a measure of material resources in a tax-supported health care system linking individual-level SES information from Statistics Denmark to clinical data from the Danish National Leukemia Registry.

Methods: We conducted a nationwide population-based cohort study and included AML patients 25 years diagnosed in Denmark 2000-2014 (end of follow-up, Feb 2016). KM curves and Cox regression (Hazard ratios; HRs) was used to compare survival by education (low, medium, and high) and income level (tertiles). We repeated the survival analysis within educational groups by year of diagnosis (2000-2004, 2005-2009, 2010-2014), stratified by time period, and outcome (CR, chance of clinical trial (CR), or survival (intensive therapy-only; high income adjusted HR 1.0, medium 1.0, low 1.0; Figure 1). In older patients, low education was associated with therapy intensity, chance of clinical trial and outcome in AML. Understanding how education affects survival in AML patients may improve prognosis through targeted support among patients with different SE risk profiles.

Results: Of 2992 patients, 1588 (53.1%) received remission induction (odds ratios; ORs) to compare treatment intensity, chance of clinical trial and outcome in AML. AML patients with somatic RUNX1 mutations had a poor prognosis (6,7) independent of other risk factors. The role of co-occurring mutations in leukemogenesis in FPD/AML patients with germline RUNX1 mutations and AML patients with de novo somatic RUNX1 mutations is not fully understood.

Aims: In order to further characterize co-occurring mutations in patients with both germline and somatic RUNX1 mutations, we analyzed a large cohort of AML tumor samples along with several paired normal tissue samples.

Methods: We sequenced a cohort of 482 diagnostic bone marrow or peripheral blood samples from AML patients by deep whole-exome sequencing. Samples were collected through the "Beat AML" project, an ongoing program at Oregon Health & Science University in collaboration with the Leukemia & Lymphoma Society. RUNX1 mutations were classified using VarScan which defined somatic and germline mutations as follows: somatic if <0.1% and germline if not called as somatic and normal variant allele frequency >0.1.

Results: Twenty AML samples had 21 germline RUNX1 mutations with a total of 6 different germline variants; 31 other patient samples had 38 somatic RUNX1 mutations with 31 unique somatic variants. One sample had 2 RUNX1 germline mutations; 6 samples had >1 somatic RUNX1 mutations. The most common germline variant, missense mutation p.L56S, was found in 16% (76/43) of the cohort. 

Figure 1.

Summary/Conclusions: In Denmark where health-care is free and uniform, high SES status does not affect treatment intensity in younger patients or response to therapy. However, educational level, but not income, influences allelic and germline mutations in AML tumor samples with a major impact on survival in younger AML patients. Since 2000, survival improvements have exclusively benefitted well-educated patients and additional attention during treatment and follow-up towards low-educated patients may increase transplantation rates and improve survival.

Background: RUNX1 plays a vital role in leukemogenesis through its interaction with core binding factor-β complex and other genes involved in hematopoiesis (1,2). Familial platelet disorder with predisposition to acute myeloid leukemia (FPD/AML) is linked to germline RUNX1 mutations (3). This autosomal dominant disorder is characterized by thrombocytopenia and potential for transformation to AML. AML patients with somatic RUNX1 mutations have a poor prognosis (6,7) independent of other risk factors. The role of co-occurring mutations in leukemogenesis in FPD/AML patients with germline RUNX1 mutations and AML patients with de novo somatic RUNX1 mutations is not fully understood.

Methods: We sequenced a cohort of 482 diagnostic bone marrow or peripheral blood samples from AML patients by deep whole-exome sequencing. Samples were collected through the "Beat AML" project, an ongoing program at Oregon Health & Science University in collaboration with the Leukemia & Lymphoma Society. RUNX1 mutations were classified using VarScan which defined somatic and germline mutations as follows: somatic if <0.1% and germline if not called as somatic and normal variant allele frequency >0.1.

Results: Twenty AML samples had 21 germline RUNX1 mutations with a total of 6 different germline variants; 31 other patient samples had 38 somatic RUNX1 mutations with 31 unique somatic variants. One sample had 2 RUNX1 germline mutations; 6 samples had >1 somatic RUNX1 mutations. The most common germline variant, missense mutation p.L56S, was found in 16% (76/43) of the cohort. 

Figure 1.

Summary/Conclusions: In Denmark where health-care is free and uniform, high SES status does not affect treatment intensity in younger patients or response to therapy. However, educational level, but not income, influences allelic and germline mutations in AML tumor samples with a major impact on survival in younger AML patients. Since 2000, survival improvements have exclusively benefitted well-educated patients and additional attention during treatment and follow-up towards low-educated patients may increase transplantation rates and improve survival.
Methods: multiple LSC markers on the outcome of AML patients. The incidence of RUNX1 mutations seen in our 482-patient Beat AML cohort (4.3% germline, 6.4% somatic) is consistent with results from other studies (8). Our study suggests that germline and somatic RUNX1 mutations in AML patients are mutually exclusive, as are several co-occurring pathogenic mutations that contribute to leukemogenesis. Our study adds to the already described mutually exclusive mutations in germline RUNX1 by identifying WT1, CHEK2, CCND3, and others. Similarly, in samples with somatic RUNX1 mutations, we found mutually exclusive mutations in CBL, JAK2, MLL, EZH2 and others, in addition to the previously described IDH1 (8). Further characterization of these results and analyses of additional samples using our whole-exome sequencing and our bioinformatics platform will help us better elucidate the molecular events underlying AML progression and help us establish novel prognostic/therapeutic markers aimed at early intervention in patients, or their family members, who carry RUNX1 mutations.

MULTIPLE LEUKEMIC STEM CELL MARKER EXPRESSION IS ASSOCIATED WITH POOR PROGNOSIS IN DE NOVO ACUTE MYELOID LEUKEMIA
T. Yabushita1,* Y. Shimomura1, D. Katoh1, Y. Ono1, N. Hiramoto2, S. Yoshioka1, N. Yonetani1, A. Matsushita1, H. Hashimoto2, T. Ishikawa1
1Hematology, Kobe City Medical Center General Hospital, 2Hematology, Institute of Biomedical Research and Innovation Hospital, Kobe City, Japan

Background: Acute myeloid leukemia (AML) is believed to originate from a small population of leukemic stem cells (LSCs). Current chemotherapy regimens target the majority of more mature leukemic blasts, but cannot efficiently eliminate LSCs, resulting in early treatment failure and relapse. Thus, the expression of LSC-specific markers could be used as a predictive factor of clinical outcomes in AML patients. Recently, the clinical impact of individual LSC markers has been documented in several reports, but the combined effect of different LSC markers remains unexamined.

Aims: This study aimed to estimate the prognostic impact of the expression of multiple LSC markers on the outcome of AML patients.

Methods: Ninety consecutive patients diagnosed with de novo AML at our institution and eligible for intensive chemotherapy were enrolled from September 2010 to March 2016. We excluded 10 patients with acute promyelocytic leukemia. This study was approved by the institutional review board of the Ethics Committee and was conducted with the Declaration of Helsinki. We analyzed the expression of three LSC markers, CD25, CD96, and CD123, in de novo AML patients. The expression of these markers on gated leukemic blasts was evaluated using 6-color flow cytometry. When over 20% of leukemic blasts were positive for any marker, the sample was defined as positive for that marker. We stratified de novo AML patients into two groups: LSCHigh was defined as positively for two or three LSC markers, and LSCLow was defined as negativity for all markers or positivity for a single LSC marker. The primary endpoint was overall survival (OS). The secondary endpoint was progression-free survival (PFS). OS and PFS were estimated using the Kaplan-Meier method, and assessed using the log-rank test. Multivariate analysis using Cox proportional hazard ratio was performed for OS and PFS.

Results: The median follow-up for patients still alive at the end of the study was 38.9 months (range: 1.5-64.8 months). The median patient age was 60 years (range: 17-78 years). There was no statistical significance between LSCHigh patients (n=30) and LSCLow patients (n=50) in sex, age, laboratory data, NPM1 mutation, or European Leukemia Net karyotype risk group. FLT3 mutation was associated with the LSCHigh group (p=0.003). Three-year OS and PFS were significantly better in the LSCLow group than in the LSCHigh group (Figure 1) (OS: 65.0% vs 18.2%, p <0.001; PFS: 49.3% vs 19.4%, p <0.001). In multivariate analysis controlled for age and karyotype (Table 1), being in the LSCHigh group was an independent prognostic factor for OS (hazard ratio: 3.17; 95% CI: 1.64-6.15; p <0.001) and PFS (hazard ratio: 2.25; 95% CI: 1.24-4.08; p=0.007). Being in the LSCHigh group had incremental value for OS compared with the karyotype risk (Harrell’s C index: 0.80 vs 0.70; p = 0.028). Moreover, this classification based on LSC marker expression allowed subgroups with unfavorable prognosis to be identified among patients in the intermediate karyotype risk group (3y-OS 54.6% vs 14.5%, p=0.013), as well as those in the favorable karyotype risk group (3y-OS 94.1% vs 50.0%, p=0.021).

P197
NEXT GENERATION SEQUENCING TARGETED PANEL FOR MINIMAL RESIDUAL DISEASE MONITORING IN ACUTE MYELOID LEUKEMIA
V. Mcclain1, A.R. Carson1, B.A. Patay1, L. Chamberlain1, C. Chander1, V. Mcclain1, A.R. Carson1, B.A. Patay1, L. Chamberlain1, C. Chander1, V. Mcclain1, A.R. Carson1, B.A. Patay1, L. Chamberlain1, C. Chander1, V. Mcclain1, A.R. Carson1, B.A. Patay1, L. Chamberlain1, C. Chander1, V. Mcclain1, A.R. Carson1, B.A. Patay1, L. Chamberlain1, C. Chander1
1Invivoscribe, 2LabPMM LLC, San Diego, United States

Background: Many personalized therapies for acute myeloid leukemia (AML) have been developed targeting specific biomarkers. Unfortunately, the efficacies of these therapies are inconsistent while the need to determine successful therapies prior to patient relapse is critical. Minimal residual disease (MRD) monitoring can help determine effective treatments and predict potential relapse. While there are now several MRD tests available on the market, most target single or small numbers of biomarkers, which can limit detection of residual AML heterogeneity. Thus, full characterization of a sample may require testing with multiple MRD assays, which can be impractical in a clinical setting. We have developed a target capture-based assay (MyMRDTM), which allows characterization of the entire therapeutic AML biomarker repertoire and can inform...
the molecular remission status of a patient’s malignancy. This targeted panel can identify the mutations in driver clones that cause relapse in ~90% of all AML patients, as well as common drivers in myeloid proliferative neoplasms (MPN) and myelodyplastic syndromes (MDS).

Aims: To establish a sensitive and reliable targeted NGS assay to comprehensively detect and monitor the majority of known driver mutations in AML and other myeloid malignancies.

Methods: Whole genome libraries, made from DNA extracted from cell lines and clinical samples, were hybridized with MyMRD probes targeting mutation hotspot in 23 genes associated with AML. In addition to single nucleotide variants (SNVs) and indels in 21 of these genes, 5 structural variant (SV) break-points in 3 genes were also targeted. Barcoded libraries were sequenced with the MiSeq® platform and analyzed using proprietary Invivoscribe (IVS) MyInformaticsTM software. To validate mutations detected by the MyMRD assay, samples were additionally tested with IVS developed capillary electrophoresis (CE) assays and NGS-based assays targeting common mutations in FLT3 and NPM1.

Results: The linearity and limit of detection (LOD) of the MyMRD assay were assessed using data generated from contrived cell line DNA containing known AML driver mutations with a range of variant allele frequencies (VAFs). The assay shows strong linearity (R²=0.96 – 0.99) in the entire range of tested VAFs (0.0001 – 100%). Overall, we established a LOD of 0.5% for >95% of the targeted sites in the assay with lower LODs for specific mutations of interest (e.g. 0.1% for a 30bp FLT3 ITD and 0.2% for FLT3 p.D385Y). In addition, using clinical samples the MyMRD assay shows excellent concordance with the standard FLT3 CE assays for variants with VAFs above the CE detection threshold (5%). Sensitivity of the CE detection threshold was additionally evaluated with IVS FLT3 ITD MRD and NPM1 amplicon assays which showed 100% concordance with the MyMRD panel assay for variants with VAFs above the MyMRD LOD.

Summary/Conclusions: The IVS developed MyMRD targeted panel is a sensitive and reliable assay to monitor residual AML driver mutations. The assay is shown to have excellent linearity and a LOD of 0.5% (tenfold lower than the standard CE assay LOD) at >95% of the targeted sites. Additionally, specific mutations of interest, such as those used for residual disease monitoring (e.g. FLT3 ITD), demonstrate LODs as low as 0.1%. The MyMRD assay provides an accurate method for detecting mutations in multiple targets in patients and can be used to effectively stratify patients for therapy and clinical trials.

IS IT POSSIBLE TO RELIABLY DETECT CLINICALLY-RELEVANT BIALLELIC CEBPA GENE MUTATIONS USING NGS PANELS?

M. Fernandez-Mercado1,2,3,*, M.J. Larrayoz3, I. Vazquez3, A. Mañu3, F.J. García-Aznárez3, F. Prosper4, M.J. Calasanz4
1Biomedical Engineering, School of Engineering, University of Navarra, 2Molecular Oncology, Biodonostia HRI, Donostia University Hospital, San Sebastián, 3Haematology and Haemotherapy, Clinic of the University of Navarra, Pamplona, Spain

Background: CEBPA gene encodes a leucine zipper transcription factor that is important for normal myeloid cell differentiation. Biallelic CEBPA (biCEBPA) mutations are associated with favourable prognosis in patients with acute myeloid leukaemia (AML); therefore, accurate molecular testing of this gene is crucial in the clinical setting. Molecular pathology labs routinely analyse CEBPA through fluorescence-based multiplex-PCR fragment analysis or, more frequently, Sanger sequencing. Lately, it is increasingly common to use next-generation sequencing (NGS) technology in the pathology labs, and CEBPA gene is indeed included in the majority of NGS panels commercially available for testing of patients with neoplasias of the myeloid lineage.

Aims: We set ourselves to compare the performance of two different NGS targeted panels with CEBPA molecular aberrations, with a particular focus on biCEBPA mutations.

Methods: DNA specimens from 173 myeloid cases were subjected to Sanger sequencing, PCR in order to amplify the whole length of CEBPA coding region, followed by cloning. Colony sequencing showed independent clones harbouring different variants (i.e. bona fide biCEBPA mutations) in the majority of the cases, but crucially, not in all of them. This result highlights the need of implementing techniques able to accurately assess CEBPA biallelism, otherwise than plain calling of more than one variant.

Figure 1.

Summary/Conclusions: Since AML patients with biCEBPA mutations have relatively favourable overall survival, it is important in the clinical setting to accurately assess CEBPA molecular status. In our study, we have tested the ability of three different assays to detect CEBPA mutations in 173 samples. Sanger sequencing was the only method actually covering the entire coding region of CEBPA. Both NGS amplicon-based panels failed to fully cover the coding region of the gene, and therefore have likely missed mutations. Crucially, even when any of the three methods detected more than one variant, cloning studies confirmed biCEBPA mutations only in a fraction of the cases. In summary, none of the amplicon-based tested methods can reliably determine if multiple mutations affect two different alleles; therefore biCEBPA mutations would still need additional confirmation. We are currently exploring the ability of capture-based NGS approaches coupled to appropriately tailored bioinformatic analysis of sequencing data to detect biCEBPA mutations.

P199

EXPERIENCE WITH MINIMAL RESIDUAL DISEASE MONITORING IN AML WITH RUNX1-RUNX1T1: A STUDY ON 186 PATIENTS

A. Hoellein1,2, M. Meggendorfer1, A. Fasan1, W. Kern1, C. Haferlach1, T. Haferlach1
1Biomedical Engineering, School of Engineering, University of Navarra, 2Molecular Oncology, Biodonostia HRI, Donostia University Hospital, San Sebastián, Germany

Background: The cure rate in AML is dependent on patient’s age and performance status, cytogenetics, early blast clearance and sustainable first complete remission. Investigation of minimal residual disease (MRD) is possible by multiparameter-flow cytometry (MFC) or molecular techniques. Recent findings have further depicted a broad spectrum of molecular markers in AML in 99% of pts (TCGA, NEJM, 2013). This broadens the set of targets for MRD monitoring. However, cases showing low percentage of leukemic cells need strategies for better individualize treatment strategies. In this analysis we focused on MRD monitoring in RUNX1-RUNX1T1 positive AML in an unselected cohort.

Aims: To understand the clinical use of PCR based MRD monitoring in AML with RUNX1-RUNX1T1 fusion.

Methods: Since 2005 und 2017 we investigated a total of 186 intensively treated AML patients with RUNX1-RUNX1T1 fusion, 130 of them diagnosed at our laboratory and 56 with follow up samples available. 1448 individual samples were analyzed during the course of disease. We applied quantitative real-time PCR to detect RUNX1-RUNX1T1/ABL ratios. Complete molecular remission (CR) was defined as one valid qPCR ratio of 0, while low MRD was assigned to patients with a >0 but <0.01 ratio and high MRD was assigned to all patients with a ratio above 0.01. As a comparator log fold change to baseline was independently assessed. Median age was 51 years
(18–83 years). All patients were treated with standard induction and consolidation protocols.

**Results:** Median time between two investigations was 2.8 months (range for all 0.1–115 months). A complete molecular remission was reached in 90/130 pts (69%) after a median of 5 months. 19/130 (14.6%) pts reached low level MRD and 20/130 (15.4%) high level MRD. Median event free survival (EFS) of patients with CMR was not reached (EFS at 2 years 82%). 16 (18%) of those patients relapsed in the course of follow up with a median time to relapse of 12.7 months (range 4.1 to 38.3 months). Median EFS for MRD low and MRD high patients was 18.4 months and 10.8 months respectively (all 3 groups, p<0.0001). For patients with CMR, rising MRD levels accurately predicted relapse with a median latency of 5.5 months from loss of CMR to relapse. We next used the widely accepted log fold change from baseline to define high and low risk patients in our cohort. 123/130 (95%) patients reached a >3 log fold reduction in \( \text{RUNX1-RUNX1T1/ABL} \) ratio within the first 200 days following first diagnosis. Median EFS for those patients was not reached (EFS at 2 years 66%). The 7/130 (5%) patients with a <3 log fold reduction had a median EFS of 14.7 months (2 groups, p=0.017). A total of 59/185 patients received allogeneic SCT. Among the 130 patients diagnosed at our laboratory 34 (26%) received allogeneic SCT, 12 (9%) were transplanted in first CR and 17 (13%) were transplanted for relapse. Following allogeneic SCT 11/17 patients (65%) reached a second CR with CMR.

**Summary/Conclusions:** Our data shows that MRD testing is routinely performed in \( \text{RUNX1-RUNX1T1} \) AML outside of clinical studies. Defining MRD levels by \( \text{RUNX1-RUNX1T1/ABL} \) ratios resulted in a better classifier for high and low risk patients than log fold change. However, despite CMR 16/90 (18%) patients relapsed with a maximum time from first achievement of CMR of 38.3 months. We conclude that 1) MRD monitoring could serve to guide BMT decisions in \( \text{RUNX1-RUNX1T1} \) AML outside of clinical studies. Defining MRD levels by \( \text{RUNX1-RUNX1T1/ABL} \) ratios resulted in a better classifier for high and low risk patients than log fold change. However, despite CMR 16/90 (18%) patients relapsed with a maximum time from first achievement of CMR of 38.3 months. We conclude that 1) MRD monitoring could serve to guide BMT decisions in \( \text{RUNX1-RUNX1T1} \) AML, 2) allogeneic BMT can rescue the majority of relapsed patients and 3) molecular monitoring can reliably identify patients with high risk for relapse.
Acute myeloid leukemia - Clinical 2

P200

NUMBER OF TP53 ABNORMALITIES AND THEIR CLINICAL RELEVANCE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES

G. Damle1, N. Hoffbrand1, C. Benetl1, T. Kadia1, F. Ravandi1, J. Cortes1, N. Daver1, K. Takahashi1, C. DiNardo1, E. Jabbour4, G. Borthakur1, N. Kornblau1, M. Konopleva1, A. Alfonso1, S. Pierce1, C. Bueso-Ramos2, S. Kornblau1, K. Patel2, H. Kantarjian1, M. Andreff1, G. Garcia-Manero1

1Leukemia, 2Hematophatology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Mutations in TP53 can be detected in up to 16-19% patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS). TP53 mutations confer adverse prognosis irrespective of currently available therapies. The clinical impact of the type and number of TP53 abnormalities is unclear.

Aims: To evaluate the prognostic impact of the number of TP53 abnormalities in AML and MDS.

Methods: We evaluated 1401 patients with previously untreated AML or MDS treated at The University of Texas MD Anderson Cancer Center from 2012 to 2016. Sequencing data was obtained by use of a 28 or 53-gene targeted PCR-based next generation sequencing platform. Response was defined following 2003 IWG criteria for patients with AML and 2006 revised IWG criteria for patients with MDS. Generalized linear models were used to study the association of overall response (OR), complete response (CR) and risk factors, Kaplan-Meier produce limit method was used to estimate the median overall survival (OS).

Results: A total of 593 (43%) patients had MDS and 808 (56%) had AML. In a total of 984 (70%) patients, data on therapy with sufficient follow up and response evaluation was available, with 494 (35%) patients receiving therapy with hypomethylating agents (HMAs) and 373 (27%) with chemotherapy regimens. A total of 384 mutations in TP53, involving 208 unique mutations, were detected among 300 (21%) patients with R273H, R248W, Y220C and R175H being the most prevalent. Overall frequency of TP53 mutations was higher among patients with MDS (25%, n=146) compared to AML (19%, n=154) (p=0.012) with 251 (84%) of detected mutations happening in patients with complex karyotype (p=0.001). Among patients with TP53-mutant disease, 221 (74%) had 1 detectable mutation, 76 (25%) had 2 and 3 (1%) had 3. Additionally, 188 (13%) patients had TP53 deletions evidenced by presence of monosomy 17 or del(17p). In 167 (89%) of these patients, chr17 abnormalities were detected in the context of a complex karyotype and in 127 (42%) a co-occurring TP53 mutation was detected. Correlation between TP53 mutations and deletions (r=0.443, p<0.001) was observed with 172 (12%) patients having 1 TP53 abnormality. 169 (12%) patients had 2 detectable TP53 mutations were less likely to have co-occurring chr17 abnormalities (79% vs 22%, OR 0.28, CI 0.15-0.50, p=0.03). Median follow up was 8.6 months (range 0-167 months). Presence of a TP53 mutation adversely impacted OS (MDS: HR=2.81, CI 2.26-3.50, p<0.001). Increasing number of abnormalities adversely impacted OS of patients with AML (Figure 1A) but not that of patients with MDS. Presence and number of TP53 mutations did not predict for response (OR: 60 vs 63% for p=0.498; CR: 34 vs 36%, p=0.695) to HMAs, but was associated with significantly lower likelihood of response to intensive chemotherapy (OR: 41 vs 86%, p<0.001; CR: 33 vs 75%, p<0.001).

Summary/Conclusions: Presence of multiple TP53 abnormalities can be observed in up to 13% patients with AML and MDS. Second TP53 abnormalities more commonly involve TP53 deletions with additional TP53 mutations being less common and generally mutually exclusive with TP53 deletions. The number of TP53 abnormalities impacts the survival of patients with AML but not that of patients with MDS. Presence and number of TP53 mutations do not seem to impact response to HMAs but are associated with lower responses to chemotherapy.

VADASTUXIMAB TALIRINE PLUS HYPMETHYLATING AGENTS: A WELL-TOLERATED REGIMEN WITH HIGH REMISSION RATE IN FRONTLINE OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA

M. Konopleva1, A. Alfonso1, S. Pierce 1, C. Bueso-Ramos 2, S. Kornblau 1, K. Takahashi1, C. DiNardo 1, E. Jabbour 1, G. Borthakur 1, N. Pemmaraju 1, M. O’Meara14, P. Ho14, A. Fathi15

1Department of Leukemia, MD Anderson, Houston, 2Gehr Family Center for Leukemia Research, City of Hope, Duarte, 3Hematologic Malignancy Program, Moffitt Cancer Center, Tampa, 4Hematology, Memorial Sloan Kettering, New York City, 5Leukemia, John Theurer Cancer Center, Hackensack, 6Hematology, Fred Hutchinson Cancer Center, Seattle, 7Hematology and Oncology, Dana-Farber Cancer Institute, Boston, 8Hematology and Oncology, Huntsman Cancer Institute, Salt Lake City, 9Hematology and Oncology, Winship Cancer Institute, Atlanta, 10Hematology and Oncology, University of Michigan Comprehensive Cancer Center, Ann Arbor, 11Hematology and Oncology, Baylor Charles A. Sammons Cancer Center, Dallas, 12Clinical Development, Seattle Genetics, Inc., Bothell, 13Hematology and Oncology, Massachusetts General Hospital Cancer Center, Boston, United States

Background: Treatment of AML among the elderly is challenging. HMAs are commonly used, but yield suboptimal response rates and modest survival. Duration of remission were difficult to achieve; in a study of MRD response by flow cytometry in patients treated with single-agent HMA therapy at MD Anderson Cancer Center, only 13/58 (22%) responding patients achieved minimal residual disease (MRD) negativity (F Ravandi, MD, unpublished data, Jan 2017). VADastuximab talirine (2GM-CD33A; 33A) is a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine (PBD) dimer. Upon binding, 33A is internalized and transported to the lysosomes where PBD dimer is released via proteolytic cleavage of the linker, crosslinking DNA, and leading to cell death.

Aims: A short in a phase 1 study (NCT01902329) was designed to evaluate the safety, tolerability, PK, and antileukemic activity of 33A in combination with an HMA.

Methods: Eligible patients (ECOG status 0-1) had previously untreated CD33-positive AML. One dose of 33A (10 mcg/kg) was administered outpatient IV every 4 weeks on the last day of HMA (azacitidine or decitabine [5-day regimen], standard dosing). CRi required either platelet count of ≥100,000/µL or positive AML. One dose of 33A (10 mcg/kg) was administered outpatient IV on day 1, and 3 doses of 33A +HMA. Patients had adverse (38%) or intermediate (62%) cytogenetics (per MRC); patients were either unfit for (40%; 75%) or declined (13; 25%) intensive therapy. The median treatment duration is currently 19.3 weeks (range, 2-86) with 8 patients still on treatment; no DLTs were reported. Adverse events (AEs) ≥Grade 3 reported in ≥15% of patients were thrombocytopenia (55%), febrile neutropenia (49%), anemia (46%), neutropenia (42%), pneumonia (19%), and leukopenia (17%); no ≥Grade 4 bleeding events were observed. Treatment-emergent (TE) liver lab elevations (≥Grade 3) were rare: ALT (8%), AST (2%), and total bilirubin (2%). Other non-heme TEAEs reported in ≥25% of patients regardless of relationship to study treatment were fatigue (60%), nausea (49%), constipation (43%), peripheral edema (36%), pyrrolobenzodiazepine (PBD) fever, headache (22%), and dizziness (26%). Thirty- and 60-day mortality rates were 2% and 8% respectively, with no treatment-related deaths reported. A total of 39% (103/263) of doses were delayed due to AEs mostly from myelosuppression (neutropenia 18%, thrombocytopenia 7%, and febrile neutropenia 3%). High remission rates (37/49 [76%] CR+CRI) were maintained across adverse disease subsets including adverse cytogenetics (16/18, 89%), TP53-mutated (67/86), secondary AML (18/22, 82%), and age ≥75 years (18/26, 69%). Of all responding patients, 19/37 (51%) achieved MRD negativity. Two patients went on to subsequence an allogeneic SCT, and no new MDS/MDW was observed. The new patient OS/pseudo-free survival was 9.1 months (range, 0.1-19.4+) and OS continues to evolve with 15 patients (28%) alive (11.3 month median follow-up) (Figure 1).

Summary/Conclusions: 33A+HMA is well tolerated with a safety profile consistent with on-target myelosuppression. The CR+CRI rate of 76% and low early mortality in older AML patients with poor risk factors is particularly encouraging, and activity appears markedly improved compared to the historical experience of HMA monotherapy. The MRD clearance rate among responding patients who received 33A+HMA is higher than the rate observed with single
agent HMAs. Survival data are evolving and compare favorably to historical controls. CASCADE, a phase 3 trial investigating 33A+HMA v. HMA alone in older AML patients, is enrolling (NCT02785900).

ACUTE MYELOID LEUKEMIA WITH INTERMEDIATE-RISK CYTOGENETICS AND A FAVORABLE GENOTYPE: PROGNOSTIC FACTORS AND RESULTS IN PATIENTS TREATED ACCORDING THE SPANISH CETLAM PROTOCOLS

J. M. Sierra1, A. Garro1, M. Diaz-Suárez2, S. Vives1, H. Pomarés3, R. Guardia1, M. Cervera6, M. Queipo de Llano7, O. Salamero8, A. García9, J. Martí-Tutusaus10, C. Pedro11, J. Bargay12, A. Sampol113, M. Hoyos1, M. Pratcorona1, L. Escoda6, D. Gallardo5, M. Arnan4, J. Ribera14, J. Esteve2, TRueta, Girona, 6Hospital Joan XXIII, Tarragona, 7Hospital Clínico de Málaga, 8Hospital del Mar, Barcelona, 9Hospital Son Llàtzer, Palma de Mallorca, 10Hospital Son Espases, Malacorrect, 11Hospital Germans Trias i Pujol, Barcelona, Spain

Background: Acute myeloid leukemia (AML) with intermediate-risk (IR) cytogenetics includes a substantial proportion of patients with favorable molecular profile (FMP); in which AML cells harbor the NPM1 mutation or CEBPA biallelic mutation without internal tandem duplication of the FLT3 gene (FLT3-ITD). The role of allogeneic hematopoietic transplantation (allo-HCT) in first complete remission (CR) in these patients remains controversial.

Aims: To analyze the results and prognostic factors of IR-FMP AML patients in a large series of patients treated by the Spanish CETLAM group.

Methods: Patients with primary AML diagnosed at 19 institutions from the Spanish CETLAM group and treated between 2003 and 2017. Induction chemotherapy included idarubicin and cytarabine (standard or intermediate-dose) in all cases, consolidation with intermediate or high-dose cytarabine (HDAC) and, depending on the protocol, additional HDAC, autologous or allogeneic hematopoietic transplantation.

Results: Two-hundred twenty-one patients were analyzed. Median age of the series was 54 years (range 18 to 72). 152 patients had an age up to 60 years and 69 (31%) were older. Median WBC count was 19x10^9/l (range 0.55-282). One-hundred eighty-two patients had a normal karyotype and it was observed in only 2 patients of the NPM1+/FLT3-ITD- group. There were no significant differences in the main clinical or biological parameters in these two groups. The CR rate in the overall group was very high (92%) without significant differences between the two molecular groups. Chemorresistance was observed in only 2 patients of the NPM1+/FLT3-ITD- group (1%). Death during induction was observed in 16 patients (7%), all of them with NPM1+/FLT3-ITD-. Induction results according to age were similar in both groups. Event-free survival and overall survival are reported at 8 years and were 52±8% and 70±4%, respectively. In univariate comparisons, better EFS and OS was observed in CEBPα+/FLT3-ITD- patients compared to those with NPM1+/FLT3-ITD- (p=0.03 and p=0.02, respectively). When analyzing post-consolidation treatment, patients treated with HDAC only had an excellent prognosis, even better than those receiving an autologous or allogeneic transplantation. One patient died in CR in the HDAC group, another in the autologous transplant group and 7 in the allo-HCT group (p<0.001). In multivariate analysis of pretransplant characteristics, age up to 60 years and CEBPα+/FLT3-ITD- associated to improved EFS (RR=0.42) and OS (RR=0.29). Interestingly, in a subgroup of 123 patients data on MRD after consolidation chemotherapy (flow citometry, cut-off: 0.12%), positivity was associated with worse EFS (0.02). Despite age was a prognostic factor, patients older than 60 years with IR-FMP AML had remarkable EFS of 36±3% and OS 54±10% at 8 years (Figure 1).

Figure 1.

Summary/Conclusions: Patients with primary AML, IR cytogenetics and FMP have a good outcome. Best results are achieved in patients with CEBPα+/FLT3-ITD-, particularly if age is up to 60 years. In this subset, OS at 8 years is 96±7%, comparable to current results achieved in acute promyelocytic leukemia. Patients above 60 years treated intensively may achieve a long term survival of more than 50%. Chemotherapy without subsequent transplantation is a valid option. MRD monitoring after treatment has to be taken into account since in the subset of patients analyzed this was an independent prognostic factor for EFS.

P203

GMI-1271, A POTENT E-SELECTIN ANTAGONIST, COMBINED WITH INDUCTION CHEMOTHERAPY IN ELDERLY PATIENTS WITH UNTREATED AML: A NOVEL, WELL-TOLERATED REGIME WITH A HIGH REMISSION RATE

Dana-Farber Cancer Institute, Boston, 2UC Davis Comprehensive Cancer Center, Sacramento, 3University of Michigan Comprehensive Cancer Center, Ann Arbor, 4Fred Hutchinson Cancer Research Center, U of Washington, Seattle, United States, 5National University of Ireland, Galway, Ireland, 6Cleveland Clinic Taussig Cancer Institute, Cleveland, United States, 7Princess Alexandria Hospital, Brisbane, Australia, 8GlycoMimetics, Inc., Rockville, 9Univ of Rochester James P Wilmot Cancer Ctr, Rochester, United States

Background: The outcomes for elderly patients (pts) with acute myeloid leukemia (AML) remain poor due to limited tolerance of intensive cytotoxic chemotherapy and low response rate, therefore newer and less toxic therapies are urgently needed. The binding of E-selectin (E-sel), an adhesion molecule expressed in the vasculature of the bone marrow, to the leukemic cell surface activates survival pathways and promotes chemotherapy resistance. GMI-1271, a novel E-sel antagonist, disrupts these survival pathways and enhances chemotherapy response (Becker ASH 2013; Winkler ASH 2014). Protection from common toxicities (neutropenia and mucositis) has also been observed in preclinical models, affording survival benefit (Winkler ASH 2013). Additionally, preclinical toxicology studies have indicated a benign safety profile. We report interim Phase 2 data for GMI-1271 plus anthracycline-based induction chemotherapy in elderly untreated pts with AML.

Aims: A Phase 2 open label trial of patients ≥60 yrs with untreated AML assessed safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and antileukemic activity of GMI-1271.

Methods: Eligible pts had ECOG 0-2, WBC <40K/uL, no active CNS disease, and adequate renal and hepatic function. Prior treatment of MDS was allowed. GMI-1271 (10 mg/kg) was given 24 hrs prior, then every 12 hrs during and for 48 hrs post induction with infusional cytarabine and idarubicin (7+3). Two cycles of induction were allowed and responders could receive consolidation with GMI-1271 plus intermediate dose cytarabine. Dose-limiting toxicity (DLT), defined as myelosuppression in the absence of disease or related Grade 3 (Gr) non-hematologic toxicity beyond day 42, was assessed in the first 3 pts. Baseline E-selectin ligand expression on leukemia blasts in the bone marrow (CD45/SSC by flow) is reported.
Results: 24 pts have been enrolled to date and 17 are evaluable for response. The median age was 69 years (range, 30-79) with 58% male pts and 25% with high-risk cytogenetics (by SWOG). 50% (12/24) were pts with secondary AML (sAML), half of whom had prior hypomethylating therapy (50%; 6/12). This study had a rolling safety run-in and the first 3 pts had no DLT, allowing enrollment to proceed. Common Gr 3-4 AEs included febrile neutropenia (47%), pneumonia (20%), cardiotoxicity (13%) and non-fatal respiratory failure (13%). A total of 2 pts died of sepsis within 60 days. The remission rate (CR/CRi) was 12/17 (71%). CR/CR rate was 75% for pts with de novo disease and 67% for pts with sAML. The PK profile in this elderly population was consistent with that of younger adults (median age <60 years) with relapsed or refractory AML in Phase 1 (DeAngelis et al., EHA 2016); no accumulation or evidence of drug-drug interactions were apparent. The median E-sel ligand expression at baseline was 29% (range, 2-67%) of blasts in the bone marrow.

Summary/Conclusions: The addition of a novel E-selectin antagonist, GM12546, to anthracycline and induction chemotherapy in untreated elderly pts with AML, including patients with secondary AML, demonstrates a high remission rate with acceptable side effect profile resulting in low induction mortality. This study compares favorably to previous studies (Lancet, ASCO 2016). E-selectin ligand was expressed on leukemic blasts in the majority of pts, therefore supporting its relevance as a target. A randomized trial is being planned.

P204

A PHASE 2 STUDY OF GLASDEGIB (PF-04449913) IN COMBINATION WITH CYTARABINE AND DAUNORUBICIN IN UNTREATED PATIENTS WITH ACUTE MYELOID LEUKEMIA OR HIGH-RISK MYELODYSPLASTIC SYNDROME

1University of Texas, MD Anderson Cancer Center, Houston, TX, 2Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD, 3Roswell Park Cancer Institute, Buffalo, NY, 4University of Southern California Cancer Center, Los Angeles, 5Fred Hutchinson Cancer Research Center, Seattle, WA, 6Emory University School of Medicine, Atlanta, GA, 7Dana-Farber Cancer Institute, Boston, MA, 8University of Colorado Cancer Center, Aurora, CO, 9Pfizer Oncology, New York, NY, 10Pfizer Oncology, La Jolla, CA, 11Pfizer Oncology, Collegeville, PA, 12Washington University Medical School, Saint Louis, MO, United States

Background: Glasdegib, a selective, once-daily (QD), oral Smoothened (SMO) inhibitor, demonstrated significant improvement in overall survival (OS) when used in combination with low-dose cytarabine (LDAC) vs LDAC alone in a randomized (2:1) open-label trial in 132 patients (pts) not suitable for induction chemotherapy (ICT). Preclinical studies showed that glasdegib limits leukemia stem cell proliferation and provided evidence of glasdegib synergy with chemotherapy.

Aims: Primary objective of this open-label, single-arm Ph 2 study (NCT01546038) was to determine complete remission (CR) rate with glasdegib in combination with cytarabine and daunorubicin in untreated AML or high-risk MDS pts. OS was the key secondary endpoint.

Methods: Pts suitable for ICT (ECOG PS 0-1, creatinine ≤1.3 mg/dL, no severe cardiac disease) gave informed consent and received glasdegib 100 mg QD from day -3 in combination with cytarabine 100 mg/m² CI for 7 days and daunorubicin 60 mg/m² IV for 3 days, followed by 2-4 consolidation cycles (cytarabine 1 g/m², 2 hrs on days 1, 3, 5). Maintenance (up to 6 months) included glasdegib 100 mg QD. Pts were assessed for efficacy, safety and tolerability.

Results: All Pts: As of 1 Dec 2016, 71 pts (66 AML, 5 MDS) were enrolled and 69 pts received glasdegib and ICT (2 pts not treated due to ineligibility). Among the 19 pts older than 65 yrs (47-93 yrs secondary, 20% had favorable, 32% intermediate, int (t)-int, 21% int-II and 26% adverse cytogenetic abnormalities (1 pt not evaluable). Among AML pts (47 de-novo; 19 secondary), 20% had favorable, 32% intermediate (int)-I, 21% int-II and 26% adverse cytogenetic abnormalities (1 pt not evaluable). Maintenance (up to 6 months) with AML, including patients with secondary AML, demonstrates a high remission rate with acceptable side effect profile resulting in low induction mortality. This study compares favorably to previous studies (Lancet, ASCO 2016). E-selectin ligand was expressed on leukemic blasts in the majority of pts, therefore supporting its relevance as a target. A randomized trial is being planned.

Summary/Conclusions: Among AML pts (47 de-novo; 19 secondary), 20% had favorable, 32% intermediate (int)-I, 21% int-II and 26% adverse cytogenetic abnormalities (1 pt not evaluable). Maintenance (up to 6 months) with AML, including patients with secondary AML, demonstrates a high remission rate with acceptable side effect profile resulting in low induction mortality. CM942 IS A NEW SMALL MOLECULE THAT TARGETS SET-PP2A INTERACTION AND INHIBITS GROWTH OF ACUTE MYELOID LEUKEMIA CELLS

P. García-Ramírez1, C. Vicente2, E. Arriazu3, M. Nerea4, J. Rifón5, A. Domínguez3, A. Alonso2, I. Vázquez5, M.J. Calasanz5, M.C. Mateos6, M.D. Otero7

1Hematology, Complejo Hospitalario de Navarra, 2University of Navarra, 3CIMA, University of Navarra, 4Clinica University of Navarra, Pamplona, Spain

Background: Acute myeloid leukemia (AML) is a heterogeneous malignant disorder of hematopoietic progenitor cells in which several genetic and epigenetic aberrations have been described. Nevertheless, outcome for most patients is poor, and it is necessary to develop more effective treatment strategies. Our group showed that the inactivation of the tumor suppressor PP2A is a recurrent event in AML, and that overexpression of SET, an endogenous inhibitor of PP2A, is a poor prognostic factor in this disease. Furthermore, the anticancer activity of FTY720, a PP2A-activating drug (PAD), depends on its interaction with SET. CM942 is a relatively nontoxic drug currently used in patients with relapsing multiple sclerosis; however, this drug cannot be used in cancer patients due to its toxicity at the needed anti-neoplastic dose. Therefore, investigation of alternative agents for reactivation of PP2A is warranted.

Aims: To test the efficacy of CM942, a FTY720 analogue, on AML cell lines and primary patient samples, and investigate its mechanism of action.

Methods: AML cell lines and 29 de novo AML samples were analyzed by treatment with FTY720 and CM942, MTS (viability), apoptosis, cell cycle and PP2A activity assays, and western blot.

Results: CM942 exhibited notable cytotoxicity on all human AML cell lines with SET overexpression (10). Using phosphatase assays we confirmed that CM942 treatment activated PP2A on cell lines, similarly to FTY720. Immunoprecipitation of PP2Ac in untreated cells confirmed that SET interacts with PP2Ac, and that treatment with CM942 effectively disrupted this association. Furthermore, CM942 had a caspase-dependent pro-apoptotic effect, and decreased phosphorylation of the PP2A target ERK1/2. Microarray data from vehicle-treated and CM942-treated HL-60 cells showed a high correlation between the gene expression profiles of the samples. This analysis identified up-regulated and down-regulated genetic pathways by treatment with CM942, providing mechanistic insights into the anti-tumor mechanism of this small molecule. Our analyses in primary AML samples showed that 7 out of 29 (24%) samples treated with CM942 had a significant reduction in proliferation. By western blot analyses we found that those patients responding to CM942 treatment had SET overexpression. Of note, treatment of peripheral blood mononuclear cells from healthy donors with CM942 had no effects on cell viability. Therefore, although FTY720 and CM942 have similar effects inhibiting cellular proliferation, CM942 was less toxic when assayed on normal peripheral blood cells.

Summary/Conclusions: CM942 inhibits growth of AML cells in both cell lines and primary patient samples, exerting its antileukemic effects through reactivation of PP2A activity. Although treatment with FTY720 was somewhat more potent than CM942 in primary samples of AML, fewer cytotoxic effects were observed after CM942 treatment in peripheral blood from healthy donors. Further experiments would be necessary to confirm the in vivo anti-tumor activity of CM942 in AML models. New compounds have been developed for the treatment of AML, although few have been translated into clinical practice; nevertheless, it is unlikely that any of these compounds, when used in combination with the drug for which they are designed, will curtail the disease for more than a few months. Therefore, the need for new anti-leukemic agents is unrelated in clinical therapy. Our results indicate that PADs may be a valid therapeutic option for AML, especially for treating leukemias characterized by SET-dependency inactivation of PP2A.

*1 pt was not classifiable by ELN-risk.

Summary/Conclusions: Although the CR rates do not appear to be higher than those reported historically for AML pts receiving ICT, the mOS for AML pts >60 yrs stratified by subgroup compares favorably by adding glasdegib. This study showed that this is the first indication of glasdegib on the leukemia stem cells. The combination of glasdegib with ICT was well tolerated, with a safety profile consistent with that in AML pts receiving standard ICT. Further studies are warranted.

P205
CLONAL HETEROGENEITY IN LEUKEMIC STEM CELLS FROM PATIENTS WITH ACUTE MYELOID LEUKEMIA

L. Manta1,*, B. Saeed1, S. Vazquez Beiro1, P. Pyli2, T. Stiehl2, K. Barth-Miesala1, V. Eckstein1, W. Hueber2, A.D. Ho1, C. Lutz1

1Department of Medicine, University of Heidelberg, 2Multi-omics and statistical computing, European Molecular Biology Laboratory, 3Interdisciplinary Center for Scientific Computing & Institute of Applied Mathematics, University of Heidelberg, Heidelberg, Germany

Background: Clonal heterogeneity occurs in many cancers, including Acute Myeloid Leukemia (AML). In cases of relapse, chemotherapy has triggered clonal selection with minor or evolved sub-clones driving relapse. A better understanding of the underlying clonal architecture, the extent of genetic heterogeneity and its response to therapy is necessary to better understand mechanisms of therapy escape and relapse.

Aims: In this study we aim to define the clonal architecture of AML during the course of therapy and in leukemia propagating cells.

Methods: We sequenced 12 AML samples at the time of diagnosis and in one case also at the time of relapse with at least 80% blasts per sample. 6/12 patients displayed a normal karyotype while the other 6 patients showed various cytogenetic abnormalities (inversion 16 (2), trisomy 8 (1), add(19)(p13.3) (1), complex aberrant karyotype (2)). Whole-exome sequencing (WES) was performed with the appropriate germ line controls. WES data were clustered using empirical Bayesian clustering.

Results: WES identified more than 3000 variants in total. By setting distinct filtration criteria (20% allele frequency (AF), ≥10 reads coverage, ≥2 reads support of the detected variant, SIFT-score <0.05 and GMAF <5%) 64 leukemia specific mutations showed that these mutations affected genes involved in various cellular functions including mutations that have been shown to be recurrently mutated in AML like DNMT3A. Sequencing data can also be used in combination with mathematical modelling approaches to reconstruct the clonal architecture of AML at the time of diagnosis and relapse allowing estimations of the clonal complexity at these time points.

Summary/Conclusions: WES can identify leukemia specific mutations that are involved in various cellular functions including mutations that have been shown to be recurrently mutated in AML like DNMT3A. Sequencing data can also be used in combination with mathematical modelling approaches to reconstruct the clonal architecture of AML at the time of diagnosis and relapse allowing estimations of the clonal complexity at these time points.

TREATMENT OF PRACINOSTAT AND AZACITIDINE IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): CORRELATION BETWEEN MUTATION CLEARANCE AND CLINICAL RESPONSE

K. Takahashi1,*, Y. Abaza1, F. Wang1, C. Gumbs1, S. Xingzhi1, A. Futreal1, E. Atallah2, B. Medeiros3, S. Khaled4, M. Arellano5, M. Patnaik6, E. Palmesino7, G. Garcia-Manero1

1University of Texas MD Anderson Cancer Center, Houston, 2Medical College of Wisconsin, Milwaukee, 3Stanford University, Stanford, 4City of Hope, Duarte, 5Emory University School of Medicine, Atlanta, 6Mayo Clinic, Rochester, United States, 7Helsinn, Pazzallo, Switzerland

Background: In a phase 2 study of 50 elderly patients (≥65 years) with AML who were not eligible for intensive chemotherapy, treatment with the investigational HDAC inhibitor pracinostat+azacitidine (AZA) was well tolerated and led to 42% complete remission (CR) rate and a median overall survival (OS) of 19.1 months (Blood 2016; 128:100). Responses were durable (median CR+CRi 17.2 months), blast clearance was rapid (median 8 weeks), and maximum clinical benefit required prolonged therapy (>6 months) in some patients.

Aims: Our aim was to understand the impact of somatic mutations and their clearance on disease response and survival outcomes in AML patients treated with pracinostat+AZA.

Methods: 88 samples from 41 study patients were sequenced. Pre-treatment samples were available for analysis from all 41 patients, and a median of 3 longitudinal samples were analyzed from 19 patients. Mutations in 295 genes that are recurrently mutated in hematologic malignancies (median coverage 507x [range: 111-777x]). Longitudinal mutation analysis was done using tracking variant allele frequency (VAF). Informed consent was obtained from all patients.

Results: At baseline, 96 mutations in 28 genes were detected in 38 (93%) patients, with the most frequent being in SRSF2 (27%), DNMT3A (20%), IDH2 (17%), RUNX1 (17%), and TET2 (17%). The median number of mutations detected per patient was 2 (range: 0-6). Among the 33 patients with evaluable treatment response, CR was observed in 13 (39%) patients. The rate of CR was significantly higher in patients with mutations in NPM1 or in one of the DNA methylation pathway genes, while patients with TP53 mutation had a trend for poor CR (Table 1). The median follow up duration of the 41 patients was 23.8 months (95% CI: 20.4-27.1 months) with median OS of 18.1 months (95% CI: 10.1-26.1 months), patients with CEBPA mutation had a trend toward better OS, whereas patients with NFI mutation had significantly worse OS (Table). Considering mutations associated with AML oncoCytogenetic aberrations (Lindsley RC, Blood 2015;125:1367-76), median OS was 17.7 months in 20 patients with mutations typically associated with secondary AML and 18.1 months in 18 patients with mutations typically associated with the de novo AML. Among the 19 patients whose longitudinal specimens were analyzed, 10 achieved CR. Of those 10 patients, 9 (90%) had persistently detectable mutations in their bone marrow at the time of CR, however, in 7 of them, continued exposure to pracinostat+AZA lowered the VAF or cleared residual mutations. Mutations in genes associated with DNA methylation, DNA splicing, clonal hematopoiesis of indeterminate potential (CHIP), and receptor tyrosine kinase (RTK) pathways had poor clearance of mutation, while transcription factors or cohesin had better clearance with pracinostat+AZA treatment. In 2 patients, relapsed samples were sequenced and showed re-expansion of the founder clone.

Table 1.

Figure 1.
Summary/Conclusions: Mutations in NPM1, and DNA methylation pathway were associated with a better response to pracinostat+AZA, while TP53 mutation was associated with a trend toward poor response. Persistent mutation at the time of CR suggests residual preleukemic clonal hematopoiesis in this elderly population. Benefit of prolonged exposure to pracinostat+AZA was also confirmed at molecular level where continued decline of mutation VAF was seen after achieving CR.

Acute myeloid leukemia - Clinical 3

P208

STABLE DISEASE WITH HEMATOLOGIC IMPROVEMENT IS CLINICALLY MEANINGFUL FOR OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA TREATED WITH AZACITIDINE

A.C. Schuh1,*, H. Döhner2, J.F. Seymour3,4, P. Turlure5, C. Junghanss6, A. MacWhannell7, N. Tu8, S. Songer8, C. Beach8, H. Dombret9

1Princess Margaret Cancer Centre/University Health Network, Toronto, Canada, 2Universitätsklinikum Ulm, Ulm, Germany, 3Peter MacCallum Cancer Centre, Melbourne, Australia, 4Centre Hospitalier Universitaire de Limoges, Limoges, France, 5Universitätsmedizin Rostock, Rostock, Germany, 7The Royal Wolverhampton Hospitals NHS Trust, Wolverhampton, United Kingdom, 6Celgene Corporation, Summit, United States, 8Hôpital Saint-Louis- Institut Universitaire d’Hématologie, Paris, France

Background: Effects on overall survival (OS) are of primary importance when evaluating AML treatments (Tx). Though complete remission (CR) rates are lower with azacitidine (AZA) than with intensive chemotherapy (IC), OS is similar with AZA and IC (Dombret et al., Blood, 2015). The 2017 European LeukemiaNet (ELN) recommendations acknowledge that hypomethylating agents, including AZA, may alter the natural course of AML in some patients (pts) who do not achieve CR (Döhner et al., Blood, 2017). According to IWG criteria for AML (Cheson et al., J Clin Oncol, 2003), stable disease (SD) is considered non-response to Tx. Yet AML is a progressive disease; potentially, stable health status may reflect delayed disease progression and result in improved OS.

Aims: This post hoc analysis evaluated OS outcomes among older pts with AML treated with AZA or conventional care regimens (CCR) who maintained SD, with or without hematologic improvement (HI), in the phase 3 AZA-AML-001 study.

Methods: Pts aged ≥65 years with AML (>30% marrow blasts), ECOG PS score ≤2, NCCN-defined intermediate- or poor-risk cytogenetics, and WBC count ≤15x10^9/L received AZA (75mg/m²x7 days [d]/28d cycle) or a CCR (IC [standard 7+3 regimen], low-dose cytarabine [20mg BID x 10d/28d cycle], or best supportive care). OS was assessed using Kaplan-Meier methods for pts with SD at 2-, 4-, and 6-month landmarks. SD was protocol-defined as the absence of an IWG-defined AML response and no progressive disease (PD), whether or not HI was attained. Pts with SD could have had an IWG-defined response or PD at any time other than at the specified landmarks. OS was also evaluated in pts with HI as their best response; attainment of HI must have begun on or before, and been sustained past, each landmark, and lasted for ≥56 consecutive days.

Table 1.

Results: Median OS for all SD pts was 2.1-2.5 months longer with AZA vs CCR, and estimated 1-year survival was ~15% higher at each landmark in the AZA arm (Table 1). Hazard ratios for OS among all SD pts treated with AZA vs CCR ranged from 0.81–0.88. Median OS among pts with SD and no HI ranged from 12.6–13.3 months in the AZA arm and from 11.1-12.2 months in the CCR arm. Within Tx arms, AZA-treated pts with HI had meaningfully improved OS at all landmarks, ranging from 3.7 to 7.9 months longer than OS for pts without HI (Table 1). In contrast, HI attained with CCR did not largely influence OS; differences between pts who attained HI vs no HI ranged from -0.2 to 2.9 months. Median durations of HI in the AZA vs CCR arms, respectively, were 183 vs 166
days at 2 months, 176 vs 148 days at 4 months, and 176 vs 138 days at 6 months. Estimated 1-year survival within the AZA arm was 4.9%–27.4% greater for pts with HI than for pts with no HI, but for CCR-treated pts with HI, 1-year survival was 0%–10.3% greater. Between Tx arms, 1-year survival with AZA in pts with HI was 9.6%–33.3% greater than for CCR-treated pts with HI.

Summary/Conclusions: Maintaining SD during AZA or CCR Tx is associated with relatively favorable OS outcomes, as median OS in pts with SD exceeded that for all pts in the AZA-AML-001 trial (10.4 months with AZA vs 6.5 months with CCR; Dombret et al., Blood, 2015). Pts with SD who also attained HI during early AZA Tx had meaningfully improved OS, whereas similar CCR-treated pts did not, suggesting that HI with AZA is qualitatively different from HI with CCR. The prognostic relevance of HI in AML requires further study.

P209 A RANDOMIZED PHASE II STUDY OF IDARUBICIN AND CYTARABINE WITH EITHER CLOFARABINE OR FLUDARABINE IN ADULTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA N. F. Marianski1,*, F. Ravaud1, R. Huang1, L. Xiao1, G. Garcia-Manero1, W. Plunkett1, V. Gandhi1, K. Sasaki1, N. Pemmaraju1, N. Daver1, G. Borthakur1, N. Jain1, M. Konopleva1, Z. Estrov1, T. Kadia1, W. Wierda1, C. DiNardo1, M. Brandt1, S. O’Brien2, J. Cortes1, E. Jabbour1

1The University of Texas MD Anderson Cancer Center, Houston, 2The University of California - Irvine, Orange, United States

Background: Fludarabine and clofarabine are purine nucleoside analogues with clinical activity in acute myeloid leukemia (AML). Aims: We designed a randomized phase II trial to evaluate the efficacy and safety of idarubicin and cytarabine with either clofarabine (CIA) or fludarabine (FIA) in adults with newly diagnosed AML. The primary objective was to compare the EFS rates of the two regimens.

Methods: Adults with newly diagnosed AML deemed suitable for intensification chemotherapy were randomized using a Bayesian adaptive design to receive CIA or FIA. All patients (pts) received idarubicin 10 mg/m² IV on D1-3 and cytarabine 1 g/m² IV daily on D1-5. Clofarabine and fludarabine were given at doses of 15 mg/m² and 30 mg/m², respectively, IV daily on D1-5. Pts with ITD mutations could receive concomitant sorafenib. Responding pts could receive 4 consolidation cycles. CRi (complete remission with incomplete blood count recovery) could receive up to 2 consolidation cycles.

Results: Between 8/2011 and 6/2016, 182 pts were enrolled (CIA, n=106; FIA, n=76; Table 1).

Table 1.

<table>
<thead>
<tr>
<th>Group</th>
<th>Consolidation Cycles</th>
<th>CRi</th>
<th>2-year EFS</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIA</td>
<td>4 (n=22)</td>
<td>84%</td>
<td>0.66</td>
</tr>
<tr>
<td>FIA</td>
<td>2 (n=34)</td>
<td>72%</td>
<td>0.41</td>
</tr>
</tbody>
</table>

The imbalance of the arms was due to the better performance of CIA during the initial period of the trial. Treatment arms were well-balanced after randomization. 12 pts (55%) in the CIA arm and 8 (33%) in the FIA arm received sorafenib. The composite CR/CRp rate was similar between the two arms (80% for CIA vs 82% for FIA; P=0.84). CR was achieved in 72% and 74% in the CIA and FIA arms, respectively. MRD negativity rates at remission by multiparameter flow cytometry were higher in the CIA arm (80% vs 65%; P=0.07). 37 pts (35%) in the CIA arm underwent allogeneic stem cell transplantation in first remission. The median duration of follow-up was 27 months (range, 1-58). Median EFS for pts who received CIA and FIA were 13 months and 10 months, respectively; the 2-year EFS rate was 44% in both arms (P=0.91). Median OS were 24 months and not reached, and the 2-year OS rates were 51% and 57%, respectively (P=0.23). No differences in EFS or OS were observed according to baseline factors, including cytogenetics, mutations or ELN risk group. CIA was generally associated with more adverse events compared to FIA, including a higher rate of transaminase elevation (29% vs 4%), hyperbilirubinemia (26% vs 9%), and rash (29% vs 12%). Early mortality was similar in the 2 arms (60-day mortality: 4% for CIA vs 1% for FIA; P=0.32). We compared outcomes of pts treated with either CIA/FIA to a historical cohort treated with IA (n=92). Pts in the CIA/FIA group with FLT3 mutations who received sorafenib (n=20) were excluded from this analysis. The two arms were similar with respect to pretreatment characteristics analyzed, including age, cytogenetics, and ELN risk. No differences were observed in CR/CRp rates, EFS or OS between the two groups. However, among pts <50 years of age, the median EFS for pts who received FIA (n=36), CIA (n=28) and IA (n=34) was not reached. 10 months and 9 months, and the 2-year EFS rates were 58%, 33% and 30%, respectively (P=0.05 for FIA vs IA; P=0.79 for CIA vs IA).

Summary/Conclusions: CIA and FIA have similar efficacy in younger pts with newly diagnosed AML, although FIA is associated with a better toxicity profile. FIA may improve outcomes compared to IA in pts <50 years of age.

1Stanford University School of Medicine, Stanford, CA, United States, 2Gordon and Leslie Diamond Health Care Centre, Vancouver, British Columbia, Canada, 3Oregon Health and Science Univ, Portland, OR, 4University of Michigan, Ann Arbor, MI, 5BMT Group of Georgia, Atlanta, GA, 6Vanderbilt-Ingram Cancer Center, Nashville, TN, 7University of Kansas Medical Center, Kansas City, KS, 8University of Alabama at Birmingham, Birmingham, AL, 9Wake Forest Baptist Comprehensive Cancer Center, Winston-Salem, NC, 10Yale Univ. School of Medicine, New Haven, CT, 11Jazz Pharmaceuticals, Palo Alto, CA, 12J. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, United States

Background: Approximately 20% to 30% of patients with acute myeloid leukemia (AML) have FLT3 mutations; these patients often experience rapid post-induction relapse, highlighting the need for therapies that provide an improved bridge to stem cell transplantation. CPX-351 is a liposomal formulation that delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin. CPX-351 demonstrated significantly prolonged overall survival (OS) versus cytarabine/daunorubicin (7+3) in a randomized, open-label, controlled phase 3 trial in patients aged 60 to 75 years with newly diagnosed, high-risk AML (Lancet, et al. ASCO 2016). A study of the ex vivo cytotoxicity of CPX-351 found that AML blasts with the FLT3-ITD phenotype were 5-fold more sensitive to CPX-351 than those with wild type FLT3 (Gordon, et al. Leuk Res. 2017;53:39-49).

Aims: The current analysis of the phase 3 trial therefore investigated outcomes in the subset of patients with FLT3 mutations.

Methods: Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m² cytarabine 100 mg/m² and daunorubicin 44 mg/m² on Days 1, 3, and 5 [2nd induction: Days 1 and 3 only]) or 7+3 (cytarabine 100 mg/m²/day x 7 days [2nd induction: x 5 days]+daunorubicin 60 mg/m² on Days 1, 2, and 3 [2nd induction: Days 1 and 2 only]). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 consolidation cycles.

Results: Of the 274 patients who were assessed for FLT3 mutations and received study treatment, 22/138 (16%) patients in the CPX-351 arm and 20/136 (15%) patients in the 7+3 arm had baseline FLT3 mutations. AML subtypes in FLT3+ patients were: therapy-related AML (19%); AML after myelodysplastic syndrome/myelodysplastic syndrome/myeloid/myeloid transformation (MDS/MDM) without or without prior MDS/MDM (17%); therapy-related AML blastic crisis (34%). FLT3+ patients were more likely to have FLT3 mutations; these patients often experience rapid post-induction relapse, highlighting the need for therapies that provide an improved bridge to stem cell transplantation. In FLT3+ patients, median OS was longer with CPX-351 than those with wild type FLT3 (Gordon, et al. Leuk Res. 2017;53:39-49).

Summary/Conclusions: CPX-351 demonstrated numerical improvement in median OS in older patients with newly diagnosed, FLT3+ high-risk AML and
allowed more patients to undergo stem cell transplantation. The safety of CPX-351 in this subpopulation was in line with the previous studies and the overall phase 3 population. This analysis was limited by small number of patients.

Figure 1.

P211
NIVOLUMAB MAINTENANCE THERAPY FOR PATIENTS WITH HIGH-RISK ACUTE MYELOID LEUKEMIA IN REMISSION
T. Kadia1,*, M. Konopleva1, J. Cortes1
1Leukemia, MD Anderson Cancer Center, Houston, United States

Background: Dose intensification and newer drug combinations during induction have led to high rates of complete remission (CR) in pts with newly diagnosed AML. However, disease relapse remains a major source of failure. With the exception of allogeneic (allo) stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk pts. Prior attempts at maintenance monotherapy with conventional toxic drugs have been unsuccessful. Immune mediated disease control by engaging tumor-specific cytotoxic T-cells may be important in suppressing leukemia relapse, as is seen with graft vs leukemia effect following allo SCT. Immune checkpoint inhibitors may be effective in restoring host immune surveillance in the setting of post-remission maintenance.

Aims: We designed a pilot phase II clinical trial studying the efficacy and safety of nivolumab (nivo) as maintenance therapy in AML pts with high-risk disease in remission, who were not being considered for SCT.

Methods: AML pts ≥18 years with a high-risk feature in 1st CR (CR1) or any patient in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Pts should be within 12 months of achieving CR, have PS ≤2, and adequate organ function. Pts were treated with nivo 3mg/kg IV every 2 weeks for 6 months. 1 cycle was 4 weeks. After 6 months, nivo could be given every 4 weeks until 12 months on study, and then every 3 months until relapse. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. Peripheral blood and bone marrow samples were collected at baseline and during treatment for immune correlative studies to explore immune cell repertoire and biomarkers for response.

Results: Eight pts have been treated, with a median age of 60 years (range, 49-71), 7 pts were in CR and 1 in CRi at the time of enrollment; 5 pts (63%) were in CR1, 2 pts (25%) were in CR2, and 1 pt (13%) in CR4 was inadvertently enrolled and treated on the trial. Baseline characteristics are outlined in Table 1. AML-related mutations detected at start of therapy include: IDH2 (n=2), NPM1 (2), TET2 (2), and 1 each of TP53, JAK2, ASXL1, and DNM3. High risk features at the time of enrollment were as follows: 2 (25%) persistent MRD, 2 (25%) adverse karyotype, 1 (13%) adverse mutational profile, and 3 pts (38%) in CR2 or beyond. Pts have received a median of 4 (1 – 13) cycles of therapy. With a median followup of 6+ months (1 – 14), the 6- and 12-month estimated RFS were 88% and 73%, respectively. The one patient who died was discovered treated with nivo could be given every 4 weeks until 12 months on study, and then every 3 months until relapse. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. Peripheral blood and bone marrow samples were collected at baseline and during treatment for immune correlative studies to explore immune cell repertoire and biomarkers for response.

HIGHER EXPRESSION OF LONG NON-CODING RNA KIAA0125 IS ASSOCIATED WITH CHARACTERISTIC CLINICAL AND BIOLOGICAL FEATURES AND IS AN INDEPENDENT POOR PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA
S.-Y. Hung1,*, C.-C. Lin1,2,3, H.-A. Hou1, W.-C. Chou1,2, H.-F. Tien1
1Division of Hematology, Department of Internal Medicine, 2Department of Laboratory medicine, National Taiwan University Hospital, 3Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei City, Taiwan, Republic of China

Background: Long non-coding RNAs (IncRNAs) are non-protein coding RNAs longer than 200 nucleotides. Recently, a number of IncRNAs have been shown to play important roles in cancer biology. IncRNA KIAA0125 is one of the 11 genes in an expression signature significantly associated with prognosis in cytogenetically normal acute myeloid leukemia (AML) patients as shown in our previous report. It is also among another set of 17 leukemia stem cell (LSC) genes, identified through xenotransplantation model in NSG mice, which predict inferior treatment response in AML.

Aims: KIAA0125 gene is localized on chromosome 14q32.33; its functions remain unexplored. One study reported that it might be involved in neurogenesis including induction of astrocytosis, preventing formation of dopaminergic neurons. Another study showed that it could potentiate cell invasion and migration in gallbladder cancer. Its clinical significance in hematologic malignancies has not been explored yet. Since independent studies have reported KIAA0125 as an important gene for unfavorable prognosis, in this study we aimed to investigate its clinical relevance in AML.

Methods: We performed global mRNA arrays for bone marrow samples from 347 newly diagnosed de novo AML patients in the National Taiwan University Hospital, who had adequate cryopreserved cells and detailed demographic, clinical, and genetic data for analysis. The KIAA0125 expression level extracted from the array data was analyzed for its clinical relevance. We also validated our findings by analyzing the public databases of AML.

Results: The 347 patients were divided into two groups based on the median level of KIAA0125 expression on the arrays. Higher KIAA0125 expression was inversely associated with favorable karyotypes including t(8;21) and t(15;17). Patients with M1 by the French-American-British classification more frequently had higher KIAA0125 expression (p < 0.001), while those with M3 (acute promyelocytic leukemia) had significantly lower levels of KIAA0125 expression (p < 0.001). To investigate the association of gene mutations with KIAA0125 expression in AML, we analyzed mutations of 17 AML-associated genes. We found that patients with higher KIAA0125 expression had significantly higher incidence of FLT3-ITD (28.7% vs 19.7%, p=0.048), and mutations of RUNX1 (18.4% vs 10.4%, p=0.034), and DNM3T3a (24.1% vs 13.9%, p=0.015), compared to those with lower KIAA0125 expression. Among the 227 patients who received standard chemotherapy, those with higher KIAA0125 expression had a lower complete remission rate (61.2% vs 84.7%, p < 0.001), and shorter overall survival (median OS, 23.7 months vs 116.8 months, p = 0.001) than those with lower KIAA0125 expression after a median follow-up of 57.0 months. The prognostic significance could be validated in another two independent cohorts, TCGA and GSE12417. In multivariate analyses, higher expression of KIAA0125 remained to be an unfavorable prognostic factor for OS independent of age, white blood cell counts, karyotype, FLT3-ITD, CEBPA double mutations,
RUNX1 mutation, MLL-PTD, WT1 mutation, and TP53 mutation (p<0.011).

Summary/Conclusions: Higher expression of KIAA0125 in AML patients was correlated with mutations of RUNX1, DMNT3A, and FLT3-ITD but negatively associated with favorable karyotypes such as t(8;21) and t(15;17). Higher expression of KIAA0125 appeared to be an independent unfavorable prognostic factor in our cohort, and its negative prognostic impact could be validated in another two large independent cohorts of AML. The close association of KIAA0125 expression with LSC signatures might in part explain its unfavorable impact on the survival of AML patients.

P213

LEUKEMIC STEM CELLS CAN BE DETECTED IN A CONSIDERABLE PERCENTAGE OF PATIENTS WITH ACUTE MYELOID LEUKEMIA AT DIAGNOSIS AND IS A SIGNIFICANT PROGNOSTIC FACTOR

O. Pérez-López1,*, T. Caballero-Velázquez 1, I. Álvarez-Laderas 1, P. Hernández-Díaz1, A. M. Márquez-Mattito 1, J. González-Campos1, R. Morales-Camacho1, C. Prats-Martín1, M.T. Vargas-de los Monteros1, R. Bernai-Ruiz1, J.A. Pérez-Simón1

Virgen del Rocío University Hospital, Sevilla, Spain

Background: There is a growing interest on the identification of leukemic stem cells (SC) as a potential prognostic factor in patients with acute myeloid leukemia (AML). Several studies identify these cells as CD34+CD38-Lin- although there is a controversy about its phenotypic identification and prognostic value.

Aims: To identify SC in a cohort of patients with AML and evaluate their prognostic value in a series of newly diagnosed AML patients.

Methods: The presence of SC (CD34+CD38-Lin-) in bone marrow samples was prospectively evaluated in a consecutive series of 67 newly diagnosed AML patients by flow cytometry, between may-13-oct 16. All patients received intensive chemotherapy according to PETHEMA protocol. We evaluated response, relapse rate and overall (OS) and event free survival (EFS).

Results: Out of the 67 patients [34 men/33 women, median age 54 (0-78)], 58 (88.6%) have SC at diagnosis, 37.9% of them (n=22) achieved complete remission (CR) with a negative minimal residual disease (MRD) vs 77.8% (7/9) among patients without SC (p=0.03). Among patients who obtained CR with a negative MRD (n=29), no one suffer a leukemic relapse in the non SC vs 5/22 (22.7%) in the SC group (p=0.02). Considering the intermediate risk group according to cytogenetic / molecular features, 100% of patients without SC at diagnosis achieve a negative MRD (5/5) vs 14/41 (34.1%) among those in the SC group (p=0.008). OS at 9 months was 89 vs 56% (p=0.043), and the EFS 78 vs 48% (p=0.054) in the non SC and SC group, respectively (Figure 1).

Figure 1.

Summary/Conclusions: SC can be detected in a considerable group of patients with AML at diagnosis. The presence of SC is a prognostic factor in terms of response, OS and EFS. Accordingly, SC detection could help to identify prognosis subgroups of patients with different prognostic among those in the intermediate risk group by genetics/molecular assays.

P214

POST-REMISSIONAL AND PRE-TRANSPLANT ROLE OF MINIMAL RESIDUAL DISEASE DETECTED BY WT1 IN ACUTE MYELOID LEUKEMIA: A RETROSPECTIVE COHORT STUDY

C. Frañia1,2, S. Aydın1, E. Audioso1, L. Riera2, S. Aliberti2, B. Allione1, A. Buscà3, S. D’Arda1, C.M. Dellacasaa2, A. Demurta2, A. Evangelista4, G. Ciccone1, P. Francia di Celle2, B. Nicollino1, A. Stacchini1, F. Marmon1, U. Vitolo1

1Department of Hematology, 2Department of Pathology, 3Bone Marrow Transplant Center, University-Hospital Città della Salute e della Scienza, Torino, Italy, 4Unit of Clinical Epidemiology, University-Hospital Città della Salute e della Scienza and CPO Piemonte, Torino, Italy

Background: In acute myeloid leukemia (AML) the detection of residual leukemic cells at a submicroscopic level (minimal residual disease - MRD) is still under investigation. In about 30-40% of AML lacking a specific molecular target, quantitative real-time polymerase chain reaction (QRT-PCR) has been used to detect transcripts commonly overexpressed in AML. Among a large number of candidates, Wilms tumor gene 1 (WT1) has been proposed as a promising MRD marker.

After the standardization of QRT-PCR on behalf of the European LeukemiaNet (ELN), subsequent studies investigated the role of WT1 expression in AML with controversial results.

Aims: To assess the role of WT1 expression as a MRD marker after intensive induction chemotherapy and before allogeneic hematopoietic cell transplantation HCT (allo-HCT) in a large cohort of AML patients treated in a single institution.

Methods: The present retrospective cohort study included adult patients with untreated AML consecutively diagnosed between 2004 and 2014 in the Hematology Unit of the University-Hospital Città della Salute e della Scienza of Torino, Italy. The study was approved by the Ethical Committee and was registered at www.clinicaltrials.gov as NCT02714790. Among 255 enrolled patients, MRD was investigated in those in first complete remission (CR) with an available at diagnosis and at two further time-points: after induction (n=117) and prior allo-HCT (n=65). Patients with baseline WT1 <250 copies were excluded. All patients underwent intensive induction chemotherapy with curative intent and subsequent consolidation chemotherapy according to the AML risk assessment (autologous peripheral stem cell transplantation for low risk and allo-HCT for intermediate and high risk patients).

Results: Effect of post induction WT1 expression on disease-free survival (DFS) and overall survival (OS) and of pre allo-HCT WT1 expression on cumulative incidence of relapse (CIR) were investigated.

Results: Baseline WT1 expression were not found significantly associated with demographic, clinical and disease biological features at diagnosis. Baseline BM WT1 expression lacked even to show an association with response to induction chemotherapy (OR 1.16; 95% CI 0.90-1.50, p=0.244).

OS and DFS were significantly shorter in patients in first CR with >350 WT1 copies after induction compared to those with ≤350 (OS 17 vs 9 months with HR 2.13; 95% CI 1.14-3.55. p=0.018 and 3-year DFS rates 15% vs 55% with a HR of 2.81; 95% CI 1.14-6.93, p=0.025).

Adding the BM WT1 in the model along with other factors determines an increase of the C-statistic from 0.6966 to 0.7193 for OS (NRI=0.384) and from 0.7413 to 0.7920 (NRI=0.4037) for DFS. Before allo-HCT, patients with WT1 >150 copies (n=18) had a significantly higher CIR compared to those with WT1 ≤150 (n=47), HR 4.61; 95% CI 1.72-12.31, p=0.002.

Summary/Conclusions: The results of the present study showed that BM WT1 is associated with survival in patients in CR in two decisive time-point for treatment planning: after induction treatment and before allo-HCT. The prognostic role of WT1 resulted independent from other well-established risk factors. Therefore, WT1 may represent an additional MRD tool for risk stratification in patients nowadays classified in CR, especially in the high risk MRD positive subgroup in which a risk-adapted approach may have a role. Published evidences available so far supported these suggestions, but mainly due to methodological issues, the role of WT1 is still a matter of debate. Perspective randomized studies are required to confirm these results.

P215

DIFFERENTIATION SYNDROME ASSOCIATED WITH ENASIDENIB (AG-221), A SELECTIVE INHIBITOR OF MUTANT ISOCITRATE DEHYDROGENASE 2 (MIDH2)

1Massachusetts General Hospital Cancer Center, 2Harvard Medical School, Boston, 3The University of Texas MD Anderson Cancer Center, Houston, 4Celgene Corporation, Summit, 5Agios Pharmaceuticals, Inc, Cambridge, 6Memorial Sloan Kettering Cancer Center, 7Weill Cornell Medical College, New York, United States, 8Institut Gustave Roussy, Villejuif, France

Background: Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of miHD2 enzymes. Preclinical studies showed that exposing myeloblasts from patients (pts) with acute myeloid leukemia (AML) to enasidenib ex vivo resulted in differentiation of leukemic marrow blasts into mature, fully functional neutrophils (Yen et al., 2017). Enasidenib can result in IDH-inhibitor-associated differentiation syndrome (IDH-DS) in treated pts, with manifestations akin to retinoic acid syndrome seen during therapy of acute promyelocytic leukemia.

Aims: To characterize the prevalence, characteristics, and course of IDH-DS in pts with AML treated with enasidenib. A phase 1/2 dose-escalation and expansion study (NCT01915498). This dose is currently under study in a multicenter, randomized, phase 3 trial comparing enasidenib with conventional care regimens in R/R AML pts (NCT02577406).
Methods: An independent Differentiation Syndrome Review Committee (DSRC) was formed to review potential cases of IDH-DS. The DSRC identified and agreed upon a series of signs and symptoms possibly characteristic of IDH-DS, including fever, lung infiltrates, pleural or pericardial effusions, rapid weight gain, edema, and azotemia. In all, 27 cases (8 of investigator-reported IDH-DS and 19 with characteristics suggestive of IDH-DS) were identified and retrospectively reviewed by the DSRC to determine their consistency with IDH-DS.

Results: The DSRC determined 13 cases (11.9% of 109 R/R AML pts in the enasidenib 100 mg/day dosing cohort) to be consistent with IDH-DS. Median time to onset was 30 days (range 7-116). Manifestations of IDH-DS in >2 pts were dyspnea (n=10), pyrexia (9), lung infiltrates (8), pleural effusion (5), and kidney injury (3). IDH-DS was effectively managed with systemic corticosteroids in 12/13 cases. Leukocytosis accompanied 4/13 cases, for which hydroxyurea was employed for cytoreduction. Enasidenib was interrupted for 9 pts (for a median of 7 days), but dose reductions or enasidenib discontinuation were not required for pts with IDH-DS. Six of the 13 pts had clinical responses (2 complete remissions [CR], 2 CRs with incomplete hematologic recovery, 1 partial remission, and 1 morphologic leukemia-free state), 6 pts had stable disease, and 1 pt had progressive disease.

Summary/Conclusions: Systemic corticosteroids, close hemodynamic management, and hydroxyurea (in the presence of leukocytosis) are effective IDH-DS management strategies; they should be administered promptly when IDH-DS is suspected, and continued until improvement. Enasidenib interruption can be considered if initial intervention is unsuccessful. IDH-DS represents a novel clinical finding in pts with m/IDH2 AML treated with enasidenib, and is likely due to its suggested mechanism of action, myeloblast differentiation.
P218

OUTCOME OF ELDERLY DLBCL PATIENTS (≥80 YEARS) TREATED WITH ANTHRACYCLINE BASED CHEMOTHERAPY: R-CHOP DOSE REDUCTION IS NOT NECESSARY FOR EVERYBODY

1 Charles University General Hospital, Prague, 2 University Hospital, Brno, 3 University Hospital, Hradec Kralove, 4 University Hospital, Olomouc, 5 University Hospital Kralovske Vinohrady, 6 CLSG Data Center, Prague, 7 University Hospital Motol, Prague, Czech Republic

Background: Management of elderly patients (above ≥80y) is difficult and only limited number of patients could be treated by curative approach with anthracycline based chemotherapy. Dose reduction of particular drugs is used very often and it varies based on pt’s characteristics and center preferences. There is however lack of randomized or at least non-randomized historical comparisons.

Aims: The objective of this study is to analyze elderly DLBCL patients prospectively registered in NiHiL Lymphoma Project and treated anthracycline based regimen in real world outside of clinical trials.

Methods: Patients (pts.) with informed consent are prospectively followed in multicenter Lymphoma Project since 1999. Diagnostic, therapeutic and follow up data are prospectively collected. There were 399 DLBCL pts older than 80year diagnosed in period 1999-2014 identified. Among 372 pts. with pathology review and essential data there were 112 pts. (30%).treated with R-CHOPlike chemotherapy. Analysis of clinical prognostic factors, therapy and toxicity was performed. Pearson, Kaplan-Meier and log rank tests were used.

Results: Median age was 81 years (80-88), 51.8% of men. Proportion of pts ≥85 was 14.3%, with PS ≥2 (ECOG) 34.0%, with higher LDH 64.3%, with high albumin ≥3.5 27.7%, with Charlson Comorbidity Score (CCS) ≥4 25%. According to treatment choice of physician (intention to treat), pts. could be divided into 3 groups R-CHOP (CH) (cyclophosphamide –CF 750 mg/m², Adriamycin – A - 50 mg/m²) or R-MiniCHOP (miniCH) (CF 400 mg/m², A 25 mg/m², Peyrade 2011) or modified R-CHOP (modiCH) (CF 750 mg/m² and A 25 mg/m²) or any other dose between CHOP and miniCHOP. There were 21 pts (18.8%) treated with CH, 38 (33.9%) with miniCH and 53 (47.3%) with modiCH. There were no significant differences between the subgroups, except higher proportion of bulk in miniCH vs miniCH and CH (35% vs 12.9% vs 7.7% resp.; p 0.04) and cardiac comorbidity (60.5% vs 33.3% vs 30.2% resp.; p 0.02). Six and more cycles were administered in 71.4%, 63.1% and 58.5% pts. in CH, miniCH and modiCH resp. Following proportion of pts. received >80% (>50%) of original CHOP dose. For cyclophosphamide it was 66.7% (81%), 0% (50%) and 62.2% (79.2%) resp. and for A it was 57.1% (76.1%), 2.6% (15.8%) and 13.2% (49%) resp. for CH, miniCH and modiCH resp. There were observed 11 treatment related deaths (6 cardiac toxicity and 4 infection), 5 in miniCH and 6 in modiCH groups. The overall response rate was 76.8% with 59.8% CR/CRu. Median PFS and OS were 2.8y and 3.5y resp. (Figure 1A) with median follow up of 3.3y. There were found high beta2microglobulin (HR 2.2, p 0.05), low albumin (HR 1.9, p 0.05) and PS (p 0.05) as the only factors correlated with OS as well as PFS (data not shown). Pts who achieved CR or PR have significantly better OS median as well as PFS compared to stable or progressive disease with 4.6 vs 3.5 vs 0.8 vs 0.5 y. There was numerically (not significantly) better OS median for R-CHOP (4.6y) vs R-miniCHOP (3.2y) and R-modiCHOP (2.9y) (Figure 1B).

Figure 1.

Summary/Conclusions: Only one third of elderly DLBCL pts (≥80y) is treated with anthracycline based regimen. Performance status, albumin and beta2microglobulin levels were significantly associated with prognosis. In minority of these pts full dose of R-CHOP could be safely used and there is trend to better overall survival. Supported by AZV 16-31092A.
pts >60 years, which might in part be related to improved diagnostic practices among the elderly. Over time, this increase in survival was primarily driven by improvements in elderly patients age 70 or below. This is largely explained by the increased use of intensive therapy over time. Although the use of CT alone gradually increased among pts >70 years, their survival is still poor. Therefore, there is an urgent need to design specific trials for elderly PCNSL pts to improve their survival.

P220

CLINICAL CHARACTERISTICS AND LONG-TERM RESULTS OF TREATMENT OF DIFFUSE LARGE B細胞性リンパ腫（DLBCL+C）

1Russian National Research Medical University named after N.I. Pirogov, 2National Research Center for Haematology, 3National Research Center for Oncology named after N.N. Blochin, 4City Clinical Hospital named after C.P. Botkin, 5City Clinical Hospital named after V.M. Buyanov, 6City Clinical Hospital named after V.M. Buyanov, Moscow, Russian Federation

Background: In the WHO classification (2008), hepatitis C virus distinguishes itself as one of the etiological factors of multifastis elopageogenesis DBLCL

Aims: The purpose of this study was evaluation of clinical features and results of treatment of diffuse krepokleutchno lymphoma associated with hepatitis C in comparison with a control group of patients with diffuse large lymphoma without viral hepatitis markers.

Methods: It was included 521 patients with DLBCL: 98 patients with DLBCL markers and hepatitis C (DLBCL+C) and a control group of 422 patients with DLBCL without markers of hepatitis C (DLBCL-C).

Results: Patient’s age ranged from 21 to 76 years (median was 47 years) in DLBCL+C compared with control (median 61 years) in DLBCL-C (p=0.02). The male: female ratio was 1: 1.3 in patients with DLBCL+C, 1: 1.7 in the group DLBCL-C. Stage I and II were in 11% patients with DLBCL+C, and 48% patients with DLBCL-C. III and stage IV were detected in 89% patients with DLBCL+C and 52% of DLBCL-C (p=0.00002). Extranodal lesions detected in 72% in DLBCL+C and in 26% in C DLBCL-C (p=0.006). In comparable groups localization of extranodal lesions was: spleen (52% to 23%), bone marrow involvement (43% and 27%), liver (26% and 18%) and lymph nodes involvement (55% and 45% in DLBCL+C, 36% / 64% in DLBCL-C) (p=0.001). Hepatitis C virus RNA in blood detected by PCR. Viral RNA was found in 78% (74 patients). High viral load was in 21% of patients. In 22% of cases markers of hepatitis C virus in blood were identified by ELISA. All patients received chemotherapy according to the scheme CHOP / R-CHOP. The frequency of complete remission was 60% in the group of patients with DLBCL+C and 63% of DLBCL-C. Median overall survival (OS) was 46 months in group DLBCL+C and 71 months in DLBCL-C (p=0.0003).

Clinical progression-free survival (PFS) was 28 months in DLBCL+C and 47 months in the control group (p=0.0002). According to the immunohistochemical variant of DBLCL: GCB DLBCL-C and non-GCB histological variant ratio was 55% / 45% in DLBCL+C; 36% / 64% in DLBCL-C (p=0.001).

Results:

Aims: The purpose of this study was evaluation of clinical features and results of treatment of diffuse krepokleutchno lymphoma associated with hepatitis C in comparison with a control group of patients with diffuse large lymphoma without viral hepatitis markers.

Methods: It was included 521 patients with DLBCL: 98 patients with DLBCL markers and hepatitis C (DLBCL+C) and a control group of 422 patients with DLBCL without markers of hepatitis C (DLBCL-C).

Results: Patient’s age ranged from 21 to 76 years (median was 47 years) in DLBCL+C compared with control (median 61 years) in DLBCL-C (p=0.02). The male: female ratio was 1: 1.3 in patients with DLBCL+C, 1: 1.7 in the group DLBCL-C. Stage I and II were in 11% patients with DLBCL+C, and 48% patients with DLBCL-C. III and stage IV were detected in 89% patients with DLBCL+C and 52% of DLBCL-C (p=0.00002). Extranodal lesions detected in 72% in DLBCL+C and in 26% in C DLBCL-C (p=0.006). In comparable groups localization of extranodal lesions was: spleen (52% to 23%), bone marrow involvement (43% and 27%), liver (26% and 18%) and lymph nodes involvement (55% and 45% in DLBCL+C, 36% / 64% in DLBCL-C) (p=0.001). Hepatitis C virus RNA in blood detected by PCR. Viral RNA was found in 78% (74 patients). High viral load was in 21% of patients. In 22% of cases markers of hepatitis C virus in blood were identified by ELISA. All patients received chemotherapy according to the scheme CHOP / R-CHOP. The frequency of complete remission was 60% in the group of patients with DLBCL+C and 63% of DLBCL-C. Median overall survival (OS) was 46 months in group DLBCL+C and 71 months in DLBCL-C (p=0.0003).

Clinical progression-free survival (PFS) was 28 months in DLBCL+C and 47 months in the control group (p=0.0002). According to the immunohistochemical variant of DBLCL: GCB DLBCL-C and non-GCB histological variant ratio was 55% / 45% in DLBCL+C; 36% / 64% in DLBCL-C (p=0.001).

MAGNETIC RESONANCE IMAGING FOR EARLY DETECTION OF ANTITHYRCYCLINE CARDIOTOXICITY IN MALIGNANT LYMPHOMA

A.H. Laursen1,*, J.J. Thune2, M.B. Elming3, P. Hasbak4, R.S. Ripa4, M. Hutchings3

1Department of Haematology, Rigshospitalet, 2Department of Cardiology, Bispierg and Frederiksborg Hospital, 3Department of Cardiology, 4Department of Clinical Physiology, Nuclear Medicine and PET, Rigshospitalet, Copenhagen, Denmark

Background: Doxorubicin is a cornerstone of curative lymphoma treatment. However, doxorubicin therapy is limited by cardiac side effects including high-mortality heart failure (HF). Signs of cardiotoxicity often appear too late to avoid irreversible myocardial damage.

Aims: The aim of our study is to investigate the value of rubidium 82 positron emission tomography (82Rb PET), iodoine 123 metidobenzoyguanidine (123I MiB) and cardiac magnetic resonance (MR) imaging in early detection of doxorubicin-induced cardiomopathy and prediction of HF in patients with malignant lymphoma. We aim to identify early signs of cardiooxygen toxicity that predict the formation of interstitial fibrosis and subsequent HF. Here we present our preliminary MR data. 82Rb PET and 123I MiB data will be analysed later.

Methods: The study is a prospective, clinical, single-centre study. The study aims to include 70 consecutive chemotherapy-naive lymphoma patients scheduled for intended curative chemotherapy without planned mediastinal radiation therapy. All patients undergo routine clinical examinations, but with supplementary imaging, including 1) baseline 82Rb PET and MR (prior to treatment); 2) acute 82Rb PET and MR (within 1 week of the first treatment); 3) subacute 123I-MiB (after 2-3 months of therapy) and 4) late MR (1 year after the start of treatment). 82Rb PET imaging is performed at rest and during pharmaco- logical stress testing with adenosine. It is primarily used to evaluate the acute effects of doxorubicin on myocardial perfusion. 123I-MiB is used for detection of doxorubicin-induced subacute changes in the myocardial adrenergic neurons. Cardiac MR is performed with low gadolinium enhancement and provides information on acute and late changes in left and right ventricular function, atrial and ventricular volumes, myocardial mass and interstitial fibrosis. Statistical analyses were done in R (version 3.2.0) as paired difference tests using Wilcoxon signed rank test. P-values <0.05 were considered significant.

Results: As of March 1st 2017, 61 patients have been included. In 33 cases, the time of intended follow-up has been reached. Four patients died prior to follow-up, including one patient who died before the acute imaging procedures. Four patients were excluded due to compliance problems. One patient was excluded due to disease downstaging resulting in omission of doxorubicin from the treatment plan. Of the 24 patients with complete data from both the baseline and late MR scans, 16 had lower LVEF values at follow-up: 0-5% (n=3), 6-10% (n=8), 10-15% (n=4) and >20% (n=1). Mean LVEF at follow-up was significantly lower (57.1%) compared to baseline LVEF (62.0%; p=0.01) and acute LVEF (64.3%; p=0.002). The LVEF decline from baseline to follow-up was paralleled by an increase in mean left ventricular end diastolic volume (LVEDV) of 10.0ml (p=0.03). Interestingly, an increase in LVEDV was already registered at the acute MR scan (7.3ml; p=0.03). The increase in LVEDV from the acute MR to follow-up was not significant. We also registered an acute increase of 7.4ml in mean stroke volume (SV) (p=0.02). However, from the acute MR to follow-up we found a significant decline in SV (p=0.02). There was no difference in SV from baseline to follow-up (p=0.7). The acute changes in LVEDV did not predict LVEF declines from baseline to follow-up (Figure 1).

Figure 1.

Summary/Conclusions: Our preliminary show that cardiac MR can be used for detection of declining LV function 1 year after after doxorubicin exposure. It appears that cardiac MR may also provide information on acute functional changes in LVEDV and SV. We hope that our 82 Rb PET and 123I MiB data will provide additional early signs of doxorubicin cardiotoxicity that can be used to predict subsequent development of HF.

RELAPSE CHARACTERISTICS AND THE ROLE OF SURVEILLANCE COMPUTED TOMOGRAPHY IN AGGRESSIVE NON-HODGKIN LYM- PHOMA

K.-W. Kang1,*, Y. Park1, D.S. Kim1, E.S. Yu1, J.H. Kim1, S.R. Lee1, H.J. Sung1, S.J. Kim1, C.W. Choi1, B.S. Kim1

1Department of Internal Medicine, Korea University School of Medicine,
The use of surveillance computed tomography (CT) is usual for cases of complete remission (CR) in aggressive non-Hodgkin lymphoma (aNHL). However, there is a lack of evidence to support this strategy. Aims: To determine whether surveillance CT could contribute to the improvement of survival in relapsed aNHL patients, we retrospectively analyzed our institutional lymphoma registry, which enrolled consecutive patients with lymphoma from June 1995 to October 2016. Of 1,385 anNHL patients in the registry, 664 patients achieved CR and received follow-up through clinical visits, with or without surveillance CT.

Methods: Patients who met the following inclusion criteria were selected: i) histologic diagnosis of anHL (diffuse large B-cell lymphoma, Burkitt lymphoma, and B-cell lymphoblastic lymphoma, peripheral T-cell lymphoma, anaplastic large cell lymphoma, NK/T-cell lymphoma, and T-cell lymphoblastic lymphoma); ii) patients who achieved CR after frontline or salvage chemotherapy with curative intent; and iii) time from treatment to surveillance CT

IDENTIFICATION OF A NOVEL GERMINE MECOM / EV1 VARIANT THAT RUNS IN A PEDIGREE WITH RADIOLNAR SYNDOSIS AND AMEGAKARYOCYTIC THROMBOCYTOPENIA AND PREDISPSES TO AGGRESSIVE T-CELL LYMPHOMA 

T. Ripperger1,2, W. Hofmann1, J.C. Koch3, K. Shimeshan3, D. Haase3, G. Wulf3, P.R. Issing4, M. Karnebogen5, G. Schmidt1, B. Aubert1, B. Schlegelberger1, T. Ilig1,2, B. Zim2, D. Steinemann1

Background: Radioulnar synostosis and amegakaryocytic thrombocytopenia (RUSAT), one of the rare bone marrow failure syndromes, is caused by a point mutation in HOXA11. In three simplex patients, de novo missense variants in MECOM have recently been reported as an alternative cause in individuals with RUSAT. MECOM, identified as a common ecotropic viral integration site 1 (EV1) in murine myeloid leukemia, is known as a key transcriptional regulator in hematopoiesis and is frequently involved in sporadic myeloid leukemia.

Aims: To screen for the causative genetic alteration in a family with four affected individuals out of three generations with radioulnar synostosis, incompletely penetrant congenital thrombocytopenia, hearing impairment due to dysplastic middle ear bones, patellar hypoplasia, and hand and foot dysmorphisms. Notably, two of four affected individuals in our family developed adult onset myeloid malignancies (i.e. myelodysplastic syndrome (MDS) with excess blasts and MDS/myeloproliferative neoplasm-unclassifiable). No HOXA11 mutation was identified in this family.

Methods: Whole exome sequencing was performed in three affected individuals using a Nextera Rapid Capture Kit and a NextSeq 500 instrument (Illumina, Munich, Germany). Identified sequence variants were filtered for those that are rare (<1%) and nonsynonymous. The top three subjects were selected to be downsampled to about 8x coverage and 100 reads per base pair (100bp LANE), the latter two were included to have an allele frequency of ≤0.1% (1000G, ESP6500, ExAC), and (iv) not listed in our in-house database of recurrent variants.

Results: Following this approach, a novel MECOM missense variant (i.e. Cys766Gly, UniProtKB Q03112-1) was identified. The missense mutation affects a heavily conserved cysteine residue in C2H2-zinc finger motif 9 in the C-terminal zinc finger domain of MECOM. This residue is crucial for the tetradehedral coordination of a zinc ion stabilizing the zinc finger conformation and thus, is essential for DNA binding of the C-terminal zinc finger domain.

Summary/Conclusions: Our findings confirm the causality of MECOM missense mutations targeting the C-terminal zinc finger domain in subjects with RUSAT and indicate that MECOM needs to be considered in RUSAT pedigrees with no HOXA11 mutation. We report here for the first time that MECOM germline mutations are associated with an increased risk for adult onset myeloid malignancies. This extends the RUSAT-associated phenotype and suggests that MECOM germline mutations can cause a genetic predisposition to adult onset myeloid malignancy.

Background: Fanconi anemia (FA) is a hereditary DNA repair disorder characterized by various congenital abnormalities, progressive bone marrow failure and cancer predisposition. RAD51 has recently been designated as a Fanconi anemia (FA) gene, following the discovery of two patients carrying dominant negative mutations. RAD51 is an indispensable homologous recombination protein, necessary for strand invasion and crossing over. It has been extensively studied in prokaroytes and lower eukaryotes. However, there is a significant lack of knowledge of the role of this protein and its regulation in an in-vivo context in vertebrates due to the early embryonic lethality of murine Rad51 mutants. As a next step, we aim to utilize the powerful genetics and translucency of zebrafish to dissect the role of rad51 in hematopoiesis and to explore the molecular basis of Fanconi anemia pathogenesis.

Methods: Zebrafish carrying homozygous loss of function mutations in rad51

Background: Radiolu...
generated by ENU mutagenesis were characterized in terms of their hematopoietic and non-hematopoietic phenotypes during embryonic development and adulthood.

Results: The rad51f mutant fish developed key features of FA, including hypocellular kidney marrow (equivalent to mammalian bone marrow), sensitivity to crosslinking agents and decreased size. Interestingly, although mutants can survive to adulthood, they develop exclusively as sterile males. We show that some of the hematological symptoms stem from both decreased proliferation and increased apoptosis of embryonic hematopoietic stem and progenitor cells. Cotransduction of p53 was able to rescue the embryonic and adult hematopoietic defects seen in the single mutants, but led to early tumor development in the adult double mutants. We further establish that prolonged inflammatory stress can exacerbate the hematological impairment, leading to an additional decrease in kidney marrow cell numbers linked to excess p53 expression (Figure 1).

Figure 1. Example image of a p53, rad51 double mutant fish with a tumor behind the eye (A). Histological analysis showed the tumour to be a malignant peripheral nerve sheath tumor (B). The scale bar is 500 and 10 pm respectively.

Summary/Conclusions: We demonstrate that zebrafish lacking functional rad51f are viable and develop symptoms resembling FA. These findings strengthen the assignment of RAD51f as a Fanconi gene and provide more evidence for the notion that aberrant p53 signaling during embryogenesis leads to the hematological defects seen during later stages of life in FA patients. Further research on this novel zebrafish FA model will lead to a deeper understanding of the molecular basis of bone marrow failure in FA and the cellular role of the RAD51 protein.

P228

A NOVEL TELOMERASE RNA COMPONENT VARIANT IN A FAMILY WITH MACROCYTOSIS AND MILD VARIABLE CYTOPENIAS

C. Burney1,2, A. Mumford2, N. Roy3, M. Proven3, A. Schuh3, K. Wray4, H. Dreau3, C. Bradbury2

1Department of Haematology, University Hospitals Bristol NHS Trust, 2School of cellular and molecular medicine, University of Bristol, Bristol, 3BRC Blood Theme and BRC/NHS Translational Molecular Diagnostics Centre, John Radcliffe Hospital, 4Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, John Radcliffe Hospital, Oxford, United Kingdom

Background: Teleromerase RNA component (TERC), encoded by the TERC gene, is an essential component of telomerase, a polymerase that adds the telomeric repeat to the 3’ lagging strand of DNA during cell replication. TERC variants have been causally associated with several hematological disorders, including autosomal dominant dyskeratosis congenita (DKC), aplastic anemia, myelodysplastic syndrome and acute leukemia, sometimes accompanied by non-hematological phenotypes. Here we report a likely pathogenic TERC variant associated with a hematological phenotype that predominantly affects the red cell lineage.

Aims: To describe the genotypic and phenotypic relationship of a new TERC variant.

Methods: Genomic DNA samples were analysed for sequence variants using the Oxford Red Cell Panel, a panel of 33 genes previously associated with human red cell diseases. Sanger sequencing was used to confirm the new variant. Telomere lengths were performed at the Laboratory for Molecular Haematology and Oncology (LMMH), Rayne Institute, Kings College Hospital.

Results: The index case AM (I.1) was a female who presented at age 56 with fatigue, and was noted to have a long-standing progressive mild macrocytic anaemia with very minimal thrombocytopenia. Further investigations (Table 1) revealed normal reticulocyte count, LDH, haematogens, thyroid function, liver and renal function. Bone marrow aspirate demonstrated abnormal erythropoiesis with nucleo-cytoplasmic asynchrony, nuclear atypia, ragged cytoplasm, basophilic stippling and bi-nucleate forms.Granulopoiesis and megakaryopoiesis were normal. The two daughters of I.1 also had abnormal blood counts and her paternal grandfather died of “pernicious anaemia”. None of the family have had isolated lifelong macrocytosis and previous mild neutropenia (Table 1). The younger daughter (age 27) BM (II.2) had macrocytic anaemia, thrombocytopenia (Table 1) and a recent pregnancy complicated by worsening thrombocytopenia, pre-eclampsia, placental dysfunction, liver dysfunction and foetal loss. Following delivery her liver function slowly returned to normal and a fibroscan was within normal limits. All three pedigree members with macrocytosis had a Chr3:169482668 (GRCh37) single nucleotide variant corresponding to a n.181A>C substitution in TERC (relative to transcript ENST00000602385.1), within the pseudoknot domain. Residue n.181 is highly conserved across mammalian species. This variant is absent from the gnomAD database of more than 230,000 TERC alleles, and the HGMD databases. The variant is within a TERC region in which previously reported variants have been associated with haematological phenotypes. In order to determine the pathogenicity of this variant, telomere lengths were assessed and found to be short in both Case I.1 and II.2 (Table 1). There were no other likely pathogenic variants in the Oxford Red Cell Panel genes. Together, these observations suggest that the n.181A>C substitution is causally associated with the macrocytosis phenotype.

Summary/Conclusions: This report demonstrates a likely causal association between a newly identified TERC variant, short telomere length and a relatively mild hematological phenotype that is largely restricted to red cells. This emphasises the phenotypic heterogeneity associated with TERC variants, justifies the rationale of screening multiple genes simultaneously and suggests that TERC variant could potentially underlie a broader range of unexplained heritable blood cell abnormalities.

P229

GENERATION OF X-LINKED DYSKERATOSIS CONGENITA-LIKE HUMAN HEMATOPOIETIC STEM CELLS

C. Carrascos1,2, H.A. Zitterstein1,2, L. Pintado-Berniches3,4, M.L. Lozano1,2, L. Sastre2,3, J.A. Bueren1,2, R. Perona2,3, G. Guenechea1,2

1Division of Hematopoetic Innovative Therapies, Centro de Investigaciones Etiológicas Medicamentosas (CIMED) and Instituto de Investigaciones Sanitarias Fundación Jiménez Díaz (IIS-FJD/UAM), 2Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), 3Instituto de Investigaciones Biomédicas Alberto Sols (CSIC/UAM), Madrid, Spain

Background: X-linked Dyskeratosis congenita (X-DC) is an inherited syndrome caused by mutations in the DKC1 gene that encodes for the dyskerin nuclear protein. These mutations reduce the telomerase activity leading to premature telomere length attrition. Several organs can be affected in these patients, although the bone marrow failure (BMF) is the main cause of death in X-DC patients (more than 70% of cases). So far, the only curative treatment for BMF in DC patients is hematopoietic stem cell (HSC) transplantation. However, risks derived from conditioning regimes and the difficulties to find a compatible donor suggest that gene therapy may constitute a promising alternative in treating DC patients.

Methods: Genomic DNA samples were analysed for sequence variants using the Oxford Red Cell Panel, a panel of 33 genes previously associated with human red cell diseases. Sanger sequencing was used to confirm the new variant. Telomere lengths were performed at the Laboratory for Molecular Haematology and Oncology (LMMH), Rayne Institute, Kings College Hospital.

Results: The index case AM (I.1) was a female who presented at age 56 with fatigue, and was noted to have a long-standing progressive mild macrocytic anaemia with very minimal thrombocytopenia. Together, these observations suggest that the n.181A>C substitution is causally associated with the macrocytosis phenotype.

Summary/Conclusions: This report demonstrates a likely causal association between a newly identified TERC variant, short telomere length and a relatively mild hematological phenotype that is largely restricted to red cells. This emphasises the phenotypic heterogeneity associated with TERC variants, justifies the rationale of screening multiple genes simultaneously and suggests that TERC variant could potentially underlie a broader range of unexplained heritable blood cell abnormalities.
Summary/Conclusions: The performance of the eculizumab can be in part explained by its action on EVs.

Results: Based on the inhibition of KC1 gene expression, 3 shRNAs were selected among 7 designed shRNAs. Intracellular HSCs showed an inhibited telomerase activity, as well as a reduced clonogenic and hematopoietic reconstitution potential in NSG mice. Additionally, an increase in DNA damage and senescence was observed in DKCl-interfered CD34+ cells.

Aims: The general purpose of this project is a better understanding about the role of EVs in thrombosis in the context of PNH patients under eculizumab. We assessed the expression of eculizumab on the EVs and on their procoagulant activity, in order to check, if the antithrombotic activity of the eculizumab could be in part explained by its interaction with the EVs.

Methods: We conducted a pilot prospective open label longitudinal clinical study with six PNH patients treated with eculizumab. The study was led according to the principles of Helsinki and approved by the local Ethics Committee. Informed consent was obtained for each patient. The aim was to measure, by flow cytometry, the production of EVs in patient’s platelet-free plasma (PFP) before the start of eculizumab, after 4 weeks and after 11 weeks of treatment. We also assessed the procoagulant activity in PFP by STA®-Procoag-PPL assay and by thrombin generation assay (TGA). A more sensitive version of TGA was also performed to study the procoagulant profile induced by the EVs (use of EVs pelleted from PFP). We used mixed-effects linear regression (R 3.1.2 with nlme package) with logarithmic transformation for flow cytometry results. We compared the results after 4 weeks of treatment against the inclusion value.

Results: We observed a decrease in platelet EVs with the eculizumab treatment (p<0.05). STA®-Procoag-PPL assay showed a decrease of the procoagulant profile induced by procoagulant phospholipids (PL) with the treatment. These results were not confirmed by TGA on PFP, due to a lack of sensitivity. By this approach, we performed an more sensitive version of TGA that allows to observe variation in the procoagulant profile induced by the EV with the eculizumab (p<0.05).

Summary/Conclusions: Eculizumab has an impact on the amount and the procoagulant profile induced by the procoagulant PL and the EVs. The anti-thrombotic performance of the eculizumab can be in part explained by its action on EVs.

Aims: Because of the difficulties associated to the use of primary HSCs from DC patients for experimental studies, this study was focused on the generation of X-DC-like human HSCs by means of the down-regulated expression of dyskerin in cord blood HSCs using different anti-DKC1 short hairpin RNAs (shRNA).

Methods: CD34+ cells were obtained by immunomagnetic purification from healthy human umbilical cord blood samples. These cells were then pre-stimulated with IL-2/LMNF and to two cycles of transduction with lentiviral vectors carrying both an anti-DKC1 shRNA and the puromycin-resistance gene. Transduced samples were then selected for 2 days with puromycin, and cultured in vitro or transplanted into immunodeficient NSG mice to evaluate the effects of shRNAs.

Results: The in vitro and in vivo data obtained from DKCl-interfered CD34+ cells confirmed that these cells can mimic the phenotype of primary X-DC-HSCs. The generation of X-DC-like HSCs will facilitate the understanding of the molecular basis of the HSC defects characteristic of X-DC and contribute to the development of new experimental therapies for the treatment of the BMF of X-DC patients.

Aims: In this study, we report the first results of such a clinical routine screening for telomeropathies carried out within the Aachen Telomeropathy Registry (ATR).

Methods: 184 patients from 52 participating centers (80% academic centers) within Germany, Austria and Switzerland were screened for premature telomere shortening and included with informed consent into the ATR since November 2014. Inclusion criteria and reason for screening was either the clinical suspicion of the treating physician for a telomere maintenance disorder and/or the recommendations of the German Society of Hematology and Oncology (DGHO) published via Onkopedia. TL analysis of peripheral blood granulocytes and lymphocytes was carried out using combined fluorescence in situ hybridization and flow cytometry (flow-FISH). Mutations in genes suspected to cause telomeropathies (i.e., TERT, TERC, DKC1, NOP10, NHP2, USB1, CT1, RTE1L1, TIN2, TAC1) were analyzed by NGS using customized primer panels and amplicon-based sequencing on a MiSeq sequencer (Illumina) in all patients with TL in lymphocytes below the 1% percentile of healthy controls.

Results: Underlying initial diagnosis by the treating physician for the routine screening was aplastic anemia (AA, n=72, 39% of cases), unexplained cytopenia (UC, n=69, 11%), myelodysplastic syndromes (MDS, n=15, 8%), family members (FM) of known DKC patients (FM-DKC, n=17, 9%), atypical chronic myelogenous leukemia (n=7, 4%), myelodysplasia (n=9, 5%), myelodysplastic syndrome (n=5, 3%) as well as other disorders (e.g. lung fibrosis, Diamond-Blackfan-Anemia, Bloom-syndrome, etc.). Median age of all patients was 39 (range: 0.5 to 88) years. TL screening revealed 20% (38/184) patients with lymphocyte TL and 16% (30/184) of patients with granulocyte TL below the 1% percentile. NGS screening identified typical mutations associated with altered telomere maintenance in 15 out of 38 patients (40%) representing 8.2% of the total patient population. Median age of patients with mutations was 45.0 years (range: 21 to 68 years). 32 of 38 patients were detected with RTE1L1 (n=3), TERC (n=6), TERT (n=6), DKCI (n=3) and DKC1 (n=3). Mutations were observed in 5% of all AA, 12% of all UC, 50% of all MDS, 13% of all SCCHN, 20% of all screened AML patients.

Summary/Conclusions: We provide the first analysis of a routine TL screening protocol in the context of clinically suspected telomeropathy patients up to the age of 88 years. TL screening is feasible in a routine clinical setting identifying approximately 20% of all samples to reside below the 1% percentile. Genetic testing confirmed the diagnosis of cryptic DKC in a variety of initial diagnoses. This study highlights both the diagnostic value of TL screening for cryptic DKC in childhood and adulthood. Routine screening of DKC however is of utmost importance given its significant clinical implications towards prognosis, treatment and family counseling.

Aims: Because of the difficulties associated to the use of primary HSCs from DC patients for experimental studies, this study was focused on the generation of X-DC-like human HSCs by means of the down-regulated expression of dyskerin in cord blood HSCs using different anti-DKC1 short hairpin RNAs (shRNA).

Methods: CD34+ cells were obtained by immunomagnetic purification from healthy human umbilical cord blood samples. These cells were then pre-stimulated with IL-2/LMNF and to two cycles of transduction with lentiviral vectors carrying both an anti-DKC1 shRNA and the puromycin-resistance gene. Transduced samples were then selected for 2 days with puromycin, and cultured in vitro or transplanted into immunodeficient NSG mice to evaluate the effects of shRNAs.

Results: The in vitro and in vivo data obtained from DKCl-interfered CD34+ cells confirmed that these cells can mimic the phenotype of primary X-DC-HSCs. The generation of X-DC-like HSCs will facilitate the understanding of the molecular basis of the HSC defects characteristic of X-DC and contribute to the development of new experimental therapies for the treatment of the BMF of X-DC patients.

Aims: The general purpose of this project is a better understanding about the role of EVs in thrombosis in the context of PNH patients under eculizumab. We assessed the expression of eculizumab on the EVs and on their procoagulant activity, in order to check, if the antithrombotic activity of the eculizumab could be in part explained by its interaction with the EVs.

Methods: We conducted a pilot prospective open label longitudinal clinical study with six PNH patients treated with eculizumab. The study was led according to the principles of Helsinki and approved by the local Ethics Committee. Informed consent was obtained for each patient. The aim was to measure, by flow cytometry, the production of EVs in patient’s platelet-free plasma (PFP) before the start of eculizumab, after 4 weeks and after 11 weeks of treatment. We also assessed the procoagulant activity in PFP by STA®-Procoag-PPL assay and by thrombin generation assay (TGA). A more sensitive version of TGA was also performed to study the procoagulant profile induced by the EVs (use of EVs pelleted from PFP). We used mixed-effects linear regression (R 3.1.2 with nlme package) with logarithmic transformation for flow cytometry results. We compared the results after 4 weeks or 11 weeks of treatment against the inclusion value.

Results: We observed a decrease in platelet EVs with the eculizumab treatment (p<0.05). STA®-Procoag-PPL assay showed a decrease of the procoagulant profile induced by procoagulant phospholipids (PL) with the treatment. These results were not confirmed by TGA on PFP, due to a lack of sensitivity. By this approach, we performed a more sensitive version of TGA that allows to observe variation in the procoagulant profile induced by the EV with the eculizumab (p<0.05).

Summary/Conclusions: Eculizumab has an impact on the amount and the procoagulant profile induced by the procoagulant PL and the EVs. The anti-thrombotic performance of the eculizumab can be in part explained by its action on EVs.

Aims: Because of the difficulties associated to the use of primary HSCs from DC patients for experimental studies, this study was focused on the generation of X-DC-like human HSCs by means of the down-regulated expression of dyskerin in cord blood HSCs using different anti-DKC1 short hairpin RNAs (shRNA).

Methods: CD34+ cells were obtained by immunomagnetic purification from healthy human umbilical cord blood samples. These cells were then pre-stimulated with IL-2/LMNF and to two cycles of transduction with lentiviral vectors carrying both an anti-DKC1 shRNA and the puromycin-resistance gene. Transduced samples were then selected for 2 days with puromycin, and cultured in vitro or transplanted into immunodeficient NSG mice to evaluate the effects of shRNAs.

Results: The in vitro and in vivo data obtained from DKCl-interfered CD34+ cells confirmed that these cells can mimic the phenotype of primary X-DC-HSCs. The generation of X-DC-like HSCs will facilitate the understanding of the molecular basis of the HSC defects characteristic of X-DC and contribute to the development of new experimental therapies for the treatment of the BMF of X-DC patients.
Background: Mortality following HSCT in SAA pts over the age of 40 is reported to be in the order of 50%, without taking into account long term sequelae such as chronic GvHD, known to be more frequent in older patients. This has prompted international guidelines to recommend first line immunosuppressive therapy above 40 years of age. The question is whether this is still true in 2017.

Aims: Assess whether TRM in SAA patients drafted 2010-2015 is reduced, as compared to the era 2001-2009.

Methods: We used the WPSAA-EBMT registry, and identified 478 pts aged 40 years or more, with acquired SAA, grafted between 2001 and 2015. We divided pts in 2 transplant eras:2001-2009 (n=327) and 2010-2015 (n=407). In the more recent period (2010-2015) pts were older (53 vs 49 year, p<0.01), were more often grafted from alternative donors (ALT) (64% vs 43%, p<0.01), with a greater use of BU (54% vs 41%, p<0.01), and with a longer interval dx-tx (317 vs 258 days , p=0.01), and more often received a fludarabine containing regimen (55% vs 42%, p<0.01).

Results: The overall survival 5 year survival of pts drafted in 2001-2009 was 57% , compared with 55% for pts drafted 2010-2015 (p=0.7). In multivariate analysis, including the interval diagnosis transplant, patient’s age, donor type, stem cell source and conditioning regimen, the lack of improved survival in 2010-2015 was confirmed (p=0.3).

A very strong age effect was shown both in univariate and multivariate analysis: survival of pts aged 40-50 years, 51-60 years and >61 years , was respectively 64%, 54%, 41% (p<0.0001) and this was confirmed in multivariate analysis. The conditioning regimen, also proved to be a significant predictor, with improved survival for ALT transplants receiving FLU containing regimens (56% vs 46%, p<0.001). In general pts receiving either CY200 or a FLU containing regimen , did significantly better than pts receiving other preparative regimens (58% vs 50%, p=0.02). The use of a sibling donor (SIB) did not prove to predict survival in multivariate analysis. Pts receiving Campath in the conditioning , did significantly better than pts not receiving Campath (65% vs 54% p<0.01); similarly survival of patients with ATG was superior 59% vs 41% compared to patients not receiving ATG (p<0.01). When pts receiving either Campath or ATG (n=564) were compared to patients not receiving either (n=161), the difference in survival was 61% vs 41% (p<0.00001), and this was significant also in multivariate analysis. Combined primary and secondary graft failure was reduced from 16% to 12% in the two time periods (p=0.02), acute GvHD grade II-IV was reduced from 15% to 11% (p=0.01) and chronic GvHD was also reduced from 32% to 26% (p=0.01). Infections remained the leading cause of death in both transplant eras (18% and 22% respectively), followed by GvHD (5% and 4%) and graft failure (5% and 2%), whereas PTLD have been reduced from 3% to 0.5% (Figure 1).

Figure 1.

Summary/Conclusions: HSCT in pts with acquired SAA aged 40 and over, continues to carry a significant risk of TRM also in 2010-2015, ranging from 36% in younger pts (40-50) to 59% in older pts (>60 years). Survival is predicted in multivariate analysis, by two crucial predictors: patients age and the use of either Campath or ATG, the latter giving a 20% survival advantage over no Campath /ATG. ALT and SIB donors produce similar survival. This study gives further support to current guidelines, suggesting first line therapy with ATG+CsA, in pts over the age of 40.
BONE MARROW FAILURE SECONDARY TO NOVEL/KNOWN PRIMARY IMMUNODEFICIENCY-RELATED MUTATIONS. A SINGLE CENTER ANALYSIS

1Haematology Unit, 2Molecular Genetic Unit, 3Stem Cell Transplantation Unit, IRCCS Istituto Giannina Gaslini, Genova, 4Haematology, Dept. of Cellular Biotechnologies and Haematology, La Sapienza University, Roma, Italy, 5Division of Human Genetics, Cincinnati Children’s Hospital Medical Center, Cincinnati, United States

Background: Differential diagnosis between acquired and congenital forms of Marrow Failure (MF) has always represented a crucial point in the diagnostic work-up, since genetic forms do require a different therapeutic approach. It is also known that patients with congenital MF may also show immunodeficiency that, in some cases, can represent the first or revalent sign of the disease and therefore can be misinterpreted as a Primary Immunodeficiency (PID). On the other hand, patients with PIDs may also show MF as a result of an immune-mediated attack of marrow precursors thus generating a phenotypic overlap that can impair the correct diagnosis.

Aims: In this report we analyzed all patients with MF evaluated in our Unit with the aim to identify the type and incidence of underlying molecular defects, in particular those related to PIDs.

Methods: We retrospectively evaluated all diagnosis performed in patients with single/multi-lineage MF followed in our Unit. DEB test was used to screen Fanconi Anemia (FA). Other congenital MFs have been searched by Sanger and/or NGS molecular analysis depending on the available tools over the years.

Results: Between 2009-2016, 88 patients have been studied for single-lineage (25) or multiligneage (63) MF. 48 (64%) were classified as having an acquired MF; 27 (30%) were diagnosed with a congenital MF (FA 11, Diskeratosis Congenita 5, Severe Congenital Neutropenia 6, Blackfan-Diamond Anemia 3, Congenital Amegakaryocytic Thrombocytopenia 2), and the remaining 13 patients (14%) were found to have an underlying PID. Table 1 shows clinical characteristics and mutations of patients with PIDs.

Table 1.

Summary/Conclusions: This report shows that patients presenting with single/multi-lineage MF may have an underlying PID in a considerable number of cases. We also show that MF represented the most relevant clinical sign in patients with PI3KCD, TACI, or CD40L mutations, thus widening their clinical phenotype. We conclude that an accurate immunological work-up should be performed in all patients with MF and that PIDs-related genes should be included in the molecular screening of MF in order to identify specific disorders that may potentially receive targeted treatment and/or the appropriate conditioning regimen for SCT.

COVERSIN, A NOVEL C5 COMPLEMENT INHIBITOR, FOR THE TREATMENT OF PNH: RESULTS OF A PHASE 2 CLINICAL TRIAL

1St James’s Institute of Oncology, Leeds Teaching Hospitals, Leeds, 2Akari Therapeutics Plc, 3Haemostasis Research Unit, University College London, London, United Kingdom, 4Department of Haematology, Medical University of Lodz and Copernicus Memorial Hospital, Lodz, 5Department of Disorders of Haematostasis and Immunodeficiencies, Institute of Haematology and Haemostasis Medicine, Warsaw, 6Department of Haematology, Gdansk University Hospital, Gdansk, Poland

Background: Paroxysmal nocturnal haemoglobinuria (PNH) leads to episodic haemolysis secondary to an acquired deficiency of PIGA anchor molecules on the surface of erythrocytes which play a critical role in protecting the cells from complement mediated lysis. Until the advent of eculizumab, a monoclonal antibody which prevents the cleavage of C5 to C5a and C5b, PNH was associated with considerable morbidity and a poor long-term prognosis. However, eculizumab needs to be administered by health care professionals by intravenous infusion which may interfere with the life-styles, occupations and personal privacy of patients and the interval dosing has led to concerning breakthrough haemolysis. Coversin is a protein suitable for small-volume subcutaneous (SC) injection which can be self-administered by patients.

Aims: The aim of this study is to investigate the safety and efficacy of the complement C5 inhibitor Coversin in the treatment of PNH.

Methods: A Phase 2 single arm open label trial of Coversin is currently ongoing under which patients, either newly diagnosed with PNH or who have not previously had access to complement inhibitors, are treated for 90 days. Coversin is supplied as a lyophilised powder, reconstituted with water for injection to give a buffered aqueous solution of Coversin 30mg/mL. The trial population consists of up to 10 adult patients with a diagnosis of PNH confirmed by flow cytometry. Treatment commences with an ablating regime (AR) consisting of a fixed dose of 60mg followed by 3 doses of 30mg q12 hours delivered by SC injection. After being suitably instructed patients are encouraged to self-inject the drug. Following the AR, a dose of 15mg q12 hours is given for a further 26 days when, if the patient’s disease is well controlled, they switch to 30mg q24 hours for the remainder of the trial. The dose can be increased by two incremental steps according to a pre-specified algorithm for patients not satisfactorily controlled on the basis of serum lactate dehydrogenase (LDH) or clinical grounds at any time during the 90-day period. The primary endpoints are safety and reduction of serum LDH to ≤1.8 X the upper limit of normal (ULN) for the local laboratory. Secondary endpoints include LDH at 28, 60 and 90 days, terminal complement activity assessed by CH50 ELISA (Quidel®), sheep erythrocyte haemolysis assay, PK (free and bound Coversin levels), anti-drug antibodies (ADA) and quality of life.

Results: The trial is still ongoing and has currently enrolled 5 patients, four of whom remain on Coversin. Three patients have required single dose increases during the initial 28-day period, one of whom was later withdrawn when a co-morbidity was suspected. Two patients have moved to a single daily dose. Updated results of these and any patients enrolled subsequently will be presented. To date 2 patients have achieved the primary efficacy endpoint, two have not yet reached the 28-day point. There have been no serious or significant adverse events and the drug has been well-tolerated. A few mild injection site reactions have been recorded but these appear to diminish with time. There has been no evidence of the formation of neutralising antibodies.

Summary/Conclusions: It currently appears that treatment with Coversin is safe and effective in controlling hemolysis in PNH and that patients are capable of self-administering the drug. Coversin may be an effective alternative for patients with PNH who prefer the independence of self-administration. The relatively short dose interval may also help to reduce breakthrough events due to trough levels of drugs administered at two weekly intervals or longer.

Background: CLL is a highly heritable cancer. Although GWAS have identified ~30 independent SNPs associated with CLL, these are estimated to account for only 6–12% of the inherited component of CLL.

Aims: We hypothesized that this missing heritability might arise from rare coding variants (MAF <0.01), and sought to identify these through an exome-wide association study comparing rare germline variants between CLL patients and controls.

Methods: We investigated 516 CLL patients of European descent who were compared to 8,920 ethnically matched, non-cancer population controls. CLL cohorts included 235 CLL patients from DFCI (128 previously reported, 107 unpublished exomes), and 281 CLL patients enrolled on the CLL8 trial of the German CLL Study Group (WES data reported previously). An additional 130 CLL patient samples in an expansion cohort included 24 from our published whole-genome sequencing study and 106 from an early publication of the ICGC. Non-cancer controls came from 3 sources: 2,520 from the 1000 Genomes Project; 6,852 from the Exome Sequencing Project; and 7,611 from a study of genetic controls available for the association analysis. We further controlled for residual population stratification by correcting for three principal components.

Results: We searched for patients with ≥5 out of 6 GWAS-identified SNPs that we have investigated so far. In 8,920 controls available for the association analysis. We further controlled for residual population stratification by correcting for three principal components.

Summary/Conclusions: We conclude that PRO-seq and dREG analysis identifies evidence of active differential transcription based on genotype in the region of 5 out of 6 GWAS-identified SNPs that we have investigated so far.

DIFFERENTIAL ENHANCER TRANSCRIPTION ASSOCIATED WITH RISK ALLELE GENOTYPE IN CLL
B. Tesar1,2, L. Werner3, N. Pochev4,5, S. Fernandes 1, M. R. Improgo 1,2, J. Kiltgaard1,2, C. Thompson 1, M. Hanna4, A. Friedman1, D. Neuberg3, M. Freedman1, L. Core6, J. Brown1,2,3
1Department of Medical Oncology, Dana Farber Cancer Institute, 2Department of Medicine, Harvard Medical School, 3Department of Biostatistics and Computational Biology, Dana Farber Cancer Institute, Boston, 4Broad Institute, Cambridge, 5Department of Neurology, Harvard Medical School, Boston, 6Department of Molecular and Cell Biology, University of Connecticut, Storrs, United States

Background: Genome-wide association studies (GWAS) have identified multiple loci that are statistically associated with CLL susceptibility. These single nucleotide polymorphisms (SNPs) are primarily located in non-protein coding genomic regions. Data suggest that these variants are enriched in regulatory elements that influence nearby target genes.

Methods: To investigate SNP allele-specific impacts on gene expression, we selected 15 SNPs from 13 loci that achieved genome wide significance in initial CLL GWAS studies. We investigated either the published GWAS SNP (if present on the Affymetrix 6.0 SNP array) or proxy SNP(s) chosen using the SNP Annotation and Proxy Search (SNAP) software, based on their high linkage disequilibrium (LD) (r^2>0.68) with the selected GWAS SNP. Genotypes were determined in tumor (n=143) and saliva (n=79) DNA from CLL patients (who had provided written informed consent); tumor and saliva DNAs were concordant in at least 96% of cases (except rs477184 at 92%). Given the high concordance with saliva, which is likely related to the stable genome of CLL, SNP genotypes from tumor samples were used for the analysis in order to significantly increase our sample size. Allele-specific gene expression was then evaluated in the tumor samples using Affymetrix U133 Plus 2.0 array and quantitative (PRO-seq) and qualitative (dREG) mapping of transcriptionally-engaged RNA polymers. The algorithm, discriminative regulatory-element detection from GRO/PRO-seq (dREG), is then used to predict the presence of TREs from raw PRO-seq data, allowing for identification of functional elements in the vicinity of SNPs and quantification of their allele-specific effect on enhancer activity and gene transcription.

Results: Our gene expression analysis demonstrated 6 significant SNP-gene associations: rs674313 (6p21.3) with HLA-DOAQ1 (p<0.0001), rs872071 (6p23.5) with IRF4 (p=0.01), rs477184 (15q23; proxy for rs7176508) with TP53 (p=0.03), rs783540 (15q25.2) with CPEB1 (p=0.01), rs305088 (16q24.1; proxy for rs305089) with C14ANBEMC8 (p=0.03), and rs402522 (18q13.32; proxy for rs11083846) with FKRP (p<0.0001). Two associations were successfully validated in a completely independent gene expression replication analysis (n=54; rs674313 with HLA-DOAQ1 (p<0.0001) and rs477184 with TP53 (p=0.0116). To annotate candidate regulatory elements, we evaluated transcription level at or near all six significant functional association elements that influence nearby target genes.

Summary/Conclusions: We present a comprehensive approach for the identification of allele-specific differential transcription in a cohort of 12 CLL samples. Transcription level at or near 3 SNPs (rs674313, rs477184, rs305088) correlated with genotype in a dose dependent manner. When we expanded the analysis to the entire region of LD around each SNP, we were able to demonstrate a dose-dependent effect in all SNPs in EIRF4.

BIALLELIC TP53 GENE MUTATIONS DUE TO COPY-NEUTRAL LOSS OF HETEROZYGOSITY AND MONOALLELIC MUTATIONS IN ABSENCE OF 17P DELETION OCCUR IN CLL WITH COMPARABLE FREQUENCY
K. Plevova1,2, J. Malickova1,2, S. Pavlova1,2, J. Kotasova1,2, L. Poppova1,2, J. Smrnarova2, E. Diviskova2, K. Durechova2, A. Oltova2, T. Bischtyova2, A. Panovska2, M. Doubek1,2, S. Pospisilova1,2
1Central European Institute of Technology, Masaryk University, 2Department of Internal Medicine - Hematology and Oncology, 3Department of Pathology, University Hospital Brno, Brno, Czech Republic

Background: TP53 gene defects represent an adverse prognostic marker in chronic lymphocytic leukemia (CLL). In the majority of affected cases, TP53 is inactivated on both alleles due to the concurrent mutation and 17p deletion (del(17p)). However, in about one third of cases, only TP53 mutation (TP53mut) without deletion is detected. It was reported that in some of these patients, copy-neutral loss of heterozygosity (CN-LOH), also leading to biallelic TP53 defect, might be present; however the frequency of such event has not been thoroughly investigated.

Aims: We aimed to perform a detailed analysis of the second TP53 allele in cases with a TP53 mutation in the absence of del(17p), and to assess genomic instability in these patients.

Methods: We searched for patients with TP53mut in absence of del(17p) within the cohort of 200 CLL patients positive for TP53mut as determined using FASAY (Functional Analysis of Separated Alleles in Yeast) coupled to direct sequencing;
17p13 deletions were assessed by FISH (MetaSystems). More than a half of the cohort (57%) was also tested using ultra-deep NGS for TP53 exons 2–11. Genome-wide analysis was performed on CytoScanHD arrays (Affymetrix) and correlated to conventional cytogenetics (CpG/IL-2 stimulation).

Results: Out of the cohort positive for TP53mut, 72/200 patients (36%) harbored single dominant TP53mut without del(17p). We selected 43 of these cases with varied copy number abnormalities (CNA) and investigated whether and how copy number loss of 17p correlated to conventional cytogenetics or to the presence of 17p cn-LOH. In 42% (18/43) of the cases, cn-LOH in 17p was detected in a proportion of CLL clone correspondingly to the TP53 VAF (median TP53 VAF 59.4%, range 12.9–99.9%). In 3/43 cases, heterozygous deletion previously undetected by FISH was newly revealed. Thus, the truly monoallelic mutations were confirmed, and CNLOH were exploited to explain potential presence of 17p cn-LOH. In 42% (18/43) of the cases, cn-LOH in 17p was detected in a proportion of CLL clone correspondingly to the TP53 VAF (median TP53 VAF 43.5%, range 10.5–51.3%). Applying a VAF cut-off of 55% indicating fully expanded heterozygous mutation (taking into account the potential unequal representation of forward and reverse strands in NGS data), 7/29 (24%) cases below the cut-off still harbored 17p cn-LOH. These results show that it is not possible to use an arbitrary VAF cut-off (>50%) to identify biallelic mutations due to cn-LOH. When we compared genomic complexity of leukemic clones with monoallelic vs biallelic TP53mut as determined by the CytoScan array, the latter group exhibited significantly more genomic abnormalities (p<0.0388) and also preference for different recurrent chromosomal abnormalities (p<0.0001: 17p locus excluded from this analysis). However, there was no significant difference in overall survival between the groups (p=0.5856).

Summary/Conclusions: cn-LOH in 17p locus is present in approximately half of the patients with single dominant TP53mut and results in biallelic TP53 gene inactivation despite the absence of del(17p). Truly monoallelic TP53 mut gene mutations with an intact second allele occur in CLL with comparable frequency. Although 17p cn-LOH is associated with increased genomic instability, it does not have worse impact on clinical outcome than truly monoallelic TP53mut.

Supported by the projects AZV-MCZ 15-31834A, 15-30015A, 15-29733A, the EU Horizon2020 project No. 692926, and MEYS CEITEC2020 LQ1601.

P239

INTERTEGRATED Oligo/SNP ARRAY AND NEXT GENERATION SEQUENCING BASED ANALYSIS IS REQUIRED TO DETERMINE TP53/17P STATUS IN CLL PATIENTS

M. Stevens-Kroef1,*, A. Eijkelenboom1, L. Kroeze1, D. Olde Weghuis1, P. Groenen1
1Radboud university medical center, Nijmegen, Netherlands

Background: B-cell chronic lymphocytic leukemia (CLL) exhibits a highly heterogeneous clinical course, with overall survival rates varying from several months to decades. Mutation status of the IGHV genes and specific genomic abnormalities, such as deletion of 11q22 and loss of the 13q14 region provide a prognostic significance. However, more importantly deletion of 17p and/or the presence of a TP53 mutation, which are both associated with a poor prognosis identify a subgroup of B-CLL patients with the highest risk of disease progression. Recently clinical trials with tyrosine kinase inhibitors such as ibrutinib and idelalisib have demonstrated good responses in CLL patients with 17p deletion and/or del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal FISH abnormalities detected by FISH at progression: sub-clonal biallelic del(13q) pre-treatment in those with del(17p) was 72%; only 1 pt had <50% del(17p) pre-treatment. All these pts had persistence of del(17p), at progression, without significant changes in allelic frequency. Two pts with del(17p) pre-treatment had additional abnormalities detected by FISH at progression: sub-clonal biallelic del(13q) was detected in 12 of the 13 pts who progressed, all of whom also had developed trisomy 12. In the absence of disease progression, the only CCE detected was emergence of small sub-clones with biallelic del(13q) in 2 patients who initially had monoallelic del(13q). Notably, in responding pts, there was no expansion of high-risk sub-clones. Conventional karyotyping was performed in 10/37 patients who progressed both pre-treatment and at progression. In 4 pts, CCE was identified at progression, including 17 new abnormalities in one pt. All 4 pts had complex karyotype and del(17p) by FISH pre-treatment and 3 of 4 had evidence of multiple, related, complex sub-clones pre-treatment. Figure 1 shows inferred clonal evolution pattern for one pt.

Figure 1.
**Summary/Conclusions:** Emergence of high-risk clones containing del(17p) and or del(11q) may be seen at disease progression in ibrutinib-treated patients. Analogous to allelic expansion of TP53 mutations after chemotherapy, we hypothesize that small del(17p) or del(11q) subclones were present prior to therapy in these pts, below the sensitivity of existing FISH techniques and expanded under the selective pressure of ibrutinib treatment. Development of a more sensitive technique to identify small sub-clones with del(17p) or del(11q) may therefore be important. Additionally, complex CCE occurred at progression in several cases, indicating genomic instability and potentially contributing to therapeutic failure.

**P241 LANDSCAPE OF SOMATIC MUTATIONS AND THEIR IMPACT ON RESPONSE AND OUTCOMES FROM LENALIDOMIDE-BASED THERAPIES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA**

B. Hu1,*, F. Wang2, Y. Yuanqing3, E. Kim4, K. Patel5, P. Strati1, C. Gumbs2, L. Little2, S. Tippen2, X. Song1, J. Zhang2, N. Jain4, P. Thompson5, K.-A. Do3, M. Keating2, J. Burger1, A. Ferrajoli1, W. Wierda2, A. Futreal1, K. Takahashi1, 2Cancer Medicine, 2Genomic Medicine, 3Biostatistics, 4Leukemia, 5Hematopathology, MD Anderson Cancer Center, Houston, Texas, United States

**Background:** Lenalidomide, either as a single agent or in combination with anti-CD20 monoclonal antibody, is clinically active in CLL and offers durable response in some pts. Predictive and prognostic impact of somatic mutations are not well known in pts with CLL who have received lenalidomide-based therapies.

**Aims:** Investigate the overall landscape of CLL gene mutations in both previously untreated and relapsed/refractory (R/R) pts. Determine associations between CLL gene mutations and clinical characteristics. Establish predictive and prognostic impact of CLL gene mutations in the context of lenalidomide-based therapies.

**Methods:** In the 288 pts with CLL who were treated in one of the lenalidomide-based clinical trials at our institution, we performed targeted gene capture therapies. In the untreated cohort, del(17p) was associated with worse OR in R/R group. In the untreated group, del(17p) and TP53 were associated with worse progression-free (PFS) (p=0.002 and 0.003, respectively). In R/R cohort, complex karyotype, del(17p) and mutations in SF3B1 and TP53 were associated in a more sensitive technique to identify small sub-clones with del(17p) (p<0.01). complex karyotype (p=0.035) and del(17p) (p=0.031) were associated with worse OR in R/R group. In the untreated group, del(17p) and TP53 were associated with worse progression-free (PFS) (p=0.002 and 0.003, respectively).

**Summary/Conclusions:** Tumor mutational heterogeneity in CLL is due to intrinsic tumor biology and selective drivers from previous treatments, which can then affect response and survival in lenalidomide-based therapies.

**P242 HIGH THROUGHPUT IMMUNOPROFILING OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS ASSIGNED TO STEREOTYPED SUBSET #4: NOVEL INSIGHTS INTO THE DEPTH, DIVERSITY AND TEMPORAL DYNAMICS OF CLONAL EVOLUTION**

K. Gemenetzit1, E. Stalika1, A. Vardi1, F. E. Psomopoulos1, E. Minga1, A. Anagnostopoulos2, K. Stamatopoulos1,3, A. Hadzidimitriou1, L. A. Sutton3,4,*, A. Hassidimotroiu1, L. A. Sutton4,5,*

1Institute of Applied Biosciences, CERTH, 2Hematology Department and HCT Lab, General Hospital of Thessaloniki, Greece, 3Department of Immunology, 4Department of Immunology, Genetics & Pathology, Upssala University, Upppsala, 5Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

**Background:** Chronic lymphocytic leukemia (CLL) clones assigned to stereotyped subset #4 are characterized clinically by a young age at diagnosis, an indolent disease course, and molecularly by B-cell receptor immunoglobulins (BcR IGs) that exhibit distinctive immunogenetic features. More specifically, they are IgG-switched, composed of heavy and light chains encoded by the IGHV4-34 and IGKV2-30 genes, respectively, and their heavy chain complementarity determining region 3 (VH CDR3s) is long and enriched in positively charged residues, reminiscent of pathogenic anti-DNA antibodies. In addition, both the VH and VK domains of subset #4 demonstrate a high impact of somatic hypermutation (SHM), highly indicative of an (auto)antigen selection.

**Aims:** To obtain comprehensive insights into the antigen and evolution of CLL subset #4 are characterized clinically by a young age at diagnosis, an indolent disease course, and molecularly by B-cell receptor immunoglobulins (BcR IGs) that exhibit distinctive immunogenetic features. More specifically, they are IgG-switched, composed of heavy and light chains encoded by the IGHV4-34 and IGKV2-30 genes, respectively, and their heavy chain complementarity determining region 3 (VH CDR3s) is long and enriched in positively charged residues, reminiscent of pathogenic anti-DNA antibodies. In addition, both the VH and VK domains of subset #4 demonstrate a high impact of somatic hypermutation (SHM), highly indicative of an (auto)antigen selection.

**Methods:** Peripheral blood samples were collected at multiple time-points over a 10-year period from 6 CLL subset #4 patients. The clonotypic BHV-IGHV-IGHD-IGHJ-IGK-D-IGK-V and IGKV-IGKJ rearrangements were amplified by PCR, using cDNA and sequenced on the MiSeq (Illumina). Our experimental design involved paired-end sequencing, thus allowing sequencing of the CDR3 twice/read, so as to increase the accuracy of results. To maintain stringency, raw NGS reads were subjected to purpose-built, bioinformatics algorithms, which filtered sequences: (i) length and quality filtering of raw quality filtered reads and quality filtering of filtered-in paired reads via local alignment; and, (ii) length and quality filtering of stitched sequences. No base calls of Q-score<30 were allowed in the 75 nucleotide stretch preceding the GXX motif, further increasing CDR3 sequencing reliability. Data was then analyzed using the IMGT/High-V-QUEST database and clonotype computation was performed using an in-house bioinformatics pipeline.

**Results:** Overall, 48 samples were analyzed, producing 12,386,554 and 4,506,464 total reads for heavy and light chain, respectively. In addition to filtering out poor quality, incomplete, out-of-frame and unproductive rearrangement products, the clonotypic repertoire was restricted to subclones with the following characteristics: usage of subset #4-specific V- and J-genes, CDR3 length and landmark residues. Applying these strict criteria resulted in 84.1% (median 401,133 reads/sample) of the total filtered-in paired reads via local alignment; and, length and quality filtering of stitched sequences. No base calls of Q-score<30 were allowed in the 75 nucleotide stretch preceding the GXX motif, further increasing CDR3 sequencing reliability. Data was then analyzed using the IMGT/High-V-QUEST database and clonotype computation was performed using an in-house bioinformatics pipeline.

**Summary/Conclusions:** Detailed molecular immunoprofiling of the clonotypic BcR IG genes, particularly focusing on analyzing intraclonal diversification (ID) within the IG gene sequences.

**Methods:** Peripheral blood samples were collected at multiple time-points over a 10-year period from 6 CLL subset #4 patient with a median of 401,133 reads/sample) and 90.3% (median 141,549.5 reads/sample) of the total filtered-in paired reads via local alignment; and, length and quality filtering of stitched sequences. No base calls of Q-score<30 were allowed in the 75 nucleotide stretch preceding the GXX motif, further increasing CDR3 sequencing reliability. Data was then analyzed using the IMGT/High-V-QUEST database and clonotype computation was performed using an in-house bioinformatics pipeline.

**Results:** Overall, 48 samples were analyzed, producing 12,386,554 and 4,506,464 total reads for heavy and light chain, respectively. **Summary/Conclusions:** Detailed molecular immunoprofiling of the clonotypic BcR IG genes, particularly focusing on analyzing intraclonal diversification (ID) within the IG gene sequences.
failed DNA hypomethylation. Mechanistically involved in insufficient hydroxymethylation and consequently indicate that alterations of an interaction between the EBF1 and TET2 are

Background: During normal hematopoiesis, a coordinated epigenetic and transcriptional programming is necessary to achieve lineage development. B cell differentiation is predominantly related to loss of DNA methylation at the enhancers and promoters of B cell-specific genes; cell differentiation is predominantly related to loss of DNA methylation at the transcriptional programming is necessary to achieve lineage development. B

Here, we investigated the role of TET2-mediated DNA demethylation through differential 5hmC accumulation in healthy and in CLL B cells. We further studied mechanisms and TFs involved in regulation of 5hmC conversion during CLL pathogenesis.

Aims: By applying high-resolution 450K methylation arrays, we studied the clinically aggressive subsets #1 (Clan I genes/IGHV(D)1-39, IGHV unmuted, n=37) and #2 (IGHV3-21/IGLV3-21, mixed IGHV mutation status, n=35) and the indolent subset #4 (IGHV4-34/IGKV(D)1-39, IGHV mutated, n=28). In addition, a series of sorted normal subpopulations spanning different stages of B-cell differentiation (e.g. naive, centricytes, centroblasts, memory) were analyzed.

Results: Unsupervised principal component analysis demonstrated that the investigated subsets formed distinct subgroups and these findings were corroborated by hierarchical clustering analysis. We next explored if and how these subsets match to the recently proposed epigenetic classification of CLL, where subsets #1 and #2 correspond to IGHV unmutated and mutated CLL, respectively; and iii) a third intermediate CLL subgroup (i-CLL), which have borderline mutated IGHV genes and an intermediate outcome. For this purpose, we utilized the same Classification Platform for Myeloid Neoplasms (CPMLN) and compared our findings to the recently proposed epigenetic classification of CLL.

Methods: By dot blot, we found decreased 5hmC levels in CLL as compared to healthy donors. We further performed genomewide 5hmC profiling by hMeDIP. We confirmed a significantly lower number of hydroxymethylated peaks in CLL subset #2 cases frequently carry del(11q) and harbor SF3B1 mutations associated with these two subsets.

Results: By dot blot, we found decreased 5hmC levels in CLL as compared to CD19+ B lymphocytes. 5hmC was further reduced in IGHV unmuted compared to IGHV mutated CLL cases. To identify distinct regions with gain or loss of 5hmC, we performed genome-wide 5hmC profiling by hMeDIP. We confirmed a significantly lower number of hydroxymethylated peaks in CLL (137114) compared to HBC (249421) which remained stable when separating to good (67K, p<0.05) and in subset #2 aggressive disease seen in these two subsets compared to the broader category of n-CLL patients. Focusing on subset #2, we observed that almost all cases clustered separately from i-CLL, which have borderline mutated IGHV genes and an intermediate outcome. For this purpose, we utilized the same Classification Platform for Myeloid Neoplasms (CPMLN) and compared our findings to the recently proposed epigenetic classification of CLL.

Methods: Clonal B cell specimens from 122 CLL patients were subjected to DNA methylation profiling using Illumina 450k arrays. 17 C and 4 healthy B cell samples (CD19+) were used for DNA methylation profiling using Illumina Epic arrays and for hydroxymethylated DNA immunoprecipitation (hMeDIP) using a monoclonal 5hmC mouse antibody and the NEBNext Ultra DNA Library Prep Kit for analysis on an Illumina HiSeq 2000 sequencer. Global 5hmC levels were quantified by dot blots. TET2, and EBFI mRNA and protein expression was evaluated by qPCR and Western Blot, respectively.

Results: By dot blot, we found decreased 5hmC levels in CLL as compared to CD19+ B lymphocytes. 5hmC was further reduced in IGHV unmuted compared to IGHV mutated CLL patients. To identify distinct regions with gain or loss of 5hmC, we performed genomewide 5hmC profiling by hMeDIP. Background: A major aim of CLL treatment is to eradicate detectable minimal residual disease (MRD). Ibrutinib is an effective treatment for CLL that results in immediate lymphocytosis persisting in most patients for several months. Obinutuzumab, a second-generation anti-CD20 monoclonal antibody which can effect rapid resolution of lymphocytosis and eradication of MRD in some CLL patients. The IcICLLe Extension Study expands on the IcICLLe trial (ISRCTN12695354) to examine the efficacy and safety of the combination treatment of obinutuzumab and ibrutinib.

Aims: The IcICLLe trial was a single-arm, multicentre feasibility study that recruited 40 patients with CLL requiring treatment to receive continuous ibrutinib therapy from day 0 and 6 cycles of obinutuzumab from day 1. 30 participants have no prior ibrutinib treatment (ibrutinib-naive), and 10 are pre-treated with ≥2 months of ibrutinib on IcICLLe. The primary outcome for the IcICLLe Extension Study is the proportion of patients achieving MRD-negative remission (<0.01% residual disease) or disease progression. The IcICLLe Extension Study expands on the IcICLLe trial (ISRCTN12695354) to examine the efficacy and safety of the combination treatment of obinutuzumab and ibrutinib.

Methods: Clinical Events are collected from registration until 30 days after end of treatment and reported using the Common Terminology Criteria for Adverse Events v4.0. MRD was assessed by multiparameter flow cytometry according to ERIC 2016 guidelines with a detection limit ≤0.004%.

Results: 31 participants (22 ibrutinib-naive and 9 pre-treated) are evaluable for response assessment after 1 month of combination treatment. There have been no reports of tumour lysis syndrome within the first month of combination treatment. There were 2 separate reports of grade 2 infusion related reactions, both on day 1 of obinutuzumab. In the 22 ibrutinib-naive cases peripheral blood (PB) CLL counts remained at or below baseline levels in 17/22 cases from week 1 onwards. After 1 month of combination therapy the PB CLL count was a median 31% of baseline levels (range <1%>174%) compared to median 215% (range 29%>3570%) for RR patients on ibrutinib monotherapy. Percentage CLL cells in the bone marrow (BM) aspirate after 1 month of combination therapy reduced from a median 83% (range 23-94%) to a median 47% (range 8-85%; P=0.003). For PB, Wilcoxon matched-pairs signed ranks. For RR patients on ibrutinib monotherapy there was no change in BM at 1 month; baseline median 85% (range 11-96%) compared to median 86% (range 50-98%, P=0.96). Changes in BM aspirate CLL percentage were confirmed by morphological assessment of a trephine biopsy with all evaluable patients receiving obinutuzumab showing improvements in the cellularity and/or extent of infiltration. BM assessment at 1 month was not mandated for the 9 pre-treated patients but all showed decreased PB CLL counts with 4/9 achieving <0.01% residual disease within 3 months of starting obinutuzumab. 13 patients have completed 6 months of obinutuzumab treatment with marrow assessment at 9 months showing a further ≥1 log depletion in CLL percentage in 9/13 patients with 4/6 pre-treated patients achieving <0.01% residual disease.

Summary/Conclusions: The data indicate that for RR patients, the addition of obinutuzumab to ibrutinib results in a substantial improvement over ibrutinib monotherapy in the depletion of CLL cells from peripheral blood and bone marrow after 1 month of combination therapy, and continued improvement after 6 months combination therapy, with MRD-negative BM responses for patients who have had >1yr prior ibrutinib monotherapy. Residual disease levels in the BM after the 6 months of combination treatment will be available for 25 participants by June-2017.
P247
DURABILITY OF RESPONSES ON CONTINUOUS THERAPY AND FOLLOWING DRUG CESSATION IN DEEP RESPONDERS WITH VENEToclAX AND RITUXIMAB
M.A. Anderson1,*, D.M. Brander2, S. Ma3, J.F. Seymour4, M.Y. Choi5, T.J. Kipps6, L. Zhou6, K. Balbarin6, B. Prine6, M. Verdugo6, S.Y. Kim6, L.L. Lash6, A.W. Roberts1
1Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, Cancer and Hematology Division, Melbourne, Australia, 2Duke University Medical Center, Durham, 3Northwestern University, Chicago, United States, 4Peter MacCallum Cancer Centre, Melbourne, Australia, 5University of California San Diego, San Diego, 6AbbVie, Inc., North Chicago, United States

Background: Venetoclax is a potent BCL-2 inhibitor that is approved as monotherapy for certain patients with relapsed or refractory chronic lymphocytic leukemia (CLL) in the United States, the European Union, and other countries. Aims: Venetoclax combined with rituximab is being assessed in an ongoing Phase 1b study.

Methods: Minimal residual disease (MRD) was assessed in bone marrow using 24-color flow cytometry (minimum sensitivity: 0.01%). Patients who achieved complete remission (CR) or MRD-negativity could stop venetoclax and remain on study. Patients who manifested progressive disease while off therapy could re-initiate venetoclax and rituximab.

Results: Forty-nine patients, with a median of 2 (range: 1–5) prior regimens, were enrolled. As of July 2016, the overall response rate was 86%, the CR rate was 51%, and the bone marrow MRD-negativity rate was 57% (28/49) [Seymour et al / Lancet Oncol 2017]. The 24-month estimate for progression-free survival was 78.8% and that for duration of response was 87.8% (100% for patients with MRD-negative CR). Of the 28 patients attaining MRD-negativity, 22 achieved this status at 7 months, which was the first mandatory time point for assessment. The remaining six patients achieved MRD-negativity at the second assessment, which ranged from 12 to 22 months, since the timing of this test was not mandated.

Twelve (41%) patients discontinued the study. Eleven had progressive disease while on therapy: five with Richter’s transformation between 1–9 months and six with CLL progression after a median of 26.4 months (range: 12–37). The other nine patients: withdrew consent (n=3), failed to report for follow-up evaluations (n=1), discontinued due to adverse events related to venetoclax (n=2; tumor lysis syndrome and worsening of peripheral neuropathy), or discontinued due to adverse events considered not related to therapy (n=3). Seventeen patients remained on therapy: 8 MRD-negative CR, 2 MRD-positive CR, 5 MRD-negative PR, and 2 MRD-positive PR. Median duration of response on therapy is 27.9 months (range: 20.3–40.2). Sixteen patients discontinued venetoclax and remained on study as allowed per protocol following the achievement of a deep response (12 MRD-negative CR, 2 MRD-negative PR, 2 MRD-positive CR) (Figure 1). Their median time on venetoclax is 16.3 months (range: 5–38). Twelve of these patients remain in active follow-up and four discontinued without evidence of progression after achieving MRD-negative CR. Two patients with MRD-positive CR had increasing absolute lymphocyte count (ALC) and asymptomatic progression 24 months after stopping venetoclax. Both re-started venetoclax 2 and 6 months after ALC >5x10^9/L, and achieved partial remissions. The 10 patients with MRD-negativity in the bone marrow who remain in follow-up have a median duration of ongoing response off venetoclax of 13 months (range: 3–34).

Summary/Conclusions: Venetoclax with rituximab induces deep and durable responses, with 51% patients achieving CR and 57% achieving marrow MRD-negativity. Patients on continued therapy have durable responses. Additionally, responses are sustained at a median of 13 months among patients who achieve bone marrow MRD-negativity and elected per protocol to stop therapy, demonstrating that it is possible to discontinue venetoclax and maintain prolonged treatment-free remission. The 2 patients who progressed at 2 years off therapy responded to the reintroduction of venetoclax.

PREDICTIVE AND PROGNOSTIC IMPACT OF GENE MUTATIONS IN THE CONTEXT OF FLUDARABINE AND CYCLOPHOSPHAMIDE WITH OR WITHOUT OFATUMUMAB TREATMENT IN PATIENTS WITH REL/REF CLL
M.A. Anderson1,*, D.M. Brander2, S. Ma3, J.F. Seymour4, M.Y. Choi5, T. Robak3, S. Grosicki4, C. Pallaud5, D. Mertens1,6, L. Bullinger1, H. Doehner1, S. Stilgenbauer1

Background: Recurrent mutations in genes such as TP53, SF3B1 and NOTCH1 are frequent in CLL and have in previous studies been associated with outcome. SF3B1mut, TP53mut, BIRC3mut and XPO1mut were adverse prognostic factors in patient cohorts with different therapies, and NOTCH1mut associated with poor outcome when rituximab was added to standard chemotherapy. TP53mut, SF3B1mut and not NOTCH1mut as a predictive factor in the context of chemomunotherapy.

Aims: We assessed the incidence and clinical associations of mutations in TP53, SF3B1, NOTCH1, ATM, BIRC3, FBXW7, MYD88, EGR2 and XPO1 in the COMPLEMENT-2 trial (relapsed/refractory CLL, FC vs FC+ofatumumab 1–6 cycles). (Robak et al., Leuk Lymphoma, 2017)

Methods: Baseline samples were available from 325 of 365 patients (89%) representative of the full analysis set of the clinical trial. Mutation analyses were performed via custom targeted Next Generation Sequencing (NGS) for TP53, ATM, BIRC3, FBXW7, MYD88, EGR2 and XPO1 in the COMPLEMENT-2 trial (relapsed/refractory CLL, FC vs FC+ofatumumab 1–6 cycles). (Robak et al., Leuk Lymphoma, 2017)

Results: In total we identified 365 mutations across the 9 genes in 202 of 325 patients (62.2%), with incidences of SF3B1mut 19.7%, TP53mut 18.8%, NOTCH1mut 16.3%, ATMmut 13.8%, XPO1mut 11.4%, BIRC3mut 4%, EGR2mut 3.1%, FBXW7mut 2.7% and MYD88mut 0.9%. We identified a variety of associations of mutational subgroups with genetic, clinical and laboratory parameters, such as TP53mut with del17p (p=0.01), NOTCH1mut, FBXW7mut and BIRC3mut with +1q2 (p=0.01, p=0.01 and p=0.05) and ATMmut with del11q (p=0.01), XPO1mut and ATMmut associated with unmutated IGHV. CD79B expression on cell surface measured via flow cytometry was lower in ATMmut patients, whereas CD20 expression did not differ among the different mutational subgroups. TP53mut, EGR2mut and SF3B1mut patients had worse overall response to therapy (88% p=0.01, 50% p=0.02 and 72% p=0.05 respectively, vs 81% overall). Similar to the full analysis set, FCO as compared to FC resulted in significant improved PFS (median 28.1 vs 18.8 months, HR=0.67, p<0.01). TP53mut and XPO1mut were adverse prognostic factors for PFS (HR 1.93 p<0.01 and HR 1.85, p<0.01 respectively), but only TP53mut for decreased OS (HR 2.11 p<0.01). All other mutations, in particular SF3B1mut and NOTCH1mut, did not significantly impact PFS or OS. To identify factors of independent clinical
impact, we performed multivariable Cox regressions for PFS and OS including treatment, IGHV status and all cytogenetic and mutational subgroups. For PFS, the following independent prognostic factors were identified: FCO therapy (HR 0.64 p<0.01), del17p (HR 5.08 p<0.01), unmutated IGHV (HR 2.0 p<0.01), TP53mut (HR 1.75 p<0.01) and XPO1mut(1.86 p<0.01). Del17p (HR 4.79 p<0.01), unmutated IGHV (HR 1.69 p=0.04) and TP53mut (HR 1.76 p=0.03) were identified as independent prognostic factors for OS. With focus on the predictive value of gene mutations, we found a beneficial effect of the addition of ofatumumab to chemotherapy irrespective of TP53 mutation (HR 0.52 p=0.02 for TP53mut and HR 0.68, p=0.02 for TP53), Regarding NOTCH1, ofatumumab alone was beneficial in NOTCH1mut but not in NOTCH1wt patients (HR 0.64, p<0.01 and HR 0.86, p=0.07) (Figure 1).

Summary/Conclusions: In the COMPLEMENT-2 trial evaluating FCO against FC in relapsed/refractory CLL patients, we found TP53mut and XPO1mut but not SF3B1mut or NOTCH1mut as independent prognostic factors for PFS. Notably, a benefit of ofatumumab as add-on to FC chemotherapy was obtained among NOTCH1mut but not among NOTCH1wt patients indicating NOTCH1 mutation status as a predictive marker in the context of type-1 CD20 antibody addition to chemotherapy.

RESULTS OF A PHASE II MULTICENTER STUDY OF OBINUTUZUMAB PLUS BENDAMUSTINE IN PTS WITH PREVIOUSLY UNTREATED CHRONIC LYMPHOCYTIC LEUKEMIA

A. Danilov1,*, H. Yimer2, M. Boxer3, N. Di Bella4, S. Babu5, J. Li6, Y. Mun6, S. Sketino6, J. Sharraman3

1Oregon Health and Science University, Portland, 2Texas Oncology, Tyler, 3Aronzon Oncology, Tucson, 4Rocky Mountain Cancer Centers, Aurora, 5Fort Wayne Medical Oncology, Fort Wayne, 6Genentech Inc., South San Francisco, 7Willamette Valley Cancer Institute and Research Center, Eugene, United States

Background: Bendamustine (B) plus rituximab (R; BR) is a commonly used first-line (1L) treatment for chronic lymphocytic leukemia (CLL). The CLL10 study reported an overall response rate (ORR) of 96% and complete response (CR) rate of 31% with BR. Obinutuzumab (GA101; G) is a glycoengineered, type II anti CD20 monoclonal antibody. A randomized Phase III trial in 1L pts showed that G significantly improved progression-free survival (PFS) and CR rate compared with R, when used in combination with chlorambucil (Goege 2014). B plus G (BG) was evaluated in a subgroup of CLL pts in the GREEN trial (Stilgenbauer 2015).

Aims: The aim of this Phase II study (NCT02320487) is to evaluate the efficacy and safety of BG as 1L treatment for CLL pts.

Methods: 102 pts with previously untreated CLL received BG, consisting of 6 cycles of G (cycle [C] 1: 100 mg day (D) 1, 900mg D2, 1000mg D8 and D15; C2– 6: 1000mg D1 and B) (80mg/m2, C1, D2 and C3–D, C2–D1 and D1 and D2). Each cycle was 28 days. The primary endpoint was CR assessed using iwCLL criteria. Secondary endpoints included ORR, PFS, overall survival, and minimal residual disease (MRD). Median follow-up at the time of analysis was 11.0 months.

Results: Median pt age was 61 yrs (range 35–90); 68.6% were male; 44.1% had Rai stage 3–4. For evaluated pts, IGHV status was 32.9% mutated and 67.1% unmutated. Incidence of trisomy 12, normal cytogenetics, and deletions of 13q, 11q, and 17p were 23.4%, 37.5%, 17.2%, 15.6%, and 6.3%, respectively. Investigator-assessed CR rate was 49.0% (95% CI 39.0–59.1) and ORR was 89.2% (95% CI 81.5–94.5) after 6 cycles. MRD negativity in blood, as measured by flow cytometry, was achieved in 42.7% of pts at the end of induction response assessment and in 75.5% of pts at any time following treatment. MRD negativity in bone marrow (BM) was 60.8% in pts with BM samples. The most common adverse events (all grades [Gr]) were infusion reactions (72.5%), nausea (58.2%), fatigue (36.3%), constipation (26.5%), and rash (26.5%). The most common Gr 3–4 adverse event was neutropenia (26.5%). Incidence of Gr 3–4 infections was 11.8%. Incidence of tumor lysis syndrome was 4.9% (all Gr 3). Three pts died; none were deemed related to study treatment or CLL by investigators.

Summary/Conclusions: BG is an effective regimen for 1L treatment of CLL pts inducing a high CR rate after 6 cycles of therapy. No unexpected safety signals were observed.

RELATIVE SURVIVAL REACHES A PLATEAU IN HAIRY CELL LEUKEMIA: A POPULATION-BASED STUDY ON INCIDENCE, PRIMARY TREATMENT AND SURVIVAL AMONG 1,427 PATIENTS DIAGNOSED IN THE NETHERLANDS, 1989-2014

A. Dinmohamed1,2,3,*, O. Visser4, W. Posthuma5, R. Raymakers5, J. Doorduijn3

1Research, Netherlands Comprehensive Cancer Organisation (IKNL), 2Public Health, Erasmus University Medical Center, Utrecht, 3Hematology, Erasmus Medical Center Institute, Rotterdam, 4Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, 5Internal Medicine, Reinier de Graaf Gasthuis, Delft, 6Hematology, Utrecht University Medical Center, Utrecht, Netherlands

Background: The introduction of cladribine and pentostatin has revolutionized the management of HCL as from the late 80s. As a result of that revolution, HCL patients (pts) are rarely included in clinical trials. Population-based studies can inform on issues related to outcomes of HCL pts managed in daily practice. At present, however, population-based studies that assess patterns of incidence, treatment and survival in HCL are very scarce.

Aims: The aim of this comprehensive nationwide population-based study was to assess trends in incidence, primary treatment and survival among HCL pts diagnosed in the Netherlands.

Methods: We selected all adult (≥18 years) pts diagnosed with classic HCL in the Netherlands between 1989-2014 from the registration of Netherlands Cancer Registry with survival follow-up through February, 2016. Age-standardized incidence rates (ASR) were calculated per 1,000,000 person-years and standardized according to the European standard population. Data on primary treatment (i.e. no therapy, chemotherapy [CT] and immunotherapy [IT]) were available for individual pts. Pts were categorized in 2 periods (1989-2000 and 2001-2014) and 3 age groups (18-59, 60-69 and ≥70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.

Results: We included a total of 1,427 newly diagnosed HCL pts in the study (median age, 59 yrs; age range, 22-95 years; 77% males). The annual ASR of HCL remained quite stable over time and was 3.1 and 3.3 in the first and last period, respectively. Men had a higher overall incidence than women (5.3 vs 1.3 in 2013-2014). The age-specific incidence rates for males were 5.5, 15.0 and 15.3 in 2001-2014 for the three age groups. The corresponding rates for females were 1.2, 3.1 and 5.5. The annual excess mortality over time for all age groups. The proportions of CT for the three age groups were 56, 51 and 34% in 1989-2000, as compared with 81, 73 and 53% in 2001-2014. The corresponding proportions for IT were 21, 13 and 17% in 1989-2000, as compared with 2, 1 and 4% in 2001-2014. Lastly, the corresponding proportions for pts who did not receive therapy were 23, 36 and 49% in 1989-2000, as compared with 17, 26 and 42% in 2001-2014. Overall, when corrected for age and sex, pts diagnosed in 2001-2014 had 49% lower excess mortality during the first 10 years after HCL diagnosis, as compared with pts diagnosed in 1989-2000 (P=.005). Ten-year RS (95% confidence intervals) was impressive for pts age 18-59, namely 92% (88% - 96%) and 98% (94% - 100%; P=.176) in the first and last period, respectively (Figure 1). Most of the significant improvement was observed in pts age ≥60. More specifically, 10-year RS for pts age 60-69 increased from 82% (71% - 92%) to 99% (89% - 100%; P=.009; Figure 1b), and for pts age ≥70 from 67% (49% - 86%) to 86% for 5% - 102%; P=.036; Figure 1c) between the first and last periods. In addition, older age (P<.001), but not sex (P=.058), was associated with higher excess mortality.

Figure 1. Summary/Conclusions: The incidence of HCL remained stable during a 26-year period in the Netherlands. RS for pts diagnosed in the period 2001-2014 eventually reached a plateau, indicating that by then their survival is comparable to that of the general population. Survival was already excellent for younger patients throughout the entire study period. Survival improvement was most pronounced for pts age ≥70. The application of CT was not statistically significant for pts age ≥70. This could be explained by the increased use CT over time. Population-based cancer registries are useful instruments to assess outcomes of pts rarely included in clinical trials.
CUMULATIVE ILLNESS RATING SCALE PROVIDES PROGNOSTIC INFORMATION BEYOND THE INTERNATIONAL PROGNOSTIC INDEX FOR CHRONIC LYMPHOCYTIC LEUKAEMIA: AN ACROSS-TRIAL ANALYSIS BY THE GCLLSG

V. Goede1,2, J. Bahlo1, S. Robrecht1, O. Al-Sawafi1, A.-M. Fenk1, C.-M. Wendtner1, S. Stilgenbauer1, K. Fischer1, B. Eichhorst1, M. Hallek1,5
1Dept. of Internal Medicine, University Hospital Cologne, 2Oncoergeniatics Unit, St. Marien Hospital, Cologne, 3Klinikum Munich-Schwabing, Munich, 4University Hospital Ulm, Ulm, 5Centre of Integrated Oncology (CIO) Cologne-Bonn, Cologne, Germany

Background: CLL-IPI is a prognostic tool to stratify patients with chronic lymphocytic leukemia (CLL) for low, intermediate, high, or very high risk. CLL-IPI uses age, Binet stage, beta-2-microglobulin, 17p deletion / TP53 mutation,IGHVmutational status, but not comorbidity as weighted factors to model prognosis. CIRS is a tool which allows assessing and quantifying burden of comorbidity in individual patients.

Aims: To validate CIRS in CLL and to assess whether CIRS is of further value when estimating prognosis by CLL-IPI in CLL.

Methods: This is a comprehensive evaluation of CIRS in 2518 patients pooled from the CLL8, CLL10, and CLL11 trials of the German CLL Study Group (GCLLSG). Median observation time was 55 months. All patients had CIRS data prospectively assessed prior to study treatment (689 FCR, 409 FC, 279 BR, 333 GCLB, 330 RCLB, 118 CLB).

Results: Median age was 64 years; 69% of patients were males, and 50% had ECOG performance score of 1 or higher. Complete information on age, Binet stage, beta-2-microglobulin, 17p deletion and/or TP53 mutation, IGHV mutational status was available in 1761 of the 2158 patients. Distribution of CLL-IPI risk groups was as follows: 275 (13%) low risk, 653 (31%) intermediate risk, 712 (40%) high risk, 121 (7%) very high risk. The median total CIRS score was 3 (range 0-22); 81% of the patients had a total CIRS score of at least 1 and 28% (40%) high risk, 121 (7%) very high risk. Total CIRS score was associated with higher risk of grade 3/4 adverse events as well as premature treatment discontinuation during or after treatment with FCR / FC / BR but not GCLB / RCLB / CLB.

Summary/Conclusions: Findings suggest that CIRS provides prognostic information beyond the CLL-IPI. Apart from adding a comorbidity assessment (e.g. by CIRS) in addition to the CLL-IPI therefore appears reasonable when estimating overall prognosis and deciding treatment in CLL.
FINAL RESULTS OF THE PHASE IB GALTON TRIAL IN CHRONIC LYMPHOCYTIC LEUKEMIA: DURABLE REMISSIONS WITH FRONTLINE OBSITUTUZUMAB (G) PLUS FLUDARABINE/ CYCLOPHOSPHAMIDE (G-FC) OR BENDAMUSTINE (G-B)

Hoffmann-La Roche Ltd, Basel, Switzerland, 8Genentech, Inc., South San Francisco, 9Muroes Cancer Center (CLL Research Consortium), University of California, San Diego, United States

Background: GALTON was an open-label, parallel-arm, non-randomized, multicenter, Phase Ib study (NCT01300247) investigating safety and preliminary efficacy of G-FC or G-B in previously untreated CLL.

Aims: We report final results for the planned 36-months’ (mo) follow-up (35/41 pts; median observation 40.4 [17.6–43.6] mo); initial results were reported previously (Brown et al. 2015).

Methods: Eligible pts met iwCLL 2008 criteria for therapy, were considered fit for chemotherapy through the investigator, and provided informed consent. Each center selected treatment (G-FC or G-B) for their pts. G was administered intravenously (IV; 100mg day [D] 1, 900mg D2, 1000mg D8 and 15 cycle [C] 1; 1000mg D1 C2–6) with FC (fludarabine 250mg/m2 IV and cyclophosphamide 250mg/m2 IV D2–4 C1, D1–3 C2–6 or B (90mg/m2 IV D2–3 C1, D1–2 C2–6). Each cycle was 28 days. The primary endpoint was safety and tolerability of G-chemotherapy.

Results: 21 pts were enrolled in the G-FC arm and 20 in the G-B arm. Median age was 60 (25–80) years, 78% of pts were male, and around one-third had Rai stage III/IV disease. Median time from diagnosis to therapy was 24 mo (G-FC median 16 mo; G-B median 32 mo). 37 pts (31/23% in the G-FC arm and 8/6% in the G-B arm) were alive in follow-up; G-FC (n=18: 2 lost to follow-up) and G-B (n=19). 1 event of progressive disease occurred in each arm, and 1 pt per arm died due to an adverse event (AE; G-B: respiratory failure; G-FC: unknown in the setting of unresolved Grade (Gr) 4 pancytopenia); neither was considered treatment related. Due to the small number of events, median PFS and OS could not be estimated; however, 3-year OS was 95% for each arm (95% CI G-FC, 68–99; G-B, 70–99). Post-treatment, 10/41 pts (24.4%) experienced ≥1 Gr≥3 AE: 2/21 pts (9.5%) in the G-FC arm and 8/20 pts (40.0%) in the G-B arm. 7 serious AEs were reported in 4 pts, all in the G-B arm; these included pneumonitis and respiratory failure (as noted above), both Gr5). Gr4 leukenemia/neutropenia, small cell lung cancer and Gr4 pneumothorax, and melanoma. During follow-up, 6 pts had ≥1 Gr3–4 AE of neutropenia, including 4/20 pts (20.0%) in the G-B arm and 2/21 pts (9.5%) in the G-FC arm. At end of treatment, all pts were B-cell depleted (B-cell count <0.07x109/L). Within 6–12 mo of follow-up, very few pts had recovered MRD-negative at 6 months (G-FC: 2/19 pts [10.5%]; G-B: 0/20 pts). At 36 mo follow-up, 9/19 pts (47.3%) in the G-FC arm had recovered, 3/15 (15.8%) were still depleted, and 7/19 did not have data available. In the G-B arm, 6/20 pts (30%) had recovered, 1 was still depleted, and 13/20 had no available data. In a single center exploratory analysis, 9 pts (G-FC) underwent 4-color flow cytometry analysis of peripheral blood for minimal residual disease (MRD) 8–14 mo after therapy; all were negative. 8 of these pts (G-FC) who were MRD-negative by 4-color flow cytometry were also tested with the ClonoSEQ immuno-globulin sequencing assay; 4 were MRD-positive and 4 MRD-negative. 4 pts who were MRD-positive always have both assays remain in remission, while 2/4 pts who were positive by ClonoSEQ died after follow-up, one of Richter’s transformation complicated by pneumonia and the other related to MDS. Another pt who was MRD positive by ClonoSEQ underwent allologeneic stem cell transplantation and remains in remission.

Summary/Conclusions: We conclude that G plus either FC or B results in excellent long-term disease control in previously untreated pts with CLL, and has comparable side-effects to other chemo-immunotherapy regimens.

We thank N Crompton, N Tyson, M Rahman (Roche Products Ltd) and R Moraru-Zafrir (F. Hoffmann-La Roche Ltd) for their support.

Medizinische Klinik, Universitätmedizin Mannheim, Mannheim, 1Institut für Medizinische Informationsverarbeitung, Biometrie und Epidemiologie (IBE), Ludwig-Maximilians Universität, München, Germany, 2Institut National de la Santé et de la Recherche Médicale (INSERM), Centre Hospitalier Universitaire (CHU) de Poitiers, Poitiers, France, 3Molecular Hematology Laboratory, 1st Department of Propedeutic Medicine, National and Kapodistrian University of Athens, School of Medicine, Laikon General Hospital, 4Hellenic Society of Hematology, Athens, Greece, 5Onkologische Praxis Heilbronn, Heilbronn, 6Klinik für Innere Medizin I, Universitätsschloss Lübeck, Lübeck, Germany, 7Medizinische Klinik II, Schwerpunkt Hämatologie und Immunologie, Universitätsschloss Lübeck, Lübeck, 8Klinik für Innere Medizin, Klinikum Rechts der Isar, Technische Universität, München, Germany, 9Medizinische Klinik, Klinikum rechts der Isar, Technische Universität, München, Germany, 10Medizinische Klinik, Klinikum rechts der Isar, Technische Universität, München, Germany, 11Klinik für Innere Medizin III, Klinikum rechts der Isar, Technische Universität, München, Germany, 12Klinik für Innere Medizin I, Universitätsschloss Lübeck, Lübeck, Germany, 13Klinik für Innere Medizin I, Universitätsschloss Lübeck, Lübeck, Germany, 14Klinik für Innere Medizin I, Universitätsschloss Lübeck, Lübeck, Germany, 15Medizinische Klinik und Poliklinik, Universitätsschloss Lübeck, Lübeck, Germany, 16Klinik für Innere Medizin I, Universitätsschloss Lübeck, Lübeck, Germany, 17Medizinische Klinik und Poliklinik, Universitätsschloss Lübeck, Lübeck, Germany, 18Medizinische Klinik und Poliklinik, Universitätsschloss Lübeck, Lübeck, Germany, 19Medizinische Klinik und Poliklinik, Universitätsschloss Lübeck, Lübeck, Germany, 20Medizinische Klinik und Poliklinik, Universitätsschloss Lübeck, Lübeck, Germany, 21Hämatologie, Onkologie und Poliattivmedizin, Vivantes Klinikum Neukölln, Berlin, 22Klinik für Innere Medizin, Klinikum Bayreuth, Bayreuth, Germany, 23Institut Bergönö, Universität Bordeaux, Bordeaux, France.

Background: Several studies showed that tyrosine kinase inhibitors (TKIs) can safely be discontinued in patients with sustained deep molecular response. So far, deep molecular response (DMR) and treatment duration were predictive for successful treatment-free remission (TFR) whereas age, risk scores, gender and molecular response level before stopping were without influence (Mahon FX, et al. 2013).

Aims: We investigated the potential role of HLA-G polymorphisms and soluble HLA-G molecules in susceptibility to chronic myeloid leukemia (CML), as well as in achievement and maintenance of deep molecular remission (MR4.5) in 68 patients treated with tyrosine kinase inhibitors (TKIs).

Methods: The entire HLA-G gene was amplified by long-range PCR and sequenced using next-generation sequencing (NGS) with Illumina’s Nextera® technology and a 300 bp paired-end read protocol. The BioVendor sHLA-G ELISA (RD194070100R sHLA-G ELISA - EXBIO Praha a.s. BioVendor) immunocassay was used for the quantitative measurement of HLA-G1 and HLA-G5 soluble forms in EDTA-plasma samples.

Results: The frequency of the G*01:03 allele was significantly associated to G*01:01 (10,29% vs 4,46%; p=0,001). Patients carrying the G*01:01:01 or G*01:01:02 allele had a significantly higher mean value of soluble HLA-G compared to patients carrying G*01:01:03 (109.2±39.5 vs 39.9±8.8 units/ml; p=0.03), and showed significantly lower EFS compared to patients with other allelic combinations (62.3% vs 90.0%; p=0.05). Moreover patients carrying the G*01:01:03 allele had significantly higher rates of MR5 (100% vs 65%), with earlier achievement of deep MR4.5 (median of 8 vs 58 months, p=0.001). TKIs were discontinued in 24 patients after 2 years of confirmed MR4.5, Treatment free remission (TFR) was 57.7%. None of the patients homozygous for the G*01:01:01 or G*01:01:02 allele remained in TFR (0% vs 68.4%, p=0.023) (Figure 1). All patients carrying the G*01:01:03 allele remained in TFR.

Figure 1.

Summary/Conclusions: HLA-G alleles with higher secretion of soluble HLA-
G would seem to be associated with lower EFS and TFR, possibly because of a stronger inhibitory effect on the immune system in favor of tumor escape mechanisms. Conversely, the allele associated to lower levels of sHLA-G promoted achievement of MR4.5 and TFR, suggesting increased cooperation of the host immune system in CML cell clearance.

Background: ENESTTop (NCT01698905) is evaluating the ability to stop treatment and remain in TFR in pts with CML-CP who achieved a sustained deep molecular response (MR) after switching from imatinib (IM) to NIL. In the primary analysis, 57.9% of pts (73/126) who stopped treatment remained in TFR (no loss of major MR, BCR-ABL1 ≤0.1% on the International Scale (IS), no confirmed loss of MR4 [BCR-ABL1 ≤0.01%], and no treatment reinitiation) at 48 wk.

Aims: To evaluate the proportion of pts remaining in TFR at 96 wk after stopping second-line NIL in ENESTop.

Methods: Eligible pts had ≥3 y of prior tyrosine kinase inhibitor treatment (>4 wk IM, then ≥2 y NIL) and achieved MR4.5 (BCR-ABL1 at ≤0.0032%) after switching to NIL. All pts provided informed consent. Enrolled pts continued NIL for 1 y in the consolidation phase (MR assessed every 12 wk). Pts without confirmed loss of MR4.5 during consolidation were eligible to enter the TFR phase (MR4.5 confirmed loss of MR4.5 during the first 48 wk or for the first 24 wk after regaining MR4.5, then every 12 wk). Pts with loss of MMR or confirmed loss of MR4.5 remained on NIL. This analysis was conducted when all pts who entered the TFR phase had completed 96 wk of TFR, reinitiated treatment, or were discontinued from the study (data cutoff, 7 Nov 2016).

Results: Of 67 pts in the phase 67 of the 126 pts (53.2% [95% CI, 44.1% - 62.1%]) who entered the TFR phase remained in TFR. Four pts who were in TFR at 48 wk reinitiated NIL due to confirmed loss of MR4 at 60, 72, 90, and 96 wk, respectively. Two other pts discontinued from the study between 48 and 96 wk due to pregnancy (last BCR-ABL IS of 0.0035% at 60 wk) and pt decision (maintained MR4.5 through 90 wk), respectively. Based on Kaplan-Meier analysis, the median duration of treatment-free survival has not been reached and the curve appeared to plateau (Figure 1). Of 56 pts who reinitiated NIL by the 20 wk, 50% of pts regained MR4.5 through 90 wk, respectively. Expression of adipogenic genes, peroxisome proliferator-activated receptor gamma (PPARγ), lipin1 (LPIN1), sterol regulatory element-binding protein 1 (SREBP1) and glucose transporter 4 (GLUT4) were investigated by microarray analysis. A dose dependent reduction in lipid accumulation was observed in clinically relevant concentrations of NILO (1-20µM) and IMA (5µM), in the presence or absence of telmisartan (1-10µM), an angiotensin receptor blocker with potential beneficial effects on insulin sensitivity and lipid homeostasis. Cytoxicity and adipogenesis were assessed by MTT assay and Oil Red O staining, respectively. Expression of adipogenic genes was increased in a dose dependent manner, suggesting increased cooperation of mechanisms behind NILO-associated metabolic adverse effects.

Aims: i) To study the effect of NILO and imatinib (IMA) on adipocyte function and adipokine secretion using an in vitro adipocyte model; ii) To utilise the in vitro model to explore potential therapeutic strategies to reverse NILO-mediated effects, and iii) To validate the in vitro results in a pilot patient cohort.

Methods: Differentiating 3T3-F442B mouse adipocytes were incubated with clinically relevant concentrations of NILO (1-20µM) and IMA (5µM), in the presence or absence of telmisartan (1-10µM), an angiotensin receptor blocker with potential beneficial effects on insulin sensitivity and lipid homeostasis. Cytoxicity and adipogenesis were assessed by MTT assay and Oil Red O staining, respectively. Expression of adipogenic genes was assessed by microarray analysis. A dose dependent reduction in lipid accumulation was observed for NILO (for 20µM incubations but full concentration response relationships were measured.

Results: Neither NILO nor IMA were cytotoxic to the adipocytes at clinically relevant concentrations. A dose dependent reduction in lipid accumulation was observed for NILO (for 20µM, 0.76 ± 0.055 absorbance units; p<0.01) but not IMA (0.98 ± 0.007), compared to vehicle control. NILO, but not IMA, dose dependently downregulated the mRNA expression of PPARγ (52% downregulation), LPIN1 (28% downregulation) and SREBP1 (54% downregulation). Both NILO and IMA resulted in significant downregulation of GLUT4 mRNA (NILO, 93%; IMA, 79%; p<0.01) and of secreted adiponectin (NILO, 5.99ng/ml; IMA, 3.19ng/ml; both p<0.01 in comparison to vehicle control, 79.2ng/ml). Co-incubation with telmisartan resulted in significant reversal of NILO-mediated effects on lipid accumulation, adipogenic gene expression and adiponectin secretion. In the patient cohort, IMA resulted in a significant increase in adiponectin levels at 3 (38.4±7.1mg/l; p=0.01) and 12 (36.7±7.2mg/l; p=0.01) month time points compared to baseline (27.3±5.7mg/l). In contrast, second line NILO showed a trend for reduction in adiponectin at both 3 (15.2±1.8mg/l; p=NS) and 12 weeks.

Background: A BCR-ABL1 transcript level at 3 months after the initiation of imatinib has shown to predict the long-term clinical outcome of patients with chronic myeloid leukemia in chronic phase (CP-CML). The levels obtained earlier than 3 months may also have a similar prognostic significance.

Aims: To assess the prognostic value of the BCR-ABL1 transcript levels at baseline, and 1 and 3 months after the initiation of a tyrosine kinase inhibitor (TKI) in predicting the major molecular response (MMR) achievement by 12 months, and to compare the patterns of molecular response (MR) to a TKI therapy between good and poor responders using a nonlinear model.

Methods: The clinical data were collected from the 178 patients with newly diagnosed CP-CML who were treated with a TKI at Seoul St. Mary’s Hospital. BCR-ABL1 transcript levels were obtained at baseline, and 1, 3, 6 and 12 months after the initiation of a TKI. The levels were reported as the percent ratio relative to the control gene ABL1 in accordance with the International Scale (BCR-ABL1/ABL1%). A confirmed MMR was defined as a BCR-ABL1/ABL1≤0.1% on two consecutive occasions. The predictability of the levels at baseline, and 1 and 3 months post TKI therapy for the achievement of a confirmed MMR by 12 months was evaluated using a logistic regression method with a receiver operating characteristic (ROC) analysis. The areas under the ROC curve (AUCs) were calculated to quantify the predictability. In addition, the patterns of molecular responses over time were described by a nonlinear model to compare the model-derived parameters between the good and poor responders using a two-sample t-test.

Results: Of 178 patients, 67 achieved a confirmed MMR by 12 months but 111 did not. At baseline, the transcript level was not useful to predict the achievement of a confirmed MMR by 12 months. At 1 month post therapy, transcript levels measured at 1 month significantly (p<0.0001) predicted the MMR with an AUC of 0.77. The patients with the level of 38% or less at 1 month had a better chance to achieve the MMR. By 3 months post therapy, the transcript level measured at 3 months (p<0.0001) accurately predicted the MMR with the AUC of 0.87. The patients with the level of 0.48% or less at 3 months had a better chance to achieve the MMR. A nonlinear sigmoid model was used to fit the transcript data from 149 patients as follows: MR=MR0 [1 − tγ/ (t50γ+tγ)]. Where MR0 is the predicted molecular response at baseline; t, time post TKI initiation; γ, slope factor; t50, time required to achieve 50% reduction in MR. Statistically significant differences were observed between the good and poor responders in the median values for the model-derived parameters of MR0 (73.3% vs 82.2%; p=0.003), y (4.98 vs 3.32; p<0.0001) and t50 (0.952 month vs 1.12 month; p=0.05).

Summary/Conclusions: A BCR-ABL1 transcript level measured at 1 month after the initiation of a TKI may be used as an early indicator to reliably predict the MMR achievement by 12 months in patients with CP-CML. The level obtained at 3 months appears to accurately predict the MMR. Further studies are needed to evaluate the association between the transcript level at 1 month and long-term clinical outcomes.
Background: Risk scores in chronic myeloid leukemia (CML) use baseline characteristics of CML patients in chronic phase to predict outcome and can be used to make decisions regarding first line TKI choice and monitoring frequencies. Until recently, risk stratification of CML patients was used based on scores developed in the pre-imatinib era (Sokal and Hasford risk score) with overall survival as the end point of interest. After the introduction of imatinib, the EUTOS score was established to predict the chance of achieving CCyR at 18 months, as a proxy for survival. However, since the major causes of death of CML patients are no longer CML-related, the need for baseline risk prediction has shifted from overall survival towards disease specific mortality. Therefore, recently the EUTOS long-term survival (ELTS) score was introduced to predict the risk of dying of CML in patients treated with first line imatinib.

Aims: The primary objective of this study was to perform a validation of the ELTS score in an independent cohort of “real-world” population-based CML patients.

Methods: Data from chronic phase CML patients were derived from the PHAROS-CML population based registry and Hemobase. Patients were stratified into a low, intermediate and high risk group according to the ELTS score. Data on “death due to CML” were provided by the Netherlands comprehensive cancer organization (IKNL) in combination with details from the patient records and a competing risk analysis was performed, to take death due to other causes into account.

Results: In total 349 patients were eligible for analysis; 273 patients (78%) were treated with first line imatinib and 76 patients (22%) were treated with a first line second generation TKI (2GTKI). Sokal, Hasford and EUTOS risk scores all did not predict differences in risk of “death due to CML”. The ELTS score identified 163 patients as low risk (47%), 127 patients as intermediate risk (36%) and 59 patients as high risk (17%) at diagnosis. The 5 year cumulative incidence of “death due to CML” was indeed significantly higher in the high risk group (11%) compared to both the intermediate risk group (2%, p<0.02) and the low risk group (1%, p<0.001). Between the intermediate and low risk group no statistically significant difference in risk of dying from CML was observed. A subgroup analysis of only imatinib treated patients showed similar results.

Summary/Conclusions: In the current study based on a “real-world” population-based CML patient cohort, we were able to validate the predictive value of ELTS high risk stratification for “death due to CML” in the current TKI era. Therefore, the ELTS score should be preferred over Sokal, Hasford and EUTOS scores in clinical practice.

Background: A second-generation tyrosine kinase inhibitor (TKI), dasatinib, is more potent in inhibiting BCR-ABL than imatinib. We had previously reported an interim analysis of 63 patients with CML-CP who had discontinued dasatinib treatment after maintaining a deep molecular response (DMR) for more than a year (Lancet Haematology, 2015; 2(12):e528-35) and demonstrated that dasatinib could be safely discontinued in patients with a DMR of at least 12 months. However, longer follow-up results would clinically be more critical in the treatment of CML.

Aims: In this trial, the total follow-up duration was set as 36 months after the discontinuation. The aim of the current follow-up study was to investigate whether those patients were able to discontinue dasatinib treatment for a longer follow-up period without relapse.

Methods: The eligibility criteria for pre-registration included CML CP patients, 15 years or older, receiving dasatinib treatment as the second-line or subsequent therapy after imatinib. All participants gave written informed consent. In this trial, DMR was defined as “no detectable BCR-ABL1 transcript determined using the international scale-based RQ-PCR at a single central laboratory (BML inc., Tokyo; the cutoff corresponded to BCR-ABL1 0.0069% IS or molecular response (MR) 4.0).” Patients who showed a sustained DMR for 1 year (1-year consolidation phase) were subsequently included in the dasatinib-discontinuation stage. RQ-PCR was performed monthly for the first 12 months, and then every 3 months for the second year, and every 6 months for the third year, after discontinuing dasatinib. Relapse was defined as any positivity of BCR-ABL1 transcript by RQ-PCR even at one analysis point. In the present study, we assessed the estimated overall treatment-free remission (TFR) after discontinuing dasatinib, with 3 years of follow-up.

Results: Sixty-three patients were included in the dasatinib-discontinuation stage. The estimated overall treatment-free remission (TFR) after discontinuing dasatinib was 88.9% at 6 months (95% CI, 71.8%–95.9%) and 82.6% at 12 months (95% CI, 68.3%–91.3%). The estimated overall treatment-free remission (TFR) after discontinuing dasatinib was 74.2% at 24 months (95% CI, 58.5%–85.5%). As the overall provability of TFR was relatively stable even for a longer follow-up period, our findings provided more compelling evidence supporting dasatinib discontinuation after a DMR for more than 1 year; this is feasible especially in patients with imatinib intolerance. We also confirmed that the counts of NK cells and functionally specific T-cells in the peripheral blood during dasatinib treatment might affect the TFR following dasatinib discontinuation.

1Hematopoietic Stem Cell Laboratory, 2Bioinformatics Unit, 3Advanced Sequencing Unit, The Francis Crick Institute, 4MRC Centre for Developmental Neurobiology, King’s College, 5Hematopoietic Stem Cell Lab, The Francis Crick Institute, 6Department of Haematology-Oncology, Barts Cancer Institute - Queen Mary University of London, 7Haematopoietic Stem Cell Laboratory, The Francis Crick Institute, London, United Kingdom

Background: The biological and clinical behavior of hematological malignancies is not only determined by the properties of the leukemic cells themselves, but it is also highly affected by the interaction with the microenvironment, pointing to the existence of an active crosstalk between the two compartments. Previous studies showed that acute myeloid leukemia (AML) actively modify endothelial cells ex vivo via several pathways, mainly mediated by VEGF. However, anti-VEGF therapies haven’t produced successful results in clinical trials.

Aims: Our aim is to perform an extensive study of the vascular niche in the bone marrow (BM) of AML xenografts to provide a global picture of the vascular lature in AML disease and design new therapeutic strategies.

Methods: We combined the use of mouse models of AML, human AML-derived xenografts (PDX) and direct analysis of patients derived samples to study the vascular niche in AML disease. We used two-photon confocal microscopy as a powerful tool to functionally image BM vascularization in vivo. We used RNA-sequencing to study the AML-associated transcriptomic profile in vascular endothelial cells.

Results: We found several abnormalities in the vascular architecture and function in PDX, such as increased number of endothelial cells, increased microvacular density (MVD), loss of normal sinusoidal architecture and increased hypoxia. Moreover, vascular permeability was increased as measured via two-photon imaging. Interestingly, induction chemotherapy failed to normalize the vascular permeability in the BM, although it significantly reduced the AML-engraftment. Via high-throughput transcriptomic analysis, we showed that AML-induced hypoxic environment altered the molecular signature of vascular endothelial cells, activating pro-angiogenic pathways and positively regulating the response to hypoxia. We identified increased nitric oxide (NO) as a major mediator of the AML-induced vascular leakiness in the BM. Notably, increased NO levels were found also in BM aspirates of patients at diagnosis compared to healthy donors, and failure in reducing NO levels after chemotherapy appeared to be associated with a higher incidence of unsuccessful treatment. Strikingly, inhibition of NO production in mouse models of AML and in AML-derived PDX reduced vascular permeability, preserved normal HSC function and significantly improved treatment response (Figure 1).

Summary/Conclusions: We have shown an altered highly permeable vascular niche in the BM of AML PDX, mainly caused by increased NO production by the endothelial niche, contributing to disease progression and treatment failure. Our data call for clinical trials incorporating NOS inhibitors during the remission phase, to target the abnormal vascular niche and improve AML treatment response.

BUILDING HUMAN BONE MARROW-LIKE MODELS TO STUDY NICHE INTERACTIONS

H.-J. Prins1, T. Csikos 1, R. de Jong-Korlaar 1, R. Ruiter 1, S. van Veen 1, H. Yuan1, J. de Bruijn2, G. Ossenkoppele1, R. Groen1

1Hematology, VU University Medical Center, Amsterdam, 2xpand Biotechnolgy BV, Bihlloven, Netherlands

Background: Previously, we have reported that our human bone marrow-like scaffold (huBM-sc) xenograft model allows the engraftment and outgrowth of normal and malignant hematopoiesis (e.g. multiple myeloma (MM) and acute lymphoblastic leukemia (ALL) (Groen et al. Blood 2012; Gutierrez et al. JCI 2014) and more recently acute myeloid leukemia (AML; Antonelli et al. Blood 2016). These studies showed that i) engraftment is not correlated with prognostic risk-groups, ii) there is preferential outgrowth in humanized scaffolds compared to the murine BM, iii) the huBM-sc environment results in better maintenance of self-renewal potential and less clonal drift of the leukemic cells. Although the presence of human osteoblasts and bone mimics a human BM niche more closely than the murine BM in standard xenotransplant models (e.g. NOD-SCID/NSG mice), still some essential components of the human BM niche, i.e. human bone vessels, are missing.

Aims: To implement human vasculature in the huBM-sc xenograft model in order to create a multi-tissue compartment that “maximalizes” the BM-like niche of our scaffolds.

Methods: Towards successful implementation of a human vascular system into our scaffolds, we studied: i) scaffolds material composition (bioceramic calcium phosphate vs tricalcium phosphate (TCP)); ii) scaffold shape (particles vs tubes); iii) different types of matrigel for cord blood-derived endothelial progenitor cells (CB-EPCs) embedding.

Results: Histological analysis of these fully humanized scaffolds showed a large hemorrhage in the CD31-positive human BM scaffold systems, and increased vascular density (MVD), LEPR and nestin-positive stromal niche cells. Comparison of the expression and position of the scaffolds indicated superiority of TCP and tubelike shaped scaffolds in supporting the formation of vessels. Engraftment of BM-derived CD34+ cells in the CB-EPC embedded huBM-sc resulted in increased multilineage hematopoietic engraftment, as compared to huBM-sc without CB-EPCs. Moreover, we observed that incorporation of CB-EPCs provides faster kinetics of engraftment of both patient-derived BM and AML cells, and proved to be essential for the engraftment of blast cells from myelofibrosis patients.

Summary/Conclusions: Thus, with the addition of human CB-EPCs and BM stromal cells, our scaffold systems now simulate both endothelial and vascular niches of the BM, thereby more closely recapitulating the human hematopoietic microenvironment.

MULTISCALE IMAGE-BASED QUANTITATIVE ANALYSIS OF BONE MARROW STROMAL NETWORK TOPOLOGY REVEALS STRICT SPATIAL CONSTRAINTS FOR HEMATOPOIETIC-STROMAL CELLULAR INTERACTIONS

Á. Gomárz1, P. Heibling1, S. Isringhausen1, U. Suessbier1, A. Becker2, A. Boss3, T. Nagasawa4, G. Paul5, O. Göksel5, G. Zékely5, S. Stoma6, N. Nerellykék6, M. Manz7, C. Nombela Arrieta1*

1Hematology, University and University Hospital Zurich, 2Radiology, University Hospital Zurich, 3Radiology, University Hospital Zurich, 4Radiology, University Hospital Zurich, 5Computer Vision, 6SCOPE M, ETH, Zurich, Switzerland

Background: Adult bone marrow (BM) cavities host continuous, demand adapted and high throughput blood cell production, which is maintained by a rare population of self-renewing, multipotent hematopoietic stem cells (HSCs). Aside from its diverse hematopoietic content, the BM is populated by a heterogeneous fraction of mesenchymal, endothelial and neural stromal cells, which provide the necessary tissue infrastructure for hematopoiesis, playing fundamental regulatory roles in hematopoietic development. Recent evidence suggests that tissue regions around BM venous microvessels (termed sinusoids), which are enriched for mesenchymal CXCL12-abundant reticular cells (CARc), serve as the principal regulatory niches for HSCs as well as other hematopoietic progenitor populations. Despite this proposed role as putative specific niche-restricted components, comprehensive data on the frequency, spatial distribution and topology of sinusoidal endothelial and CAR cell networks is largely lacking to date.

Aims: The principal aim of our work is to employ state of the art imaging tech-}

niques and perform a detailed 3D quantitative and structural analysis of the BM stromal infrastructure, with a special focus on sinusoidal microvasculature and the CAR cell mesenchymal component, both of which are essential regulators of HSC maintenance.

Figure 1.

Summary/Conclusions: We have shown an altered highly permeable vascular niche in the BM of AML PDX, mainly caused by increased NO production by the endothelial niche, contributing to disease progression and treatment failure. Our

data call for clinical trials incorporating NOS inhibitors during the remission phase, to target the abnormal vascular niche and improve AML treatment response.
Methods: We have developed i) advanced microscopy techniques allowing multiscale 3D visualization of entire bone marrow cavities with cellular and sub-cellular detail ii) customized computational tools enabling the detection and quantification of discrete cell subsets/structures in 3D images of the BM in an unbiased fashion, as well as a rigorous spatial statistical analysis of cellular interactions.

Results: Using 3D-quantitative microscopy (3D-QM) we uncover that BM stromal cells are in fact 15-20 fold more abundant than previously reported. The massive underestimation of these relevant cell subsets results from the highly inefficient isolation of these cellular types with currently employed flow cytometry protocols. Our image-based analyses further reveals that sinusoidal and CAR cell stromal networks occupy a disproportionately large fraction of the BM space, consequently constraining the tissue volume available for hematopoietic cell distribution. In fact, the vast majority of BM resident hematopoietic cells are unavoidably in direct contact with the CAR cellular projections and in close proximity to the sinusoidal endothelium.

Summary/Conclusions: Collectively, our quantitative description of stromal microarchitecture, challenges current models of cell type-specific niche interactions in the BM, which are based in largely inaccurate estimations of cell frequency and spatial confinement of stromal cells in this organ.

TEMPLATED V(D)J INSERTIONS ARE A NOVEL BIOLOGIC MECHANISM FOR B-CELL RECEPTOR REPertoire DIVERSIFICATION

M.T. Koning1, I. Trolldmann1, R. Rademaker2, R. Toes3, H. Veelken1
1Department of Hematology, Leiden University Medical Center, Leiden, 2Gen-Mab, Utrecht, 3Department of Rheumatology, Leiden University Medical Center, Leden, Netherlands

Background: Recently, large LAIR1 insertions at the V-D junction were described as a novel mechanism to generate antibodies against P. falciparum RIFIN antigens on infected erythrocytes (Tan et al., Nature 2016). These templated insertions potentially add a novel biological mechanism used by the immune system to generate B-cell receptor repertoire diversity.

Aims: We investigated whether templated insertions occur in the B-cell repertoire of healthy donors and whether such insertions could be functionally exploited to explore their biological function.

Methods: We obtained >52,000 unique full-length VDJ sequences of IgM, IgG, IgA, and IgE isotypes by unbiased ARTISAN PCR (Koning et al., BJH 2016) from 6 healthy donors. Abnormally long sequences and junctions were searched for templated insertions by BLAST. Identified VDJ carrying templated insertions were co-expressed with a panel of 172 light chains on multiple myeloma cell lines and assessed for surface expression of transgenic immunoglobulin. The VDJ described by Tan et al. were included as controls.

Results: Six unique VDJ sequences, all from the same donor, carried a templated insertion in-frame (E=10⁻⁶ – 0). These sequences represented all VDJ sequences with a CDR3 region >150 bp. Exonic sequences from RPLP0, ZNF316, and an inverted IGHV-IGHD sequence were identified as insertions in unmutated IgM VDJ transcripts. The LAIR1 exon described by Tan et al. and an intergenic region adjacent to IGHD3-22 were identified as insertions in IgG VDJ transcripts. One IgA VDJ contained two intergenic sequences positioned close to each other. Remarkably, 4 VDJ were sequenced from 22 somatic hypermutation correlated strongly between the IGHV segment and the templated insertions (r=0.9944; p<0.001). All templated insertions harboured cryptic RSS sites at their termini. All three IgG VDJ carrying templated insertions and the IgG rearrangement with two templated insertions gave rise to detectable surface immunoglobulin after coexpression with at least one light chain in the panel.

The IgG VDJ carrying the LAIR1 templated insertion produced no detectable surface immunoglobulin. In contrast, the VDJ sequences carrying LAIR1 templated insertions as described by Tan et al. could be expressed with the majority of the light chains. The IgA rearrangement remains to be tested in this system.

Summary/Conclusions: Templated insertions represent a novel antibody diversification mechanism. Their presence in naïve B-cells, their exclusive positioning in VDJ junctions, and the universal presence of cryptic RSS sites point to primary VDJ recombination or secondary V gene editing as the generating mechanism. Certain loci (e.g. LAIR1) and individuals appear to have increased susceptibility. The available data suggest RAG to be involved in these insertions. We propose that templated insertions represent inserted insert sequences from aberrantly rearranged chromosome sequences with cryptic RSS sites.

Background: The available data suggest RAG to be involved in these abnormally rearranged chromosome sequences with a CDR3 region >150 bp. Exonic sequences from RPLP0, ZNF316, and an inverted IGHV-IGHD sequence were identified as insertions in unmutated IgM VDJ transcripts. The LAIR1 exon described by Tan et al. and an intergenic region adjacent to IGHD3-22 were identified as insertions in IgG VDJ transcripts. One IgA VDJ contained two intergenic sequences positioned close to each other. Remarkably, 4 VDJ were sequenced from 22 somatic hypermutation correlated strongly between the IGHV segment and the templated insertions (r=0.9944; p<0.001). All templated insertions harboured cryptic RSS sites at their termini. All three IgG VDJ carrying templated insertions and the IgG rearrangement with two templated insertions gave rise to detectable surface immunoglobulin after coexpression with at least one light chain in the panel.

The IgG VDJ carrying the LAIR1 templated insertion produced no detectable surface immunoglobulin. In contrast, the VDJ sequences carrying LAIR1 templated insertions as described by Tan et al. could be expressed with the majority of the light chains. The IgA rearrangement remains to be tested in this system.

Summary/Conclusions: Templated insertions represent a novel antibody diversification mechanism. Their presence in naïve B-cells, their exclusive positioning in VDJ junctions, and the universal presence of cryptic RSS sites point to primary VDJ recombination or secondary V gene editing as the generating mechanism. Certain loci (e.g. LAIR1) and individuals appear to have increased susceptibility. The available data suggest RAG to be involved in these insertions. We propose that templated insertions represent inserted insert sequences from aberrantly rearranged chromosome sequences with cryptic RSS sites.

MULTIPLE MYELOMA-POLARIZED M2C MACROPHAGES PROMOTE A TUMOR-SUPPORTIVE OSTEOCLYTIC MICROENVIRONMENT VIA CXCL13

K. Belder1, V. Voelvoet1, H. Bilmer1, E. Rosenberg1, H. Magen1, O. Ostrovsky1, E. Ribakovskiy1, A. Shimoni1, L. Weiss3, M. Abraham3, A. Peled3, A. Nagler1
1Hematology Division, Bone Marrow Transplantation, SHEBA MEDICAL CENTER, Ramat-Gan, 2Institute of Hematology, Davidoff Cancer Center, Rabin Medical Center, Petach-Tikva, 3Institute of Gene Therapy, Hadassah Hebrew University Hospital, Jerusalem, Israel

Background: Previous studies including our work revealed a role of MM-educated M2-like macrophages (MΦ) in MM survival and drug resistance. However, the mechanism by which neoplastic plasma cells shape BM microenvironment and affect MΦ polarization is still poorly defined.

Aims: To investigate tumour-educated MΦ in the BM niche of MM patients.

Methods: We used our in vivo xenograft model of BM-disseminated human myeloma. The CRISPR/cas9 technology was used to knockdown CXCL13 expression in MM cell lines.

Results: Analysis of mice inoculated with human CXC4R-expressing RPMI8226 cells revealed a significant increase in M2C in comparison to non-injected controls (p<0.01). Characterization of MM-associated changes in the BM milieu revealed myeloma chemotractant CXCL13 being one of the most profoundly increased factors upon MM development. Elevated CXCL13 was also detected in blood of MM-bearing animals comparing to healthy controls. High CXCL13 expression in MM cell lines and primary human CD138+ cells. Mechanistically, TGFB signaling was involved in CXCL13 induction in both MM cells and MΦ, as TGFB receptor inhibitor SB431542 interfered with CXCL13 induction. Osteo-
clastogenic assays were used to elucidate the down-stream effects of the elevated CXCL13. Recombinant CXCL13 as well as medium produced by co-cultured MM-MF increased RANKL expression and induced TRAP+ osteoclast (OC) formation in vitro, while CXCL13 neutralization blocked these activities. We next abrogated CXCL13 expression in MM cell lines using the CRISPR/Cas9 technology. The loss of CXCL13 had no effect on MM in vitro growth or drug sensitivity. However, mice inoculated with CXCL13-silenced MM cells developed significantly weaker BM disease compared to mice receiving the non-manipulated cells. Reduced tumor load correlated with decreased numbers of M2c/MF in BM, decreased bone disease, and lower expression of OC-associated genes. Finally, the presence of CXCL13 in primary MM samples was evaluated. Low levels of CXCL13 transcript and protein were detected in BM aspirates from MM patients (n=24) in comparison to normal BM (n=5) and were in correlation with gene expression signature associated with OC activation and M2c MF phenotype (Figure 1).

Figure 1.

Summary/Conclusions: Our findings suggest that bidirectional interactions of MF with MM tumor cells result in M2c MF polarization, CXCL13 induction and subsequent OC activation, enhancing their ability to support bone resorption and MM progression. CXCL13 may thus serve as potential novel target for the diagnosis and treatment of MM.

RE-ORDERING THE B CELL DEVELOPMENT HIERARCHY IN HUMAN FETAL BONY MARROW: CHARACTERISATION OF A NOVEL HUMAN FETAL B PROGENITOR

S. O’Byrne1, N. Elliott1, G. Buck1, L. Liu1, B. Povinelli 1, N. Fordham2, E. Louka2, K. Bartolovic3, A. Karadimitris1, A. Mead2, I. Roberts12, A. Roy3, S. McKinney-Freeman1

1Experimental Hematology, 2Department of Computational Biology, 3Department of Biostatistics, St. Jude Children’s Research Hospital, Memphis, United States

Background: The cellular hierarchy of normal human fetal B-lymphopoiesis remains poorly defined. We have previously identified a novel population of PreProB progenitors (CD34+CD19+CD10+) in fetal liver (FL) that is further expanded in fetal bone marrow (FBM) [2], and co-exists with adult-type CD34+CD19+CD10+ ProB progenitors. Increasing evidence indicates that infant ALL and many cases of childhood ALL arise in fetal life, suggesting that ontogeny-related changes in B-cell development may be important for in utero leukemia initiation. Therefore, understanding the human fetal B cell hierarchy, especially the differences between PreProB and ProB progenitors may be key to understanding the origins of infant and childhood leukemia.

Aims: To define B cell developmental stages throughout malignant transformation. We determined that sample-to-sample variance of the distribution of Confetti colors in the blood of the following adult mice inversely correlated with the number of hematopoietic precursors specified during the indicated window of embryo disruption, transplantation assays and concluded that very few HSC emerge from endothelial precursors during embryogenesis to establish life-long hematopoiesis. An alternative approach independent of embryo disruption or transplantation would more accurately reflect the true dynamics of HSC emergence during mammalian development.

Methods: Here, we employed the Confetti allele, in which a cassette targeted to the ROSA26 locus randomly and permanently marks cellular progeny with GFP, YFP, RFP or CFP when exposed to Cre recombinase. We determined empirically that sample-to-sample variance in the distribution of Confetti colors in the blood of the following adult mice inversely correlated with the number of hematopoietic precursors specified during the indicated window of Cre recombinase activity: ROSA26(Confetti+/+) Flk1+/Cre (mesodermal precursors, E7), ROSA26(Confetti+/+) VE-cadherin+/Cre (mesodermal endothelial precursors, E8.5-E10.5), and ROSA26(Confetti+/+) Vav1+/Cre (hematopoietic progenitors E11.5-E14.5). This correlation was used to estimate the number of hematopoietic precursors emerging during each stage of development.

Results: An inverse correlation of sample-to-sample variance in the distribution of Confetti colors and number of labeled initiating events was established in vitro by plating limiting dilution replications of immortalized Confetti+ fibroblasts and assessing the resulting sample-to-sample variance of each cell dose plated. We thus derived a linear formula to estimate numbers of initiating events using the sample-to-sample variance of the Confetti color ratio in a particular tissue (e.g. peripheral blood (PB)). We tested this formula in vivo via limiting dilution transplantation with Confetti+ bone marrow. Classic limiting dilution analysis of transplanted mice revealed about 1/120,000 repopulating units in the transplanted BM. The sample-to-sample variance in the distribution of Confetti colors in the PB of recipients yielded a similar estimate of the frequency of repopulating units validating our mathematical formula. We further validated our approach in vivo by calculating 222 repopulating units in transplant recipients of dissociated cultured E11.5 aorta-gonad-mesonephros (AGMs) explants. This finding correlates very well with previous reports that E11.5 cultured AGM explants contain about 150 transplantable HSCs. Analyses of the sample-to-sample variance of the Confetti color in the blood of cohorts of ROSA26(Confetti+/+) Flk1+/Cre, ROSA26(Confetti+/+) VE-cadherin+/Cre and ROSA26 (Confetti+/+) Vav1+/Cre mice revealed that about 719 mesodermal precursors, 633 endothelial precursors and 545 fetal liver hematopoietic precursors contribute to the emerging hematopoietic system. Our findings are in sharp contrast with previous reports that very few HSCs and pre-B progenitors establish the hematopoietic system. We further suggest that an effective method to study hematopoietic ontogeny that restricts the numbers of precursors that ultimately contribute to life-long hematopoiesis.

Summary/Conclusions: We report here a novel approach to examine the complexity of the emerging hematopoietic system without perturbing the developing embryo. This represents a new platform to identify biologically relevant processes that govern the dynamics of different populations during embryonic...
development. We thereby report for the first time that the clonal origin of blood is much more complex than previously thought, with hundreds of precursors contributing to the establishment of the mammalian blood system at multiple stages of ontogeny.

A2O RESTRAINTS THYMIC REGULATORY T CELL DEVELOPMENT

T. Haas1, J. C. Fischer1, V. Otten1, S. Spoerl1, H. Hoeck1
1Klinik und Poliklinik für Innere Medizin III, Klinikum rechts der Isar, TU München, München, Germany

Background: Maintaining immune tolerance requires the production of Foxp3 expressing T regulatory (T reg) cells in the thymus. Activation of NF-κB transcription factors is critically required for Treg cell development, partly via initiating Foxp3 expression. NF-κB activation is controlled by a negative feedback regulation through the ubiquitin editing enzyme A2O, which reduces pro-inflammatory signaling in myeloid cells and B cells. In naive CD4+ T cells, A2O prevents necroptosis and promotes inflammation.

Aims: This study is aimed at analyzing the role of the NF-κB regulator A2O in Treg cell development and function.

Methods: We used A2O−/− CD4Cre mice, which specifically lack A2O in T cells, to analyze the Treg cell compartment in vivo. We characterized expansion and differentiation of A2O-deficient Treg cells in vitro. We performed competitive bone marrow engraftment between WT and A2O-deficient bonemarrow in vivo to analyze whether one bone marrow compartment would outperform another or would favor development of certain T cell or other immune cell subsets. We performed allogeneic hematopoietic stem cell transplantation with WT BM+T cells at 4 weeks after engraftment to analyze whether A2O-deficient Treg cells would reduce GvHD to the same extent as WT Treg cells.

Results: Using mice deficient for A2O in T lineage cells, we show that thymic and peripheral Treg cell compartments are quantitatively enlarged due to a cell-intrinsic developmental advantage of A2O-deficient Treg cells. A2O−/− Treg cells efficiently suppressed effector T cell mediated graft-versus-host disease after allogeneic hematopoietic stem cell transplantation, demonstrating normal suppressive functionality. Holding thymic production of natural Treg cells in check, A2O thus integrates reduced regulatory T cell activity and increased effector T cell survival into an efficient CD4+ T cell response.

Summary/Conclusions: In light of the largely anti-inflammatory effects that have been attributed to A2O in many cell types, this proinflammatory aspect of A2O physiology in effector and regulatory CD4+ T cells is particularly important since it may contribute to a change of perception of the functions of A2O as a negative regulator of NF-κB in the context of inflammation. Whether targeted modulation of A2O activity allows the induction of Treg cell mediated immune tolerance or, alternatively, boosting of favorable T cell immunity is a question of translational relevance that needs to be addressed in the future.

THE TRANSCRIPTION FACTOR C/EBPG REGULATES MAST CELL DEVELOPMENT AND FUNCTION

M. Kardosova1, L. Potuckova2, I. Halova2, P. Zajbolovskaia1, L. Draberova2, P. Drabern2, M. Alberich-Jorda1

Background: Mast cells are key effector cells involved in protection against infection and allergic responses. Defects in mast cells are related to immunological disorders, and therefore it is critical to fully understand the transcriptional network that controls their generation and activity. Differentiation of progenitors to mature mast cells is promoted by several transcription factors, such as GATA1, GATA2, STAT5, and MITF, and requires downregulation of C/EBPα. Recently, we identified another member of the C/EBP family of transcription factors, C/EBPγ, as a direct C/EBPα target gene. However, the role of C/EBPγ in mast cells remains so far elusive.

Aims: In this study we aim to determine the role of the transcription factor C/EBPγ in mast cell development and function. Next, we investigate the mechanisms by which C/EBPγ is controlling these processes.

Methods: In order to determine the role of C/EBPγ in murine mast cells, we generated Cebpg conditional knockout mice, which allow excision of Cebpg in the hematopoietic system from the early embryogenesis. We employed Cebpgfl/flaro: Vav-1Cre- and Cebpgfl/flaro: Vav-1Cre- mice, referred here as WT and Cebpg KO, respectively. Excision of Cebpg was assessed by RT-PCR and western blot analysis in bone marrow and spleen cells. Using flow cytometry, we enumerated mast cell counts in the peritoneal cavity of healthy WT and Cebpg KO mice. To elucidate whether C/EBPγ plays a role in mast cell response to bacterial infection, we challenged these mice intraperitoneally with lipopolysaccharide. We used intraperitoneal injection of distilled water to eradicate peritoneal mast cells and then monitored repopulation of peritoneum over time. To further explore the role of C/EBPγ in mast cells in vitro, we established bone marrow derived mast cells (BMMCs) and determined their growth (cell numbers), morphology (toluidine blue staining), and transcription factors expression (RT-PCR) at different time points. Degranulation potential of BMMCs was specified by measuring the percentage of b-glucuronidase released to the supernatant upon anti-TNP IgE sensitization and TNP-BSA activation. To investigate the effects of absence of Cebpg during mast cell migra-
Hodgkin lymphoma

LONG-TERM OUTCOME OF PATIENTS WITH NODULAR LYMPHOCYTE-PREDOMINANT HODGKIN LYMPHOMA TREATED WITHIN THE RANDOMIZED HD7-HD15 TRIALS: AN ANALYSIS FROM THE GERMAN HODGKIN STUDY GROUP

D.A. Eichenauer1,*, A. Plütschow1, M. Fuchs1, B. von Tresckow1, V. Diehl1, P. Borchmann1, A. Engert1
1First Department of Internal Medicine, 2German Hodgkin Study Group, University Hospital Cologne, Cologne, Germany

Background: Nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) is a rare entity accounting for approximately 5% of all Hodgkin lymphoma (HL) cases. Pathological and clinical features differ from classical HL (cHL). Pathologically, the malignant lymphocyte predominant (LP) cells stain consistently positive for CD20 and are negative for CD30. Clinically, NLPHL often has a rather indolent course. Despite of these differences, the first-line treatment of NLPHL is mostly very similar to cHL. However, analyses on the long-term course of patients with NLPHL who were treated identically to cHL are scarce.

Aims: To shed more light on characteristics and outcome of NLPHL patients treated identically to cHL, we performed an analysis using the database of the German Hodgkin Study Group (GHSG).

Methods: A total of 471 patients with NLPHL who had received first-line treatment within the randomized GHSG HD7-HD15 trials for newly diagnosed HL were identified. The studies were conducted between 1993 and 2009. Patients at all stages (early favorable: HD7, HD10, HD12; early unfavorable: HD8, HD11, HD14; advanced: HD9, HD12, HD15) were included.

Results: Among the 471 NLPHL patients, the median age was 39 years; 76% of patients were male; 53% of patients had early favorable, 16% had early unfavorable and 31% had advanced-stage disease. Study treatment consisted of ABVD- or BEACOPP-based chemotherapy alone, radiotherapy (RT) alone or combined-modality treatment (CMT). After a median observation of 9.2 years, the 8-year progression-free survival (PFS) rate for the whole patient group was 81.3% (83.2% for early favorable, 85.2% for early unfavorable, 76.2 for advanced stages). 80 of 471 patients (17%) had refractory disease or relapsed during the course of follow-up (primary disease progression for 56 patients; early relapse: 6 patients). Second malignancies including histological transformation into aggressive B-cell non-Hodgkin lymphoma (NHL) occurred in 48/471 patients (10%) (solid tumor: 25 patients; leukemia: 7 patients; NHL: 13 patients; unspecified malignancy: 4 patients). For all 471 patients included in the present analysis, the 8-year overall survival (OS) rate was 95.1% for early favorable, 98.6% for early unfavorable, 87.4% for advanced stages). A total of 43 deaths were observed during follow-up resulting in a death rate of 9%. However, only a minority of these deaths was NLPHL-related (n=10). In contrast, most patients died from second malignancies (n=20) or due to other causes (n=13) such as heart failure and lung disease.

Summary/Conclusions: Taken together, the results from this large analysis on NLPHL patients prospectively treated and followed within randomized clinical studies for newly diagnosed HL indicate an excellent lymphoma-specific outcome. Nonetheless, further treatment optimization is necessary as the majority of the deaths were caused by second malignancies or other treatment-related late effects. Thus, future clinical trials including NLPHL patients should evaluate whether it is possible to reduce the treatment intensity without compromising efficacy. This goal may be achieved by the partial replacement of conventional chemotherapy by targeted drugs such as anti-CD20 antibodies as well as the reduction of RT fields and doses.

P276

ADVANCED HODGKIN LYMPHOMA IN THE EAST OF ENGLAND CANCER NETWORK: A 10-YEAR COMPARATIVE ANALYSIS OF OUTCOMES FOR ABVD AND ESCALATED-BEACOPP TREATED PATIENTS Aged 16–59

J. Russell1,*, A. Collins2, A. Fowler3, M. Karanth4, C. Saha2, V. Shyamsundar1, S. Docherty1, K. Maw5, J. Padayatty6, A. Hodson7, J. Wimperis2, S. Sadullah5, N. Pugliese1,*, L. Simeone1, R. Della Pepa 1, C. Giordano1, I. Cappuccio1, N. Grigoropoulos1, B. Uttenthal1, G. Follows1
1Hematology, University of Naples Federico II, Naples, 2Department of Medicine and Surgery, University Medical School, Salerno, Salerno, 3Department of Economics, University of Molise, Campobasso, Italy

Background: Advanced HL is a rare entity accounting for approximately 5% of all Hodgkin lymphoma (HL) cases. Pathological and clinical features differ from classical HL (cHL). Pathologically, the malignant lymphocyte predominant (LP) cells stain consistently positive for CD20 and are negative for CD30. Clinically, NLPHL often has a rather indolent course. Despite of these differences, the first-line treatment of NLPHL is mostly very similar to cHL. However, analyses on the long-term course of patients with NLPHL who were treated identically to cHL are scarce.

Aims: To shed more light on characteristics and outcome of NLPHL patients treated identically to cHL, we performed an analysis using the database of the German Hodgkin Study Group (GHSG).

Methods: A total of 471 patients with NLPHL who had received first-line treatment within the randomized GHSG HD7-HD15 trials for newly diagnosed HL were identified. Results: Among the 471 NLPHL patients, the median age was 39 years; 76% of patients were male; 53% of patients had early favorable, 16% had early unfavorable and 31% had advanced-stage disease. Study treatment consisted of ABVD- or BEACOPP-based chemotherapy alone, radiotherapy (RT) alone or combined-modality treatment (CMT). After a median observation of 9.2 years, the 8-year progression-free survival (PFS) rate for the whole patient group was 81.3% (83.2% for early favorable, 85.2% for early unfavorable, 76.2 for advanced stages). 80 of 471 patients (17%) had refractory disease or relapsed during the course of follow-up (primary disease progression for 56 patients; early relapse: 6 patients). Second malignancies including histological transformation into aggressive B-cell non-Hodgkin lymphoma (NHL) occurred in 48/471 patients (10%) (solid tumor: 25 patients; leukemia: 7 patients; NHL: 13 patients; unspecified malignancy: 4 patients). For all 471 patients included in the present analysis, the 8-year overall survival (OS) rate was 95.1% for early favorable, 98.6% for early unfavorable, 87.4% for advanced stages). A total of 43 deaths were observed during follow-up resulting in a death rate of 9%. However, only a minority of these deaths was NLPHL-related (n=10). In contrast, most patients died from second malignancies (n=20) or due to other causes (n=13) such as heart failure and lung disease.

Summary/Conclusions: Taken together, the results from this large analysis on NLPHL patients prospectively treated and followed within randomized clinical studies for newly diagnosed HL indicate an excellent lymphoma-specific outcome. Nonetheless, further treatment optimization is necessary as the majority of the deaths were caused by second malignancies or other treatment-related late effects. Thus, future clinical trials including NLPHL patients should evaluate whether it is possible to reduce the treatment intensity without compromising efficacy. This goal may be achieved by the partial replacement of conventional chemotherapy by targeted drugs such as anti-CD20 antibodies as well as the reduction of RT fields and doses.

P277

IMPACT ON SURVIVAL OF EARLY DETECTION OF RECURRENCE IN THE FOLLOW-UP OF HIGH RISK HODGKIN LYMPHOMA IN FIRST COMPLETE REMISSION

N. Pugliese1,*, L. Simeone1, R. Della Pepa1, C. Giordano1, I. Cappuccio1, I. Zacheo1, G. Campagna1, C. Cerchione1, P. Zeppez1, C. Salvatore3, F. Pane1, M. Picardi1
1Hematology, University of Naples Federico II, Naples, 2Department of Medicine and Surgery, University Medical School, Salerno, Salerno, 3Department of Economics, University of Molise, Campobasso, Italy

Background: Despite the high complete response (CR) rate to anthracycline-including first-line therapy, approximately one-third of patients with advanced-stage Hodgkin lymphoma (HL) relapses. Many relapses (30–50%) are clinically asymptomatic, without any physical and/or laboratory signs. For patients at high-risk of relapse, a close monitoring, based on imaging procedures is justified if an early detection of recurrence would allow a timely administration of salvage therapy and a survival improvement.

Aims: The purpose of this study was to evaluate the response rate to salvage therapy of relapsed HL by comparing patients who received surveillance with conventional clinical assessments versus patients who received surveillance with imaging procedures. The primary end-point was to assess the rate of CR to salvage therapy at first relapse (confirmed by FDG PET/CT performed before A1402 trial): the first analysis will be performed after 130 patients have been enrolled. The study has been approved by the Institutional Review Board.

Methods: Between June 2001 and December 2009, we analyzed 306 patients with high-risk HL in CR after anthracycline-including induction treatment. In this case-control study, the first cases (n=150) consisted of patients who received a conventional follow-up program including symptom assessment, blood tests and physical examination; in these patients imaging procedures were performed only in case of suspected relapse (Historical group). Subsequent patients (n=156) received routine imaging procedures comprising ultrasonography, chest radiographs, bone scan, abdominal, and pelvic lymph nodes (SMAP US), and chest radiography (CXR), as integrated part of the follow-up strategy (Imaging group). Follow-up procedures were performed at 4, 8, 12, 16, 20, 24, 30, 36, 48, 60, 84, and 108
months after treatment discontinuation in both groups. Relapses were documented by histologic examination in both groups. When relapse was documented all patients received salvage therapy with high dose chemotherapy (DHAP), for at least two courses, followed, in case of CR, by ASCT.

**Results:** After a median 62-months observation (range, 4–108), 83 patients, evenly distributed in the two groups, had a relapse of disease. Of these, 29 of 43 patients (67.4%) of the historical cohort vs 17 of 40 patients (42.5%) of the imaging cohort, showed a larger spread of disease at restaging, i.e. stage superior to IIb, and a more frequent extranodal involvement, 10/43 (23.3%) patients in the historical group vs 3/40 (7.5%) patients in the imaging group (p=0.01).

Furthermore, if we considered only asymptomatic patients, one recurrence was detected in 26 of 43 patients in the imaging group and 17 of 40 patients in the historical group, p=0.02. CR rate with second line therapy were higher in the imaging group (27, 67.5%) compared with the historical group (19, 44.2%; p=0.032). The 3-years DFS was 75% in the imaging group and 36% in the historical group, p=0.03.

**Summary/Conclusions:** This is the first prospective case-control study using SMAP-US plus CXR to monitor patients with advanced stage HL. We show that SMAP-US plus CXR is a valuable tool to improve follow-up in patients with a high risk of recurrence. Our data indicate that the early detection of HL recurrence allows to begin rescue therapy in patients with a more limited disease and, consequently, increase its effectiveness in terms of probability to response and DFS.

**P278**

**LATER LINE DRUG TREATMENT PATTERNS OF CLASSICAL HODGKIN’S LYMPHOMA PATIENTS IN CANADA, FRANCE, GERMANY AND THE UNITED KINGDOM.**

K. Byrne¹, A. Juarez Garcia², P. Hallworth¹, S. Blackburn¹, M. Lees³

¹Adelphi Real World, Bollington, United Kingdom, ²WW HEOR, Bristol-Myers Squibb, Mexico City, Mexico, ³WW HEOR, Bristol-Myers Squibb, Paris, France

**Background:** Whilst cHL is seeing increasing ‘cure’ rates, a cohort of patients remain who, due to multiple relapses, require 3rd or 4th line (4L) lines of drug treatment. Real world treatment patterns for RRHL patients are currently less understood.

**Aims:** To understand the drug treatment patterns of cHL patients in 3rd or later line.

**Methods:** Real-world data were collected through a cross-sectional survey administered to physicians in Canada (Ca), France (Fr), Germany (Ge), and the UK between May and Sep 2016. Physicians provided data on the last 8 cHL patients receiving 3rd or 4th line drug treatment. Data captured included demographics, disease history and treatment patterns. Auto/allo stem cell transplants (auto/alloSCT) were not classified as a treatment line and limited data was available to determine when a SCT was received. Summary statistics were reported and differences between sub-groups assessed using chi-square tests.

**Results:** In total 116 physicians (Ca, 16; Fr, 31; Ge, 44; and UK, 25) provided information on 959 cHL patients (Ca, 128; Fr, 243; Ge, 351; and UK, 237) on 3rd or later lines of drug treatment. Data for 954 cHL patients on 3rd line drug treatment was captured. Patients had a mean age of 54.0 years (SD: 16.79) at the point of data capture. 57% were male, 43% female. 30% had bulky disease. 84% of patients had been tested for the Epstein Barr virus (EBV), 36% confirmed as positive. The most commonly prescribed 3rd line drug treatment was a brentuximab-vedotin (BV) based regimen (35%). BV use was significantly different across the markets; Canada (34%), France (35%, Germany (30%) and the UK (44%) (p<0.010). The next most commonly prescribed 3rd line treatments were DHAP (8%), BEAM (7%) and bendamustine (7%), 4% of 3rd line patients received a PD-1 inhibitor. Of 3rd line BV patients the majority received ABVD (69%) or BEACOPP (19%) at 1st line. Their most common 2nd line drug treatments were DHAP (21%), ICE (10%), ESHAP (9%) and BEACOPP (9%). 59% of all 3rd line BV patients had undergone an auto/alloSCT at some point during their treatment history. Of 3rd line patients receiving non-BV-based regimens 6% had been treated with BV previously (1st or 2nd line). Of 3rd line patients treated with a PD-1 inhibitor 7% had been previously treated with BV. For 453 cHL patients on 4th line drug treatment was captured. 4th line patients had a mean age of 55.5 years (SD: 16.79) at the point of data capture. 56% were male, 44% female. 83% had been tested for EBV, 38% confirmed as positive. 30% of 4th line patients received a BV based regimen – BV use across markets was significantly different; Canada (20%), France (38%), Germany (23%) and the UK (36%) (p=0.007). At 3rd line this cohort had most commonly received DHAP (16%), BEAM (15%) or ICE (11%). 5% of 4th line BV patients also received a BV based regimen at 1st line. 12% of 4th line patients had received a BV regimen at 3rd line. At 4th line 38% of this cohort received a PD-1 inhibitor, 19% bendamustine and 9% gemcitabine.

**Summary/Conclusions:** Real-world data indicates an unmet medical need for cHL patients with multiple relapses, reinforced by the use of PD-1 inhibitors in those relapsing post BV based regimen at 3rd line. There also appears to be no clear standard of care at 3rd line, again highlighted by use of a range of regimens and PD-1’s.

*This study was sponsored by Bristol-Myers Squibb.*
results of our study strongly suggest that BV improves OS in patients with HL relapsed after auto-SCT. To our knowledge this is the first study showing an OS advantage of treatment with BV.

The following variables were included in a multivariate Cox proportional hazard regression analysis model: 1) age of patient, 2) Sex, 3) B-symptoms (yes vs no), 4) Stage of disease (II vs III-IV), 5) extralymphatic disease, 6) time from auto-SCT to relapse (≤12 vs >12 months), 7) relapse before or after BV availability (Cohort 1 vs Cohort 2). In order to exclude any confounding effect of subsequent treatments, analysis was performed by censoring patients at the time of post-auto-SCT relapse. In order to examine the impact of BV on OS, patients were divided in 2 cohorts depending of the date of BV availability (Cohort 1 vs Cohort 2). In order to exclude any confounding effect of subsequent treatments, analysis was performed without censoring patients at the time of post-auto-SCT relapse.

### Summary/Conclusions

Patients in Cohort 2 survived longer even when censored for allo-SCT or treatment with IC-inhibitors. All patients in Cohort 2 treated with BV while only 18% of patients in Cohort 1 received treatment with BV. The

### Background

Patients with Hodgkin Lymphoma (HL) who relapse after autologous Stem Cell Transplantation (auto-SCT) have a dismal prognosis. Advanced disease stage, presence of B-symptoms, extranodal involvement at the time of relapse and duration of remission of less than 12 months are parameters associated with decreased overall survival (OS). Brentuximab Vedotin (BV), an anti-CD30 monoclonal antibody conjugated to a microtubule-disrupting agent, has shown clinical efficacy in HL. Although in the setting of post-auto-SCT relapse, BV produces an overall response rate of approximately 75% with a median progression free survival (PFS) of 9 months, the impact of BV on OS has not been addressed in previously published studies.

### Aims

To examine the impact of treatment with BV on OS of patients with HL relapsed after auto-SCT.

### Methods

Data for patients with HL who underwent auto-SCT in Greece during the last 20 years were collected. Study group consisted of 214 patients who experienced post-auto-SCT relapse. In order to examine the impact of BV on OS, patients were divided in 2 cohorts depending of the date of BV availability in Greece (January/2013). Cohort 1 consisted of 178 patients who relapsed before January/2013, while Cohort 2 consisted of 36 patients relapsed after BV became available. Patient’s characteristics are shown in Table 1.
tion was defined as imaging at or before week 12 of treatment, whereas late radiological evaluation was performed at or after week 16. Response evaluation was performed according to the Lugano Classification and its update regarding immunomodulatory therapy.

Results: Between 06/2015-11/2016, 87 patients were enrolled in a name-based program in Turkey. Two, 19, and 3 patients who had not yet received nivolumab, had not reach the time for early radiological evaluation, and who died before any radiological evaluation were excluded from the analysis. Thus, 63 patients from 23 centers were retrospectively analyzed. Median follow-up was 6 months, median age was 29 (18-75) and patients had a median 5 (2-11) previous lines of therapy. 44 patients (70%) had been treated by stem cell transplantation (SCT) and 48 (76%) patients had been treated by GV. The ORR was 66% with 15 CR (95%CI 0.020-0.028; CR 26%, PR 42%, SD 12%, PD 20%) among 59 patients evaluated in 12 weeks of nivolumab treatment. The ORR was 67% with 9 (24%) patients with CR after 16 weeks of treatment (95%CI 0.004-0.26; CR 24%, PR 43%, SD 6%,PD 27%). Estimated OS was 95% (95%CI 0.80-0.98) and estimated PFS was 71% (95%CI 0.55-0.82) at 12-months. Median OS was not reached, while, according to the late response rates, the median PFS was 14 months. However, it was only 3 months in patients with PD at the late radiological evaluation. Regarding responses to last treatment prior to nivolumab, we detected that 28 (67%) of 42 PD cases had objective early responses and 70% of PD cases had ORR in the late response evaluation (CR in 4, PR in 12 pts). 8 patients underwent transplantation following nivolumab. Among 5 patients who had been treated by allo-SCT, 4 had CR at the time of transplantation and they are alive with ongoing response. Safety profile was acceptable and only two patients required cessation of nivolumab due to serious adverse events: one due to autoimmune encephalitis and one due to aggravation of graft versus host disease. At the time of analysis, 40 cases were still on nivolumab treatment (64%). Among the 40 cases with early objective responses to nivolumab, 35 (88%) showed ongoing objective responses. All 24 cases with objective responses in the late evaluation had ongoing responses at the time of analysis (Figure 1).

Results: In newly diagnosed cHL, genotyping of plasma cfDNA identified non-synonymous somatic mutations in STAT6 (43%), TNAIP3 (43%), ITPKB (32%) B2M (21%), GNA13 (14%), CIITA (7%), XPO1 (7%) and CD58 (4%) among the most recurrently affected genes (Figure 1A-B). In refractory cHL patients, genotyping of plasma cfDNA identified non-synonymous somatic mutations in ITPKB (44%), TNAIP3 (33%), KMT2D (33%), B2M (33%), GNA13 (33%), XPO1 (22%), TET2 (22%), IKBKB (22%), BIRC3 (22%) and STAT6 (22%) among the most recurrently affected genes. Mutations of KMT2D (33%) and TET2 (22%) were enriched in refractory chL patients compared to newly diagnosed cases, suggesting that they contribute to the chemorefractory phenotype (Figure 1C-D). Using high sensitivity techniques, most of the mutations discovered in cfDNA were also identified in pair tumor DNA from the tissue biopsy and/or macrodissected RS cells, thus confirming their tumor origin (Figure 1F). By pathway analysis, the mutational profile pointed to the involvement of PI3K/AKT signaling, GSK3beta signaling, NF-kB signaling and the immune escape in cHL. ITPKB (a negative regulator of the PI3K/AKT signaling pathway) was specifically mutated in cHL across aggressive B cell lymphomas.

Figure 1.

Summary/Conclusions: In conclusion PD-1 blockers are new options to meet the unmet need in patients with chL refractory to BV treatment, and possibly a bridge for these patients before transplantation.

P282

GENOTYPING OF HODGKIN LYMPHOMA ON THE LIQUID BIOPSY

V. Spina1,*, A. Bruscaggin1, M. Di Trani2, M. Martini3, S. Locatelli2, E. Cupelli4, C. Deambrogi6, F. Diop6, G. Stüssi 5, F. Cavalli5, F. Bertoni1,5, E. Zucca 5, G. Forestieri 1, A. Condoluci 1,5, A. Cuccaro 4, A. Moccia 5, A. Stathis 5, O. Spina1, Institute of Oncology Research, Bellinzona, Switzerland, 2Department of Oncology and Haematology, Humanitas Cancer Center, Humanitas Clinical and Research Center, Milan, 3Division of Pathology and Histology, 4Institute of Hematology, Catholic University of the Sacred Heart, Rome, Italy, 5Oncology Institute of Southern Switzerland, Bellinzona, Switzerland, 6Division of Hematology, Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy

Background: In classical Hodgkin lymphoma (cHL) the low representation (1-5%) of Reed-Sternberg cells (RS) challenged tumor genotyping on the diagnostic tissue biopsy. Consistently, the mutational profile of newly diagnosed cHL is poorly characterized, and the genetics of refractory disease is completely unknown. Cell free DNA (cfDNA) is shed into the blood by tumor cells undergoing apoptosis and can be used as source of tumor DNA for the identification of somatic mutations. In addition cfDNA is representative of the entire tumor heterogeneity, thus allowing the identification of mutations from tumor cells residing in non-biopsied sites.

Aims: This study aims: i) to providing the evidence that the mutational profile of cHL can be tracked by using plasma cfDNA; and ii) at characterizing the genetics of newly diagnosed cHL and, for comparative purposes, of refractory chL.

Methods: The study incudes 28 newly diagnosed cHL and 9 chemorefractory cHL. All cases were provided with cfDNA from plasma collected at baseline, before treatment start, and paired DNA from granulocytes as source of germline DNA to filter out polymorphisms and sequencing noise. Paired genomic DNA from formalin fixed paraffin embedded (FFPE) tumor tissue biopsies was available for 17 patients, including 3 cases for which RS enriched areas were macroadsected. A targeted resequencing panel optimized to include the coding exons and splice sites of 77 genes (192Kb) that are recurrently mutated in B-cell lymphomas was used for genotyping. Libraries were prepared from plasma cfDNA, germline gDNA and tumor gDNA according to the CAPP-seq targeted enrichment strategy (Nimblegen) and subjected to ultra-deep-next generation sequencing (NGS) on the MiSeq platform (Illumina). The sequencing was tailored to obtain a depth of coverage >2000x in >80% of the target region in all samples, which allowed a sensitivity of 3x10^-3. The somatic function of VarScan2 was used to call non-synonymous somatic mutations, and a stringent bioinformatic pipeline was applied to suppress the background noise and to filter out sequencing errors.

Results: In newly diagnosed cases, genotyping of plasma cfDNA identified non-synonymous somatic mutations in STAT6 (43%), TNAIP3 (43%), ITPKB (32%) B2M (21%), GNA13 (14%), CIITA (7%), XPO1 (7%) and CD58 (4%) among the most recurrently affected genes (Figure 1A-B). In refractory chL patients, genotyping of plasma cfDNA identified non-synonymous somatic mutations in ITPKB (44%), TNAIP3 (33%), KMT2D (33%), B2M (33%), GNA13 (33%), XPO1 (22%), TET2 (22%), IKBKB (22%), BIRC3 (22%) and STAT6 (22%) among the most recurrently affected genes. Mutations of KMT2D (33%) and TET2 (22%) were enriched in refractory chL patients compared to newly diagnosed cases, suggesting that they contributed to the chemorefractory phenotype (Figure 1C-D). Using high sensitivity techniques, most of the mutations discovered in cfDNA were also identified in pair tumor DNA from the tissue biopsy and/or macrodissected RS cells, thus confirming their tumor origin (Figure 1F). By pathway analysis, the mutational profile pointed to the involvement of PI3K/AKT signaling, GSK3beta signaling, NF-kB signaling and the immune escape in cHL. ITPKB (a negative regulator of the PI3K/AKT signaling pathway) was specifically mutated in cHL across aggressive B cell lymphomas.

Figure 1.

Summary/Conclusions: This study provides the evidence that cHL can be genotyped using plasma cfDNA as source of tumor DNA, pointed to a non-overlapping genotype between newly diagnosed and refractory cases, and identified ITPKB as a new gene specifically involved in ~30-50% of cHL patients.
Background: Doxorubicin (DXR) induced cardiotoxicity is related to several mechanisms, including interference of mitochondrial respiratory chain and acceleration of glycolysis. We previously reported that this treatment may enhance myocardial FDG uptake.

Aims: The present study aimed to verify whether this metabolic response on serial PET/CT imaging can predict myocardial function, non-invasively evaluated by follow-up echocardiography (ECHO).

Methods: 18F-FDG PET/CT of 25 patients affected by Hodgkin Disease (HD), treated following ABVD scheme were analyzed. Inclusion criteria were: 1) availability of 4 consecutive PET/CT scan for staging (PET1), interim (PET2), post-therapy (PET3) and six months follow-up evaluation (PET4); 2) full remission after two ABVD cycles; 3) normal baseline EKG and ECHO findings and 4) no concurrent treatment with external thoracic radiotherapy. A volume of interest was manually drawn on the left ventricular myocardium. Average standardized uptake value within this region was normalized for the corresponding blood pool index measured in the inferior vena cava to obtain LV-SUV. All patients uptake value within this region was normalized for the corresponding blood pool index measured in the inferior vena cava to obtain LV-SUV. All patients showed signs or symptoms potentially related to DXR cardiotoxicity.

Results: LV-SUV progressively increased from PET1 to PET4 in 6 patients (24%, 2 females, mean age 39±17, termed “increasers”) being 1.34±0.9, 3.34±2.6, 4.32±2.8 and 4.43±1.5 respectively. In the remaining 19 patients (76%, 7 females, 36±14), FDG uptake showed a largely variable response without any progressive increase. Accordingly, the ratio between PET4 and PET1 LV-SUV in the two subgroups was 3.05±0.8 and 1.06±0.4, respectively (p<0.001). Up to six months after therapy discontinuation, none of the 26 patients showed signs or symptoms potentially related to DXR cardiotoxicity. However, late follow-up ECHO detected the appearance of first-degree diastolic impairment in respect with baseline in 9 of the 25 examined patients (36%, 4 females, mean age 36±18). This finding occurred in 5/6 “increasers” (83%) and in only 4/19 non-increasers (21%) (p<0.001).

Summary/Conclusions: The present data indicate that DXR related myocardial damage can be preceded by an enhanced glucose uptake. 18F-FDG PET/CT imaging might represent a useful tool to identify high-risk patients and to implement personalized program to monitor and prevent DXR-induced cardiotoxicity.
METHODS: A retrospective pre-post cohort study was conducted in pts switching from DFX DT to FCT using pharmacy and medical claims (06/2014 - 05/2016) from the Symphonie Health Solutions’ Integrated Dataavater (IDB®) database. Eligible pts were ≥2 years old, had a diagnosis of an inherited or acquired hematological disorder requiring transfusions (e.g., sickle cell disease, myelodysplastic syndrome), ≥2 DFX DT claims (1st claim= Index date), ≥2 DFX dose claims, and 56 months of continuous clinical activity (i.e., ≥2 claims in pre-index, and ≥2 claims in the DFX period) pre-index. Medication possession ratio (MPR) (percentage of time with access to medication) was computed for DFX DT during the “DFX DT period” (from earliest DFX DT claim to index date) and for DFX FCT during the “DFX FCT period” (from Index date to end of data availability/ICT switch). Proportion of days covered (PDC) and persistence (without a gap ≥30 or 60 days between claims) were assessed in the DFX DT and DFX FCT periods over fixed intervals of 3 and 6 months, which started from the index date in the DFX FCT period, or dispensing date of the most recent DFX DT claim prior to the beginning of the 3- or 6-month interval in the DFX DT period. Comparisons between the two periods were done using Wilcoxon sign-rank test for continuous data and McNemar’s test for dichotomized data.

RESULTS: Of the 606 eligible pts, 56% were female, 64% were <35 years old, and 42% had transfusions during the baseline period. The median durations of the DFX DT and DFX FCT periods were 355.0 days and 290.2 days, respectively. Compared with adherence to DFX DT, adherence to DFX FCT was significantly improved across all measures. Mean MPR of DFX DT vs DFX FCT was 0.80 vs 0.76 (p<0.001); 60.9% pts had a mean MPR ≥0.8 during the DFX FCT period compared to 54.3% during the DFX DT period (p<0.01). Mean 3-month PDC of DFX DT vs DFX FCT was 0.83 vs 0.71 (p<0.001); 50.0% pts had mean 3-month PDC ≥0.8 during the DFX FCT period compared to 34.5% during the DFX DT period (p<0.001). The proportion of pts with 3-month persistence to DFX DT vs DFX FCT (without a gap ≥30 days) was 87.2% vs 63.4% (p<0.01). Similarly consistent and significant results for PDC and persistence were observed using a 6-month time interval and/or a 60-day gap between claims.

Summary/Conclusions: Adherence and persistence to ICT was significantly improved in pts who switched from DFX DT to DFX FCT. Reasons for switching, which may contribute to improved adherence, were not examined in this study. Nevertheless, since the majority of pts were already adherent to DFX DT, the improved persistence and adherence to DFX FCT can be further augmented with this formulation. This real-world study complements the ECLIPSE trial results and supports previous evidence of improved adherence to DFX FCT.

P287 ASSESSMENT OF THE PERFORMANCE OF A WIDELY AVAILABLE T2*/R2* LIVER IRON CONCENTRATION METHOD USED IN CLINICAL PRACTICE IN A POPULATION OF THALASSEMIA PATIENTS. "A.T. Taher1,*, R. Origa2, S. Perrotta3, A. Kouraklis4, K. Belhoul5, V. Huang6, N. Anh Tri2, B. Quoc Khanh2, M. House3, W. Pang4, S. Boulos4, T. St Pierre3,1. 1Radiology Department, Bach Mai Hospital, 2National Institute of Haematology and Blood Transfusion, Hanoi, Vietnam, 3School of Physics, The University of Western Australia, Crawley, 4Resonance Health, Claremont, Australia.

Background: Measurements of liver iron concentration (LIC) by magnetic resonance imaging (MRI) have become established and validated in several research intensive centers. While the validity of spin density projection assisted (SDPA) R2-MRI together with a core laboratory service has been validated in routine clinical practice settings, methods relying on in-house liver iron acquisition protocols and data analysis have not yet been validated in this way.

Aims: To determine the limits of agreement between measurements of LIC by a widely available T2*/R2* MRI method and a reference standard SDPA R2-MRI method in a routine clinical practice setting.

Methods: Pts (N=300) referred by the National Institute of Haematology and Blood Transfusion, Hanoi, Vietnam for routine LIC measurement by MRI were prospectively recruited with informed consent. Patients were randomized to be scanned in either a Philips Ingenia or a Siemens Avanto 1.5T scanner. The LIC of each patient was measured twice, once by a T2*/R2* technology using freely available software and protocols (Iron Health Calculator: http://www.ironcalculator.com) and once by SDPA R2-MRI using a quality controlled core laboratory data analysis service (FerrScan®). Analyses using the T2*/R2* data analysis method were blinded from the SDPA R2-MRI results and vice versa. Reported data were analysed using the statistical methods of Bland and Altman.

Results: A plot of the T2*/R2* LIC against the SDPA R2-MRI LIC (Figure 1) shows the vast majority of the data falling below the line of equivalence indicating that the T2*/R2* method is underestimate the LIC relative to the SDPA R2-MRI validated reference standard. The geometric mean ratio of T2*/R2* LIC to SDPA R2-MRI LIC was 0.44 (95% CI 0.36–0.55) indicating severe underestimation of LIC by the T2*/R2* method. The geometric mean ratios of the two LIC measurements were significantly different for the two scanners (0.28 for Philips and 0.68 for Siemens, p < 0.0001) indicating that the bias of the T2*/R2* method against the reference standard is not universal but is dependent on both/either scanner type and/or data acquisition method. Bland Altman analysis indicates that 95% of pairs of measurements are predicted to have ratios between 3.73 and 0.05 indicating a very large random variation between the T2*/R2* method and the reference standard. The performance of the T2*/R2* method in predicting SDPA R2-MRI LIC values above the clinically relevant thresholds of 7 and 15 mg Fe/g dw is characterized in the Table 1 showing the model adjusted for hypothesized mediators to an unadjusted model (Lin DY, et al. Stat Med. 1997), was used to compute proportion mediated (PM). PM quantifies how much of the association between tx with DFX FCT versus DT and SF reduction from baseline is operationalized through pt-reported adherence scores, other PRO scores, and frequency of GI-related AEs during tx. The analysis was adjusted for confounders including age, sex, race, underlying hematological disease, prior use of DFX DT, baseline level of iron overload severity, average planned dose, and number of blood transfusions on tx. Sensitivity analyses were conducted in subgroups of pts who had prior use of DFX DT, the improvement with DFX-FCT suggests that ICT can be further aug-

Table 1.
Mean (SD) duration of deferasirox exposure in group A was 7.5 (1.7) years; mean daily deferasirox dose was 43.6 mg/kg.
In both subgroups analyzed, mean SCr was within normal limits and remained stable over time during the retrospective period (Figure 1). Analysis in adults showed mean SCr values were stable over time. As expected in growing children who are gaining height and weight, pediatric mean SCr absolute values increased from baseline in proportion with an almost linear increase in muscle mass over time.

Figure 1.

Summary/Conclusions: The data indicate that the T2*/R2* method of measurement of LIC is not safe for routine clinical measurement of LIC because of the extremely poor NPVs which could result in inappropriate clinical decision making. The severe discrepancies of the T2*/R2* method from the reference standard are likely caused by several factors including non-optimal curve fitting algorithms, lack of a method to identify non-analysable data, and the use of a calibration curve from the literature generated from data acquisition and analysis methods different from those used locally. These or similar pitfalls are likely to be encountered in many MR centres using non-regulated MR methods of LIC measurement.

P288

SIMILAR TRENDS IN RENAL FUNCTION AS MEASURED BY SERUM CREATININE DURING LONG-TERM IRON CHELATION TREATMENT WITH OR WITHOUT DEFERASIROX IN PATIENTS WITH TRANSFUSIONAL HEMOSIDEROSIS

R. Origa1,*, A. Piga2, I. Tartagliona3, G. Della Corte4, A. Bruedeler5, J. Han6, C. Castiglioni7, G. L. Forni for Renal Chart Review Study Investigators8
1Ospedale Pediatrico Microcitemico ’A Cao’, University of Cagliari, Cagliari, Italy, 2Novartis Pharma AG, Basel, Switzerland, 3Novartis Farma SpA, Origgio, Italy, 4Ospedale Galliera, Genoa, Italy, 5Novartis Pharmaceuticals Corporation, East Hanover, United States, 6Novartis Farma SpA, Origgio, Italy, 7Novartis Farma SpA, Origgio, Italy, 8Ospedale Galliera, Genoa, Italy

Background: Regular transfusion and iron chelation therapy (ICT) are often indicated for patients with β thalassemia, sickle cell disease (SCD) and other anemias, and can be lifelong requirements. As most patients now survive into adulthood and many experience prolonged exposure to ICT, there is increased risk of age-, disease- or drug-related complications, including changes in renal function. Evidence suggests that some patients receiving ICT experience changes in markers of renal function, mostly within normal limits, non-progressive and reversible with dose reduction and/or interruption. Recently, we reported a retrospective analysis of patients with transfusion-dependent anemias during a decade of deferasirox treatment indicating stable and a lack of any progressive worsening of renal function (Origa R et al. Blood 2016).

Aims: To assess serum creatinine (SCr) during long-term deferasirox treatment in subgroups of Italian patients with transfusional hemosiderosis who participated in the deferasirox registration studies and were then followed retrospectively.

Methods: Italian patients with β thalassemia, SCD, myelodysplastic syndromes or other anemias who received ≥1 deferasirox dose in the registration studies (studies 105, 106, 107, 108 or 109), had ≥1 post-baseline (BL) SCr measurement, and had medical records available were included. SCr values were collected retrospectively in 3-month periods from registration trial end until the last patient assessment. Primary endpoint was SCr over time. SCr values during the retrospective period were evaluated by subgroups: here we report those who received only deferasirox and those who received no deferasirox but other ICT during the retrospective period.

Results: 282 patients were included in the retrospective study who received ≥1 deferasirox dose in registration studies; of these, during the retrospective period, 98 (35%) received only deferasirox (group A) and 82 (22%) received no deferasirox but other ICT (group B). In group A, mean (SD) age at first quarter was 25.9 (12.1) years and 36 (37%) were male; in group B, mean (SD) age at first quarter was 27.0 (10.9) years and 25 (40%) were male. The proportion of pediatric patients was 28% (n=27) in group A and 19% (n=12) in group B.
Methods: A cohort of 25 well-characterized patients was analyzed. Eighteen were initially referred to our center for unexplained hyperferritemia (HF), two for proven iron overload (IO) by MRI, 2 for chronic hemolysis and 3 for aregenerative anemia. A set of phenotypic tests was systematically assessed, including CBC, reticulocyte count, serum haptoglobin and measure of the Liver Iron Content (LIC) by MRI. For all patients with HF, causes linked to hepatic disease, inflammation or malignancies were ruled out and screening for transfusional iron overload was also performed. Phenotypic investigations failed to clearly identify the cause of the disorder. Therefore, each patient was tested for a panel of 32 genes involved either in iron homeostasis or hereditary anemias, using NGS. Libraries were obtained using the Custom SureSelectXT OX Variant Enrichment system (Agilent, Santa Clara Ca USA) and sequenced on a MiSeq platform (llumina, San Diego, Ca, USA). Each deleterious variant was independently checked using conventional Sanger sequencing. Written informed consent was obtained from all the patients for NGS genetic analyses.

Results: Initial phenotypic reassessment allowed classifying the patients into 5 different groups: 1) isolated hyperferritemia (n=11), 2) HF and IO (MRI >90 µmol/g dry weight) (n=17); 3) hemolytic anemia (HA) without IO (n=2); 4) HA and IO (n=2); 5) aregenerative anemia with IO (n=3). Among patients with an initial diagnosis of iron disorder, the reticulocyte count identified 2 undiagnosed chronically fully compensated hemolytic anemias. Systematic screening using the gene panel identified a total of 14 sequence variations of clinical significance in 9 different genes and 9 patients. An isolated mutation was found in 7 and 2 patients with an initial diagnosis of iron or of red cell disorder respectively. A combined anomaly of red cell and iron genes was identified in 3 patients who displayed IO and compensated hemolysis or anemia. Digestion involving an HFE C282Y or C282Y/H63D genotype and another “iron gene” was also shown in 3 patients with IO (without anemia or hemolysis). No sequence variation of clinical significance was found in the sequenced genes of eleven of the studied patients.

Summary/Conclusions: On the phenotypic point of view, the present study highlights the importance to check for hematological data (CBC and reticulo-cytes) in patients with HF, because this can allow discovering fully compensated hemolysis and bringing towards a red cell disorder. On the other hand, it also underlines the importance to systematically check for IO all patients with a red cell disorder, who may display high LIC. Our present genotypic data (and previous ones) suggest a relative frequency of combined inherited disorders of iron and red cells, making the combined search for both disorders quite relevant in clinical practice. This is now possible with the use of NGS analysis, which allows sequencing large numbers of genes. For those patients with no identified mutation, approaches using whole exome or genome can be proposed as the next step.

P290
CHANGES IN LIVER IRON CONCENTRATION R2 MRI MEASUREMENT ACROSS DIFFERENT CHELATION REGIMENS IN PATIENTS WITH HEMATOLOGICAL DISORDERS: REAL-LIFE EXPERIENCE FROM LICNET

Background: The liver plays a central role in iron regulation and remains the primary site of iron storage, with liver iron concentration (LIC) being a strong surrogate of total body iron. Both R2 and T2* can accurately measure LIC. R2 MRI provides the opportunity to characterize the frequency of combined hereditary disorders of iron and red cells, making the combined search for both disorders quite relevant in clinical practice. This is now possible with the use of NGS analysis, which allows sequencing large numbers of genes. For those patients with no identified mutation, approaches using whole exome or genome can be proposed as the next step.

Results: A total of 130 patients were evaluated in this analysis, with a median age of 35 years (range: 6–78) and including 60 (46.2%) men. The underlying diagnoses were regularly transfused thalassemia major (n=86, 66.2%), thalassemia Intermedia (n=33, 25.4%), sickle cell disease (n=6, 4.6%), myelodysplastic syndrome (n=3, 2.3%), and Diamond-Blackfan anemia (n=2, 1.5%). The median duration (range) between the first and second MRI was 483 days (184–1076) and was comparable between iron chelation regimens. Median pre-transfusion hemoglobin level and blood requirement were similar at both MRIs. The median change in LIC (range) in mg Fe/g dw was not significant in patients receiving DFP (n=29, median change -1.9, p=0.55), DFX (n=52, median change -0.5, p= 0.515), DFO+DFP (n=10, median change -2.2, p=0.074), or other combinations (n=7, median change -1.3, p=1,000), while it decreased significantly on DFO monotherapy (n=32, median change -1.4,p=0.002). Among oral chelators, DFX showed to be more effective, during the period of the study, in stabilizing iron body burden in 65.4% patients even if they had baseline LIC values <7mg Fe/g dw (median 4.0 mg Fe/g dw) and with similar response as combined treatment DFO+DFP (Figure 1).

Summary/Conclusions: This cohort study suggests that stabilization of LIC is achievable, during a median of 483 days, with different iron chelation regimens in real life experience, with considerable proportions of patients shifting to more favourable LIC categories. Therefore, the periodic evaluation of LIC by MRI has to be strongly recommended for management and prevention of iron overload and subsequent complications in haematological disorders.
Summary/Conclusions: IDA during late pregnancy adversely affects cord blood iron and hearing status. ABR results are closely related to the severity of maternal and neonatal iron status. Antenatal screening of pregnant mothers is needed to improve fetal iron status and prevent abnormal auditory maturation.

P292

THE RELATIONSHIP BETWEEN SERUM FERRITIN AND LIVER IRON CONCENTRATION IN PEDIATRIC CANCER SURVIVORS

M. House1,2, K. Sadak1, J. Lee1, A. Smith1, T. St. Pierre1,2

1Resonance Health, Claremont, 2School of Physics, The University of Western Australia, Crawley, Australia, 3Dept. of Pediatrics, University of Minnesota, Minneapolis, United States

Background: There is increasing recognition that pediatric cancer survivors are at risk of transfusion-related iron overload related to intensive treatment regimes and improved survival rates. Current screening approaches rely on serum ferritin (SF). However, little is known about the SF to liver iron concentration (LIC) relationship in pediatric cancer survivors and whether SF thresholds derived from other iron overload disorders or age groups are appropriate.

Aims: The aim of this study was to investigate the relationship between SF and LIC in pediatric cancer survivors and to determine SF thresholds for predicting clinically significant LICs in this patient group.

Methods: In this retrospective study, patient data were extracted on survivors with elevated ferritin or iron overload from the University of Minnesota Childhood Cancer Survivor Program research database. All patients were enrolled into the database via an informed consent process according to the guidelines of the University of Minnesota Institutional Review Board. Survivors were retrospectively selected once they reached 18 years of age. Seventeen individual survivors were identified where both SF and LIC data were available and the time between the SF and LIC measurement was less than 30 days. Eleven of the 17 survivors had multiple SF measurements producing a final dataset with 34 pairs of SF and LIC measurements. Blood for serum ferritin was collected during an inpatient clinic visit and analyzed by the University of Minnesota Medical Center, Fairview CLIA-certified clinical laboratory. Liver iron concentration measurements were made using spin density projection-assisted R2-MRI (FerriScan®). Linear regression was used to determine the relationship between SF and LIC. Receiver operating characteristic (ROC) curve analysis was used to assess the sensitivity and specificity of SF concentrations for predicting LIC.

Results: The average age of the cohort (6 females and 11 males) at their first SF/LIC measurement was 18.3 years (range 9 to 30.3 years). Acute lymphoblastic leukemia (N=5) and acute myeloid leukemia (N=4) were the most common diseases and 15 of the 17 survivors had received a hematopoietic stem cell transplant (HSCT). The average length of time between the final treatment and the first SF/LIC measurement was 5.4 years (range 0 to 12.5 years). A linear fit to all 34 LIC-SF measurement pairs (Figure 1) produced a gradient of 63 ± 15 (mg ferritin)/(g dry liver tissue)/(mg Fe)/(L serum) and an intercept of 509 ± 157 mg ferritin/L (r²=0.36). The ROC curve analysis (Table 1) indicated that, in this cohort, a SF cut-off of 1270 mg/L potentially has good sensitivity and specificity for predicting a LIC above 15 mg Fe/g and a SF cut-off of 1076 mg/L has poor diagnostic performance for predicting a LIC above 7 mg Fe/g.

AUC, area under the receiver operating characteristic curve.
Methods: Prospective randomized controlled study conducted in department of Obstetrics & Gynecology, in a tertiary care hospital in Delhi, India. 60 women having Iron deficiency Anaemia with Hb 6-8 g% were randomized 1:1 into two groups and were given 1000mg parenteral iron. One group received intravenous 500mg Ferric Carboxymaltose on day 0 and 8. 200mg iron Sucrose complex was given in second group on alternate days for 5 doses. Haematological parameters - Hb, Reticulocyte count, RBC indices, S. ferritin; clinical parameters - fatigue, dyspnoea on exertion and adverse effects were studied on day 0, 7, 14 & 28. Results: Two FCM infusions vs five ISC infusions were required. On day 28 Hb increment ≥3g%seen in 63.33% and MCV>80FL seen in 100% of FCM group vs 0%and 43.33% in ISC group. FCM group had 3.17 g/dl increment in Hb vs 1.9 g/dl in ISC group. S. Ferritin increased to 147ng/ml in FCM group vs 98 ng/ml in ISC group. Significant improvement in RBC indices & retic count was seen in FCM group. Earlier and significant improvement in fatigability & dyspnoea on exertion was observed in FCM group. Both groups had similar safety profile except for thrombophlebitis was observed in 8.67% FCM group vs 50.00% ISC group.

Summary/Conclusions: Intravenous Ferric Carboxymaltose is more effective and safer than Iron Sucrose complex in treatment of Iron deficiency anaemia.

Background: Several susceptibility loci for Hodgkin lymphoma (HL) have been reported, however much of the heritable risk and biological relevance remains unknown.

Aims: To identify novel risk loci for HL and histological subtypes and to further our understanding of how genetic risk loci influence disease susceptibility.

Methods: To our knowledge, we have performed the largest genome-wide association study of HL totalling 5,156 cases and 16,763 controls across 10 million single nucleotide polymorphisms. We have integrated gene expression, chromatin state, transcription factor (TF) binding and capture Hi-C in model B-cells to functionally annotate new and existing risk loci.

Results: We identified risk loci for all HL at 6q22 (rs9842849, PTPRK, P=1.52 × 10−10) and for nodular sclerosis HL (NSHL) at 3q28 (rs4459895, LPP, P=9.43 × 10−14), 6q23 (rs9298977, AHFI, P=4.62 × 10−11), 10p14 (rs3781093, GATA3, P=0.49 × 10−13), 13q34 (rs112988813, UFPP3, P=4.58 × 10−8) and 16p13 (rs34972832, CLEC16A, P=1.29 × 10−10). Additionally, independent loci within the HLA region were observed for NSHL (rs269801, HLA-DPB1*03:01, Val86 in HLA-DRB1) and mixed cellularity HL (rs1633096, rs13196329, Val86 in HLA-DPB1). Expression quantitative trait loci were observed in lymphoblastoid cells from 825 individuals at 6q22 (AHFI, PSMR=8.63×10−6) and 10p14 (GATA3, PSMR=4.70×10−4). Across new and established risk loci we confirmed a significant enrichment of Dnase hypersensitivity in GM12878 cells (P=1.20 × 10−5), as well as regulatory elements in primary B-cells (P=6.0 × 10−10) and myeloid cells (P=6.85 × 10−3). Analysis of ChIP-seq data on 82 transcription factors (TFs) in GM12878 cells showed an over-representation of the binding of TFs that play a central role in B-cell signalling-networks such as RELA (nuclear factor NF-kappa-B p65), EBF1 (early B-cell factor 1), RUNX3 (run-related transcription factor 3) and BAF60C (basal leucine zipper transcription factor, ATF family).

Summary/Conclusions: These observations support the assertion that risk loci for HL mediate their effects through B-cell developmental networks, and are involved in transcriptional initiation and enhancement. Furthermore, our findings emphasise the differences between the major subtypes, which are likely reflective of differences in disease aetiology.

Background: Mantle Cell lymphoma (MCL) is one of the most aggressive forms of
phoid neoplasms characterized by highly infiltrated tumor cells in lymphoid tissues and extra nodal sites. The patients have short responses to current therapies and frequent relapses. However, recent studies have identified a subset of MCL with indolent clinical behavior that tends to present with leukemic dissemination instead of extensive nodal infiltration, and that is characterized by the absence of the transcription factor SOX11 (SRY (Sex determining region-Y)-box 11). The use of SOX11 oncopathy in malignant B cells characterized disease biology.

Aims: The goal of our study was to identify the spectrum of genes regulated by SOX11 in malignant lymphoid cells and provide insights on how the constitutive overexpression of SOX11 may contribute to the oncogenic development of MCL. Methods: We overexpressed a stable transduced SOX11-silenced MCL cell line with reduced SOX11 protein levels by infecting MCL cell lines with lentiviral particles carrying shRNA plasmids specifically targeting SOX11. SOX11-positive MCL cell line was infected with the empty vector and used as a control. These two MCL cell lines were injected in two different mice models to analyze in vivo the tumor growth and angiogenesis. We profiled then the DNA methylation landscape of neoplastic B cells of primary DLBCLs samples, classified as AICDA-high and AICDA-low cases according to their AICDA expression.

Results: We observed more aggressive lymphoma phenotype in VavP-Bcl2+/- Aicda mice (n=7) compared to VavP-Bcl2+/- mice (n=9), based on greater disruption of the splenic architecture and higher degree of B cell infiltration in organs such as lung, liver and kidney. Notably, the overexpression of AICDA reduced significantly the lifespan of the mice (Log-rank test p=0.0289). Neoplastic B cells from VavP-Bcl2+/-Aicda (n=4) and VavP-Bcl2+/- (n=4) mice displayed similar mutation and indel burdens, suggesting that the more aggressive phenotype in VavP-Bcl2+/- Aicda mice was not likely due to increased mutation and reduced methylation heterogeneity in Aicda+/- compared to Aicda+/- GC B cells (64,323 AICDA-perturbed CpGs), suggesting a conserved epigenetic function of AICDA in GC B cells and human GC-derived lymphomas. Finally, we found significant overlap between genes affected by AICDA-perturbed CpGs in human AICDA-high DLBCLs and murine VavP-Bcl2+/- AICDA lymphomas (P=2.21e-23) and with the genes affected by AICDA in GC B cells (P=8.48e-3).

Summary/Conclusions: Our results demonstrate that AICDA acts as a methylome modifier in GC-derived lymphomas, introducing epigenetic heterogeneity, promoting angiogenesis, invasion and drug resistance. Inhibition of SOX11-target genes may represent an efficient strategy for the treatment of aggressive MCL.

AICDA DRIVES EPIGENETIC HETEROGENEITY IN GERMINAL CENTER-DERIVED LYMPHOMAS AND ACCELERATES LymphomaGROWTH.

P.M. Dominguez1,2,3, M. Teater2,3, D. Redmond2,3, Z. Chen2,3, E. Nennishi2,3, D.W. Scott1,2, L. Cimmino4, P. Ghione2, J. Chaudhuri5, R.D. Gascoyne3, D.W. Scott1, *, M. Teater2, D. Redmond2, Z. Chen2, D. Ennishi3, D.W. Scott1, 2, 3, 5Memorial Sloan-Kettering Cancer Center, New York, 4Gene Expression and Cancer Therapy, Memorial Sloan-Kettering Cancer Center, New York, United States

Background: Diffuse large B-cell lymphomas (DLBCLs) are aggressive tumors derived from germinal center (GC) or post-GC B cells. Previous work from our group established that inferior outcome in DLBCL is associated with higher degrees of intra-tumor and inter-tumor cytotoxic methylation heterogeneity, although the molecules driving this epigenetic perturbation remain unknown.

Aims: We investigated the contribution of activation-induced cytokine deaminase (AICDA) to cytotoxic methylation heterogeneity in DLBCLs. AICDA is highly expressed in GC B cells where it drives somatic hypermutation (SHM) and also mediates DNA hypomethylation and epigenetic heterogeneity. AICDA is also expressed in a subset of DLBCLs and high level of AICDA in CHOP-treated DLBCL patients is associated with unfavorable prognosis. Thus, we hypothesized that AICDA contributes to the aggressive behavior of DLBCLs by facilitating epigenetic plasticity through the redistribution of cytotoxic methylation.

Methods: We expressed AICDA in bone marrow cells from VavP-Bcl2+/- transgenic mice, which develop B cell lymphomas of GC origin. We transplant- ed AICDA-overexpressing (VavP-Bcl2+/-Aicda) or control (VavP-Bcl2) mice into lethally irradiated recipients. We studied survival, characterized disease biology and analyzed epigenome, genome and transcriptome of lymphomas. In addition, we studied the effect of AICDA overexpression from WT and AICDA-knockout (AICDA<sup>−/−</sup>) B cells on the phenotype of primary DLBCLs samples, classified as AICDAb<sup>high</sup> and AICDA<sup>low</sup> cases according to their AICDA expression.

Results: We observed more aggressive lymphoma phenotype in VavP-Bcl2+/-Aicda mice (n=7) compared to VavP-Bcl2+/- mice (n=9), based on greater disruption of the splenic architecture and higher degree of B cell infiltration in organs such as lung, liver and kidney. Notably, the overexpression of AICDA reduced significantly the lifespan of the mice (Log-rank test p=0.0289). Neoplastic B cells from VavP-Bcl2+/-Aicda (n=4) and VavP-Bcl2+/- (n=4) mice displayed similar mutation and indel burdens, suggesting that the more aggressive phenotype in VavP-Bcl2+/- Aicda mice was not likely due to increased mutation and reduced methylation heterogeneity in Aicda+/- compared to Aicda+/- GC B cells (64,323 AICDA-perturbed CpGs), suggesting a conserved epigenetic function of AICDA in GC B cells and human GC-derived lymphomas. Finally, we found significant overlap between genes affected by AICDA-perturbed CpGs in human AICDA-high DLBCLs and murine VavP-Bcl2+/- AICDA lymphomas (P=2.21e-23) and with the genes affected by AICDA in GC B cells (P=8.48e-3).

Summary/Conclusions: Our results demonstrate that AICDA acts as a methylome modifier in GC-derived lymphomas, introducing epigenetic heterogeneity, promoting tumor growth and angiogenesis, invasion and drug resistance. Inhibition of SOX11-target genes may represent an efficient strategy for the treatment of aggressive MCL.

P298

XPO1 INHIBITION SYNCHRONIZES WITH BCR INHIBITION, BLOCKS TUMOR GROWTH AND PROLONGS SURVIVAL IN A BIOLUMINESCENT ANIMAL MODEL OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

M. Crespo1, I. Jimenez1, J. Carabia1, S. Bobillo2, P. Abriguete2, C. Palacio2, C.D.C. Carpio2, J. Castellvi2, J. Seoane4, F. Bosch1,1Experimental Hematology, 2Hematology, Vall d’Hebron Institute of Oncology, 3Pathology, Vall d’Hebron Research Institute, 4Gene Expression and Cancer Laboratory, Vall d’Hebron Institute of Oncology, Barcelona, Spain

Background: Primary central nervous system lymphoma (PCNSL) is an non-Hodgkin lymphoma localized in the CNS. Approximately 95% of PCNSL are classified as diffuse large B-cell lymphoma (DLBCL), being most of them related to activated B-cell type (ABC-DLBCL). PCNSL is associated with poor prognosis, particularly because of the difficulty for drugs to cross the blood brain barrier. High dose methotrexate is the most effective treatment, but relapse is very common and salvage treatment options are scarce. Also, in patients with systemic lymphoma, the secondary infiltration of the CNS is a fatal event, with a global overall survival of less than six months. Therefore, the development of new drugs with ability to penetrate the CNS is highly needed. Selinexor (KPT-330) is a Selective Inhibitor of Nuclear Export (SINE) that inactivates XPO-1 protein and induces anti-tumor effects mainly due to forcing nuclear retention of activated tumor suppressors. Selinexor has shown excellent brain penetration and promising results in pre-clinical models of glioblastoma and can inhibit both BCR and NF-kb signaling in malignant B-cells.

Aims: In order to provide a pre-clinical rationale for the design of new therapies for patients with CNS lymphoma our main aim is to assess the role of XPO-1 inhibition in intracerebral xenograft murine models.

Methods: We in vitro tested the sensitivity of DLBCL cell lines to selinexor and ibrutinib by MTS and AnnexinV/PI assay. We established an orthotopic xenograft model of PCNSL by stereotactic injection of OCI-Ly10 (ABC, MYD88 and CD79b mut) cells expressing luciferase into the cerebral parenchyma of specific pathogen-free NOD/SCID mice. This model longitudinally quantified intracerebral tumoral growth by bioluminescence detection.

Results: To compare the sensitivity of DLBCL cell lines to selinexor we determined the IC50 in terms of survival and proliferation in 4 ABC and 5 GCB DLBCL cell lines. DLBCL cell lines had equivalent sensitivity to selinexor, regardless cell of origin (COO). In detail, survival by AnnexinV/PI exclusion showed that mean ID50 for ABC cell lines was 4.98 µM +/- 3.6 and 6.3 µM +/- 3.8 for GCB (p=0.9). Proliferation by MTS was also blocked by selinexor (mean ID50 for ABC-DLBCL was 1.35 µM +/- 0.7 vs 16.16 µM +/- 11.17 for GCB-DLBCL (p=0.41)). Since SINE compounds have been shown to inhibit anti-apoptotic survival pathways, we tested the combined effect of selinexor and ibrutinib in OCI-Ly10 xenografts. In 3 out of 4 ABC-DLBCL cell lines there was a strong synergy. In contrast, none of the 3 GCB-DLBCL cell lines analyzed were sensitive to up to 100 µM ibrutinib; interestingly, however, treatment with selinexor sensitized SUDHL4 cells to ibrutinib and showed strong synergism between the two drugs. In our xenograft model, mice treated with selinexor by stereotactic injection of OCI-Ly10 cells expressing luciferase into the cerebral parenchyma of nude athymic mice. Eleven days after the injection of cells all animals had developed detectable tumors confined to the CNS. Tumor size
was measured and animals were randomly distributed into drug or vehicle group. At this time point mice were treated with 5mg/kg of selinexor or vehicle via oral gavage three times a week; subsequently, bioluminescence was assessed twice a week. Treatment with selinexor significantly increased mice survival, with a median survival of 48 days in the treatment group compared to 34 days in the vehicle group (p<0.0001; Figure 1A). Mice in the treatment group also showed a significant longer increasing survival time compared with vehicle group in two-way ANOVA (p<0.0001; Figure 1B). Specific time-point analysis showed that differences were significant as soon as 8 days after treatment. At final point, histopathological analysis showed diffuse infiltration in meninges and cerebral parenchyma of highly proliferative CD20-positive B-cells. Currently, we are evaluating the synergy between inbrutinib and selinexor in vivo. For that we have used the same experimental setting and assigned 12 mice to each of the following: selinexor only (5mg/kg three times a week via oral gavage), inbrutinib only (25mg/kg daily in drinking water), combination or vehicle. Results will be available at the time of the meeting.

Figure 1.

Summary/Conclusions: Selinexor inhibits proliferation and survival of DLBCL cell lines regardless of COO and it can synergize with inbrutinib. Treatment of mice with CNS confined ABC-DLBCL with selinexor significantly reduces tumor growth, suggesting a potential role for selinexor in increasing survival. Our results provide pre-clinical evidence for the development of selinexor as a new therapeutic option for PCNSL or DLBCL with CNS involvement.

P299

MOLECULAR HETEROGENEITY IN PERIPHERAL T-CELL LYMPHOMA NOT HEREBEFORE SPECIFIED REVEALED BY COMPREHENSIVE MUTATIONAL PROFILING

1Department of Pathology and Tumor biology, Kyoto university, Kyoto, 2Department of Pathology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, 3Department of Pathology, Kurume University School of Medicine, Fukuoka, 4Laboratory of DNA Information Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, 5Department of Advanced Diagnosis, Clinical Research Center, Nagoya Medical Center, Nagoya, Japan.

Background: Peripheral T-cell lymphomas (PTCLs) are a highly heterogeneous group of mature T-cell neoplasms. In particular, accounting for the majority of PTCL, PTCL-not other specified (PTCL-NOS) is a diagnosis of exclusion and as such, is expected to include many heterogeneous tumors. In fact, recent genetic studies have suggested that a subset of PTCL-NOS is closely related to angioimmunoblastic T-cell lymphoma (AITL); both lymphoma types show follicular helper T-cell (TFH) phenotypes and share mutational targets in common, such as RHOA, TET2, DNMT3A, and IDH2. However, with the lack of comprehensive genetic analyses, the molecular pathogenesis is poorly understood in the majority of PTCL-NOS cases.

Aims: The aim of this study is to clarify a landscape of somatic mutations in PTCL-NOS.

Methods: We performed whole-genome exome and transcriptome sequencing of PTCL-NOS and other related PTCLs, followed by targeted-capture sequencing of candidate drivers in T-cell lymphomas in 100 PTCL-NOS samples.

Results: Consistent with previous reports, TET2 (38%) was the most frequently mutated gene in PTCL-NOS, followed by RHOA (28%), TP53 (18%), KMT2C (13%), IDH2 (11%), and PLCG1 (11%). Frequently altered genes included signal transduction molecules (such as RHOA, PLCG1, STAT3 and SOCS1), chemokine receptors (CCR4 and CCR7), epigenetic modifiers (TET2, KMT2C, IDH2, DNMT3A, CREBBP, and KDMEA), and molecules associated with immune evasion (HLA-A, HLA-B, B2M, and CD58). Novel targets of recurrent mutation were also identified, including PDCD1, YTHFD2, and LRPIB, which were frequently targeted by nonsense and frameshift mutations distributed throughout the entire genes. Among these, PDCD1 encodes PD-1, which transmits an inhibitory signal from PD-L1 and PD-L2 ligands, and therefore loss of function of this gene is predicted to enhance malignant T-cells to escape from the negative signaling. By contrast, recurrent mutations in YTHFD2 and LRPIB mutations in T-cell lymphoma genesis is unexpected. These genes encode a reader protein of N6-methyladenosine (YTHFD2), and a member of the low density lipoprotein receptor family (LRPIB). Although the function of these genes in T-cells are unknown, our findings suggest their unresolved roles, whose dysfunction may lead to malignant T-cell proliferation. Finally, we investigated the co-occurrence between frequently mutated genes in PTCL-NOS. In accordance with previous observation, mutations characteristic of TFH lymphomas (TET2, RHOA, IDH2, and DNMT3A) tended to co-occur in a subset of PTCL-NOS cases, but were almost mutually exclusive with mutations in TP53 and chemokine receptor genes. These observations further support the molecular distinction between TFH and non-TFH lymphomas in PTCL-NOS: the former is more related to AITL and discriminated from the latter in terms of their mutational profiles.

Summary/Conclusions: In summary, our findings illustrate the landscape of somatic alterations in PTCL-NOS and provide a novel insight into their genetic and molecular heterogeneity, which should help to devise a novel molecular classification of PTCLs and to exploit a new therapeutic strategy to combat these intractable T-cell malignancies.
Aims: We designed this study to investigate STAT3 activation and its contribution to CAEBV development, because it was recently indicated that STAT3 was constitutively activated in some T- or NK-cell malignancies. We also examined the effects of JAK inhibitors on CAEBV.

Methods: The EBV-positive T- and NK-cell lines SNT8, SNT15, SNT16 and the NK-cell lines SNK1, SNK6, SNK10 were examined. EBV-positive T or NK cells were isolated from peripheral blood mononuclear cells (PBMCs) of CAEBV patients who were diagnosed according to the previously described diagnostic criteria (Blood 2012; 119:673-86). To detect and isolate EBV-infected cells, T and NK cells were separated from PBMCs using magnetic beads. Gene expression was examined using one-color microarray-based analysis (Agilent Technologies). The JAK inhibitors ruxolitinib and tofacitinib suppressed STAT3 activation and cell survival by inducing apoptosis of the cell lines and PBMCs from CAEBV patients. Ruxolitinib also inhibited the mRNA expression of TNF-α and interferon-γ in CAEBV patient-derived cells.

Summary/Conclusions: STAT3 is constitutively activated in EBV-positive T or NK cells from CAEBV patients. Inhibition of STAT3 activation by ruxolitinib could be an attractive and effective treatment for CAEBV by suppressing not only EBV-infected cell survival but also the accompanying inflammation.

P303
RECURRENT MUTATIONS IN MICRO-RNA BINDING SITES MAY BE POTENTIALLY RELEVANT IN FOLLICULAR LYMPHOMA
E. Larrea1, M. Fernandez-Mercado1, J. Ceberejo1, J. Okosun5, J. Fitzgibbon6, C. Lawrie1,7,8

Aims: We set ourselves to find predictive biomarkers of transformation for FL, which accounts for ~20% of all non-Hodgkin lymphomas. Approximately 30% of the FL cases suffer a histological transformation to a much more aggressive subtype of lymphoma drastically reducing the overall survival from 10 years to just 14 months. Despite being a critical event during disease progression it is molecularly poorly understood and no biomarkers exist to predict this phenomenon. Previous studies have suggested the possibility that deregulation of microRNA expression (miRNAs, small endogenously produced non-coding RNAs) could be implicated in the development of FL disease as well as in the transformation event. We hypothesise that mutations in miRNA binding sites may also have a role in this process.

Methods: We interrogated whole genome sequencing (WGS) data from 6 FL patients that underwent trans-
formation using a bespoke bioinformatic pipeline based on TargetScan prediction algorithm in order to identify mutations in putative miRNA binding sites. Once identified, in order to validate them and test their recurrence in an extended cohort (60 samples from 31 FL patients who underwent transformation plus 21 samples of non-transformed FL patients) we designed an Ampliseq (Ion Torrent, Life Technologies) NGS custom panel. Finally, we selected a number of variants for assessing the variant effect on the miRNA:mRNA interaction, by means of a combination of an in silico predictive algorithm and in vitro luciferase assays.

Results: 36% of somatic variants from WGS data arose in 3’UTR, and 68% of these were putative miRNA-binding sites (525 mutations in 497 genes). Interestingly, the ontology analysis showed that these mutations were not randomly distributed but rather there was enrichment in genes associated with haematological malignances (P=2.18x10^{-4}). We then validated 85% of these mutations using targeted resequencing and found a total of 103 recurrent variants located in putative miRNA binding sites. QC criteria filtering led us to prioritise 38 variants in 25 genes to be functionally tested. Crucially, ontology analysis showed that these genes were highly enriched for GC-like B-cell lymphoma genes (P=4.39x10^{-5}), strongly suggesting that these variants may have a biological significance in the disease. We then performed an in silico approach based on TargetScan miRNA target prediction algorithm to evaluate the effect of the mutations on the binding of the miRNAs to their target sites. Based on these results we prioritized some of these genes to perform luciferase assays. We experimentally demonstrated not only that the majority of these loci are bona fide miRNA targets sites, but also that the presence of a number of these variants cause a dysregulation of the normal miRNA regulatory activity (Figure 1).

Results for luciferase assays. Figures A and B show an abrogation of the miRNA binding due to the effect of the mutations.

***p < 0.0001

Summary/Conclusions: Our data show that the identified mutations do not occur randomly, but preferentially in putative microRNA binding sites of genes related to lymphomagenesis, supporting their role in FL pathogenesis. Furthermore, the presence of some of the identified variants in miRNA binding sites indeed promotes a dysregulation of the normal miRNA regulatory activity, suggesting that they might have a biological significance in FL.

Background: Within the landscape of mutated genes in mantle cell lymphoma (MCL), only TP53 disruption has been so far associated with outcome.

Aims: Here we present the clinical update of the deep sequencing MCL gene panel analysis in the prospective FIL-MCL0208 phase III trial (NCT022354313, high-dose immunochemotherapy followed by autologous transplantation for untreated, advanced stage <65 years MCL) based on the data from the second interim analysis.

Methods: A targeted resequencing gene panel, including coding exons and splice sites of the ATM, BIRC3, CCND1, KMT2D, TP53, TRAF2, WHSC1, and NOTCH1 genes was analyzed in tumor DNA from baseline bone marrow CD19+ purified MCL cells and, to filter out polymorphisms, in the paired normal genomic DNA (55% of cases) using a TruSeq Custom Amplicon target enrichment system followed by deep next generation sequencing (Illumina, median depth of coverage 235x). Variants represented in >10% of the alleles were called with VarScan2 with the somatic function when the paired germline DNA was available. For patients lacking germline DNA, a bioinformatics pipeline including a number of stringent filters was applied to protect against the misclassification of polymorphisms as somatic variants. Clinical data were updated at the time of the second interim analysis (January, 2017).

Results: Out of the 300 enrolled patients, 174 were evaluable for mutations. Median follow-up of the cohort was 36 months, and 3-years PFS and OS were 67% and 86%, respectively. Patients not included in the study, due to unavailable tumor DNA (n=126) showed superimposable clinical features and outcome. Mutations of TP53 (8% of cases) and KMT2D (11% of cases) were associated with an increase in the hazard of progression both in univariate analysis as well as after adjusting for MIPI, Ki67 and blastoid variant: HR 3.87 (95% CI 1.64 to 9.13), p<0.002 and HR 3.66 (95% CI 1.77 to 7.56), p<0.001, respectively. These results translated into an increase of the hazard of death in both TP53 and KMT2D mutated patients both in univariate analysis as well as adjusting for MIPI, Ki67 and blastoid variant: HR 4.26 (95% CI 1.34 to 13.57), p=0.014 and HR 3.09 (95% CI 1.07 to 8.86), p=0.036, respectively. On these bases, a survival model was proposed based on the TP53 and KMT2D mutation status: 3-years PFS and OS were 26% and 64% for patients carrying either TP53 or KMT2D mutations or both vs 75% and 92% for patients without any of these mutations (Figure 1).

Summary/Conclusions: The updated clinical results of the FIL-MCL0208 trial show that: i) both TP53 and KMT2D mutations independently associate with shorter PFS and OS in younger MCL patients receiving high-dose therapy; ii) KMT2D mutations seem to be as detrimental as TP53 mutations, at least in terms of PFS; iii) given the negative prognostic impact of these mutations, they might be used to select high-risk patients for novel therapeutic approaches.
Multifaced aspects of bleeding disorders

A LOOKBACK AT VWD TYPE 2A AND 2M CLASSIFICATION IN A LARGE COMPREHENSIVE HAEMOPHILIA CENTRE.
S. Jaafar1,2, T.T. Yeel1
1Haematology, Royal Free Hospital /NHS, 2Haematology, katharine dornandy haemophilia centre/royal free hospital, london, United Kingdom

Background: Von Willebrand Disorder (VWD) has a prevalence of approximately 1% in the general population and is due to quantitative deficiencies or qualitative defects of the Von Willebrand Factor (VWF) protein. VWF is a large multimeric protein with multiple functions. It carries and protects factor VIII and helps in the binding of FVIII, platelets and the vascular endothelium at sites of injury. VWF binding to platelets is through several receptors most notably the glycoprotein 1b (GP1b) and collagen exposed at site of injury is important for VWF adhesion to the subendothelial matrix forming an adhesive anchor. Classification of VWD is based on the quantitative deficiencies (Type 1 and 3) and VWD type 2 are qualitative defects of the VWF protein with or without quantitative deficiency as well. Type 2 VWD is further subdivided into type 2A,2B,2M and 2N. These subtypes depend on a number of laboratory assays that measure the FVIII activity, VWF protein level (VWF:Ag assay) and the function of the protein (i.e its ability to bind to 1) FVIII(2), VWF binding assays(2), platelets (VWF Ristocetin assay) and (3) collagen (VWF CB assay). Other tests include ristocetin induced platelet aggregation (RIPA), multimer analysis, assay ratios and VWF genetic analysis. No single commercially available laboratory method can achieve to test all the parameters required to clinch the accurate diagnosis of the subtypes of VWD. Use of these multiple assays with VWF:Ag/1 ratio, VWF CB (VWF-CB)/VWF Ag ratio have helped in the better identification of VWD and the subtypes.

Methods: Clinicians who have made a diagnosis of VWD for individuals referred for a bleeding state work up would classify the subtypes of the VWD according to the results of the investigations available at the time of seeing the patients. All patients with an inherited bleeding disorder would then be registered in the centre and details would be put into a database. We have looked back into the database from the period of 2000 to end of 2016 and focussed on the VWD types 2A and 2M. Current VWD diagnostic panel in our centre includes the following tests: FVIII one stage assay, VWF:Ag Elisa,VWF ristocetin, Platelet agglutination method, VWF CB Elisa methods. VWF multimeric patterns of the VWF protein in accurate diagnosis of the VWD subtypes. VWD 2A and 2M shows similarities in certain aspects and it is important to differentiate these 2 subtypes as new therapies become available and personalised treatment approaches of VWD become a reality.

Aims: To assess recent various VWF investigation panels and assay ratios, VWF genetic analysis, multimeric patterns of the VWF protein in accurate diagnosis of the VWD subtypes. VWD 2A and 2M shows similarities in certain aspects and it is important to differentiate these 2 subtypes as new therapies become available and personalized treatment approaches of VWD become a reality.

Results: In the VWD database 38 patients classified as 2M and 19 patients as type2A have been recorded from 2000 to end of 2016. With the updated results and genetic analysis and the response to DDAVP, around 30% of the patients have had their subtypes changed. This exercise confirms that no singular test can be used to accurately diagnose the VWD and its subtypes and illustrates the importance of DDAVP testing and the difficulty of interpreting assay ratios for VWD 2M.

Summary/Conclusions: VWD may be misdiagnosed, underdiagnosed or undiagnosed. Appropriate and complete investigative panel is necessary for complete classification of VWD and its subtypes.

Background: Dysfibrinogenemia (DF) and hypofibrinogenemia (HDF) patients (pts) experience hemorrhages or thromboses, and the clinical management can be difficult.

Aims: Aim of this study is to obtain information on DF/HDF clinical phenotype and management.

Methods: This is a spontaneous, retrospective, multicenter national study. Data are collected from clinical records.

Results: Forty-one pts have been enrolled in 3 centers: 35 DF (85%), 6 HDF (15%); 18M, 23F. Median follow-up: 7.4 months (1-203). Median age at diagnosis: 36 years (range 3-81). Median fibrinogen activity/antigen level: 53 mg/dL (0-156) and 250 mg/dL (66-380), respectively. Fourteen pts experienced hemorrhagic events, especially epistaxis, hematuria or spontaneous bleeding. Thrombosis occurred in 3 patients: 2 venous and 1 arterial. DF/HDF were treated with fresh frozen plasma in 3, fibrinogen concentrate (FC) in 1, tranexamic acid in 6; in 5/41 (12%) cases, low molecular weight heparin (LMWH) was administered; no hemorrhage occurred. Thirteen pregnancies were initiated in 9 women. In 1 case, LMWH prophylaxis was administered during pregnancy, and in 1 other during puerperium. In 2 cases, FC was administered at the time of spontaneous delivery (SD). Nine SD and 4 cesarian sections were performed without complications.

Summary/Conclusions: Pts from this case series experienced few hemorrhagic/thrombotic events. The majority was asymptomatic and the most severe events were related to concomitant pathologies. Nonetheless, this study has the potential to collect data from a numerous population of pts who live in the same country, and therefore to provide useful information to better characterize and manage these rare diseases.

OSTEOPOROSIS IN PATIENTS WITH HEMOPHILIA
V. Zoreno1,2, T. Poyanaskaya1, E. Karpov1, A. Kovrigina1, T. Tupoleva1, A. Golobokov1, N. Sadykova1, G. Mishin1, M. Sampiev1, D. Vasiliev1, D. Petrovskii1, A. Korolev1
1National Research Center for Hematology, Moscow, Russian Federation

Background: Osteoporosis is often a co-morbidity of hemophilia, which exacerbates the hemophilic arthropathy and affects the long-term stability of the components after the arthroplasty. We present our results for the presence of osteoporosis in 148 patients with haemophilia and hemarthritic arthropathy.

Aims: To prevent progression of hemarthritic arthropathy and increase the long-term stability of the components after the arthroplasty.

Methods: In the period from 2015 to 2016, the presence of osteoporosis surveyed 148 patients with haemophilia who are hospitalized in the department of reconstructive orthopedics for patients with hemophilia (Moscow, Russia): 121 (81.8%) - hemophilia A, 21 (14.2%) - and hemophilia B 6 (4%) – haemophilia with inhibitor. The average age of the patients was 39.3 years (range 10 to 69 years). 121 patients with hemophilic arthropathy performed primary total arthroplasty (98 knee, 20 hip, 3 shoulder joints); 18 patients underwent revision arthroplasty (5 - purulent infection, 7 - instability of the implants, 4 - fractures, 2 - loss of motion in the operated joint). 40 patients underwent ultrasound densitometry. 29 women were pregnant: 16 (55.2%) - hemophilia A, 13 (44.8%) - hemophilia B. As a result of ultrasound densitometry in 17.5% (7 patients) of cases revealed osteopenia and 20% (8) T-thighest index. 105 patients underwent histological study in which 93 (88.6%) bone resorption, 58 (55.2%) intraosseous hemorrhage which 53 (50.5%) cases were accompanied by bone resorption. In total (histologically and of ultrasound densitometry) 99(66.9%) patients with haemophilia had osteoporosis.

Summary/Conclusions: The data indicate that osteoporosis at patients with haemophilia considerably more common than in the general population. Intraosseous hemorrhage identified in more than half of the cases, exacerbate the decline in bone mineral density.

P308

PREVALENCE OF GENETIC MARKERS OF OXIDATIVE STRESS IN PATIENTS WITH SEVERE HEMOPHILIA FROM NORTH-WESTERN RUSSIA
S. Kapustin1,*, L. Aleksanay1, L. Rybakova1, V. Kargin2, V. Burakov2, S. Svitina1, A. Tito2, V. Soldatenkov3, A. Chechetkin3
1Laboratory of Biochemistry, 2Surgery Department, 3Russian Research Institute Of Haemotology And Transplantology, Saint-Petersburg, Russia, Russian Federation

Background: Severe haemophilia (SH) is often complicated by chronic arthropathy due to recurrent haemorrhagic events and activation of such biological mechanisms as oxidative stress (OS) and inflammation. We have previously shown that the biochemical markers of OS and/or deficiency of antioxidant system (AOS) are frequently seen in SH patients affected with joint(s) destruction. Until now, there is a little data on the frequency of genetic variants predisposing to OS or decreased AOS activity in patients with SH.

Aims: To assess the prevalence of several genetic variants predisposing to OS or decreased AOS activity in patients with SH from North-Western Russia (NWR).

Methods: We studied 71 men with severe haemophilia A or B (62 and 9 patients, respectively). Osteoarthritis of large joint(s) was detected in each
patient, with the rate of recurrent haemorrhagic events in joint(s) from 6 to 13 per year. The control group consisted of 255 age-matched healthy men. Gene polymorphism of apolipoprotein E (ApoE e2/e3/e4), paroxanase (PON1 Gln192Arg), methylenetetrahydrofolate reductase (MTHFR C677T), catalase (CAT C-262T) and plasmatic glutathione peroxidase (GPX3 T-165C) was studied by PCR-RFLP technique. Statistical differences between the patient and control group were assessed by Fisher’s exact test. Odds ratios (OR) with their 95% confidence intervals (CI) and p-value were calculated by using GraphPad Prism 5.0 software.

Results: We found abnormal distribution of ApoE genotypes in the patient group. Absence of ApoE e3 allele was observed in 7 (9.9%) men with SH and 9 (5.1%) controls (OR=3.4, 95% CI: 1.2-9.7, p=0.025). In particular, the frequency of ApoE e2/e2 genotype was 10-fold increased in patients when compared to healthy men (4.2% vs 0.4%, OR=11.2, 95% CI: 1.1-109.5, p=0.034). ApoE e2/e4 and e4/e4 genotypes were also more prevalent in SH than in the control group (2.8% vs 0.8% and 2.8% vs 0.2%, respectively). In the patient group, we observed the positive association between the PON1 192Gln/Gln variant and heterozygous GPX3 -65TC genotype (OR=5.8, 95% CI: 1.3-25.7, p=0.021). Simultaneous presence of these genetic variants was more than 5-fold frequently found in SH than in controls (8.5% vs 1.6%, 95% CI: 1.3-22.8, p=0.016).

Summary/Conclusions: Our results indicate that OS-provoking variants of ApoE, PON1 and GPX3 genes are frequently seen in SH patients with chronic arthropathy and joint(s) destruction.

Background: Congenital factor XIII deficiency (CFXIIIID) is a rare bleeding disorder. Intracerebral hemorrhage (ICH) is a leading cause of mortality and morbidity in this disorder. Matrix metalloproteinase-2 (MMP-2) and MMP-9 are known to be involved in the pathogenesis of ICH. Absence of ApoE e3 allele was observed in 7 (9.9%) men with SH and 9 (5.1%) controls (OR=3.4, 95% CI: 1.2-9.7, p=0.025). In particular, the frequency of ApoE e2/e2 genotype was 10-fold increased in patients when compared to healthy men (4.2% vs 0.4%, OR=11.2, 95% CI: 1.1-109.5, p=0.034). ApoE e2/e4 and e4/e4 genotypes were also more prevalent in SH than in the control group (2.8% vs 0.8% and 2.8% vs 0.2%, respectively). In the patient group, we observed the positive association between the PON1 192Gln/Gln variant and heterozygous GPX3 -65TC genotype (OR=5.8, 95% CI: 1.3-25.7, p=0.021). P311
HPA-3A/3A GENOTYPE IS A POSSIBLE RISK FACTOR OF SEVERE HEMORRHAGIC SYNDROME IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA
Z. Ilna1,*, K. Sergey1, G. Sergey1, M. Natalya1, G. Svetlana1, B. Stanislav1, C. Aleksandr1
1Hematology, Russian Research Institute of hematology, Saint-Petersburg, Russian Federation

Background: The main clinical manifestation of primary immune thrombocyto- penia (ITP) is hemorrhagic syndrome (HS) which can range from minimal cutaneous hemorrhages to severe life-threatening bleeding. It is well known, that there is no stable correlation between the platelets count or other parameter(s) and the hemorrhage grade in ITP patients. Especially, the genetically-based individual mechanisms of immune response impairment could affect the course of ITP, the severity of HS and the response to treatment.

Aims: To reveal genetic risk factor(s) for severe HS in patients with chronic ITP.

Methods: A total of 67 patients (58 women and 9 men) with chronic ITP were involved in the study. The median age of the group was 57 years (range: 24-77). The mean duration of ITP was 7 years (2-48). Hemorrhage was graded according to WHO scale. Taking into account the severity of HS, all the patients were divided into two groups. The first group included 40 patients with HS of 0-1 grade and the second group consisted of 27 patients with HS of 2-3 grade. All patients of the second group needed the use of different methods of emergency haemostatic therapy and we consider it as a “severe ITP”. We analyzed DNA polymorphism of 8 genes responsible for the formation of specific human platelet alloantigen systems (HPA-1, -2, -3 and -5) or associated with impaired immune response (IL-1B, IL-6, IL-10 and TNF-A). The differences in genotype frequencies between the groups 1 and 2 were assessed by Fisher’s exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated with GraphPad Prism 5.0 software.

Results: The frequency of HPA-3a/3a (Gpplb 2622TGT, 843 lle/ile) genotype was more than 2-fold increased in ITP patients with severe HS (55.6% vs 25.0% in the group with HS of 0-1 grade; OR=3.8, 95% CI: 1.3-10.7; p=0.02). HPA-1a/1a and HPA-2a/2a genotypes were also more frequently seen in patients with ITP severe HS compared with other groups (2-3 grade 26.9% vs 15.0% in HS 0-1; OR=2.1, 95% CI: 0.6-7.1, p=0.34). Patients positive for IL-10 -592A allele were also more frequently seen in the group with “severe ITP” (26.9% vs 15.0% in HS 0-1; OR=2.1, 95% CI: 0.6-7.1, p=0.34). Moreover, in the group with “severe ITP” we found 2-fold increase of the IL-6 -174CC genotype frequency (26.9% vs 15.0% in HS 0-1; OR=2.1, 95% CI: 0.6-7.1, p=0.34). Our data indicate that HPA-3a/3a variant could be a possible risk factor for severe HS in ITP patients.
Routine COLLECTED HEALTHCARE DATA

AN ALGORITHM TO IDENTITY CASES OF SEVERE HEMORRHAGE IN ROUTINELY COLLECTED HEALTHCARE DATA

Aims: The aim of this study was to develop an algorithm that can be used to find patients who suffered from major hemorrhages (WHO grade 3 or 4) within electronic health records.

Methods: An algorithm was developed using electronic health record data of a cohort of patients with acute leukemia, who received platelet transfusions between June 2011 and December 2015 at the Leiden University Medical Center in the Netherlands. Chart review was performed for a stratified, random sample of observation days. Discriminative performance of three indicators was assessed: CT-brain, drop in hemoglobin level and transfusion need within 24 hours. The cut off values for hemoglobin drop and transfusion need with the best discriminating capacity and CT-brain were entered in the final algorithm. The C-statistic was calculated and calibration plots were made. The algorithm will be externally validated in two other academic hospitals.

Results: The derivation cohort consisted of 255 patients comprising 10,638 observation days and chart review was performed for 353 days. The incidence of major hemorrhage was 0.22 per 100 observation days. The final algorithm consisted of information on CT-brain (yes/no), a hemoglobin drop of ≥2.8 g/dl and the need of six or more transfusions (yes/no). The C-statistic of the algorithm was 0.93 (95% confidence interval (CI) 0.86 to 0.99). The incidence of bleedings with all grades of severity was 8.4 per 100 days. The algorithm for the bleeding of all grades had a c-statistic of 0.54 (CI 0.53 to 0.55). The results of the external validation are not available yet.

Summary/Conclusions: An algorithm using information on CT-brain, hemoglobin drop and transfusion can accurately identify cases of major hemorrhage within electronic health care data. External validation will be performed.

MOLEcular MECHANISMS AND CLINICAL SIGNIFICANCE OF REDUCED PTPN1 EXPRESSION IN MOLEyLODYSPLASTIC SYNDROMES

Background: Previously we determined common deleted region (CDR) of del(20q) observed in MDS by CGH-array. Our data showed that the PTPN1 gene is located within CDR of del(20q). The PTPN1 gene encodes PTP-1B, a non-receptor type protein tyrosine phosphatase, which is involved in multiple physiological and pathological cellular processes via dephosphorylation of several tyrosine kinases, and other molecules. Although roles of PTP-1B in normal and pathological hematopoiesis has not been elucidated, it may function negative regulator for cellular processes mediated by tyrosine kinases, including JAK2, and SRC. We hypothesized that the PTPN1 gene is a target gene disrupt by del(20q), resulting in haplo-insufficiency, and involved in MDS molecular pathogenesis.

Aims: We attempted to examine PTPN1 expression level in bone marrow cells of MDS patients with or without del(20q), and to investigate its clinical and biological significance.

Methods: Total RNA was extracted for cDNA synthesis from bone marrow samples taken at the time of diagnosis with written informed consent from patients and control subjects were used for the present study. Real-time RT-PCR was carried out to quantify PTPN1 expression by the TaqMan probe method using an ABI 7500 real-time PCR system (Applied Biosystems). Data including patients’ demographic, disease status, medical history, clinical and laboratory findings, and outcome, were collected from medical records and laboratory data base. A non-parametric Mann-Whitney-Wilcoxon test was used to examine whether expression levels among groups are statistically different. The Kaplan-Meier model was used to analyze the impact of PTPN1 expression on overall survival, and log-rank test was used for statistical analysis. We also examined the effect of 5-azacytidine treatment on PTPN1 expression in primary bone marrow cells from MDS patients. Bone marrow cells were cultured with or without 5μM of 5-azacytidine for 48 hours. Expression level of PTPN1 was examined by quantitative RT-PCR described as above.

Results: A total of 118 MDS patients, 71 males and 47 females with median age of 68 years (range: 20-91 years) and 19 control subjects were included in the present study. The patients were classified as RCUD (n=18), RCMD (n=58), RARS (n=8), RAEB-1 (n=20), and RAEB-2 (n=14) according to WHO classification. Relative PTPN1 expression level was significantly decreased in MDS patients with del(20q) (P<0.001) compared with control subjects. Moreover, relative PTPN1 expression level in MDS patients without del(20q) also significantly decreased (P<0.001). Expression patterns of PTPN1 among five WHO-subtypes, were statistically different (P=0.0201). Median values of relative PTPN1 expression level in RCUD, RCMD, RARS, RAEB-1, and RAEB-2 were 1.52, 1.95, 1.91, 1.46, and 1.26 respectively. Relative PTPN1 expression level in WHO-subtypes with high blast counts (RAEB-1 and RAEB-2) was significantly lower than that in WHO-subtypes with less blast counts (RCUD, RCMD, RARS) (median value: 1.41 vs 1.89, P=0.0074). To investigate prognostic implication of PTPN1 expression in MDS, we analyzed impact of PTPN1 expression on overall survival (OS). Based on PTPN1 expression level, 118 patients were divided into four groups, high (Q1), intermediate (Q2, Q3), and low (Q4) quartiles. Kaplan-Meier analysis demonstrated that the lowest quartile (Q4) showed significantly worse survival compared with remaining quartiles (Q1, Q2, Q3) (P=0.048). The estimated 5-year OS rates in Q1-3 group and Q4 group were 69% and 49.8%, respectively. We examined whether PTPN1 expression is induced by 5-azacytidine in primary bone marrow cells of 17 MDS patients.

Real-time PCR analyses indicated that 5-azacytidine treatment significantly induced PTPN1 expression.

Summary/Conclusions: The present study demonstrated that PTPN1 expression is induced in MDS patients with haplo-insufficiency due to del(20q) and methylation of promotor region of the PTPN1 gene. Low PTPN1 expression is associated with advanced disease and poorer clinical outcome, indicating that PTPN1 expression level could be a useful prognostic marker in MDS.
Background: DNA hypomethylating agents (HMAs) comprise standard therapy for non-transplant-candidate high-risk myelodysplastic syndromes (MDS). However, little is known about the exact mechanism of their effects to MDS or no reliable makers predicting the response to HMAs have been developed, although a recent study reported a very high response rate of TP53-mutated AML and MDS to decitabine.

Aims: The purpose of this study is to elucidate the clonal dynamics and molecular signatures that correlate with response to azacitidine therapy for MDS, focusing on the role of TP53-mutations.

Methods: We conducted a prospective multicenter trial of azacitidine treatment for high-risk MDS patients, in which the efficacy was compared between the 5-day and 7-day regimens. A total of 107 patients were enrolled between 2013 and 2016. For all cases, a bone marrow specimens collected before treatment was analyzed for mutations using targeted-capture sequencing. Mutations were also interrogated after 4 cycles of azacitidine therapy in 48 (45%) cases. An additional 22 cases were analyzed for mutation in patients who received azacitidine therapy for MDS and whose bone marrow specimens were available both before and after therapy. DNA baits were designed for detection of both oncogenic variants in 67 known driver genes in myeloid neoplasms and copy number alterations on the same platform. Response was evaluated according to the IWG 2006 criteria. We also evaluated the difference in the size of clones showing the maximum allelic burden between pre- and post-treatment specimens (ΔTCF: tumor cell fraction).

Results: On average, 2.7 mutations (range 0-9) were detected per sample before azacitidine treatment. TP53 represented the most common mutational target in newly diagnosed patients (40% [24]-70% [17]) and off-protocol cohort, respectively, followed by ASXL1, RUNX1, TET2, and SRSF2. TP53-mutated cases had significantly lower number of driver mutations (1.7 v. 3.1/sample, p<0.001) and higher number of copy number changes (9.6 v. 2.1, p=0.001), compared with unmutated cases. Clinical response was observed in 25 cases in the on-protocol cohort, including 6 complete remission (CR) (5.6%) and 19 marrow CR (17.8%) and 7 (29%) cases (all CR) in the off-protocol cohort. Notably, CR was obtained almost exclusively in TP53-mutated cases (5/6 and 5/7 CR cases in the on- and off-protocol cohort. No other mutations were significantly associated with clinical response. Median time to CR was 119 days (range: 81–721), which lasted for a median duration of 217 days (range 10–783). ΔTCF was evaluable for 62 cases who had one or more follow-up specimens and showed at least one mutation in either pre- or post-treatment with an average of -0.075 (range: -0.75–0.72). ΔTCF was significantly lower in responders than non-responders (-0.18 vs -0.0002, p=0.0068) and in TP53-mutated cases (-0.25 vs 0.00568, p=0.001).

Summary/Conclusions: Our study revealed a significant positive association of TP53 mutations with favorable responses to azacitidine for MDS, although the response was transient and the expected response rate seems to be much lower compared to that reported for decitabine. Given that decitabine is not approved for MDs in most areas (e.g. EU and Japan), our results suggest a potential role of azacitidine as a key agent to improve the notoriously dismal clinical outcomes of TP53-mutated tumors. Further study should be warranted to confirm its efficacy and to develop an optimal post-remission therapy to overcome the short remission period.
with non complex del(7q) (>P<ns for complex vs non complex, chi-square test). The ORR was 37.5% in "de novo" and 38.4% in secondary MDS, respectively (>P<ns). Impact of AZA treatment compared to BSC on overall survival: Results of this multivariable analysis of OS at different time points are presented in Table 2. Chromosome 7 cytogenetic categories and IPSS retained a poor prognosis over time with a constant value of poor prognosis. AZA treatment had a favorable impact on OS during the first 3 years of treatment, compared to BSC, confirming results obtained in univariable analysis. Nevertheless, the benefit of AZA treatment as compared to BSC approach decreased as time spends and the HR value increased over time: HR of 0.3 at 6 months, 0.5 at 1 year and 0.7 at 2 and 3 years after treatment. (Figure 1). This benefit was present in all chromosome 7 categories with a a trend towards better impact among patients with complex karyotype but no significant differences between the 3 categories (-7, del(7q) and CK).

Results:
This initial cohort allowed evaluation of toxicity, pharmacokinetic analysis, and determination of PK levels and PK/PD after repeated dosing. PK profiles for OPN-305 in patients treated with escalating doses of OPN-305 are shown in Figure 1. PK/PD analysis determined the drug concentration range in serum were >200 h at 5 mg/kg and >300 h at 10 mg/kg. There was a greater-than-dose proportional increase in mean OPN-305 exposure (AUC) between 5 and 10 mg/kg. PK profiles after repeated dosing at 5 mg/kg in N=2 subjects and pre-dose (trough) levels in other subjects indicated some variability in the potential for accumulation. TLR-2 receptor occupancy in blood PBMCs and bone marrow aspirates was complete in virtually all samples taken after OPN-305 administration. There is no evidence of antigenicity or antibodies. Compared with baseline, no significant changes of IL-23, IL-18, IFN-γ, IL-10, IL-18, IL-6, IL-12 (p40), IL-12 (p70) and IL-8 levels where observed among responders or non-responders or based on OPN-305 dosing. A trend to increased response was observed in patients with higher TLR2 expression, although this was not significant.

Summary/Conclusions: Treatment with OPN-305 in pts with previously treated lower-risk MDS was well tolerated with no significant toxicities and 53% ORR including 20% transuduction independence, and potential association between TLR2 levels and response.

P318
IN PATIENTS UNDEGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR MDS DEVELOPMENT OF CHRONIC GVHD COULD AMELIORATE THE ADVERSE IMPACT OF SPECIFIC SOMATIC MUTATIONS

1Hematology Department, University Hospital of Salamanca, 2Department of Statistics, 3Centro de Investigación del Cáncer, IBMC (Instituto de Biología Molecular y celular del cáncer, University of Salamanca, 4Molecular Biology Department, University Hospital of Salamanca, Salamanca, 5Hematology Department, University Hospital La Fe, Valencia, 6Hematology and Medical Oncology Department, University Hospital Morales Meseguer, Murcia, 7Hematology Department, University Hospital Vall d’Hebron, Barcelona, 8Area of Genetic and Cellular Therapy, IBSAL Instituto Bioanitoxián de Salamanca, Salamanca, Spain

Background: Approximately 90% of patients with Myelodysplastic Syndromes (MDS) have somatic mutations in driver genes detected by Next Generation Sequencing (NGS). In the last years, several studies have related these mutations with prognosis, disease characteristics and response to therapy, including allogeneic Hematopoietic Stem Cell Transplantation (HSCT). Development of Chronic Graft Versus Host Disease (cGVHD) has been reported as one of the most powerful antineoplastic mechanisms after HSCT.

Aims: To evaluate the impact of specific somatic mutations in patients with MDS undergoing HSCT and if the development of cGVHD can modify their impact.

Methods: The results of HSCT in 115 MDS patients from five centres in Spain were retrospectively analyzed. Bone marrow samples were collected a median of 27 days prior to transplant and DNA was screened for somatic mutations by NGS, using a NextSeq platform (Illumina). Two myeloid gene panels that included the most frequently mutated genes in myeloid malignancies were used.

Results: Median age was 53 years (range from 19 to 70). Fifty-eight percent were male and 79.13% were classified as de novo MDS. According to WHO 2008 classification 4 (3.5%) were RCUD, 2 (1.8%) RARS, 22 (19.50%) RMDS, 28 (24.8%) RAEB-1, 32 (28.3%) RAEB-2, 12 (10.6%) Unclassifiable MDS, 9 (8%) CMMML and 4 (3.5%) were AML (FAB RAEB-T). Among patients with calculated Revised IPSS (R-IPSS) (85 of 115 patients) 2 (2.4%) had very low risk, 15 (17.6%) low risk, 21 (24.7%) intermediate risk, 22 (25.9%) high risk and 16 (18.6%) had very high risk; 9 patients with CMMML (10.6%) were categorized as very high risk. Among patients with Karyotype (101 of 115 patients) 43 (41%) had a complex karyotype (CK). Among patients with CK, 26 (60.5%) did not show any mutation before transplant; 27 patients (23.5%) had 1 mutated gene, 15 (13%) had 2, 19 (16.5%) had 3, 6 (5.2%) had 4, 3 (32.6%) had 5 and only 1 patient (0.9%) had 6 different mutated genes. The most frequently mutated genes were: TET2 in 13 patients (15%), SF3B1 in 14 (12.2%), ASXL1 in 10 (11.3%), RUNX1 in 9 (7.8%), SF3B1 in 9 (7.8%) and ASXL1 in 8 (7%) patients. After a median of follow up for survivors of 2.02 years, Overall Survival (OS) was 48.1% (63.4% at 1 year; median 5.96). Patients were divided into 2 groups: group 1, with 2 or less mutated genes and group 2, more than 2 mutated genes. Group 1 had a lower OS (46.9% vs 69.6% at 1 year; p=0.035) and a higher Cumulative Incidence of Relapse (CIR) (25.3% vs 10.1% at 1 year; p=0.007). Development of cGVHD significantly improved outcome in both groups (Figure 1). Univariate analysis determined that developing of cGVHD, CK, number of mutated genes (more than 2 mutated genes) and mutations in TET2 significantly impacted on outcome. Nevertheless, only the development of cGVHD as a time-dependent variable (HR 0.046, 95%CI 0.016-0.138, p<0.001) and TE2 mutations (HR 2.562, 95%CI 1.018-6.447, p=0.046) significantly influenced on OS in multi-

Figure 1.

Summary/Conclusions: Chromosome 7 cytogenetic categories and IPSS retained a poor prognosis over time with a constant value of poor prognosis. AZA treatment had a favorable impact on OS during the first 3 years of treatment, compared to BSC, confirming results obtained in univariable analysis. Nevertheless, the benefit of AZA treatment as compared to BSC approach decreased as time spends and the HR value increased over time: HR of 0.3 at 6 months, 0.5 at 1 year and 0.7 at 2 and 3 years after treatment. (Figure 1). This benefit was present in all chromosome 7 categories with a a trend towards better impact among patients with complex karyotype but no significant differences between the 3 categories (-7, del(7q) and CK).
We also observed the unfavourable impact of TP53 mutations on relapse risk; CIR was 41.7% (95% CI 22.5-77.1) at 1 year for TP53 mutated vs 9.8% (95% CI 5.3-18.1) at 1 year for non TP53 mutated patients (p=0.006).

Summary/Conclusions: We conclude that the number of mutated genes prior to transplant could be a prognostic factor of OS and CIR. Mutations in some genes, like TET2 and TP53, could also have an adverse impact on outcome. However, cGVHD could ameliorate the poor prognosis of somatic mutations in transplanted patients with MDS.

P319

VOSAROXIN PLUS AZACITIDINE TREATMENT FOR PATIENTS WITH MYELODYSPLASTIC SYNDROME: A PHASE 1/COHORT EXPANSION STUDY

M.A. Jacoby1,*, M.J. Walter1, J.F. DiPersio1, C.N. Abboud1, P. Westervelt1, A.F. Cashen1, K. Stocker-Goldstein1, T. Fletcher1, G.L. Uy1

1Medicine, Washington University Medical School, St. Louis, United States

Background: Although hypomethylating agents are the mainstay of treatment for myelodysplastic syndromes (MDS), these agents result in remissions in a minority of patients and are not curative. Vosaroxin is a first-in-class quinolone derivative that intercalates DNA and inhibits topoisomerase II. Vosaroxin is active with a tolerable safety profile in acute myeloid leukemia (AML) and the novel combination of vosaroxin and azacitidine was found to be synergistic in primary myeloblasts.

Aims: This phase 1/cohort expansion study was designed to determine the maximum tolerated dose (MTD) and dose-limiting toxicity (DLT) of vosaroxin when given in combination with azacitidine, and to evaluate the efficacy and safety of the combination treatment.

Methods: Patients with MDS ≥18 years old with cytopenias requiring transfusions, an IPSS score of intermediate (INT)-1 or greater, or chronic myelomonocytic leukemia were eligible. Vosaroxin (initial dose: 50 mg/m²/d) was administered on Days 1 and 4, and azacitidine (75 mg/m²/d) on Days 1-7 of a 28-day cycle, in an outpatient setting, for up to 6 cycles in a 3+3 design (additional cycles were permitted if a clear benefit for the patient was demonstrated). Once the MTD was determined, an expansion cohort of 20 evaluable patients (≥1 cycle) was enrolled.

Results: A total of 35 patients enrolled in the dose escalation (n=13) and expansion (n=22) phases. The median age of the entire cohort was 66 years (range 38-77) with IPSS scores of low (n=1); INT-1 (n=13); INT-2 (n=15); and high risk (n=6). The median ECOG score for the entire cohort was 1 (range 0-2). In the dose escalation phase, at the initial dose of vosaroxin 50 mg/m²/d (n=6), the median number of total cycles was 2 (range: 1-4); 2 of 6 patients experienced a DLT at this dose (grade 4 hyperbilirubinemia and grade 4 neutropenia >42 days). At the de-escalated dose of 34 mg/m²/d (n=7), the median number of cycles was 2 (range: 1-18); 1 patient experienced a DLT at this dose (grade 4 mucositis). The MTD of vosaroxin was determined to be 34 mg/m²/d when given on Days 1 and 4 with a fixed dose of 75 mg/m² of azacitidine on Days 1-7. The major non-hematologic toxicities were infections, febrile neutropenia, and bleeding. The combination of vosaroxin and azacitidine showed promising activity with responses rates comparable or better than those generally observed with azacitidine alone. Additionally, the transplant rate observed was encouraging in this patient population.

Table 1.

Summary/Conclusions: The MTD of vosaroxin in MDS patients was 34 mg/m²/d when given on Days 1 and 4 with a fixed dose of 75 mg/m² of azacitidine on Days 1-7. The major non-hematologic toxicities were infections, febrile neutropenia, and bleeding. The combination of vosaroxin and azacitidine showed promising activity with responses rates comparable or better than those generally observed with azacitidine alone. Additionally, the transplant rate observed was encouraging in this patient population.

ADVANCED STAGE MYELOMA IS CHARACTERIZED BY A SIGNIFICANT INCREASE OF MUTATIONS IN GENES ASSOCIATED WITH DRUG RESPONSE

1Hematology, Würzburg University Hospital, Würzburg, Germany, 2Hematology-Oncology, IRCCS Policlinico San Matteo, Pavia, Italy, 3Hematology, Mayo Clinic, Scottsdale, United States, 4Hematology, Doce de Octubre University Hospital, Madrid, Spain, 5Hematology, Erasmus Medical Center, Rotterdam, Netherlands, 6Hematology, Heidelberg University Hospital, 7German Cancer Research Center, Heidelberg, 8Pathology Institut, Würzburg University Hospital, 9Comprehensive Cancer Center Mainfranken, Würzburg University Hospital, Würzburg, Germany, 10Center of Individualized Medicine, Mayo Clinic, Rochester, United States

Background: The amount of genomic data available in Multiple Myeloma (MM) is exponentially increasing, however, hardly any of that information is translated into the clinic. A number of genes has been associated with resistance to commonly used anti-MM compounds. This, most importantly, includes immunomodulators (IMiDs) and proteasome inhibitors (Ps). However, no mutation screening has yet been amended to our MM routine diagnostic workflows. We investigated 458 MM patients by targeted sequencing, including the largest cohort of previously treated MM patients so far. We identified an increased mutation incidence in treated patients, yet unreported mutations and functionally validated a subset.

Aims: To describe the mutational spectrum in genes of pathways targeted by standard of care (SOC) therapies in a cohort of pretreated and previously untreated patients.

Methods: Tumor-germline paired samples of five contributing sites were pooled (Würzburg, Heidelberg, Madrid, Rotterdam and Mayo Clinic). Analysis included 310 untreated and 148 IMiD and/or PI treated patients. Targeted sequencing was performed using the MP-P (v2.0 or v3.0) gene selection, that includes most commonly mutated MM genes, actionable drug targets and genes being associated with drug resistance. Average sequencing depth increased 700X. Functional analyses of PSMB5 mutations were conducted using Sleeping beauty vectors transposed into AMO1 cell line.

Results: Our analysis included five genes each with known association to drug response to IMiDs (CRBN, CUL4B, IKZF1, IKZF3 and IRF4) and Ps (PSMB5, PSMB8, PSMB9, PSMD1 and XBP1). Based on the increased sequencing depth, the mutation incidence in untreated patients is higher than in the CoMMPass dataset (IMiDs: 5.8% vs 3.9%; Ps: 1.9% vs 1.4%). Furthermore, pre-treated patients showed a significant mutational increase compared with untreated pts (IMiDs: 19.7%, Z-score: -4.2, p<0.001; Ps: 7.3%, Z-score: -2.6, p=0.009). We observed a Gly159Arg mutation within the Lenalidomide (Len) degron sequence of IKZF3 in a patient progressing on Len and Portalidomide (Rom), as well as two XBP1 truncating mutations in PI refractory patients. Of note, among three treated cases with mutations in the β5 (PSMB5) or β5i (PSMB8) PI binding subunit of the proteasome, one patient harbored not less than 4 subclonal mutations. This is the first description of PSMB5 mutations in human MM, identified in a patient with long term history of PI treatment. All mutations were located in or close to the Bor binding site of PSMB5. The functional analysis demonstrated induced resistance not only to Bor (IC50PSMB5mut= 2 nM vs IC50PSMB5wt= 4.5-8 nM), but also to the second generation PI Ixazomib (IC50PSMB5mut= 5.2 nM vs IC50PSMB5wt= N/A) and Carfilzomib (IC50PSMB5mut= 8 nM vs IC50PSMB5wt= 13-22 nM). Of interest, the P97 blockade of the protein homeostasis by the investigational compound CB5083 remains still possible in the mutated cell lines and the resistance can be overcome. Finally, Pom treatment eradicated two of the PSMB5 containing subclones (Figure 1).

Summary/Conclusions: Under the selective pressure of anti-MM therapy the incidence of mutations in genes associated with drug resistance increases in treated patients. Resistance mechanisms evolve in parallel in competing (sub)clones of the disease, mimicking phenotype and behavior. Remarkably, despite our restrictive gene selection, a quarter of our treated cohort is affected by at least one mutation. Aim of future therapy may be the eradication of selected clones or subclones, which, according to our data, appears possible.

Figure 1. A: Mutation incidence in IMID related and PI related genes. B: Functional analysis of PSMB5mut expressing AMO1 cells with different PI inhibitors and the P97 inhibitor CB5083.

ILF2-YB1 INTERACTION MODULATES RNA SPlicing TO INDUCE RESISTANCE TO DNA-DAMAGING AGENTS IN 1q21-AMPLIFIED MULTIPLE MYELOMA

1Leukemia, MDAnderson Cancer Center, Houston, United States, 2Neurology, University of Milan, Milan, 3Clinical and Experimental Medicine, University of Parma, Parma, Italy, 4Genomic Medicine, MDAnderson Cancer Center, Houston, TX, 5Hematology, Doce de Octubre University Hospital, Madrid, Spain, 6Hematology, Erasmus Medical Center, Rotterdam, Netherlands, 7German Cancer Research Center, Heidelberg, 8Pathology Institut, Würzburg University Hospital, 9Comprehensive Cancer Center Mainfranken, Würzburg University Hospital, Würzburg, Germany, 10Center of Individualized Medicine, Mayo Clinic, Rochester, United States

Background: The 1q21 amplification, which occurs in approximately 40% of de novo and 70% of relapsed Multiple Myeloma (MM), is among the most frequent chromosomal aberrations in MM patients and is considered a very high-risk genetic feature that is especially correlated with disease progression and drug resistance. The 1q21 amplicon contains many genes, and while it is unlikely that all contribute to the pathobiology of high-risk MM, the critical genes that do drive this high-risk phenotype have not yet been fully clarified. Identifying such genes and their contributions to this phenotype would enable the development of new and effective targeted therapy strategies for high-risk MM and thus improve their survival outcomes.

Aims: In our study we wanted to investigate the biological and molecular mechanisms behind the 1q21 amplification’s contribution to high-risk MM with the ultimate goal of obtaining a list of validated therapeutic targets to inform the design of novel translational clinical trials for this subgroup of patients.

Methods: We conducted a high-resolution analysis of recurrent copy number alterations and expression profiles in a collection of 254 MM samples included in MRMC database. To define the discrete minimal common 1q21 region that is recurrently amplified in MM, we used Genomic Identification of Significant Targets in Cancer, a systematic method that identifies regions of genome that are recurrently amplified or deleted across a set of samples. These regions were enlisted into an in vitro screening strategy that employed a single-stranded-sRNA-per-96-well approach and GFP-competitive cell growth assay to identify 1q21 genes whose loss of function resulted in the selective death and/or growth inhibition of MM cells carrying the 1q21 amplification but not MM cells without the 1q21 amplification.

Results: We identified MCL1, UBA2P2L, INITS3, LASS2, KRTCAP2 and ILF2 as potential 1q21-specific vulnerability targets whose expression is driven by copy number. We functionally validated, both in vitro and in vivo, Interleukin-2-enhancer binding factor 2 (ILF2) as a key 1q21 amplification-specific gene. Our results show that ILF2 interacts homologous recombination (HR) and induces resistance to DNA damaging agents routinely used in the treatment of MM, which is consistent with the observation that ILF2 expression correlates with poor survival in MM patient treated with high-dose melphalan followed by tandem autologous transplantation. On the mechanistic level, ILF2 interacts with numerous RNA binding proteins directly involved in the regulation of DNA Damage Response (DDR) by modulating alternative splicing of specific pre-mRNAs. RNA sequencing experiment confirmed that ILF2 knockdown results in aberrant splicing of genes involved in the DDR pathways and, strikingly, ILF2 RIP-seq analysis showed that ILF2 directly binds to transcripts involved in the regulation of the HR pathway, including components of BRCA1 protein complex. Furthermore, we found that ILF2 mediates drug resistance in dose-dependent manner by modulating YB-1 nuclear localization and interaction with the splicing factor U2AF65 to promote mRNA processing and stabilization of DDR genes in response to DNA damage (Figure 1).

Summary/Conclusions: In conclusion, our study reveals an intimate relationship among 1q21 amplification, mRNA splicing and DNA repair in the control of DDR in MM. On the basis of our findings, we propose that 1q21-driven ILF2 overexpression deregulates HR by stabilizing the mRNA splicing of critical HR
effectors, which enables genomic instability, promotes adaptive mechanisms to genotoxic stress, and enhances cell survival, thereby promoting drug resistance and disease progression. Given that 1q21 amplification is one of the most frequent copy number alterations in cancer, synthetic lethality approaches based on targeting gain-of-function associated to ILF2 may have a broad spectrum of application to potentiate the sensitivity of cancer cells to chemotherapeutic agents.

Background: High throughput techniques, such as next generation sequencing, are becoming an appealing approach to characterize multiple myeloma (MM) genomic profiles and better define risk assessment. However, the clinical relevance of such approaches is still largely unknown. The Multiple Myeloma Research Foundation (MMRF) CoMMpass trial (NCT01454297) has collected data from 1154 newly-diagnosed MM patients enrolled worldwide. Comprehensive analysis of somatic mutations in MM cells at diagnosis could unravel prognostically relevant disease characteristics not detectable with traditional approaches.

Aims: We analyzed data from the interim analysis 8 cohort (August 2015) to create a prognostic model.

Methods: CD138+ purified MM specimens from bone marrow aspirates and peripheral blood cells were collected at diagnosis. Whole exome libraries from both tumor and constitutional DNA samples were created. Somatic single nucleotide variants (SNV) were identified, only nonsynonymous SNV were included in the analysis. We evaluated the impact on progression free survival (PFS) of recurrently mutated genes (with at least a nonsynonymous SNV with a nonbiased manner (Table 1): group I (score 0-2, 17%); group II (score 3, 51%), group III (score 4-5, 26%) and group IV (score >5, 6%). After a median follow-up of 371 days, the 18-month PFS was 93% for group I, 85% for group II, 73% for group III and 40% for group IV (Figure 1). The hazard ratio was 2.31 (p=0.118) for group II versus group I. 4.45 (p=0.006) for group III versus I and 17.38 (p<0.001) for group IV vs I. The prognostic trend of the score was confirmed in different patient subgroups including ASCT/no ASCT, standard/high risk cytogenetic profile, ISS I, II, or III. Of note, 23% of patients in group I had ISS III and 34% of patients in group IV had ISS I.

Table 1.

Summary/Conclusions: The use of a prognostic model based on the mutational status of 9 recurrently mutated genes could improve risk assessment of newly-diagnosed MM patients. Longer follow-up and validation in independent cohorts of patients are needed to confirm our findings. Updated results with a longer follow-up will be presented at the meeting.

TARGETING GENE DEPENDENCY OF 1Q AMPLIFICATION IN MULTIPLE MYELOMA

S. Manier1,2,*, D. Huynh2, J. Park2, K. Salem2, X. Leleu3, I. Ghobrial4
1Hematology, Lille Hospital, Lille, France, 2Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, 3Hematology, University of Lille 2, Lille, France, 4Medical Oncology, Dana-Farber Cancer Institute- Harvard Medical School, Boston, United States

Background: Gain of 1q is one of the most frequent copy number variations across cancer types and in Multiple Myeloma (MM). Gain of 1q is associated with a poor outcome, indicating it is a potential driver in MM progression and resistance to treatment. While the whole 1q arm can be amplified in some cases, a specific minimal amplified region has been identified by CGH array, including approximately 500 genes in the 1q21.1-23.3 region. However, the driver genes in the 1q region are unknown.

Aims: We hypothesize that specific genes present in the 1q minimal amplified region are critical regulators of clonal evolution and tumor progression in MM.

Methods: To explore gene dependency in 1q21.1-23.3 in MM, lung, breast and
ovoian cancers, we performed a shRNA targeted screen, using the C911 technology. We used 14 cell lines including MM, lung, and breast cancer cell lines. We designed a pooled library targeted shRNA/C911 screen containing 6 shRNAs along with their matched control for each of the 500 genes in the 1q21-23.3 region, including IncRNA and mRNA in addition to protein coding genes. The pooled library contained 6500 shRNAs, including C911 controls as a control. We used the RIGER software to call hits, using the Kolmogorov-Smirnov algorithm. To complement the 1q-targeted shRNA screening, we studied both the Achilles dataset and patients’ gene expression profiling from the Multiple Myeloma Genomic portal (MMGP) and the Cancer Genome Atlas (TCGA). Using lists of candidate genes from a large expression-profiling resource developed by the Library of Integrated Network-based Cellular Signatures (LINCS) program to identify potentially active drug targeting our candidate genes. Finally, a targeted drug screening was performed using 170 compounds identified through the LINCS program and using the Proliferation and Cytotoxicity Assay (PCIA). Compounds that significantly altered the expression-profiling platform were further validated in 1q+ (OPM2, H929 and KMS11) and non 1q cell lines (KMS18). Results: We were able to identify 10 candidate genes, for which knockdown significantly impaired proliferation of gain of 1q cell lines. Several candidate genes were identified as being the top genes preferentially affecting the proliferation of gain of 1q cell lines. To further confirm that our candidate genes are overexpressed in gain of 1q patients, we studied publicly available gene expression profiling from the MMGP and TCGA. Five of the 10 genes were significantly overexpressed in patients with gain of 1q. We then generated a gain of 1q signature by analyzing publicly available gene expression profiling from patients with MM, lung, and breast cancer. These data showed a high correlation to IMiD resistance. Compounds causing this to targeted signature further validated in 1q+ (OPM2, H929 and KMS11) and non 1q cell lines. We next queried the core signature against the MSigDB ‘c2’ canonical pathways and ‘c3’ transcription factor pathways in GSEA and consistently identified a significant enrichment of cell cycle and E2F pathways. A targeted drug screen was then performed using FDA approved drugs and based on specific targets identified by analyzing the expression of non 1q+ MM cell lines, and showed significant differential activity of these compounds on 1q vs non 1q+ MM cell lines. Summary/Conclusions: Gain of 1q is one of the defining features of high-risk MM and is associated with adverse outcomes. We developed a systematic approach to identify dependencies in gain of 1q MM combining a loss-of-function pooled screen, a computational approach and a drug screen to identify novel therapeutic targets in MM.

1Hematology, 2Pathology, Rigshospitalet, 3ERIC, Copenhagen, Denmark, 4Urology, USC, Los Angeles, United States

Background: The introduction of novel agents for the treatment of multiple myeloma (MM), mainly proteasome inhibitors and immunomodulatory agents (IMiDs), has significantly improved the survival rates of the patients, and both classes of drugs stand as the main treatment options for MM. Several studies have identified Cereblon (CRBN) as the direct target of not only thalidomide, but also lenalidomide and pomalidomide, and suggested that its expression is critical for the anti-myeloma effect of these drugs. However, even though the expression levels of CRBN have been associated with response to IMiDs, not all patients respond to CRBN-targeted therapy. As an alternative approach, we aimed to use the epigenome profiling resource developed by the Library of Integrated Network-based Cellular Signatures (LINCS) program to identify potentially active drug targeting our candidate genes. Finally, a targeted drug screening was performed using 170 compounds identified through the LINCS program and using the Proliferation and Cytotoxicity Assay (PCIA). Compounds that significantly altered the expression-profiling platform were further validated in 1q+ (OPM2, H929 and KMS11) and non 1q cell lines (KMS18). Results: We were able to identify 10 candidate genes, for which knockdown significantly impaired proliferation of gain of 1q cell lines. Several candidate genes were identified as being the top genes preferentially affecting the proliferation of gain of 1q cell lines. To further confirm that our candidate genes are overexpressed in gain of 1q patients, we studied publicly available gene expression profiling from the MMGP and TCGA. Five of the 10 genes were significantly overexpressed in patients with gain of 1q. We then generated a gain of 1q signature by analyzing publicly available gene expression profiling from patients with MM, lung, and breast cancer. These data showed a high correlation to IMiD resistance. Compounds causing this to targeted signature further validated in 1q+ (OPM2, H929 and KMS11) and non 1q cell lines. We next queried the core signature against the MSigDB ‘c2’ canonical pathways and ‘c3’ transcription factor pathways in GSEA and consistently identified a significant enrichment of cell cycle and E2F pathways. A targeted drug screen was then performed using FDA approved drugs and based on specific targets identified by analyzing the expression of non 1q+ MM cell lines, and showed significant differential activity of these compounds on 1q vs non 1q+ MM cell lines. Summary/Conclusions: Gain of 1q is one of the defining features of high-risk MM and is associated with adverse outcomes. We developed a systematic approach to identify dependencies in gain of 1q MM combining a loss-of-function pooled screen, a computational approach and a drug screen to identify novel therapeutic targets in MM.

MULTILAYER EPIGENOMIC ANALYSES REVEAL OF NEW CANDIDATE ONCOGENES INVOLVED IN THE PATHOGENESIS OF MULTIPLE MYELOMA

R. Ordoñez1, M. Kulis2, N. Russinhio2, B. Paiva3, R. Beekman3, C. Meydan4, N. Ralfs5, A. Carro1, V. Trauger2, J.I. Martin-Subero1, A. Melnick4, F. Prósper1, J. Agirre1, J.I. Martin-Subero2

1Oncohematology, Center for Applied Medical Research (CIMA), Pamplona, 2Departamento de Fundamentos Clínicos, Universitat de Barcelona, 3Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, 4Dept. of Medicine, Weill Cornell Medical College, New York, United States, 5Radboud Institute for Molecular Life Sciences, Nijmegen, Netherlands, 6Center for Applied Medical Research (CIMA), 7Clínica Universitaria de Navarra, Pamplona, 8Hospital Clinic, Barcelona, Spain

Background: Most of the published omics studies in multiple myeloma (MM) have focused on the analysis of the genome, transcriptome and DNA methylation. Over the last years, the chromatin structure and histone modifications are emerging as essential epigenetic layers to understand gene deregulation in MM. Although this field remains widely unexplored in MM.

Aims: We herein aim to elaborate a comprehensive description of the MM epigenome including multiple layers of information.

Methods: We performed ChiP-seq of six histone modifications with non-overlapping functions (H3K4me3, H3K4me1, H3K79ac, H3K36me3, H3K27me3, and H3K9me3), ATAC-seq for chromatin accessibility, Whole Genome Bisulfite Sequencing (WGBS) for DNA methylation, and RNA-seq for gene transcription in purified bone marrow plasma cells from four MM patients and, as healthy controls, naive B cells, germinal center B cells, memory B cells and plasma cells. Data were extensively mined using a battery of different bioinformatic tools.

Results: An integrative analysis of ChiP-seq data from six histone marks allowed us to segment the genome into functional chromatin states, such as promoters, enhancers, transcriptional regions with repressed histone modification activity, and to detect regions with significant differences in chromatin activity between MM and normal plasma cells, we elaborated a new algorithm that allowed us to transform the qualitative chromatin state data into a quantitative chromatin activation score (ChromAS). When we compared the ChromAS between MM and normal plasma cells, we detected over 13000 DNA methylation or transcriptional changes that were unique to MM, near 90% were gaining activity in MM, suggesting a widespread activation of their chromatin landscape. To further characterize this phenomenon, we calculated the mean ChromAS per gene and performed a K-means clustering of MM and control cells. Interestingly, we identified the presence of a cluster comprising genes whose chromatin was increasing activated in MM as compared to all normal cells. These findings were further validated by ChiP-seq in an additional series of 10 MM patients. We next focused on the genes that gained novel activity in MM and were completely inactive (i.e. hypomethylated) in normal
cells. Out of this list, we observed that two adjacent genes, PRDM5 and NID1, were co-activated in MM. The analysis of their expression in additional patient cohorts indicated that their co-activation is a consistent event in MM pathogenesis and that their levels were negligible in bone marrow and tonsillar plasma cells. When analyzing chromatin topology by 4C-Seq, we identified 3D interactions between both gene loci only in MM cells, suggesting that DNA looping between the two genes may be related to their co-activation in MM. Finally, knockdown of each of these genes using inducible shRNAs, decreased cell proliferation and induced apoptosis in MM cells.

Summary/Conclusions: Collectively, our initial exploration of histone modification profiles in MM has revealed an extensive activation of the MM chromatin landscape, which harbor a new candidate oncogene. Reversing this global activation by epigenetic drugs, such as BET inhibitors, may represent an attractive therapeutic option for MM.

P326
CLINICAL IMPLICATIONS OF CLONAL CDS4+ CELLS: STEM CELL HARVEST FROM PATIENTS WITH PLASMA CELL DYSCRASIAS

S. Chitre1, F. Stölzel2, K. Cuthill1, M. Streetly1, C. Graham1, M. Bornhaeuser2, G. Mufti1
1Haematological Medicine, KINGS COLLEGE LONDON, London, United Kingdom, 2Department of Internal Medicine I, University of Dresden, Dresden, Germany

Background: Introduction of novel treatments; Lenalidomide, high-dose alkylating agents (Melphanal) conditioning prior to autologous stem cell transplant (ASCT) over the last few decades has improved overall survival in patients with multiple myeloma (MM). In spite of enhanced survival rates, bone marrow abnormalities (especially Lenalidomide maintenance post ASCT) have come under scrutiny for causing therapy related myeloid neoplasms and secondary malignancies (SPM) like Myelodysplastic syndrome (MDS) and Acute myeloid Leukaemia (AML). Clonal haematopoiesis resulting in sequential accumulation of a combination of driver-passenger genetic mutations (in upto 80% of MDS & ~95% AML patients) steer MDS/AML disease pathogenesis and clinical outcome. Therefore, we hypothesised that detection of Clonal Haematopoiesis of Indeterminate Potential (CHIP) in haematopoietic stem cells (HSCs) prior to ASCT in patients with MM treated with a range of therapies could be utilised for predicting patients at risk of developing SPMs i.e. MDS/AML.

Aims: To ascertain baseline mutational spectrum [especially low-level clones with variant allele frequency (VAF) ≤5%] of MDS/AML associated gene mutations in HSCs prior to ASCT in order to predict patients at risk of clonal evolution, transformation to MDS/AML.

Methods: DNA was isolated from mononuclear cells (MNCs) collected by leukopheresis prior to ASCT from 128 MM patients. A customised amplicon-based Illumina MiSeq panel was used for the sensitive interrogation of 24 most common genes harbouring mutations in MDS/AML (splicing factor genes; NPM1, SRSF2, U2AF1 and ZRSR2, genes implicated in epigenetic regulations; IDH2, IDH1, ASXL1, EZH2 & DNM3A, known cancer driver genes involved in cell signalling/transcription regulation and cohesion complex; TP53, FLT3, NRAS, KRAS, ETV6, RUNX1, CBL, C-KIT, JAK2, MPL, CEBPA, STAG2, GATA2, KDM6A and NPM1). Variant analysis was performed using Illumina Variant Studio (>5% VAF & read depth ≥150X threshold) and dbSNP132, UCSC genome browser, Exome sequencing project (esp6500), Exome Aggregation Consortium (ExAc)

Results: Seven patients (6.25%) contained heterozygous somatic mutations (VAF range 7-50%) in DNM3TA, IDH1, IDH2, ET2, ET2, and CBL genes (Table 1). Four missense mutations identified in DNM3TA were aggregated in the Mase domain responsible for its methyltransferase activity indicating a strong intent to abrogate this function. Previous studies confirm R882 variant (accounts for ~60% DNM3TA mutations) as a founder lesion in MDS/AML stratifying with clonal haematopoietic dysfunction, HSC differentiation and DNMT3A mutation in CBL (I429F) has been previously reported in CML cases (while translocations and deletions of ETV6 are more common in AML). 50% comparison to mutations suggesting its role as a tumor-suppressor. Genes identified in our cohort are frequently associated with MDS & AML; IDH1/IDH2 (5 & 20%), ET2 (12 & 20%), DNM3A (8 & 20%) and associated with poor prognosis (DNM3TA, IDH1/IDH2, SNPs array karyotyping on 4/7 cases (patients 1-4) displayed no chromosomal abnormalities. Median age at diagnosis in these four cases was 65 (range 60-70), long-term follow up (3-5 yrs) revealed relapse of MM in patient 1 and 3, acute kidney injury with myeloma in patient 2 and transformation to AML in patient 4.

Summary/Conclusions: Our data identifies for the first time a subgroup of MM patients (6.25%) with no morphological evidence of MDS/AML prior to ASCT but harbouring CHIP in CD34+ harvest stem cells and later developing MDS/AML. These findings are pivotal for identification of such patients at risk of clonal evolution and transformation prior to ASCT since it can be a significant parameter in determining appropriate treatment modality i.e. whether or not to employ CHIP harbouring CD34+ harvest stem cells as therapy for these patients.

P327
PATHOPHYSIOLOGICAL FUNCTIONS AND CLINICAL IMPACT OF THE NEW IMMUNORECEPTOR SLAMF3 IN MULTIPLE MYELOMA

M. Ishibashi1,2,*, H. Tanaka3, Y. Asayama1, Y. Kuribayashi-hamada1, A. Onodera1, K. Moriya1, M. Sasaki2, H. Handa3, Y. Imai4, J. Tanaka5, S. Tanoaka6, S. Ito7, K. Inokuchi1
1Division of Hematology, Department of Medicine, Nippon Medical School, 2Division of Hematology, Department of Internal Medicine, Juntendo University School of Medicine, Tokyo, 3Department of Hematology, Kyorin University School of Medicine, 4Department of Hematology, Tokyo Women’s Medical University, 5Department of Hematology, Fraternity Memorial Hospital, Tokyo, 6Department of Medical Oncology, Iwate Medical University School of Medicine, Morioka, Japan

Background: The signaling lymphocytic activation molecule family 3 (SLAMF3) is a member of the immunoglobulin superfamily expressed on T, B, and natural killer cells and modulates the activation and cytotoxicity of these cells via self-ligand binding. SLAMF3 is also expressed on plasma cells from patients with multiple myeloma (MM), although its role in MM pathogenesis remains unclear.

Aims: To clarify this, we investigated the expression and functions of SLAMF3 in MM.

Methods: 1) Two hundred thirty patients comprising 153 newly diagnosed (19 asymptomatic and 134 symptomatic) MM patients, 30 refractory/relapsed MM patients, and 47 patients with monoclonal gammopathy of undetermined significance were enrolled. SLAMF3 and CD138 expression levels on clonal plasma cells were analyzed using flow cytometry (FCM). Soluble SLAMF3 (sSLAMF3) serum levels were measured using ELISA. 2) Drug sensitivity to antimielyoma agents (melphalan and bortezomib) and the proliferation potential in MM cell lines KMS18 and U266 were analyzed using FCM and the MITT assay. SLAMF3 knockdown MM cell lines were obtained using the lentiviral shRNA system and siRNA. Stable transfected KMS34 cell lines overexpressing full-length SLAMF3 and cytoplasmic domain-truncated SLAMF3 were established through corresponding vectors. Single-nucleotide polymorphism (SNP) genotyping was analyzed by real-time PCR. The adaptor protein of SLAMF3 was identified by Western blotting and immunoprecipitation.

Results: 1) SLAMF3 was highly expressed on plasma cells in almost all MM patients, even in relapsed/refractory disease, although CD138 expression levels were decreased in some with advanced disease. 2) The proliferative potential and percentage of antimyeloma agent-induced apoptosis in SLAMF3 expressing MM cells were significantly higher and lower than in SLAMF3 knockdown cells, respectively. 3) The cell proliferation and drug resistance in SLAMF3-expressing KMS34 cells were promoted in comparison with SLAMF3 knockdown cells. That malignant potential in MM cells was cancelled by SLAMF3 knockdown. Furthermore, the proliferation of MM cells and resistance to antimyeloma agents were inhibited by anti-SLAMF3 antibody. Adaptor proteins, SHP2 and GRB2, were expressed in MM cell lines, but neither SAP nor EAT-2 were. SLAMF3 interacted directly with SHP2 and GRB2, and SHP2 also interacted with GRB2. SHP2 inhibitor-treated or SHP2/GRB2 knockdown cells had characteristics similar to SLAMF3-knockdown cells. 3) The frequency of GG genotypes of SLAMF3 SNP rs509749 in MM patients was 63.6% (n=28), of AG 29.5% (n=13), and of AA 6.8% (n=3). Patients with GG genotypes tended to have shorter overall survival times than patients with AG genotypes. 4) sSLAMF3 levels were significantly higher in symptomatic MM than in asymptomatic MM and markedly increased in advanced MM. MM patients with high levels (≥3.3 ng/ml, n=62) of sSLAMF3 progressed to the
Background: CD74 is a transmembrane glycoprotein involved in MHC protein formation and transport. CD74 expression has been observed in up to 90% of B-cell malignancies, including multiple myeloma (MM), with minimal expression in normal tissues. CD74 is rapidly internalized, making it an attractive target for ADCs. STRO-001 is a novel ADC comprised of an aglycosylated anti-CD74 human antibody (SP7219) conjugated covalently to the non-natural amino acid para-azido-methyl-L-phenylalanine (pAMF) with a non-cleavable dibenzocyclooctyne (DBCO)-maytansinoid linker-warhead. Highly efficient site-specific conjugation enabled by novel cell-free antibody production and click chemistry results in a well-defined homogeneous ADC drug product with a drug-antibody ratio (DAR) of 2.

Aims: The in vitro cytotoxicity and in vivo efficacy of STRO-001 was investigated in MM cell lines and xenografts. An exploratory toxicity study was conducted in a non-human primate model.

Methods: DSBO-Alexa647-conjugated SP7219 staining and flow cytometry were used for detection and quantitation of CD74 expression on MM cell lines. STRO-001 was used to determine the EC50 and percent span of killing in MM. Furthermore, high levels of serum sSTRO-001 may reflect MM disease progression and be a useful prognostic factor in MM. Thus, SLAMF3 molecules may be a new potential target for future immunotherapy and chemotherapy.

Summary/Conclusions: STRO-001 demonstrates potent in vitro cytotoxicity in MM cell lines and reduces tumor burden in MM xenograft models, including significant prolongation of survival in the MM.1S model. Based on these encouraging observations, STRO-001 is advancing to the clinic for the treatment of CD74-expressing B-cell malignancies.

P329

GENOTYPE CHARACTERIZATION OF LIGHT CHAIN AMYLOIDOSIS BY WHOLE EXOME SEQUENCING

1Hematología traslacional, Hospital 12 de Octubre, Madrid, 2Centro de Investigacion Medica Aplicada, Pamplona, 3Hospital Universitario de Salamanca, Instituto de Investigacion Biomedica de Salamanca (IBSAL), Centro de Investigacion Biomolecular (SMCC-CSIC-USAL), Salamanca, 4Hospital Clinico Universitario de Valladolid, Valladolid, 5Hospital Virgen del Puerto, Plasencia, 6Hospital German Trias i Pujol, Badalona, 7Hospital de Cabuérniga, Gijón, 8Complejo Hospitalario de León, León, 9Hospital Universitario de Burgos, Burgos, Hospital Clinico Universitario Lozano Blesa, Zaragoza, 10Hospital Rio Carrión, Palencia, 12Clinica Universidad de Navarra, Pamplona, Spain

Background: Immunoglobulin light-chain amyloidosis (AL) is a heterogeneous and multifactorial disease with high genetic complexity. Until now, no common factor or unique mutation associated with this disease has been described. Whole exome sequencing in Multiple Myeloma (MM) patient’s tests allowed to know important genes and pathways that are involved in the disease. However, few evidences through next generation sequencing (NGS) analysis were described in AL. Consequently, the application of NGS technologies permits unraveling the genomic landscape of AL to better disentangle the biology of the disease, allowing the identification of new therapeutic targets as in MM.

Aims: Genotype characterization of novel molecular alterations in AL plasma cell by whole-exome sequencing technology.

Methods: We studied 40 paired samples (sorted pathological plasma cells and peripheral blood) from 20 patients with AL. Whole exome and regulatory regions were captured using Agilent’s SureSelect Human All Exon V6+UTR kit and sequenced on the Illumina NextSeq 500 platform with pair-end sequencing technique with a global mean depth coverage of 70x, on target coverage of 96.5% and a Phred quality score of 91.3% up to Q30. Data were analyzed with wANNOVAR for functional annotation, and a data reduction strategy to identify candidate variants.

Results: After analysis of patient samples we got an average of 76 (range 18-177) mutations per patient. 28.4% of the mutations was located on regulatory regions (5' UTR, 3' UTR). So far, we did not identify recurrent mutations between the patients, although some patients presented different mutations on the same gene.

The mutation pattern was very heterogeneous between patients. We identified alterations in genes involved in extracellular matrix (MMP2), cell proliferation, differentiation and development (TFGA), transcription factors (ZFHX3, HNRP-NPL), adherent junction function (RASSF8), GTPases (RASSF8), and genes of the collagenase family (COL9A1, COL1A2) among others.

Summary/Conclusions: Taken together, these results suggest that the mutation pattern in AL is heterogeneous with no common mutated gene among all patients. However, we described novel mutations in the context of AL in regulatory genes or over-representing cancer-related pathways that can help to elucidate the molecular biology of the disease.

**IMPROVED SURVIVAL IN 21,465 MULTIPLE MYELOMA PATIENTS: RESULTS FROM A POPULATION-BASED STUDY**

S. Thorsteinsdottir1, 2, P.W. Dickman3, I. Turesson1, O. Landgren1, M. Hultcrantz5, 6, M. Björkholm5, S.Y. Kristinsson1, 5

1Department of Internal Medicine, Landskäffet - The University National Hospital of Iceland, Reykjavik, Iceland, 2Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, 3Department of Hematology and Coagulation Disorders, Skane University Hospital, Malmö, Sweden, 4Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, United States, 5Division of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, 6Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, Sweden

**Background:** Multiple myeloma (MM) is generally considered an incurable disease, however advances in the treatment options for MM have been great in recent years. Recent studies on these new agents indicate an improvement in survival, nevertheless population-based studies have had contradicting findings, especially in the elderly patients.

**Aims:** The aim of the study was to evaluate the survival of all patients diagnosed with MM in Sweden in the years 1973 to 2013 and to relate the survival pattern to trends in treatment strategies.

**Methods:** Patients diagnosed with MM in the period from January 1, 1973 to December 31, 2013 were identified from the Swedish Cancer Registry. Information on sex, date of birth, date of diagnosis, and date of death was collected. Relative survival ratios (RSRs) were used to provide a measure of excess mortality of MM patients compared to a comparable group from the general population. RSRs with 95% confidence intervals (CIs) were found for 1-, 5-, and 10-year survival for 4 calendar periods; 1973-1982, 1983-1992, 1993-2002, and 2003-2013 and furthermore for 6 age categories at diagnosis (0-40, 41-50, 51-60, 61-70, 71-80 and >80). Short-term survival, as defined by RSR of less than 3 months, was also defined for all calendar periods.

**Results:** A total of 21,465 patients (54% males, median age at diagnosis 72 years) with MM were recorded in the time period. Overall, the 1- and 5- and 10-year RSRs improved in the whole period, with the greatest improvement in the two most recent calendar periods. The 1-year RSR increased significantly between all calendar periods (0.69, 0.74, 0.77 and 0.82, respectively). The 5-year RSR increased significantly between the two last calendar periods (0.28, 0.31, 0.33 and 0.41, respectively; Figure 1) as well as the 10-year RSR (0.10, 0.12, 0.14 and 0.20, respectively). Short-term survival increased significantly between the first two and last two calendar periods (the RSR were 0.83, 0.88, 0.89 and 0.93 respectively). Females had a lower excess mortality compared to males (excess mortality ratio 0.91).

**Summary/Conclusions:** In this population-based study, based on more than 21,000 MM patients diagnosed during more than a 40-year period, we showed that with an increased use of novel agents in MM patients, survival has improved significantly. This is especially prominent during the last 10 years. Our findings are important, since new agents are approved based on clinical trials, where certain groups, such as older patients and patients with significant comorbidities are often excluded.

**Figure 1.**

**P331**

**PROGNOSTIC IMPLICATIONS OF MULTIPLE CYTOGENETIC HIGH-RISK ABNORMALITIES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA**

1Department of Internal Medicine, 2Division of Hematology, 3Department of Laboratory Medicine and Pathology, 4Division of Nephrology and Hypertension, Mayo Clinic, Rochester, United States

**Background:** Cytogenetic evaluation using fluorescence in situ hybridization (FISH) at the time of diagnosis is essential for initial risk stratification in multiple myeloma. The presence of specific cytogenetic high-risk abnormalities (HRA) is known to confer a poor prognosis, less is known about the cumulative effect of multiple such abnormalities.

**Aims:** To evaluate the prognostic implications of the presence of multiple HRA at the time of diagnosis.

**Methods:** We studied 1181 patients who were diagnosed with multiple myeloma between July 2005 and July 2015 at Mayo Clinic Rochester, underwent FISH evaluation within 6 months of diagnosis, and received first-line therapy with at least 1 novel agent (immunomodulator or proteasome inhibitor). HRA were defined as t(4;14), t(14;16), del(17p), and gain(1q). Bone marrow aspirates were evaluated for deletions, monosomies, trisomies, and tetrasyomies using chromosome- or centromere-specific FISH probes. IGH rearrangements were evaluated using an IGH break-apart probe and evaluating up to 5 potential partners (FOFR3, CCND1, CCND3, MAF, and MAFB). Kaplan-Meier overall survival estimates were calculated and the log-rank test was used to compare overall survival in patients with and without HRA (stratified by the number of HRA). A multivariable-adjusted Cox regression model was used to assess the effect of HRA on overall survival adjusting for age, sex, International Staging System (ISS) stage, and first-line therapy (immunomodulator, proteasome inhibitor, upfront autologous hematopoietic stem cell transplantation). Patients diagnosed after 2014 (approximately 15% of the cohort) routinely underwent evaluation for gain(1q), therefore the hazard ratios represent conservative effect estimates. P-values below 0.05 were considered statistically significant.

**Results:** The median age at diagnosis was 65 years (28 - 95), 708 (60%) of the patients were male. There were 372 HRA in 327 patients (28% of the cohort); 170 (45%) del(17p), 110 (29%) t(4;14), 45 (12%) t(14;16), 8 (2%) t(14;20), and 42 (12%) gain(1q). Of the 280 patients with 1 HRA 130 (46%) had del(17p), 120 (43%) had a high-risk translocation, and 30 (11%) had gain(1q). Of the 46 patients with 2 HRA 34 (76%) had del(17p) and a high-risk translocation, 6 (13%) had a high-risk translocation and gain(1q), 5 (11%) had del(17p) and gain(1q), and 1 had 2 high-risk translocations. There was 1 patient with 3 HRA: del(17p) and t(4;14) and gain(1q). The median overall survival was 6.6 years (6.0 - 8.0) for the entire cohort (n=1181), 8.3 years (6.7 - 8.9) for those without HRA (n=854, 72%), 4.8 years (3.9 - 5.6) for those with one HRA (n=280, 24%), and 2.7 years (2.1 - 3.8) for those with 2 or more (2+) HRA (n=47, 4%). Figure 1 shows the Kaplan-Meier overall survival estimates stratified by the number of HRA (n=1181). The presence of 1 HRA (versus 0, HR 1.57, 95% CI 1.26 - 1.96, p <0.001, n=1181) and the presence of 2+ HRA (versus 1, HR 3.37, 95% CI 2.21 - 5.14, p <0.001, n=1181) were of prognostic significance after adjusting for age, sex, ISS stage, and first-line therapy. When adjusting for the revised ISS instead of the ISS the hazard was attenuated for 1 HRA (versus 0, HR 1.42, 95% CI 1.12 - 1.80, p=0.004, n=1087) and 2+ HRA (versus 1, HR 2.82, 95% CI 1.81 - 4.40, p <0.001, n=1087).

**Summary/Conclusions:** Approximately 1 in 4 patients with newly diagnosed multiple myeloma presented with 1 HRA at the time of diagnosis, approximately 1 in 25 with 2 or more HRA. These patients experienced inferior overall survival suggesting a cumulative effect of multiple HRA.
P332
LENALIDOMIDE MAINTENANCE VS PLACEBO AFTER STEM CELL TRANSPLANT FOR PATIENTS WITH MULTIPLE MYELOMA: OVERALL SURVIVAL AND PROGRESSION-FREE SURVIVAL AFTER ADJUSTING FOR TREATMENT CROSSOVER IN CALGB

P.L. McCarthy1, S.A. Holstein2, S.-H. Jung3, M. Cooper4, C.J. Gibson5, E.A. Stadtmueller6, B. Winograd7, P. Richardson7
1Blood and Marrow Transplant Program, Roswell Park Cancer Institute, Buffalo, NY, 2University of Nebraska Medical Center, Omaha, NE, 3Alliance Statistics and Data Center, Duke University, Durham, NC, United States, 4BresMed, Sheffield, United Kingdom, 5Celgene Corporation, Summit, NJ, 6Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA, 7Dana-Farber/Partners CancerCare, Boston, MA, United States

Background: At a prespecified interim analysis (December 2009), the phase 3 CALGB/EOCG 100104 (Alliance) study results surpassed the prespecified superiority boundary (significantly improved progression-free survival [PFS] for lenalidomide [LEN] maintenance vs placebo [PBO] after SCT) and the majority of PBO arm patients without progressive disease (PD) crossed over to LEN maintenance. An updated analysis (cutoff March 2015) showed significantly longer overall survival [OS] with LEN maintenance (HR 0.56; 95% CI, 0.42-0.76). However, the crossover from PBO to LEN makes it difficult to assess the true treatment effect of LEN.

Aims: To examine the effect of LEN vs PBO on OS and PFS from randomization, adjusting for effects of crossover.

Methods: The rank-preserving structural failure time model (RPSFTM: Robins, *Commun Stat Theory Methods*, 1991) was used for crossover adjustment; the iterative parameter estimation (IPE; Branson, *Stat Med*, 2002) algorithm was used as validation. Survival was partitioned assuming a residual LEN effect after discontinuation. A landmark analysis was also performed at the Dec 2009 interim for patients who remained on treatment. Patients in the trial provided informed consent.

Results: Patients were randomized to LEN maintenance (n=231) and PBO (n=229) (intent-to-treat [ITT] population); 76 patients without PD crossed over from PBO to LEN. The median time from randomization to crossover was 11.5 months. The relative treatment effect for OS and PFS increased for LEN vs PBO when adjusting for crossover using RPSFTM and IPE (Table 1). The landmark analysis at the Dec 2009 interim (PBO crossover, n=76; No crossover, n=153) showed the treatment effect is not dissimilar to the ITT analysis (HR 0.53; 95% CI, 0.25-1.13). Sensitivity analyses showed consistent results. Updated data will be presented at the meeting.

Summary/Conclusions: Adjusting for the potential diluting effects of crossover reduced median OS and PFS with PBO, and improved the treatment effect in the ITT analyses for OS and PFS for LEN vs PBO maintenance after SCT. The statistical significance of the ITT analyses was maintained throughout.

P333
UPDATED RESULTS FROM ASPIRE AND ENDEAVOR, RANDOMISED, OPEN-LABEL, MULTICENTRE PHASE 3 STUDIES OF CARFILZOMIB IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

D. Siegel1, A. Oriol2, P. Rajic3, J. Minarik2, V. Hungria2, J.H. Lee4, K. Song5, M. Obreja6, S. Aggarwal7, R. Hajek8
1Johann Theurer Cancer Center, Hackensack University Medical Center, Hackensack, United States, 2Institut Català d’Oncologia and Institut Josep Carreras, Hospital Germans Trias i Pujol, Barcelona, Spain, 3Department of Hematology, Mar Kaposi Teaching Hospital, Kaposvar, Hungary, 4Department of Hemato-Oncology, University Hospital Olomouc and Faculty of Medicine and Dentistry, Olomouc, Czech Republic, 5Irmandade da Santa Casa de Misericórdia de Sao Paulo, Sao Paulo, Brazil, 6Gachon University Gil Medical Center, Incheon, Korea, Republic of, 7Leukemia/Bone Marrow Transplant Program, Division of Hematology, University of British Columbia, Vancouver, Canada, 8Amgen Inc., Thousand Oaks, United States, 9University Hospital Ostrava, Ostrava, Czech Republic

Background: In RRMM, carfilzomib, lenalidomide, and dexamethasone (KdR) was superior to Rd in ASPIRE (Stewart, N Engl J Med. 2015), and carfilzomib and dexamethasone (Kd) was superior to bortezomib and dexamethasone (Vd) in ENDEAVOR (Dimopoulos, Lancet Oncol. 2016) for the primary endpoint of progression-free survival (PFS) by independent review.

Aims: To report safety and efficacy data after 6-7 months of additional follow-up.

Methods: Adults with RRMM who received 1–3 prior regimens were randomised 1:1:1. In ASPIRE, patients received lenalidomide (25 mg) on days 1–21 and dexamethasone (40 mg) on days 1, 8, 15, and 22 (28-day cycle). KdR patients received carfilzomib on day 1 at 20, 35, and 40 mg/m², and dexamethasone [days 1 and 2 of cycle 1]: 27 mg/m² thereafter; carfilzomib was omitted on days 8 and 9 in cycles 13–18. In ENDEAVOR, Kd patients received carfilzomib (20 mg/m² on days 1 and 2 of cycle 1; 56 mg/m² thereafter) on days 1, 2, 8, 9, 15, and 16 and dexamethasone (20 mg) on days 1, 2, 8, 9, 15, 16, 22, and 23 (28-day cycle). In the Vd group, bortezomib was given (1.3 mg/m² intravenously or subcutaneously) on days 1, 4, 8, 11, and dexamethasone (20 mg) on days 1, 2, 4, 5, 8, 9, 11, and 12 (21-day cycle). Comparisons were per stratiﬁed log-rank test; data presented here are per investigator assessment.

Results: In ASPIRE, 792 patients were randomised. Baseline characteristics were well balanced between the median follow-up of 9.6 months (KdR) and 37.0 months (Rd), median PFS was 26.1 months (Krd) and 16.6 months (Rd) (hazard ratio [HR]: 0.67; 95% conﬁdence interval [CI]: 0.56–0.80; P <0.0001). Updated data will be presented at the meeting.

Summary/Conclusions: Consistent with the primary analyses, these results show that incorporation of carfilzomib into treatment regimens in patients with RRMM results in clinically meaningful improvements in PFS and a favourable beneﬁt-risk proﬁle.
Figure 1.

Summary/Conclusions: DRD significantly improved outcomes compared with Rd alone, including PFS, ORR, depth of response, and MRD-negative rates, with a favorable safety profile that was maintained after longer follow-up. These updated data continue to support the use of DRD in patients with RRMM who received ≥1 prior therapy.

P335

DARATUMUMAB-BASED COMBINATION REGIMENS IN ELDERLY (≥75 YEARS) PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA: SUBGROUP ANALYSIS OF THE PHASE 3 CASTOR AND POLLUX STUDIES

M.-V. Mateos1,2, A. Spencer2, A. Nooka3, L. Pour4, K. Weisel5, M. Cavolo6, J. Laubach7, G. Cook8, S. Iida9, L. Benboubker10, S. Z. Usmani11, S.-S. Yoon12, 10Service d’Hématologie et Thérapie Cellulaire, Hôpital Bretonneau, Centre Hospitalier Régional Universitaire (CHRU), Tours, France, 11Levine Cancer Institute/Carolinas HealthCare System, Charlotte, NC, United States, 12Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of, 13Tom Baker Cancer Center, University of Calgary, Calgary, Alberta, Canada.

Background: Daratumumab (D) used in combination with bortezomib and dexamethasone (Vd; CASTOR) or lenalidomide and dexamethasone (Rd; POLLUX) significantly prolonged progression-free survival and improved other measurable endpoints in elderly patients (pts) ≥75 years old (7). In CASTOR and POLLUX studies, a safety review demonstrated a manageable safety profile compared with either Vd or Rd alone in patients (pts) with RRMM.

Aims: Here in this subgroup analysis we investigated the safety and efficacy of DVD and DRD in elderly pts aged ≥75 years from the CASTOR and POLLUX phase 3 studies.

Methods: Overall, pts enrolled in the CASTOR and POLLUX studies had ≥1 prior line of therapy. Pts in CASTOR received up to 8 cycles of Vd with or without D; pts in the DVD group then continued to receive D monotherapy q4w until disease progression or unacceptable toxicity. Pts in POLLUX were treated until progression. Dosing schedules for D (16 mg/kg) were different between CASTOR (qw in Cycles 1-3, q3w for Cycles 4-8, and q4w thereafter) and POLLUX (qw for Cycles 1-2, q2w for Cycles 3-6, and q4w thereafter). All elderly pts received a reduced dose of dexamethasone (20 mg once weekly vs 40 mg once weekly) in both studies.

Results: In CASTOR, 23/251 pts in the DVD group and 35/247 pts in the Vd group were ≥75 years; the median (range) age for this group of pts was 78 (75-88) and 78 (75-85) years, respectively, with 100% and 94% with an ECOG status ≤1. At a median follow-up of 13.0 months, discontinuation rates due to treatment-emergent adverse events (TEAEs) were similar with Vd and Rd (15% vs 20%). Common (≥10%) grade 3/4 TEAEs for Vd were thrombocytopenia (45% vs 37% with Vd), fatigue (15% vs 11%), pneumonia (15% vs 17%), and anemia (10% vs 11%). Infusion-related reactions (IRR) occurred in 13 (65%) pts with 10% having grade 3/4 IRR, but no pts discontinued due to IRR. Median PFS was significantly prolonged with DVD versus Vd (not reached [NR] vs 12.1 months; HR, 0.27; 95% CI, 0.12-0.61; P=0.0007), consistent with the overall PFS observed in CASTOR (Figure). Higher overall response rate (ORR; 95% vs 79%) and rates of complete response (CR) or better (25% vs 3%) and very good partial response (VGPR) or better (70% vs 18%) were achieved with DVD versus Vd, respectively, consistent with the overall population. In the POLLUX study, 29/286 pts in the DRD group and 35/283 pts in the Rd group were aged ≥75 years; the median (range) age for this group of pts was 77 (75-89) and 78 (75-87) years, respectively, with 86% and 91% with an ECOG status ≤1. At a median follow-up of 17.3 months, 10% of pts in the DRD group and 11% in the Rd group discontinued due to TEAEs. Common (≥10%) grade 3/4 TEAEs for DRD were neutropenia (45% vs 31% with Rd), hypokalemia (14% vs 3%), and pneumonia (10% vs 11%). D-associated IRR occurred in 12 (41%) pts in the DRD group, with 4 (14%) pts having grade 3/4 IRR. No patient discontinued DRD because of IRR. Median PFS was significantly prolonged with DRD compared with Rd in the elderly subgroup (NR vs 11.4 months; HR, 0.19; 95% CI, 0.06-0.55; P=0.0007), consistent with the overall PFS observed in POLLUX (Figure 1). ORR was higher with DRD versus Rd (93% vs 77%), and rates of CR or better (52% vs 9%) and VGPR or better (72% vs 41%) were also higher with DRD versus Rd.

Figure 1.

Summary/Conclusions: The results in elderly pts were consistent with those observed in the overall study populations in terms of efficacy. Rates of most common grade 3/4 hematologic TEAEs were similar to that of the overall populations, and IRR were manageable. This subgroup analysis supports the addition of D to standard-of-care regimens in elderly pts with RRMM.
ALL ORAL COMBINATION OF IXAZOMIB PLUS THALIDOMIDE AND Dexamethasone FOR RELAPSED OR REFRACTORY MULTIPLE MYELOMA: INTERIM DATA OF AN ONGOING PHASE II Trial

Background: ixazomib is a novel, effective oral proteasome inhibitor with a favorable toxicity profile. Recent studies showed significant activity as single agent with dexamethasone and in combination with other agents. The Tourmaline trial showed superior PFS with ixazomib plus lenalidomide and dexamethasone in pts with relapsed or refractory myeloma (RRMM).

Aims: Here, we evaluate the activity and tolerability of ixazomib plus thalidomide and dexamethasone (IxaThalDex) in pts with RRMM.

Methods: Pts with RRMM and one or more prior lines of therapy (TX) within the following criteria were eligible: Measurable disease, ECOG PS ≤2, ANC ≥1000/µL, platelet count ≥50000/µL, GFR ≥15mL/min. Treatment regimen: ixazomib (4mg, d 1, 8 and 15), thalidomide (100mg/d), and dexamethasone (20mg). Pts were scheduled for 8 cycles followed by ixazomib maintenance therapy (4mg, days 1, 8, 15 of a 28 cycle and 3mg in pts aged ≥75 years) for one year. Primary objective was PFS, and secondary objectives were ORR, OS, impact of cytogenetic risk and of renal impairment, safety and health related QoL.

Results: Sixty-seven of 77 planned pts have been enrolled so far. The following patient characteristics were recorded in the intent-to-treat group (ITT): median age: 67, range 41 to 84 years, ISS stage I: 28, II: 22, III: 16, not known: 1, median number of prior TX lines: 1 (range: 1–5), 9 pts discontinued TX before completion of 2 cycles. Presently, 23 pts are too early for evaluation per protocol (PP). Full documentation of ≥2 cycles is available for 52 pts, with a median number of 4 cycles and a median FU of 7.4 mos. A PR or better was achieved in 33 pts (63%), nCR: 2 pts (4%), VGPR: 10 (19%), PR: 21 (40%), MR: 2 (4%), yielding a clinical benefit rate (CBR) of 67%.

Summary/Conclusions: The first oral IxaThalDex regimen showed an ORR of 63% with no difference in pts with high-risk cytogenetics, a CBR of 67%, and a PFS of 10.4 mos in pts with RRMM. The regimen was well tolerated and was associated with a low incidence of mainly grade ≤2 PNP, which required dose reduction in one patient only. Response rates improved with continuation of therapy and treatment was associated with an increase in health related QoL. P337

EVALUATION OF GROWTH DIFFERENTIATION FACTOR-15 (GDF15) AS A NEW BIOMARKER FOR RENAL OUTCOMES IN DIFFERENT COHORTS OF PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS

Background: Growth differentiation factor-15 (GDF-15), is a member of the TGF-beta family, and is involved in several pathological conditions, including inflammation, cancer, cardiovascular, pulmonary and renal diseases. Serum GDF-15 levels add prognostic information to conventional prognostic factors, such as NT-proBNP and troponins, in cardiovascular disorders and has also shown to be associated with renal damage and risk of end stage renal disease in patients with diabetes. Increased serum GDF-15 levels have also shown to be correlated with early death and shorter survival independently of other biomarkers and Mayo stage. Because GDF-15 was also associated with renal outcomes we evaluated the prognostic value of GDF-15 levels in two independent cohorts of patients with AL amyloidosis and renal involvement who were treated in two different centers (Pavia Amyloidosis Center and Department of Clinical Therapeutics, Athens).

Aims: To evaluate the prognostic value of GDF-15 levels in independent cohorts of patients with AL amyloidosis and renal involvement.

Methods: Circulating levels of GDF-15 were measured by a novel pre-commerical immunoassay (Tina-quant Diagnostics) in stored sera. The Pavia cohort included 135 and the Athens cohort included 76 patients with AL amyloidosis and renal involvement. Standard criteria were used for the diagnosis, evaluation of organ involvement and biomarker-based risk stratification. Renal staging was based on the system proposed by Palladini et al., based on baseline proteinuria (>5 g/day) and eGFR (<50 mL/min).

Results: Median age and involved FLC levels were similar between the two cohorts. However, heart involvement was more common in Pavia cohort (72% vs 53%, p=0.005). Mayo stage disposition was also different (17%, 46% & 37% for stage 1, 2 & 3 in Pavia vs 30%, 43% & 27% in Athens cohort, p=0.08), but stage 3 was similar (13% vs 12%). There were differences in peripheral nerve involvement (9% in Pavia vs 21% in Athens cohort, p=0.025). Median eGFR and renal stage distribution (26%, 54%, 20% vs 20%, 54%, 26% for renal stage 1, 2 & 3 respectively) were similar between the two cohorts (p=0.544). Median follow up for the Pavia cohort was 18 months and for the Athens cohort was 45 months (p<0.001). Survival at 2 years was 59% for Pavia and 56% for Athens cohort. Median GDF-15 levels was 3454 pg/mL in Pavia (range 624 to >100000) and 4152 pg/mL (range 626 - 71475) in Athens cohort (p=0.09), while 93% and 94% of patients in the two cohorts had GDF-15 levels >1200 pg/mL (the upper limit of normal for individuals without cardiovascular disease). We then evaluated the prognostic significance regarding renal outcomes (dialysis): GDF-15 >4000 pg/mL was associated with a HR of 6 (95% CI 2015.6, p=0.001) in Athens cohort (progression to dialysis within 2 years in 7% vs 47%); while, by applying the same cutoff in patients in Pavia cohort, 2-year dialysis rate was 10% vs 37% (HR: 3, 95% CI 1.6-15, p=0.004). Although renal stage discriminated 3 groups in univariate analysis in each cohort, in multivariate analysis, GDF-15 >4000 pg/mL outperformed renal stage by eGFR and proteinuria and was the only independent prognostic factor for progression to dialysis in each cohort (Figure 1).

Figure 1.
Summary/Conclusions: Our study validated and confirmed in two independent cohorts, with differences in their characteristics, the prognostic value of GDF-15, which emerges as a novel biomarker with prognostic implications for different outcomes in patients with AL amyloidosis. Importantly, GDF-15 emerges as a strong biomarker for renal outcomes in patients with AL amyloidosis.

P338

AN OPEN-LABEL, PHASE 2 STUDY TO EVALUATE THE ORAL COMBINATION OF IZAXOMIB, CYCLOPHOSHAMIDE AND DEXAMETHASONE IN TRANSPLANT-INELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

M.A. Dimopoulos1,*, S. Grosicki2, W. Jędrzejczak2, H. Nash3, A. Gruber4, M. Hansson5, C. Byrne6, R. Labokta7, Z. Teng8, H. Yang9, N. Grzasko8, S. Kumar8

Background: Proteasome inhibitor (PI)-based combinations are standards of care in all lines of MM therapy. As the treatment paradigm moves to focus more on extended therapy, new combinations are needed that will be efficacious and tolerable, while giving pts the flexibility of taking their treatment at home. Combinations of ixazomib, the first oral PI, with immunomodulatory drugs (IMiDs) are feasible and effective; however, there may be pts for whom the use of IMiDs is not desirable. Therefore, triplet combinations of ixazomib with alkylators have been studied.

Aims: This phase 2 study (NCT02046670) evaluated the safety and efficacy of the all-oral ICd regimen in transplant-ineligible pts with NDMM. Primary endpoints were rate of CR/VI+PRR+PR through treatment, time to response, PFS, and quality of life (QoL).

Methods: Adult pts with NDMM who were transplant-ineligible were randomized (1:1) to receive oral ixazomib 4.0 mg plus oral cyclophosphamide 300 mg/m² (Arm A) or 400 mg/m² (Arm B) on days 1, 8, 15, and 22, for up to 13 x 28-day cycles as induction. Pts with ≥SD and an acceptable toxicity profile then received single-agent ixazomib maintenance therapy until PD, death, or unacceptable toxicity.

Results: 70 NDMM pts were enrolled (n=36 Arm A; n=34 Arm B): median age 73 years (range 61–87); 47% male; 31%/33%/29% ISS stage I/II/III MM; 50% had a cardiovascular/pulmonary comorbidity; 9% had high-risk cytogenetics (t(4;14), t(14;16), del 17p). At data cut-off (29 June 2016), pts had received a median of 19 cycles; 66% had completed 13 ICd induction cycles and proceeded to ixazomib maintenance therapy; 10% were ongoing on therapy, and 53% had discontinued due to AEs (24%), PD (16%), patient withdrawal (3%), or other reasons (10%). Confirmed responses by investigator assessment are shown in the Table 1. Median time to first/best response across arms was 2/4 months. After a median follow-up of 17.9/18.5 months in Arm A/B, median PFS was not reached. Combined PFS at 12/18/24 months was 81%/66%/59% (24-month PFS 84%/56% for Arm A/B). In Arm A/B, 94%/100% reported AEs; 72%/74% reported grade ≥3 AEs; and 47%/56% reported SAEs. The most common all-grade AEs were neutropenia (22 [31%]), anemia (19 [27%]), diarrhea, nausea, peripheral edema (each 18 [26%]), vomiting (15 [21%]), fatigue, anorexia, constipation (each 14 [20%]). The most common grade ≥3 AEs were neutropenia (22 [31%]), anemia (10 [14%]), lower respiratory tract and lung infections (9 [13%]), and supraventricular arrhythmias (5 [7%]). There were 5 on-study deaths, none considered related to treatment. QoL (by EORTC QLQ-C30; Global Health Status) was maintained from baseline during the study.

Table 1.

Summary/Conclusions: Based on this phase 2 study, ICd is an active treatment regimen for pts with NDMM who are ineligible for transplant. This trial captured a population of pts that was elderly and with multiple comorbidities. In this context, the results with ICd, an all-oral triplet including a PI and alkylator, provide evidence of clinical efficacy with a manageable safety profile. With a median follow-up of ~18 months, median PFS was not reached and outcomes appear comparable to other regimens in elderly transplant-ineligible pts with NDMM. The preferred cyclophosphamide dose for ICd phase 3 studies is 300 mg/m², based on the similar PFS, higher response rate, and numerically lower rate of AEs vs 400mg/m². Updated PFS results will be presented at the meeting.

P339

THE ORAL PROTEASOME INHIBITOR IZAXOMIB IN COMBINATION WITH MELPHALAN-PREDNISONE FOR PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: PHASE 1/2 DOSE-ESCALATION STUDY

J. San Miguel1,*, M.A. Echeveste Gutierrez2, I. Špicka3, M.-V. Mateos4, K. Song5, M. Craig6, J. Bladé7, R. Hájek8, C. Chen9, N. Gupta10, C. Byrne10, V. Lu10, H. van de Velde10, S. Lonial11

Background: Bortezomib-MP is a standard-of-care regimen for elderly NDMM pts. Whereas bortezomib is administered IV or SC, ixazomib is an oral proteasome inhibitor with a safety profile amenable to extended dosing that is approved in the US and EU, in combination with lenalidomide-dexamethasome, for the treatment of MM pts who have received at least 1 prior therapy. Based on the demonstrated feasibility and efficacy of a proteasome inhibitor-MP combination, the all-oral ixazomib-MP (IMP) regimen was evaluated in elderly, transplant-ineligible NDMM pts.

Aims: Primary phase 1 objectives were to determine the safety, MTD, and recommended phase 2 dose (RP2D) of ixazomib in combination with MP. The primary phase 2 objective was to determine the rate of CR/VGPR, secondary objectives included PFS and OS.

Methods: In phase 1, pts were enrolled to 4 arms – Arm A: ixazomib 3.0–3.7 mg (days 1, 4, 8, 11, 22, 25, 29, 32) plus M 9 mg/m² and P 60 mg/m² (days 1–4) in 42-day cycles (max 9 cycles); Arm B: ixazomib 3.0–4.0 mg (days 1, 8, 15) plus M 9 mg/m² and P 60 mg/m² (days 1–4) in 28-day cycles (max 13 cycles); Arm C/D: ixazomib 3.0–4.0 mg (days 1, 8, 15, 22, 29) plus M 9 mg/m² and P 60 mg/m² (days 1–4) in 42-day cycles (max 9 cycles). In phase 2, an expansion cohort was enrolled at the RP2D. On all arms, after IMP induction, pts could receive maintenance with single-agent ixazomib (days 1, 8, 15; 28-day cycles).

Results: 61 pts were enrolled, 11, 34, 11, and 5 to Arms A, B, C, and D (median age 74 yrs; 31% ISS stage III, 56% creatinine clearance ≤60 mL/min). Among
38 DLT-evaluable pts in phase 1, 10 had DLTs of Gr 3 rash (n=2, Arm A), Gr 3-4 thrombocytopenia (n=4, 1 pt in each arm), Gr 3-4 neutropenia (n=1, Arm A; n=4, Arm C, n=1, Arm D), Gr 4 hemorrhagic oesophageal ulcer (n=1, Arm B), Gr 3 ileus/neurogenic bladder (n=1, Arm B), Gr 3 vomiting/diarrhea (n=1, Arm B), and Gr 3 respiratory infection (n=1, Arm C). The RP2D was ixazomib 4.0 mg in Arm B, based on observed rates of toxicity; this cohort was expanded to 26 pts. Among all 61 pts, the median number of treatment cycles was 16; 36 pts (13 at RP2D) completed IMP induction and entered maintenance. Median number of maintenance cycles was 12. The maximum treatment duration was 1841 days (>5 yrs) at RP2D. Five pts remain on treatment (2 at RP2D); primary reasons for discontinuation were disease progression (48%) and adverse events (AEs, 21%). CR+VGPR rate was 43% (43% at RP2D), including 28% (22%) ≥CR and 19% (17%) sCR; median time to first response was 1.7 mos, and responses continued to mature over a long period (Table 1). Depth of response improved during ixazomib maintenance in 9/36 (25%) pts (VGPR to sCR in 5 pts; VGPR to CR in 2 pts; CR to sCR in 2 pts). Median TTP/PFS are shown in Table 1; median OS was not reached after median follow-up of 42.6/46.9 mos overall/at RP2D.

Summary/Conclusions: The RP2D was weekly ixazomib 4.0 mg plus M 6 mg/m² and P 60 mg/m² (days 1–4) in 28-day cycles, consistent with the ixazomib dose and schedule in TOURMALINE-MM1. AEs were mainly hematologic, infections, PN, and diarrhea. The all-oral IMP regimen is active in NDMM, with a 28% CR rate (19% sCR), a 43% ≥VGPR rate, and a median PFS of 23.5 mos; responses continued to improve over a prolonged period.

Myeloma and other monoclonal gammopathies - Clinical 2

P340
FEASIBILITY AND EFFICACY OF DOSE ADJUSTED MELPHALAN – PREDNISONE – BORTEZOMIB IN PATIENTS ≥75 YEARS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA; PRELIMINARY RESULTS OF THE PHASE II HOVON 123 STUDY
1Hematology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, 2Internal Medicine, Albert Schweitzer ziekenhuis, Dordrecht, 3Internal Medicine, Meander Medisch Centrum, Amersfoort, 4Internal Medicine, ZNB, Leeuwarden, 5Internal Medicine, Haga Ziekenhuis, Den Haag, 6Internal Medicine, Sint Jans Dal, Harderwijk, 7Internal Medicine, MCA, Alkmaar, 8Internal Medicine, Tergooi ziekenhuizen, Hilversum, 9Internal Medicine, Groene Hart Ziekenhuis, Gouda, 10Internal Medicine, VU University Medical Center, Cancer Center Amsterdam, 11Hematology, UMCG, Utrecht, 12HOVON Data Center, 13Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: There is a high rate of toxicity-related discontinuation in elderly patients with NDMM, negatively affecting outcome. In order to predict feasibility of treatment the IMWG developed the frailty score based on age, (instrumental) Activities of Daily Living and the Charlson comorbidity index.

Methods: Patients were treated with 9 cycles of MPV: Mel 6 mg/m², day 1-4; Pred 30 mg/m², day 1-4; and Bort 1.3 mg/m² day 1,8,15 and 22 of a 35-day cycle. This first planned analysis was restricted to the first 140 consecutive patients out of 240 planned patients.

Results: Of the 139/140 eligible patients none were fit (because of age ≥75 years), 30/139 (22%) were unfit, 100/139 (72%) were frail, and 9/139 (6%) unknown. The median follow up was 17.0 months. The discontinuation rate of MPV in the total population was 42%; 27% in unfit and 46% in frail patients (p=0.09). When also patients were included who discontinued bortezomib only these numbers were 27% in unfit and 52% in frail (p=0.02). Importantly, 6 cycles of MPV were found to be feasible in 70% of patients, both in unfit (80%) and frail (69%) patients. Age >80 years was associated with a significantly higher discontinuation rate of MPV or bortezomib only (70% versus 35% in patients aged 75-80 years, p<0.01). WHO performance was not associated with discontinuation rate. Response on protocol was ≥PR 73%, ≥VGPR 38% and ≥CR 11%, not significantly different in unfit versus frail patients. Response after 6 cycles was ≥PR 69%, ≥VGPR 35% and ≥CR 2%. Median progression free survival (PFS) was 17 months: 20 for unfit and 16 months for frail patients (p=0.13). Overall survival at 18 months was 76%: 89% for unfit and 72% for frail patients (p=0.22). Frail patients were found to have significantly less grip strength and lower walking speed as compared to unfit patients (Table 1).

CHEMOTHERAPY BEFORE AND AFTER HEART TRANSPLANTATION FOR PATIENTS WITH REFRACTORY MULTIPLE MYELOMA AND RENAL IMPAIRMENT

To present updated safety and efficacy analyses from the multicenter, phase 2 MM-013 trial, in which pts with RRMM and moderate or severe RI, including those on hemodialysis, were treated with POM+LoDEX.

Methods: Three cohorts of pts with RRMM and RI were enrolled: (A) moderate RI (eGFR ≥30 to <45 mL/min/1.73m²), (B) severe RI (eGFR <30 mL/min/1.73m²) without hemodialysis, and (C) very severe RI (eGFR <15 mL/min/1.73m²). Pts received POM+LoDEX until disease progression or >2 prior treatment lines. The primary endpoint was OS from the start of HTx.

Results: Pts were treated with POM+LoDEX. The median OS from HTx was 37 months, and >50% of pts were event-free at >1 year.

Conclusion: The combination of POM+LoDEX is promising in pts with advanced cardiac amyloidosis and severe RI following HTx.
or unacceptable toxicity. Supportive care was allowed; thrombophlebitis was required for all pts on hemodialysis. The primary endpoint was overall response rate (ORR). Key secondary endpoints included safety, renal response, time to myeloma response, time to renal response, duration of response, progression-free survival (PFS), time to progression, and overall survival (OS). All pts provided informed consent.

Results: Enrolment has been completed with 81 pts (33 in cohort A; 34 in cohort B; 14 in cohort C), of which 13 (16.0%) were still on treatment as of January 28, 2017. Median follow-up for OS was 7.8 months. A total of 68 pts (84.0%) discontinued treatment; 39 (48.1%) due to PD. Median age was 72 yrs (range, 52-86 yrs). 60.5% of pts were male, and median time from diagnosis was 3.8 yrs (range, 0.03-19.44 yrs). Pts received a median of 4 (range, 1-110) prior anti-myeloma therapies. All pts had prior treatment with LEN (100%) and nearly all with BORT (97.5%). Median relative dose intensity of POM was 94.0% in both cohorts A and B, and 99.0% in cohort C. ORR was 39.4%, 29.4%, and 14.3% in cohorts A, B, and C respectively. PFS and OS results are presented in the Table 1. Grade 3/4 anemia and thrombocytopenia occurred more frequently in cohort C, likely due to severe RI requiring dialysis (Table 1). AEIs leading to dose reductions were 18.2%, 14.7%, and 14.3% in cohorts A, B, and C, respectively.

Table 1.

Summary/Conclusions: POM+LoDEX is efficacious in pts with RRMM with moderate or severe RI, including those on hemodialysis, who had more advanced disease due to worse renal function. The safety profile was acceptable among the three groups and no new safety signals were observed. This study demonstrates that POM+LoDEX can be administered in pts with moderate or severe RI, including those on hemodialysis.

P344 PEMBROLIZUMAB MONOTHERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: PHASE 1B KEYNOTE-013 STUDY

1Institut Gustave Roussy, Villejuif, France, 2Beth Israel Deaconess Medical Center Harvard Medical School, Boston, United States, 3Institute of Hematology “L. e A. Seragnoli,” University of Bologna, Bologna, Italy, 4University of Washington, Seattle, Washington, United States, 5Institute of Cancer Institute, Cincinnati, 6Central Texas Veterans Affairs Health Care System, Temple, Texas, University of Houston School of Medicine, St. Louis, Missouri, 7Merck Co., Inc., Kenilworth, New Jersey, 8Hackensack University Medical Center, Hackensack, United States

Background: Treatment options are needed for patients with RRMM. PD-L1 expression in patients with multiple myeloma, and blocking the programmed cell death 1 (PD-1) pathway may provide antitumor activity. Pembrolizumab is a humanized, high-affinity monoclonal antibody directed against PD-1 with robust antitumor activity and favorable safety in several solid and hematologic malignancies. KEYNOTE-013 (NCT01953692) is a multicohort phase 1b study of pembrolizumab monotherapy in patients with hematologic malignancies; results are reported for patients with RRMM.

Aims: To determine the safety, tolerability, and antitumor activity of pembrolizumab monotherapy in patients with RRMM.

Methods: Patients with RRMM who have failed ≥2 prior lines of therapy including a proteasome inhibitor and immunomodulatory drug (IMiD) received pembrolizumab 10 mg/kg every 2 weeks or 200 mg fixed dose every 3 weeks. Primary end points were safety, tolerability, and objective response rate (ORR) as determined by investigators, per International Myeloma Working Group 2006 criteria.

Results: At data cutoff of January 2, 2017, 30 patients were treated. The median (range) duration of follow-up was 15 (1-32) months. 28 (93%) patients discontinued the study; the most common reason was disease progression in 14 (47%) patients, and clinical progression in 9 (30%) patients. 2 (7%) patients are still on treatment. Median (range) age was 70 (56-81) years. 21 (70%) patients had an ECOG performance status of 1. Patients received a median (range) of 4 (2-10) prior lines of therapy. 20 (67%) patients were lenalidomide refractory, 10 (33%) were double-refractory. 9 (30%) were triple refractory, and 1 (3%) patient was quadruple refractory. Among patients receiving pembrolizumab at 10 mg/kg, the median (range) of pembrolizumab exposure was 6 (2-15) cycles; among those who received 200-mg fixed dose of pembrolizumab, the exposure was 3 (2-6) cycles. No patient experienced a response. Seventeen (57%; 95% CI, 37-75%) patients had stable disease, 13 (43%; 95% CI, 26-63%) patients had progressive disease as their best response. Treatment-related adverse events (TREAs) occurred in 12 (40%) patients. The most common TRAE was anemia (n=5, 17%); arthralgia, aspartate aminotransferase increased, fatigue, hyperglycemia, hypothyroidism, myalgia, pruritus, and blurred vision occurred in 1 patient each. A grade 3 TRAE (myalgia) occurred in 1 (6%) patient. There were no grade 4 TREAs. Median duration of continuing treatment; 39 (48.1%) due to PD. Median age was 72 yrs (range, 52-86 yrs). 60.5% of pts were male, and median time from diagnosis was 3.8 yrs (range, 0.03-19.44 yrs). Pts received a median of 4 (range, 1-110) prior anti-myeloma therapies. All pts had prior treatment with LEN (100%) and nearly all with BORT (97.5%). Median relative dose intensity of POM was 94.0% in both cohorts A and B, and 99.0% in cohort C. ORR was 39.4%, 29.4%, and 14.3% in cohorts A, B, and C respectively. PFS and OS results are presented in the Table 1. Grade 3/4 anemia and thrombocytopenia occurred more frequently in cohort C, likely due to severe RI requiring dialysis (Table 1). AEIs leading to dose reductions were 18.2%, 14.7%, and 14.3% in cohorts A, B, and C, respectively.

Table 1.

Summary/Conclusions: POM+LoDEX is efficacious in pts with RRMM with moderate or severe RI, including those on hemodialysis, who had more advanced disease due to worse renal function. The safety profile was acceptable among the three groups and no new safety signals were observed. This study demonstrates that POM+LoDEX can be administered in pts with moderate or severe RI, including those on hemodialysis.

P345 ASSESSMENT OF MOBILIZATION COST FOR MULTIPLE MYELOMA USING 2 DIFFERENT STRATEGIES: HIGH-DOSE CYCLOPHOSPHAMIDE VERSUS PLERIXAFOR. ON BEHALF OF IFM

Background: Treatment with autologous transplantation (ASCT) remains the standard of care upfront for Multiple Myeloma patients considered eligible for transplant. Peripheral blood stem cell (PBSC) collection, also called mobilisation, is needed prior to ASCT. The optimal methodology for mobilising PBSC has yet to be defined, with either G-CSF alone, also called steady state procedure, or use of Plerixafor, a CXCR4 antagonist (Mozobil®)+G-CSF or high dose cyclophosphamide (usually administered at a dose of 1.5 to 6g/m² IV for 3 days) plus G-CSF. Treatment regimens have not been compared as the different regimens, and the 2 latter have demonstrated similar PBSC collection rates. Because of the intense competition for hospital resources and the staff required to manage patients preparing for mobilization and transplantation, it is important to quantify the total impact of mobilization on staff resource and waiting time for the hospital.

Aims: We aimed at better evaluate the respective cost of the 2 techniques of mobilization for the French health care system, high dose cyclophosphamide (n=57) versus plerixafor (n=55).

Methods: This is an observational cohort database analysis of 112 consecutive patients with MM treated upfront with ASCT between 2009 and 2013 and that had been mobilized with either high dose cyclophosphamide or plerixafor from 15 IFM centers. Patients must have successfully underwent ASCT. This study was not aimed at evaluating the suitability or advisability of one therapy versus another. A cost-consequences analysis of the different regimens of mobilization was not performed. Costs were obtained using micro-costing as only direct medical costs are included in this economic analysis. Hospital resources will be calculated using two different approaches: per diem hospitalization costs (excluding direct medical costs) versus French public diagnosis-related group
A STUDY OF UTILITY OR FUTILITY OF PERFORMING SKELETAL SURVEYS IN PARAPROTEINEMIA: A MULTICENTER EXPERIENCE FROM UK

O. Gamage1, M. Zaw1, S. Gurung1, G. Pratt2, S. Shafeeke1, A. Macwhanenell1, S. Lee1, S. Basul1
1Department of clinical Haematology, Royal Wolverhampton NHS Trust, Wolverhampton, 2Department of Haematology, University Hospital, Birmingham, UK, Birmingham, 3Department of Haematology, Worcestershire Acute Hospital Trust, Worcester, United Kingdom

Background: Recent International Myeloma Working Group (IMWG) guidelines recommend that conventional skeletal surveys should be supplanted by low dose whole body computed tomography (CT), whole body magnetic resonance imaging (MRI) and or 18fluoro-deoxyglucose ([18F-DG]PET). However, resource, funding and radiology capacity issues, have posed significant challenges to implementing these recommendations. The risk of progression of Monoclonal Gammopathy of Undetermined Significance (MGUS) to a neoplastic plasma cell disorder is approximately 1% per year and even lower in low risk MGUS. It is thus not necessary to perform imaging in unselected MGUS patients.

Aims: To look at all skeletal surveys requested across 3 large hospitals in UK over a year and analyze their justification, effectiveness and utility. To decide if a rational clinic–biochemical algorithm could be used to reduce the number of imaging requests, thereby avoiding unnecessary radiation exposure, and make a possible switch to modern imaging methods cost effective.

Methods: A total of 397 skeletal surveys were performed across three hospitals over one year. The data set was analyzed for clinical indications, paraprotein level, rationale for requesting the skeletal survey, the diagnostic yield and also the number of follow up CT/PET or MRI required.

A pragmatic algorithm was developed and applied to see if the requests were justified and could have been safely reduced. (Figure 1).

Results: Of the 397 analyzable skeletal surveys performed, 266 were on myeloma, 81 for MUGS, 48 were for non-paraprotein related indications. Of the 266 myelomas, 30% of skeletal surveys were reported as positive according to IMWG criteria1. A detailed analysis of 130 myeloma patients revealed a significant proportion of false negatives (6%) and false positives (7%), highlighting the insensitivity and poor specificity of this imaging modality. More importantly more than a third (38%) of myeloma patients required follow up imaging with MRI, PET or WBCT irrespective of the initial skeletal survey result, indicating a significant duplication rate and waste of resources. In the MGUS group, majority of skeletal surveys were negative (91%) but 9% were reported as positive. Follow up imaging with CT and MRI was performed in 23% of the MGUS group. However none these were positive. When the clinic-biochemical algorithm was applied, the number of requests was reduced by at least a quarter (24%), avoiding unnecessary radiation exposure and precious resources.

Figure 1.

Summary/Conclusions: - Skeletal survey has very limited role in investigation of paraproteinaemia and should be abandoned. - Our pragmatic clinic-biochemical imaging algorithm reduced imaging requests significantly (24%) allowing the preferred imaging modalities to be performed productively in a cost effective way in face of ever increasing health care cost and demands.

P347
Background: In multiple myeloma (MM), abnormal serum free light chain ratios (FLCr) after therapy associate with poor prognosis, independent of depth of response. However the value of FLC in the context of minimal residual disease (MRD) remains unclear. A proportion of MRD-negative patients experience early relapses and conversely, some MRD-positive patients can endure long-term survival, which may result from improved immunosurveillance following normal plasma-cell recovery.

Aims: We hypothesised that serum FLC levels and ratios add clinical value at the time of MRD assessment.

Methods: The study included 275 intact immunoglobulin MM patients from the IFM2009 clinical trial who achieved at least a very good partial response (VGPR) after consolidation therapy. Median PFS from the end of consolidation was 38.3 months; median OS was not reached. Serum FLCs were measured using monoclonal antibodies (The Binding Site). Normal range for k/l FLCr was 0.26-1.25. We defined immunosuppression as levels of both the uninvolved (polyclonal) FLC+uninvolved heavy+light chain (HLC; measured with Hevylite) below their normal range. MRD assessment in bone marrow samples was based on 4-colour multiparametric flow cytometry (MFC).

Results: At the end of consolidation, 79/275 (29%) patients were MRD-positive, 79/275 (29%) had abnormal FLCr, 16/275 (6%) had elevated iFLC, with immunosuppression identified in 52/275 (19%). Using Cox regression all the variables associated with shorter PFS (p<0.001 for all) and OS (p<0.050 for all; except elevated iFLC which showed a trend towards shorter OS (p=0.070)). Among 363 MRD-negative patients, 37/196 (19%) had abnormal FLCr. 2/196 (1%) had elevated iFLC with immunosuppression identified in 23/196 (12%). Median PFS for MRD-negative patients was not reached; however both an abnormal FLCr (median PFS: 31.4 months; p<0.001) and immunosuppression (median PFS: 31.4 months; p=0.005) identified a group of patients with poorer outcomes. On the other hand, median PFS for MRD-positive patients was 21.3 months; 42/3% of these patients had abnormal FLCr and dismal outcomes (median PFS 12.6 vs 30.7 months for abnormal vs normal FLCr, respectively; p=0.004). Absolute FLC measurements did not reach statistical significance for PFS in these patients.

Summary/Conclusions: Serum FLC measurements in combination with low-sensitivity MFC bone marrow assessment at the end of consolidation therapy render the most powerful prognostic information in MM patients achieving deep responses. In those where disease is no longer detected using MFC, abnormal FLCr confer poor prognosis, which may partly be due to inefficient immune recovery. Absolute FLC measurements were not informative, supporting the rationale of evaluating biomarkers of the tumour and immune system recovery. Our results warrant further studies to validate the clinical utility of FLC measurements in combination with next-generation (8-colours) flow cytometry.
RAS-PATHWAY MUTATION PATTERNS DEFINE EPIDEMIC SUBCLASSES IN JUVENILE MYELOMONOCYTIC LEUKEMIA

Aims: The primary objective of this study is to report cytogenetic abnormalities that are associated with a large scale genomic and phenotypic characterization of JMML patients.

Methods: Diagnosis of SMF was performed according to the IWG-MRT criteria (2008). The MYSEC study was approved by the Review Board of each Institution.

Results: Within the whole cohort of 781 SMF patients, 376 had cytogenetic data. Cytogenetic abnormalities were reported in 128 (34.1%) cases: 72 (60%) were sole, 22 (18.3%) double, 26 (21.7%) complex. Eleven (9.2%) MK (all included in complex karyotype) and eight unilineage. The presence of three or more aberrations defined a complex karyotype; two or more distinct autosomal monosomies or single autosomal monosomy associated with at least one structural abnormality defined monosomy karyotype (MK). Continuous values were compared via non-parametric Mann-Whitney U tests, with Holm corrections for multiple testing; categoric data were analyzed using Kaplan-Meier estimators and Cox models for regression.

Summary/Conclusions: Our integrated approach identified three JMML subgroups characterized by distinct clinical and biological features. We provide evidence for a molecular mechanism by which additional aberrations are additively or further activating the RAS-RAF-MEK-ERK pathway, mediate DNA hypermethyl-ation via up-regulation of DNMTs in more aggressive JMML cases.

CytoGenetic Abnormalities in Primary Myelofibrosis: CytoGenetic Abnormalities in Primary Myelofibrosis: CytoGenetic Abnormalities in Primary Myelofibrosis: CytoGenetic Abnormalities in Primary Myelofibrosis: CytoGenetic Abnormalities in Primary Myelofibrosis:
Figure 1.
Summary/Conclusions: Abnormal karyotype was found in 34.1% of SMF patients at diagnosis and was over-represented in post-PV MF. No different distribution was detected among genotypes. Abnormal karyotype was associated with lower platelet count, larger splenomegaly, higher circulating blast cells and presence of constitutional symptoms. Concerning outcome, the presence of abnormal karyotype implied inferior survival and, among subtypes, MK remained the most powerful predictor.

P352 MUTATIONAL LANDSCAPE OF MYELODYSPLASTIC SYNDROME/ MYELOPROLIFERATIVE NEOPLASM - UNCLASSIFIABLE
P. Bose1, A. Nazhra2, R. Komorki3, M. Savona4, K. Patel5, S. Pierce1, N. Al Ali6, A. Sochacki7, A. Shaver8, N. Daven9, C. DiNardo1, G. Garcia-Manero10, B. Bueso-Ramos3, H. Kantarjian1, M. Sekeres12, J. Maciejewski11, S. Verstovsek1

Background: MDS/MPN-U is a rare, poorly characterized myeloid neoplasm within the MDS/MPN category in the World Health Organization (WHO) classification. A median survival of 12.4 months from time of referral was previously reported for a cohort of 97 patients with MDS/MPN-U seen at the MD Anderson Cancer Center (DiNardo, et al. Leukemia 2018). The International Prognostic Scoring System (IPSS) for MDS (Greenberg et al. Blood 1997) discriminated amongst prognostically distinct categories in that cohort, while neither the IPSS for primary myelofibrosis (PMF, Cervantes et al. Blood 2009) nor the revised IPSS (IPSS-R) for MDS (Greenberg et al. Blood 2012) did. Median survival of 21.4 months from the time of diagnosis was reported in a multi-institutional cohort (n=69, Wang et al. Blood 2014). Information on the genomic landscape of MDS/MPN-U is limited to one report on the frequency of SETBP1 mutations (8.3%, Meggendorfer et al. Leukemia 2013).
Aims: To describe the mutational landscape of MDS/MPN-U using targeted multi-gene sequencing.
Methods: Targeted sequencing was performed on DNA from 97 patients with WHO-defined MDS/MPN-U (diagnosed per WHO 2008 criteria but excluding refractory anemia with ringed sideroblasts and thrombocytemia) seen across 4 US institutions (MDACC, 43; Cleveland Clinic, 29; Moffitt Cancer Center, 16; Vanderbilt University, 9). Gene panels used varied between institutions, with 20 genes (ASXL1, CBL, DNMT3A, ETV6, EZH2, IDH1, IDH2, JAK2, KIT, NPM1, NRAS, PHF6, RUNX1, SETBP1, SF3B1, SRSF2, TET2, TP53, U2AF1, ZRSR2) in common.
Results: Mutational frequencies for the 20 genes tested in all 97 patients were as follows: TET2, 28%; ASXL1, 27%; JAK2, 25%; SRSF2, 22%; EZH2, 15%; SF3B1, 12%; RUNX1, 12%; ZRSR2, 11%; SETBP1, 11%; U2AF1, 11%; NRAS, 10%; DNMT3A, 9%; TP53, 8%; CBL, 4%; ETV6, 4%; NPM1, 4%; IDH2, 2%; KIT, 2%; PHF6, 1% and IDH1, 0%. In addition, the frequency of mutations in ten other genes of interest in hematologic malignancies was assessed: BRAF, 0% (n=52); CSF3R, 4% (n=52); CALR, 4% (n=53); MPL, 3% (n=88); MPL, 1% (n=107); TET2, 6% (n=72); CEBPA, 4% (n=73); KRAS, 4% (n=81); TET2, 4% (n=82) and FLT3, 2% (n=82). Median survival for the whole cohort (n=97) was 12.4 months (range, 1-173). The 43 MDACC patients in this analysis were included in the cohort of 85 previously reported by DiNardo et al. Median age was 70 years (21-89). Median (range) values for leukocytes, neutrophils, hemo-globin, platelets and bone marrow blasts at the time of sample collection for sequencing were 13.4 (1-179) x 10^9/L, 7.9 (0.4-152.4) x 10^9/L, 9.1 (3.1-15) g/dL, 123 (6-1168) x 10^9/L and 2% (0-17), respectively. On univariable analysis (n=97), only the presence of EZH2 and ZRSR2 mutations were associated with trends towards statistical significance for survival. Mutated EZH2 adversely impacted survival (p=0.060) and mutated ZRSR2 associated with survival (p=0.074). The IPSS-R for MDS was useful to differentiate between risk groups with different survival times (p=0.065) while the dynamic IPSS for PMF (Passamonti et al. Blood 2010) was not (p=0.39). On multivariable analysis, only EZH2 mutations and IPSS-R very low risk (versus all other categories combined) were statistically significantly associated with inferior and superior survival, respectively.
Summary/Conclusions: In this cohort of 97 patients with WHO-defined MDS/MPN-U, mutations in genes encoding epigenetic regulators (e.g., TET2, ASXL1, EZH2), spliceosom components (e.g., SRSF2, SF3B1, ZRSR2, U2AF1), signaling molecules (JAK2, NRAS), thymes (KRA, 4%; FLT3, 4%) and SETBP1 were found at frequencies ≥10%. Although the analysis is limited by small numbers, EZH2 mutations were independently associated with poor survival. This represents the largest cohort of patients with MDS/MPN-U interrogated for mutations in multiple genes to date.

P353 GENOME WIDE DNA METHYLATION PROFILING IS PREDICTIVE OF OUTCOME IN JUVENILE MYELOMONOCYTIC LEUKEMIA
E. Stiegitz1,2, T. Mazor3, A. Olsen4, A. Heng5, D. Lipka6, C. Plass7, C. Flotho8, J. Costello3, M. Loh9,10
1Department of Pediatrics, UCSF Benioff Children’s Hospital, 2Helen Diller Family Comprehensive Cancer Center, 3Department of Neurosurgery, 4Department of Epidemiology and Biostatistics, 5Departments of Laboratory Medicine and Cellular and Molecular Pharmacology, University of California, San Francisco, San Francisco, United States, 6Division of Epigenomics and Cancer Risk Factors, German Cancer Research Center (DKFZ), 7German Cancer Consortium (DKTK), Heidelberg, Germany, 8Department of Pediatrics and Adolescent Medicine, Division of Pediatric Hematology and Oncology, Medical Center, University of Freiburg, Freiburg, Germany
Background: Juvenile myelomonocytic leukemia (JMML) is a myeloproliferative disorder of childhood that is initiated by mutations in the Ras pathway. Outcomes in this disease vary dramatically from resolution with minimal or no therapy to relapse despite hematopoietic stem cell transplantation. Identifying biomarkers to distinguish patients with aggressive disease courses from those who can receive minimal therapy remains a priority for clinicians.
Aims: We utilized an unbiased screening approach to investigate genome-wide DNA methylation in newly diagnosed JMML patients. We then sought to determine whether a specific DNA methylation signature was capable of predicting outcomes in this heterogeneous disease, with a particular emphasis on identifying a biomarker predictive of spontaneous resolution.
Methods: Genome-wide DNA methylation analysis was carried out using the Illumina 450k BeadChip platform in a discovery cohort of 39 well-characterized patients with JMML enriched for those who experienced spontaneous resolution without chemotherapy. A separate cohort of 40 patients with JMML were recruited for validation. Of note, patients with Noonan syndrome were excluded from both cohorts. All 79 patients were then compared to 22 healthy controls between 1 and 5 years of age using peripheral blood derived DNA.
Results: JMML patients with aggressive disease have a distinctly hypermethylated DNA profile at the most variable CpG sites compared to patients with less aggressive disease as well as healthy controls. Methylation patterns did not differ based on the tissue of origin (peripheral blood, splenic tissue, or bone marrow) and were similar between monocyte enriched cell populations and unsorted mononuclear cells. Unsupervised clustering of the discovery cohort based on the most highly variable CpG sites (top 0.5% ranked by correlation, 15,411 sites) identified three clusters with the highest level of methylation. The proportion of patients with events differed significantly by cluster (p=0.0039) and remained independently prognostic in multivariable analysis (p=0.033) in the context of age and the number of somatic mutations at diagnosis. We next sought to validate our findings in an independent cohort of 40 patients. We classified each patient in the validation cohort into one of the three clusters defined by the discovery cohort. The proportion of patients having an event at four years was 8% (1/12) (CI, 0-38%) in those with the lowest level of methylation, only one patient out of 15 (7%) had an event at 4 years (95% confidence interval [CI], 2-32%). This compared to 45% (5/11) (CI, 17-77%) for patients in the cluster of intermediate levels of methylation and 61% (8/13) (CI, 32-86%) in those patients with the highest level of methylation. The proportion of patients with events differed significantly by cluster (p=0.0039) and remained independently prognostic in multivariable analysis (p=0.033) in the context of age and the number of somatic mutations at diagnosis. We next sought to validate our findings in an independent cohort of 40 patients. We classified each patient in the validation cohort into one of the three clusters defined by the discovery cohort. The proportion of patients having an event at four years was 8% (1/12) (CI, 0-38%) in those with the lowest level of methylation. This compared to 36% (4/11) (CI, 11-69%) for patients with intermediate levels of methylation and 76% (13/17) (CI, 50-93%) for those with the highest levels of methylation. We then compared our combined cohort of 79 JMML patients with 22 healthy, age-appropriate controls. Remarkably, using the same set of CpG sites defined in the discovery cohort, 27/79 JMML patients clustered more closely with the controls than with other patients. Of these 27 patients, 14 (52%)...
LEUKEMIC TRANSFORMATION OF MYELOPROLIFERATIVE NEOPLASMS: IS NGS PROFILE THE BEST PROGNOSTIC BIOMARKER?

CANCERS IN ADULT PATIENTS WITH MASTOCYTOSIS: INCIDENCE AND OUTCOME OF SECONDARY NON HEMATOLOGICAL

Aims: We retrospectively analyzed the survival outcome of patients with myeloproliferative neoplasms (MPNs) who progressed to acute myeloid leukemia (AML) based on the treatments received, response, different prognosis groups according to the (ELN) and based on a next-generation DNA sequencing profile (NGS).

Methods: A total of 72 patients diagnosed in our institute with AML secondary to MPNs between 2000 and 2016 were retrospectively analyzed. NGS was performed in 44 cases. Mutations found by NGS were classified according three different cellular functions of interest (Tumors suppressor (TP53), Activation/Deactivation of epigenetic (DNMT3A, EZH2,HD1/2,ASXL1) and alternative splicing (SRFS2,U2AF1, ZRS2,PRPF8, SF3B1)) and three groups were determined: Group A: patients without altered cellular function; Group B: patient with one altered function; Group C: patients with more one altered functions. AML treatment response was evaluated according Mascarenhas' proposed criteria for response assessment of AML secondary to MPNs. Overall survival (OS) was calculated according the different treatments, treatment response and NGS profiles.

Results: 72 patients who developed AML secondary to MPNs were included in the study. 43.6% (N=31) had prior ET, 25% (N=18) PV, 20.8% (N=15) PMF and 11.1% (N=8) secondary myelofibrosis. The median age at AML transformation was 70 (range: 38-89). The median time to AML transformation from MPNs diagnosis was 108 months (range: 2.4-408). Among these 72 AML, 5.6% (N=4) belonged to the favorable risk category according to ELN 2017. 13.9% (N=10) belonged to the intermediate risk category and 55.6% (N=40) to the adverse risk category. 45.8% (N=33) patients were treated with intensive chemotherapy (IC), 15.3% (N=11) with azacitidine (AZA) and 38.9 (N=28) with supportive care (BSC). Median OS was 4.5 months (range, 0.1-65), with no significant difference between the three ELN 2017 risk categories (respectively 2.5 months (range, 1-9), 5.5 months (range, 1-60) and 5.5 months (range, 1-60) in the favorable, intermediate and adverse risk categories). Patients who received IC (p<0.01) or AZA (p<0.05) have a significant better OS (median OS of 7 months (range: 0.5-65) and 8.5 months (range: 3-24) respectively) than patients who received BSC (median OS of 2 months, range: 0.1-36). However, there was no significant difference between the IC and HMA groups (p=0.44). 7 Patients in Complete Cytogenetic Response (CCR) or Acute Leukemia Response-Complete (ALR-C) received an alloSCT had a better median OS than the 9 patients who did not (23 vs 6.5 months, p=0.063). Patients with group A and B NGS profiles have a significant better median OS (respectively 14 and 8 months) than Group C (3 months) (p<0.05).

Summary/Conclusions: Our results confirm the poor outcome of patients with secondary AML treated with IC and suggest that AZA provides comparable OS.
Background: The World Health Organization (WHO) classification system for myeloid neoplasms was recently revised in 2016. The revised WHO criteria are two entities with a different clinical phenotype at diagnosis and a different outcome. The clinical phenotype at disease onset of MPNUs and ET is similar.

Methods: A retrospective study was conducted to assess natural history and identify risk factor(s) for survival in patients with CSF3R-mutated CNL. Survival analysis was performed by the Kaplan-Meier method taking the interval from diagnosis to the appearance of death or last contact. The Cox regression model was used to compare survival data. Cox regression model was used for multivariable analysis.

Results: Data of 47 patients with CSF3R-mutated CNL were collected and analyzed. 35 (76%) patients were male. Median age was 62 years (range, 16-92 years). At diagnosis, 17 (36%) patients had fatigue, 2 (4%) a fever, 8 (17%) experienced diarrhea or abdominal discomfort, 20 (43%) were asymptomatic and leukocytosis had been mostly an incidental laboratory finding. 20 (43%) patients had palpable splenomegaly, and 4 (9%), palpable hepatomegaly. PB parameters, median and (range), were WBC 42.4×10^9/L (14.4-217.0), hemoglobin 100g/L (42-157), platelets 165×10^9/L (17-570), blast percentage 0% (0-10), neutrophil percentage 82% (70-99). The median of blast cells in bone marrow were 1% (range, 0-12%). 46 (98%) patients were in the chronic phase and 1 (2%) in the accelerated phase at diagnosis. Most of the CSF3R mutations were T618I (n=45, 96%), others were T568M (n=1), 193delN (n=1, 2%), 194-195del (72.3%) patients and 41 (87.2%) patients were screened for ASXL1 and SETBP1 mutations, respectively. 21 (61.8%) patients harbored ASXL1 mutation and 22 (53.7%) harbored SETBP1 mutation. All patients were BCR-ABL1, PDGFR and FGR mutation negative, 2 were CALR mutation and JAK2V617F mutation positive, respectively. Hydroxyurea was the most frequently used therapy (n=48). Other therapies included interferon-α (n=7), hypomethylating agents (n=4), thalidomide (n=2), ruxolitinib (n=1), imatinib (n=3), dasatinib (n=1), chemotherapy (n=6), and transplant (n=2). With a median follow up of 17 months (range, 2-103 months), 7 patients progressed to blast crisis or acute myeloid leukemia (n=6) or myelodysplastic syndrome (n=1), 17 patients died. Survival rate at 30 months was 82%. Median survival was 39 months (95% CI 8.5-69.5). Multivariate analysis showed that WBC >40×10^9/L (HR=3.26, 95% CI 1.14-9.30, p = 0.027) was the sole risk factor for survival. However, SETBP1 or ASXL1 mutation was not associated with survival.

Summary/Conclusions: High WBC count was independently predictive of shortened survival in patients with CSF3R-mutated CNL.

P357

CLINICAL PHENOTYPE AND OUTCOME OF ESSENTIAL THROMBOCYTHESIA AND PREFMF DIAGNOSED ACCORDING TO THE REVISED 2016 WHO DIAGNOSTIC CRITERIA

1Department of Molecular Medicine, University of Pavia, 2Department of Hematology, Fondazione IRCCS Policlinico San Matteo, 3Anatomic Pathology Section, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: To explore the clinical course of patients with prePMF and PMF diagnosed according to 2008 WHO criteria who satisfied two requirements: a bone marrow fibrosis grade 0-1 at diagnosis and at least one DNA sample to define the mutational status. Firstly, the bone marrow morphology of all 404 identified patients was reviewed by an expert pathologist. Then, we reclassified patients according to the new 2016 WHO criteria as follows: patient with ET morphology were classified as ET, patients with PMF morphology and at least one clinical feature (leukocytosis, anemia, increased LDH, splenomegaly) were classified as prePMF, patients with PMF morphology but without clinical criteria were classified as myeloproliferative neoplasms unclassifiable (MPNUs).

Results: According to the new criteria our cohort included 269 patients with ET, 109 patients with prePMF and 26 with MPNUs. By comparing clinical phenotype at diagnosis in prePMF, MPNUs, and ET respectively, we observed that prePMF showed higher leukocyte count, lower hemoglobin levels, higher platelet count, higher LDH values, higher number of circulating CD34-positive cells, and showed more frequently splenomegaly (Table 1). The higher frequency of CALR mutations in prePMF compared to ET might contribute to the high level of platelet count observed in prePMF. ET and MPNUs did not differ in terms of leukocyte count, hemoglobin, platelet count, LDH, circulating CD34-positive cells and splenomegaly (Table 1). The 26 patients with MPNUs were not further considered in the analysis of disease complications and overall survival due to the low number. PrePMF patients had lower overall survival (overall survival at 10 years 86.4% vs 96.6%, P<0.001) and a trend to a higher incidence of leukemic evolution (cumulative incidence of acute myeloid leukemia at 10 years 2.3% vs 1.9%, P = 0.067) compared to ET patients, while they did not differ in terms of thrombotic complications (cumulative incidence of thrombosis at 10 years 18.5% vs 18%, P = 0.9). Finally, we analyzed the subgroup of “old” ET diagnosed according to 2008 WHO criteria. Of 358 “old” ET, 268 were reclassified as ET, 25 as MPNUs and 65 as prePMF. The “old” ET reclassified as prePMF had a higher risk of overt myelofibrotic evolution compared to the “old” ET reclassified as ET (cumulative incidence of overt myelofibrosis at 10 years 9.7% vs 0%, P = 0.03).

Table 1.

Summary/Conclusions: ET and prePMF diagnosed according to 2016 WHO criteria are two entities with a different clinical phenotype at diagnosis and a different outcome. The clinical phenotype at disease onset of MPNUs and ET is similar.
Background: The minimal effective treatment in Essential Thrombocytopenia (ET) patients is tailored mainly on the basis of thrombotic risk scores (primarily non-nocturne). The Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) is based on different combinations of Age >60 yrs (Age >60), JAK2 V617F mutations (JAK2+), Low Risk (LR) or Intermediate Risk (IR: only Age >60), and recent Thrombosis (PrTh+). The Th-FUP were 103 (14.0%), with a rate increasing with the risk group (Kaplan Meier analysis), and the curves were compared with the log-rank test.

Methods: The web-based Registro Italiano Trombocitemia (RIT) recruited since 2005 patients with thrombocytthemic/br/abl negative chronic myeloproliferative neoplasms (MPN). ET patients (reclassified according to the R-IPSET-Th score) were complete information (characteristics at diagnosis, antiplatelet and/or cytoreductive treatment, date and description of thrombotic events during the follow-up) were considered for this analysis. According to the R-IPSET-Th score, the patients were divided in 4 thrombotic risk groups: Very Low Risk (VLR: Age <60, absence of JAK2 mutations, no PrTh+), Low Risk (LR: Age >60), Intermediate Risk (IR: only Age >60), High Risk (HR: PrTh+, or Age >60 with JAK2+). The median follow-up was 12, 12, 9, and 11 years, respectively (whole cohort, 11 years). The rates of treatment were: 88%, 94%, 92%, 91%, respectively (whole cohort, 11 years). The median Th-FUP/100 pt-yrs increased (p <0.01) as follows: 0.60%, 1.08%, 1.52%, and 1.61%, respectively. TFS progressively decreased (p <0.001) at 5 years, and 0.79%, 1.61%, and 1.91%, respectively. The Th-FUP/100 pt-yrs of first thrombotic events during thrombosis in ET (R-IPSET-Th) was determined for each risk group (Kaplan Meier analysis), and the curves were compared with the log-rank test.

The concordance between the R-IPSET-Th score and the IPSET-Th score was evaluated (Harrell C concordance index).

Results: Overall, 734 ET patients were analyzed (females 62%). Data at diagnosis were: Age >60 in 286 (39%), JAK2+ in 417 (57%), and PrTh in 126 (17%). The Th-FUP were 103 (14.0%), with a rate increasing with the risk group (p <0.001): in VLR (n 15, 8%), in LR (n 20, 10%), in IR (n 12, 15%), and in HR (n 56, 21%). The Th-FUP/100 pt-yrs increased (p <0.01) as follows: 0.60%, 0.79%, 1.61%, and 1.91%, respectively. TFS progressively decreased (p <0.001) from VLR group to HR group (Figure 1). In detail, the probability of TFS was 0.98, 0.97, 0.94, and 0.88 at 5 years, and 0.85, 0.78, 0.70, 0.54 at 20 years. The patient stratification according to the R-IPSET-Th and the IPSET-Th scores showed a concordance of 0.82 (Harrell C index).

Summary/Conclusions: In this study of the Registro Italiano Trombocitemia (RIT), we confirmed that the Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) separated ET patients in 4 groups with increasing risk of thrombosis during the follow-up (p <0.001). According to the R-IPSET-Th score, an over-treatment seems to have occurred in this cohort of ET patients (anti-platelets in almost all cases, and cytoreduction in around 2/3 of VLR and LR cases), probably because other adjective risk factors have been considered.
Platelet disorders: Basic

NOVEL HETEROZYGOT ITGB3 p.T746DEL MUTATION INDUCING SPONTANEOUS ACTIVATION OF INTEGRIN αIIbβ3 CAUSES AUTOSONAL DOMINANT MACROTHROMBOCYTOPENIA WITH ABNORMAL αIIbβ3 LOCALIZATION

N. Miyazaki1, *, M. Onozawa2, K. Hayasaka3, S. Kunishima1, T. Teshima1
1Department of Hematology, Hokkaido University Graduate School of Medicine, 2Department of Hematology, 3Clinical Laboratory, Hokkaido University Hospital, Sapporo, Japan

Background: Congenital macrothrombocytopenia is a rare platelet disorder and its cause is genetically heterogeneous. Recently, integrin αIIb and β3 mutations have been identified in congenital macrothrombocytopenia patients with platelet aggregation dysfunction. Here, we found a novel, heterozygous ITGB3 mutation in a pedigree and examined how this mutation contributed congenital macrothrombocytopenia.

Aims: To detect gene mutations responsible for the congenital macrothrombocytopenia in this pedigree and reveal the molecular pathophysiology.

Methods: Whole exome sequencing (WES) was performed to detect gene mutations. Expression and activation state of αIIbβ3 in platelets was evaluated by flow cytometry (FCM) and western blotting (WB).

Results: The effects of mutations on αIIbβ3 activation state, phosphorylation of FAK, and morphological changes were analyzed in transfected cells by WB and immunofluorescence staining.

Summary/Conclusions: FCM showed decreased expression level of αIIbβ3 in the affected member’s platelets. However WB of platelet lysates showed that there was no difference in the total amount of αIIbβ3 among the affected and unaffected members and normal controls. FCM showed a constitutive activation of αIIbβ3 on the patient’s platelets as reflected by the spontaneous binding of PAC-1 antibody. Immunofluorescence staining using CHO cells showed membrane localization of αIIbβ3 in wild-type αIIbβ3-expressing cells and cytoplasmic localization in αIIbβ3 (p.T746Del) transfected cells. Other activated pathways modified before and during the ETP treatment in chronic immune thrombocytopenia (ITPc) patients.

Aims: To assess the gene expression profile (GEP) and the underlying signaling pathways modified before and during the ETP treatment in chronic immune thrombocytopenia (ITPc) patients.

Methods: ITPc patients (n=14) treated with ETP were evaluated. Complete response (CR) was defined as a platelet count of ≥100x10^3/µl and treatment failure was defined as a platelet count ≤50x10^3/µl for 2 consecutive weeks at the highest recommended dose of ETP. Complete or partial response, or the need to change therapy. RNA was isolated from mononucleated cells pre/post ETP treatment. The “paired” GEP of the ITPc patients included the semi-supervised analysis cluster samples before and after (28 day) the treatment with ETP to detect changes attributed to ETP. The paired GEP was showed in Figure 1.

Summary/Conclusions: In ITPc patients, ETP can induce overexpression of genes involved in platelet activation and megakaryopoiesis and also alter key/relevant/important-signaling pathways such as JAK/STAT and PI3K/Akt.
antibodies against glycoprotein IIb (GPIIb)IIa and/or GPIb/IX are considered to play a crucial role. B cell homeostasis and function are controlled by cell surface receptor-ligand interactions. The activation of PI3K is initiated by engagement of the pre-B cell receptor (BCR) and the BCR. The phosphatase and tensin homolog (PTEN) suppress the activity of the PI3K pathway. As a consequence, loss of PTEN function leads to excessive PI3 (3, 4, 5) P3 at the plasma membrane and to recruitment and activation of Akt family members that potently drive cell survival and proliferation. PTEN regulates normal signaling through the B cell receptor (BCR). In immune thrombocytopenia (ITP), enhanced BCR signaling contributes to increased B cell activity, but the role of PTEN in human ITP has remained unclear.

Both IL-21/IL-21R signaling and PI3K-PTEN molecules are involved in maintaining normal humoral immunity and deletion of autoreactive B cells. In this study, we want to determine whether abnormalities in PTEN might contribute to increased B cell responsiveness in this disease and IL-21 mediated PTEN induction was defective. Meanwhile, we want to evaluate the relation between the expression of PTEN in B cells and the prognosis of ITP which will provide a theoretical basis of new treatment strategy for the ITP patient.

**Aims:** PTEN is involved in maintaining normal B cell function. Since B cell overactivity is characteristic of immune thrombocytopenia (ITP), we sought to determine whether abnormalities in PTEN might contribute to increased B cell responsiveness in this disease.

**Methods:** 1. This study recruited 28 newly-diagnosed CITP patients and 26 sex and age matched health volunteers as health controls (HC) Peripheral blood mononuclear cells were isolated from collected anti-coagulated blood. 2. Flow cytometry and real-time quantitative PCR were used for detecting the level of PTEN from PBMC cells of HC and CITP patients. 3. The relationship between PTEN levels and the disease severity of CITP was analyzed. 4. PBMC cells were incubated with human rIL-2 rIL-21 rCD40L or anti-IgM alone or in combination for 72 h and after that the PTEN level was detected by flow cytometry. The proportion and surface activated marker of B cells were determined by flow cytometry.

**Results:** 1. Compared to HC the expression of PTEN was diminished in each CITP B cell population except IgD-CD38low/-memory B cells. In addition PTEN mRNA was also decreased in ITP B cells. 2. The level of PTEN in B cells was slightly correlated with blood platelet count (p=0.008) and also directly correlated with the positive serum platelet-specific antibody (P=0.03). 3. The capacity of IL-21 to induce PTEN protein up-regulation in B cells in CITP patients. 4. These immature B cells in CITP patients had a greater expression of CD95 but less PTEN compared to HC suggesting that down-regulation of PTEN was associated with an increasing proportion of immature B cells with a more activated phenotype in CITP patients (Figure 1).

**Summary/Conclusions:** Immune thrombocytopenia (ITP) is a bleeding disease caused by autoantibodies (AAbs) directed against platelet (PLT) glycoproteins (GPI). A novel mechanism of antibody-mediated PLT destruction based on Fc-independent PLT clearance via Ashwell-Morell receptors (AMRs), which recognize glycan modifications on the surface of PLTs, has been suggested.

**Aims:** In this study we investigated the effects of human AAbs from ITP patients on the glycan pattern of human PLTs and the consequent impact on their survival in vivo.

**Methods:** Monoclonal platelet antigen capture assay (MAIPA) and lectin binding assay were used to pattern sera from ITP patients and healthy donors. In LBA, after incubation with sera and PLTs from healthy donors, the modifications on the glycan pattern were investigated by flow cytometry using lectins; Ricinus communis agglutinin (RCA), Erythrina cristagalli lectin (ECL) and Peanut agglu-
tinin (PNA) that bind to galactose, N-acetyllactosamine and N-acetylgalactosamine residues, respectively. The NOD/SCID mouse model was used to study the impact of different glycan patterns on the survival of human PLTs.

Results: In this work 37 sera from ITP patients and 25 sera from healthy donors were analyzed. In the LBA, after incubation with AAbs, different patterns of glycan modification were observed. 17/37 sera caused a significant increase in PNGase A-treated, as compared to healthy donors (median fold increase (FI): 1.21, range: 1.08 – 1.40). 9/37 sera induced higher ECL binding (median FI: 1.02, range: 1.08 – 1.15). In contrast, 8/37 sera showed strong decrease in RCA binding (median FI: 0.52, range: 0.50 – 0.59). Sera from healthy donors did not induced significant change. Interestingly, not only GP-Ib/IX AAbs but also GP-IIb/IIIa AAbs were able to modify glycan pattern. In NOD/SCID mice the administration of AAbs induced an accelerated clearance of human PLTs from the circulation. The destruction of human PLTs by ITP-AAbs was decreased but not completely prevented by a specific neuraminidase inhibitor that blocks glycan changes on PLT surface (survival of human PLTs after 5h: 48%, range 41.5%-53% vs 29%, range 22%-38%).

Summary/Conclusions: Our results demonstrate that AAbs from ITP patients are able to induce cleavage of glycan moieties on the PLT surface in distinct manners. Antibody-modified modification of glycan patterns seems to contribute to AAb-mediated PLT destruction.

Camerlingo”, Francavilla Fontana, Bari, Italy, 7Instituto de Investigaciones Médicas Alfredo Lanari, Universidad de Buenos Aires, IDIM-CONICET, Buenos Aires, Argentina, 8Department of Medical Sciences, University of Trieste, Trieste, Italy

Background: Familial platelet disorder with propensity to acute myeloid leukemia (FPD/AML) is a rare autosomal dominant inherited thrombocytopenia (IT) caused by mutations in the hematopoietic transcription factor RUNX1; an important hallmark of this IT is the increased risk of developing myeloid neoplasms, such as AML and myelodysplastic syndromes (MDS). FPD/AML is caused by different mutations of RUNX1 encoding the DNA binding subunit (known as core binding factor-alpha, CBF-alpha) of the CBF transcription complex. The N-terminus domain of RUNX1 (run-homologous domain) mediates DNA binding and heterodimerization to CBF-beta, the other subunit of the CBF complex. The C-terminus of RUNX1 includes domains that are involved in transcription activation and repression. This IT is characterized by impaired megakaryopoiesis and moderate thrombocytopenia, with normal-sized and dysfunctional platelets.

Aims: To unravel the molecular basis of ITs and to improve our knowledge on the molecular basis and clinical-laboratory picture of FPD/AML.

Methods: Whole exome sequencing (WES) was performed in 86 proposit with an unknown IT after the diagnostic workup based on the most updated diagnostic algorithm for ITs (Clin Genet 2016;89:141). RUNX1 variants detected by WESs were confirmed by Sanger sequencing in the propositi and all available family members, which also undergo clinical-laboratory characterization. The study was approved by the Institutional Review Board of the IRCCS Policlinico S. Matteo Foundation; all patients gave written informed consent.

Results: We identified three pedigrees (families 1-3) with different RUNX1 heterozygous mutations, all segregating with thrombocytopenia in the respective families: the novel variants c.578T>A and c.967+2_Sdel, and the known c.351+1G>A. The thirteen individuals carrying the RUNX1 mutations had mild thrombocytopenia (platelet count ranging from 70 to 130 x 10⁹/L) with mild bleeding tendency. Platelet sizes were within the normal range in all the six patients analyzed, and the serum level of thrombopoietin was normal or moderately increased. No specific morphological alteration of platelets was detected, except for moderate reduction in the alpha-granule content in family 1, confirmed by immunofluorescence analysis. The surface expression of the major platelet glycoprotein (GP) complexes GP Ib-IXa and GP IIb-IIIa-V was normal. In family 1, a moderate reduction of GPVila was detected, regardless of genotypes at the ITG42 locus. A defective aggregation was detected after platelet stimulation with collagen 4 mcg/ml and ADP 2 mcM in the five patients investigated; normal responses were obtained using collagen 20 mcg/ml, ADP 20 mcM and ristocetin 1.5 mg/mL, suggesting mild functional platelets defects. Of note, three patients from two families developed AML, with a prevalence lower than reported in literature, probably because of a different criteria of enrolment (RUNX1 germline mutations are usually searched in ITs associated with AML). No solid/hematological cancer was reported in family 1.

Summary/Conclusions: FPD/AML is an IT lacking pathognomonic laboratory criteria: it is characterized by a mild functional defect and, much more importantly, by a normal platelet size, similarly to the other ITs predisposing to hematological malignancies (ANKRD26 and ETV6-related thrombocytopenias). Given the importance of recognizing these diseases for patients counseling, follow-up, and therapeutic approach, we recommend a systematic screening for RUNX1, ANKRD26, and ETV6 mutations in all patients with an autosomal dominant IT and normal platelet size.

Dmitry Rogachev, Moscow, Russian Federation, 8Amgen Ltd., Uxbridge, United Kingdom, 9Amgen Inc., Thousand Oaks, United States

Background: The use of romiplostim in children with ITP has been evaluated in phase 1/2 and 3 studies. Here we describe children with ITP who will receive open-label SC romiplostim for up to 3 years (y).

Aims: To assess platelet responses in children with ITP receiving romiplostim.

Methods: Eligible children, recruited in 16 countries worldwide, had ITP for ≥6 months, >1 prior ITP therapy, and platelet (plt) counts ≤30×10⁹/L. Weekly SC dosing started at 1 µg/kg and was titrated in 1 µg/kg increments up to 10 µg/kg to maintain plt counts of 50-200×10⁹/L. The primary endpoint was the % of time in the first 6 months with a plt response (plt count ≥20×10⁹/L without rescue medication use in the past 4 weeks).

Results: As of 15 Mar 2016, 145 patients received ≥1 dose. At baseline, median (min-max) age was 10 (2-17) y; 51% were female; 4% had prior splenectomy. Median (min-max) ITP duration was 1.9 (0.5-12.3) y and plt count was 13 (2-168)×10⁹/L. The median (Q1, Q3)% of time with a plt response (plt count ≥20×10⁹/L without rescue medication use in the past 4 weeks).

Figure 1.
first 6 months was 50% (0%, 83.3%); that of months 7-12 was 92% (33%, 100%). Overall, 80% (114/143) of patients had a plt response. The median (Q1, Q3)% of time with an increase in plt counts ≥20×10^9/L above baseline was 60% (25%, 84%). The median dose increased to 10 µg/kg by week 32. Median (min-max) treatment duration to date was 25 (1-67) weeks for a total exposure to date of 79 patient-years. Median (min-max) average weekly romiplostim dose over the course of the study was 6.1 (0.4-9.0) µg/kg. 32 patients (22%) discontinued treatment for lack of efficacy (n=17), required other therapy (n=5), patient request (n=4), noncompliance (n=2), adverse event (AE) (n=2) (interstitial lung disease in a 15 y old boy and abdominal pain, vomiting, and headache related to treatment) in 9 y old girl), administrative decision (n=1), and investigator decision (n=1). 34 (23%) patients received rescue medications. 15 (10.3%) patients had serious AEs (SAEs) including epistaxis (n=4), petchia (n=2), decreased plt count (n=2), and thrombocytopenia (n=2). A case of abdominal pain was the only SAE deemed treatment-related by the investigator. CTCAE grade 3 bleeding was seen in 8 patients (6%) and included epistaxis (n=5), ecchymosis (n=2), petchia (n=2), and 1 case each of hematemesis, hematology, SC hemorrhage, injection site hemorrhage, and mouth hemorrhage. No grade 4 or 5 bleeding was observed. No neutralizing antibodies against romiplostim or TPO were identified. Of 30 patients with baseline bone marrow biopsies (bone marrow biopsies were obtained at European sites), all had modified Bauermeister scores of grade 0 (no reticulin) or 1 (fine fibers) and bone marrows typical for TIP. Of these 30 patients, 21 had evaluable on-study biopsies obtained after ~1 year of treatment, with no increases in or more grades, findings of collagen, or bone marrow abnormalities (Figure 1).

Summary/Conclusions: In this year 1 data cut of an ongoing open-label study of romiplostim in children with iTP, the end time in the first 6 months with a plateau treatment response was 50%, with 80% of children having a plateau response at some point on study. The median romiplostim dose reached 10 µg/kg and there were no new safety signals. No effects of romiplostim were observed on the bone marrow in the subset of patients with bone marrow biopsies. Future data cuts for years 2 and 3 in this study, the largest of romiplostim in children with iTP, will have 97 patients with years of exposure to date, will provide more information on plateau treatment response, dose requirements, and safety.

P368 NOVEL THIENOPYRIDINES AS POTENT PLATELET INHIBITORS: FUTURE TREATMENTS FOR PLATELET HYPERACTIVITY DISORDERS?

N. Binsaleh, C. Wiegley, K. Whitehead, D. Moreno-Martinez, S. Danie1, S. Jones1, M. van Rensburg2, L. Pilkington3, D. Barker4, N. Dempsey-Hibbert1

1School of Healthcare Science, Manchester Metropolitan University, Manchester, United Kingdom, 2School of Chemical Sciences, University of Auckland, Auckland, New Zealand

Background: Platelet hyperactivity is associated with a number of disorders including Acute Coronary Syndromes (ACS) and manifests as increased platelet activation and often inappropriate thrombus formation. The thiopyridine class of anti-platelet drugs, of which clopidogrel and prasugrel are the most well known, target the P2Y12 receptor on platelets, blocking the effects of the platelet agonist ADP. However, the effect of these drugs is variable among patients, with some patients responding well and some remaining at risk of thrombosis. This variability highlights a need for a refinement of this class of P2Y12 inhibitor.

Aims: The aim of this study was to assess the efficacy of six novel thienopyridine derivatives synthesized by our group by examining their potential as in vitro inhibitors of platelet function.

Methods: Healthy human platelets were isolated and incubated with novel thienopyridine compounds (D.J.0081, DJ.0199, DJ.0201, DJ.0206, DJ.0171, DJ.0097) (10µM, 30min) prior to stimulation with ADP (10µM) and analysis of alpha granule secretion (CD62P expression), GPIIb/IIa activation (PAc1 expression) and platelet leukocyte aggregate (PLA) formation using flow cytometry. Furthermore, light transmission aggregometry (LTA) was used to assess ADP-induced platelet aggregation after these treatments. As clopidogrel is usually prescribed in combination with the COX-1 inhibitor acetylsalicylic acid (ASA), synergy of the novel compounds with ASA (30µM) was also analysed by LTA. All results were compared to ADP-stimulated samples and samples treated with clopidogrel (10µM, 30min) prior to ADP stimulation.

Results: All six novel compounds demonstrated a significant reduction in ADP-mediated platelet aggregation (P<0.001), CD62P expression (p<0.001), PAC1 expression (p<0.01) and PLA formation (p<0.05). These compounds were also shown to enhance the inhibitory effects of ASA. DJ.0171 and DJ.0199 were particularly potent, displaying greater inhibitory effect than clopidogrel.

Summary/Conclusions: The study demonstrates the potential for new thienopyridine compounds as modulators of platelet function and points to the possibility of future use in patients at risk of platelet hyperactivity and thrombosis.

Quality of life, palliative care, ethics and health economics 1

P369 PATIENT-REPORTED OUTCOMES AND HEALTHCARE RESOURCE UTILIZATION BEFORE AND DURING TREATMENT WITH ECULIZUMAB: RESULTS FROM THE INTERNATIONAL PAROXYSMAL NOCTURNAL HEMOGLOBINURIA REGISTRY

M. Mus1,2, S. Langemeijer1, B. Hochsmann2, A. Hill1, L. Arnold3, G. Tjønnfjord4, B. Donato5, P. Gustovic6, A. Wilson5, J. Szer7

1Radboud University Medical Center, Nijmegen, Netherlands, 2Institute for Clinical Transfusion Medicine and Immunogenetics, University Hospital Ulm, Ulm, Germany, 3St. James’s University Hospital, Leeds, United Kingdom, 4Ospedali University Hospital, Oslo, Norway, 5Alexion Pharmaceuticals, Inc, Lexington, MA, United States, 6Alexion Pharma GmbH, Zurich, Switzerland, 7Royal Melbourne Hospital and University of Melbourne, Melbourne, Australia

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare disease caused by somatic phosphatidylinositol glycan class A (PIGA) gene mutation in bone marrow stem cells. Clinical manifestations may include fatigue, abdominal pain, dyspnea, dysphagia, erectile dysfunction, anemia, sudden hemoglobin level reductions due to complement-induced hemolysis, and PNH-related complications such as thrombosis, chronic kidney disease, and pulmonary hypertension, all of which impair quality of life (QoL) and could impact survival. Eculizumab, a humanized monoclonal antibody approved for treatment of PNH, reduces intravascular hemolysis, thrombosis rates, and other PNH-associated comorbidities. The International PNH Registry (NCT01374360) is an ongoing prospective, multinational, observational study established to record the natural history of patients with PNH and collect data on long-term efficacy and safety of eculizumab treatment.

Aims: Analyze patient-reported outcomes (PRO) and healthcare resource utilization (HRU) before and during eculizumab treatment.

Methods: Patient assessment questionnaire (PAQ) data for patients with PNH who commenced eculizumab after Registry enrollment and had data available as of August 1, 2016, were analyzed. Patients had to have non-missing data on demographics, ≥1 recorded PAQ within 12 months prior to eculizumab initiation, and ≥1 PAQ recorded ≥6 months after initiation. Outcomes of interest included changes in QoL assessments (Functional Assessment of Chronic Illness Therapy [FACIT]-Fatigue score, EORTC QLQ-C30 fatigue subscale), fatigue (FACIT-Fatigue score; EORTC QLQ-C30 fatigue score), disease symptoms, Karnofsky Performance scale, HRU, and missed work days.

Results: Of 4082 enrolled patients, 649 had non-missing data on demographics and initiated treatment with eculizumab as of August 1, 2016; 229 patients (55% female, 86% white, 74% from Europe) of the 649 met inclusion criteria for the current analysis. Median (min, max) interval between PNH disease start and initiation of treatment was 4.4 (0.1, 44.9) years. Clinically meaningful improvement in FACIT-Fatigue score (≥4-point increase) was reported by 53% of patients after initiating eculizumab (mean change, 5.2 points, Figure 1). Clinically meaningful improvement ≥10-point increase was also observed in EORTC QLQ-C30 mean scores for global health/QoL (mean change, 15.1), role functioning (16.3), emotional functioning (12.1), and social functioning (13.9) subscales. PNH-related symptoms disappeared in 19–44% of patients who reported the symptom prior to eculizumab across all assessed symptoms except erectile dysfunction, which did not disappear in any of the 21 patients who answered this question both before initiation and during eculizumab treatment. Mean Karnofsky scale scores improved by 8.4 points after eculizumab initiation. HRU decreased for emergency room visits and number of missed work days while patients received eculizumab (incidence rate ratio [IRR] [95% confidence interval (CI)], 0.33 [0.20, 0.54] and 0.48 [0.25, 0.93], respectively) and increased for healthcare provider visits and hospital admissions (IRR [95% CI], 1.47 [1.22, 1.77] and 1.17 [0.60, 2.27], respectively).

Figure 1.
Summary/Conclusions: In this cohort of patients from the International PNH Registry, treatment with eculizumab was associated with clinically meaningful improvements in PROs, including assessments of fatigue, global health status, patient functioning, and disease-related symptoms, as well as a decrease in emergency room visits and number of missed work days.

P370

ECONOMIC IMPACT OF INTRODUCING AGE-ADJUSTED D-DIMER CUT-OFF LEVELS IN THE DIAGNOSIS STRATEGY OF VENOUS THROMBOEMBOLISM

P. Toulon1,*, N. De Pooter2, M. Brionne-François3, M. Smahi4, L. Abecassis5

1Hematology, Pasteur University Hospital, Nice, 2Hematology, General Hospital, Grasse, 3Hematology, University Hospital, Caen, 4Hematology, Simone Veil Hospital, Euabonne, 5Hematology, General Hospital, Aulnay, France

Background: The diagnosis of venous thromboembolism (VTE) can be safely excluded in the case of D-dimer levels below a well defined cut-off value in patients with a low or intermediate pre-test probability (PTP) (i.e., as defined by the Chest pain rule-out algorithm), as the negative predictive value (NPV) is close to 100%. As age is associated with increased D-dimer levels, the question arose whether D-dimer measurement was useful to rule out VTE in elderly patients.

Aims: The aim of the present study was to evaluate the clinical performance of a diagnosis strategy based on age-adjusted cut-off values calculated by multiplying the patient’s age by 10 in patients aged over 50, and to evaluate its economic impact.

Methods: We included 1255 consecutive outpatients with non-high PTP of VTE referred to the emergency departments at 5 French centres (2 university hospitals, and 3 general hospitals, in whom D-dimer testing was prescribed. The same standardized procedure was used in the 5 centres i.e. D-dimer measurement in patients with a non-high PTP, and imaging techniques (ultrasonography, computed tomography, magnetic resonance imaging) in the case of suspected PE and Doppler ultrasonography in case of suspected DVT) in the case of D-dimer above the cut-off level. D-dimer levels were evaluated using the same fully automated latex-based assay (Hemosil D-dimer HS 500, Instrumentation Laboratory) in all patients with VTE and in 521 of the 1140 patients without VTE (45.7%), leading to test NPV and sensitivity of 100%. The overall test specificity was 54.3%, even though it significantly decreased in an age-dependent manner over 60 years old. This is due to increased D-dimer levels in older patients particularly in those above 80 years. Using age-adjusted cut-off levels, calculated by multiplying the patient’s age by 10, significantly improved the overall test specificity (60.2%). The NPV remained high (99.9%), even though a 78-y-old female with a low PTP of PE would have been misdiagnosed as her D-dimer level (540 ng/mL) was above 500 ng/mL but below the age-adjusted cut-off value. Such an improvement in test performance was found both in patients with suspected PE and DVT (Table). As such an increase in test specificity would have led to exclude VTE in a higher percentage of patients in the studied population, we evaluated the cost-effectiveness of both strategies, taking into account the local reimbursement rates of D-dimer testing, angiography and Doppler ultrasonography (16.20, 58.72, and 75.60 Euros respectively). The economic impact of the proposed diagnosis strategy was a decreased of 6.9% (263.77 Euros) for PE diagnosis and survival and to significant use of health care resources. Despite the selection bias, only patients who received cellular based therapy, either DLI or another HSCT, enjoyed a prolonged survival. Healthcare resources devoted to the care of patients in relapse post AHSCt provide a comparative basis for cost efficiency analysis in the development of innovative cellular therapy.

Summary/Conclusions: Relapse following AHSCt is associated to a poor prognosis and survival and to significant use of health care resources. Despite the selection bias, only patients who received cellular based therapy, either DLI or another HSCT, enjoyed a prolonged survival. Healthcare resources devoted to the care of patients in relapse post AHSCt provide a comparative basis for cost efficiency analysis in the development of innovative cellular therapy.

P371

IMPACT OF CELLULAR THERAPY ON THE ECONOMIC BURDEN AND SURVIVAL FOLLOWING RELAPSE AFTER HLA IDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE LEUKEMIA AND MYELODYSPLASTIC SYNDROME

S. Lachance1,*, J. Bibeau2, N. Ladjemil3, J. Lachaine4

1Hematology, Hematopoietic cell transplantation, Université de Montréal, Hôpital Maisonneuve-Rosemont, 2Peripharm Inc., 3Peripharm, Montréal, 4Pharma-cie, Université de Montréal, Montréal, Canada

Background: Relapse following allogeneic hematopoietic stem cell transplant (aHSCt) is associated to a very poor outcome and remains an unmet medical needs. The impact of treatment approach on costs and survival remains unknown. The development of innovative cellular therapy for the treatment of relapse following aHSCt may change its dismal outcome but the cost of such intervention has prohibited its large-scale development.

Aims: The objective of this study was to measure the economic burden associated with the management of relapse following aHSCt and to evaluate the impact of treatment choice on survival and health care costs.

Methods: A retrospective medical chart review was conducted at Maisonneuve-Rosemont Hospital (HMR) after research and ethic committee approval. Patients were selected using the Hematopoietic Stem Cell Transplant (HSCT) program database. Eligible patients were diagnosed with acute leukemia (AL) or MDS and relapsed following aHSCt between January 1th 2011 and December 31st 2014. Patients’ and disease characteristics and relapse-related health care resource utilization were collected from the date of post transplant relapse until death or last follow-up. Canadian unit costs for each intervention/treatment were obtained from literature and governmental publications.

Results: During the study period, 645 HSCT were performed at HMR, 303 were allogeneic. A total of 36 patients met the inclusion criteria and were included in the analysis. 32 recipients were diagnosed with AL and 4 with MDS. Treatment approaches following aHSCt relapse were divided in three groups according to patient and physician choices: group 1 received supportive care (n=9), group 2 received chemotherapy or tyrosine kinase inhibitors (n=21) and group 3 received a cellular based therapy, either donor lymphocyte infusion (DLI) or a second aHSCT (n=6). The median cost of care per patient per month was C$20,239 (SD=17,079). The median survival following relapse for the entire cohort was 12.4 months (SD=2.8). For group 1, 2 and 3, the mean cost of care per patient per month was C$17,436 (SD=16,447), C$22,914 (SD=18,474) and C$15,082 (SD=12,954), respectively. The median survival was 4.0 months (SD=2.0), 7.2 months (SD=1.6), and 46.6 months (SD=8.4), for treatment group 1, 2 and 3 respectively (Figure1).

Figure 1. Survival according to treatment group.

Summary/Conclusions: Relapse following AHSCt is associated to a poor prognosis and survival and to significant use of health care resources. Despite the selection bias, only patients who received cellular based therapy, either DLI or another HSCT, enjoyed a prolonged survival. Healthcare resources devoted to the care of patients in relapse post AHSCt provide a comparative basis for cost efficiency analysis in the development of innovative cellular therapy.
not continuously enrolled for 12-months (mos) before the first AML claim (index date); evidence of acute promyelocytic leukemia anytime during the study period; missing enrollment information; or ≥1 hospitalizations during follow-up (FU) with missing cost. Pts were classified as treated or untreated, with treatment defined based on receipt of CT (inpatient or outpatient) or SCT. For treated pts, FU was partitioned into 2 periods: index date to 6 mos and >6 mos post index date. Mean HRU and costs over the FU period were calculated by receipt of treatment and, for treated pts, by time since index date.

Results: 10,197 pts met study criteria including 6,862 treated pts (67%) and 3,335 untreated pts (33%). Mean age was 55 and 60 years in treated and untreated pts, respectively. Mean follow-up was 19.3 mos in treated pts and 18.1 mos in untreated pts. Mean total costs were higher for treated pts ($386,771) vs untreated pts ($83,274). In treated pts, mean total costs were $166,156 during the first 6 mos (mean duration 3.9 mos), and $220,555 during the remaining follow-up period (mean duration 19 mos), 26% of treated pts had SCT. Costs of inpatient and outpatient CT during the first 6 mos were $86,188, representing 22% of the total cost for treated pts (Table 1).

Summary/Conclusions: HRU and costs of managing AML pts are considerable, with greatest HRU and cost in pts receiving CT or SCT.

P373
HEALTH-RELATED QUALITY OF LIFE IN AL AMYLOIDOSIS PATIENTS WITH NERVOUS SYSTEM INVOLVEMENT
M. Yokota1, S. D. Guthrie2, T.P. Quock3, K.L. McCasland1, M.K. White1, M. Bayliss1
1Optum, Lincoln, 2Prothena Biosciences Inc, South San Francisco, United States

Background: In light chain (AL) amyloidosis, misfolded light chains accumulate and cause progressive peripheral neuropathy (PN) and failure of critical organs such as the heart and kidneys. Consequently, a progressive, ascending sen-somotor neuropathy is often a related clinical finding.

Aims: This study describes disease characteristics and health-related quality of life (HRQoL) in AL amyloidosis patients with peripheral nerve involvement (AL-PN).

Methods: An online survey was administered to AL-PN (n=126) and non-nerve–affected (n=215) patients to assess patient characteristics and HRQoL (based on the SF-36v2 Health Survey [SF-36v2]). The survey measures eight health concepts: physical functioning (PF), role physical (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role emotional (RE), mental health (MH), in addition to physical (PCS) and mental component summary (MCS) measures. Patient characteristics were compared using chi-square tests. Differences in symptomatic and HRQoL burden were tested with multivariable logistic and linear models, respectively. Differences in mean HRQoL between AL-PN and non-AL-PN patients were compared to established minimally important differences (MIDs).

Results: Compared to non-nerve–affected patients, greater proportions of AL-PN patients visited ≥6 doctors (42.1 vs 19.5%, p <0.001) and ≥6 specialists (24.6 vs 9.9%, p <0.001). AL-PN patients also had symptoms for ≥1 year prior to receiving a diagnosis (50.8 vs 39.1%, p=0.035), relative to non-nerve–affected patients. Nearly all AL-PN patients (97.6%) reported multi-system involvement (e.g. pericardial effusion, atrial fibrillation). AL-PN vs non-AL-PN patients (68.3 vs 28.8%, p <0.001). There were greater odds of experiencing numbness (OR=4.23, 95% CI: 2.45–7.30, p <0.001) and fatigue (OR=3.09, 95% CI: 1.36–7.02, p <0.01) among AL-PN patients as compared to non-AL-PN patients, even after controlling for other types of organ involvement. Gastrointestinal involvement was more prevalent in AL-PN patients versus non-AL-PN patients (68.3 vs 28.8%, p <0.001). There were greater odds of experiencing numbness (OR=4.23, 95% CI: 2.45–7.30, p <0.001) and fatigue (OR=3.09, 95% CI: 1.36–7.02, p <0.01) among AL-PN patients as compared to non-AL-PN patients, even after controlling for other types of organ involvement. Similar findings were observed for gastrointestinal symptoms, such as alternating bouts of constipation or diarrhea (OR=1.92, 95% CI: 1.12–3.34, p=0.019) and early satiety/feeling fullness in the stomach (OR=1.80, 95% CI: 1.03–3.16, p=0.04). With the exception of RE, MH, and MCS, there were significant differences in SF-36v2 scores among AL-PN patients as compared to non-AL-PN patients (p <0.05 for all). These significant differences also exceeded the thresholds for clinically meaningful differences between the two groups.

Summary/Conclusions: This study suggests that the burden of illness from AL amyloidosis may be greater for those with PN involvement versus those without. AL-PN patients also experienced more complicated journeys to diagnosis and significantly worse symptoms related to nervous systems and physical HRQoL. The SF36v2, a reliable and valid assessment of HRQoL in AL amyloidosis studies, was sensitive to differences in HRQoL between AL-PN and non-AL-PN patients. Future research should examine whether improvements in neuropathy symptoms following treatment subsequently lead to improvements in HRQoL among patients with AL-PN. These findings are helpful for patient-focused drug development and supportive treatments.
which will have a substantial price difference compared with nilotinib. However, given the possible changes in switching of TFR, this price difference may not translate into a similar magnitude of difference in drug budget for first-line nilotinib vs imatinib due to better MR with nilotinib.

**Aims:** To estimate the budget impact for first-line nilotinib vs imatinib when considering generic imatinib pricing, early treatment-switching, and TFR.

**Methods:** The model was based on the ELN guidelines for first-line nilotinib switching and TFR use on clinical outcomes and treatment costs. Analyses were run for 1000 patients with newly diagnosed CML, starting either nilotinib or imatinib, over a 5-year time horizon and using French drug pricing. It was assumed that all patients in the model would switch therapy (imatinib to nilotinib, and nilotinib to dasatinib) based on the failure criteria of the ELN guidelines. As such, ENESTnd trial data were re-analyzed to estimate switching based on the model. The model assumed that patients could enter first-line or second-line TFR after 36 months of continuous therapy where the last 12 months were at MR. Duration of first-line or second-line TFR was based on an extrapolation of ENESTnd trial data, and treatment durations and survival curves, respectively. Monthly drug costs were €2,952 for first-line nilotinib and €1,063 for generic imatinib, assuming a 50% discount to brand pricing.

**Results:** A greater number of patients in the first-line nilotinib arm remained on first-line therapy (690 vs 479 at 15 mos., and 542 vs 366 at 60 mos.); achieved complete cytogenetic response (44% vs 248 by 60 mos.); entered TFR on first-line therapy (347 vs 183 by 60 mos.); entered TFR on either first- or second-line (494 vs 400 by 60 mos.); and was in any TFR at 60 mos (293 vs 200). The incremental budget impact per patient for first-line nilotinib vs imatinib decreased each year from €16,482 in Year 1 to €377 in Year 5. Overall, the 64% lower drug acquisition costs per patient of imatinib (€1,063) vs nilotinib (€2,952) provided only a 17% lower total budget impact over five years (€141,204 vs €170,002) per patient.

**Summary/Conclusions:** Results from the model considered more switching as per 2013 ELN guidelines, which resulted in greater and quicker switching that occurred more rapidly than the ENESTnd. Overall, it was projected that compared with imatinib, patients who receive first-line nilotinib would have earlier and more sustained molecular response requirements for TFR eligibility—and be subject to less treatment-switching. The model projected that less than 50% of patients would remain on first-line imatinib at 15 months. This would significantly reduce the budget benefit of a lower imatinib acquisition price. The budget impact between first-line imatinib and nilotinib would be further reduced by TFR, which occurred in the model more frequently in the nilotinib group. The superior efficacy of nilotinib and the associated differences in switching and TFR eligibility are predicted to substantially offset the lower unit cost for generic imatinib.

**Background:** Cachexia, weight loss, and malnutrition in cancer patients are important contributors of adverse outcomes of cancer patients. MPN patients have abnormal cytokine expression (e.g., IL-1, IL-6, IL-8, and TNF-α) that contributes to symptom burden (e.g., fatigue, pruritus, night sweats, bone pain) and decreases the quality of life [1]. Nutrition assessment (meal, nutrition, weight loss). Diets rich in fruits, vegetables, legumes, whole grains, fish, nuts, and low-fat dairy products are associated with a decrease in inflammatory (e.g., TNF-a, IL-6, and CRP) and thrombotic markers (e.g., homocysteine, fibrinogen; Chrysosou 2004, Smidowicz 2015). To date, no studies have evaluated the nutritional needs or preferences of MPN patients in regards to dietary treatment.

**Aims:** The aim of this project was to determine the nutritional needs and preferences that will help inform the creation of a tailored MPN dietary intervention.

**Methods:** An internet-based survey was hosted by the Mayo Clinic Survey Center to determine dietary needs and preferences of MPN patients. The survey was promoted on multiple MPN-based forums, Facebook pages and websites during February of 2017. The survey included data on demographics, MPN characteristics, nutritional habits, supplement use, and symptom burden using the MPN-SAF TSS/MPN-10 (Emmanuel 2012).

**Results:** Demographics and symptom burden: 919 international MPN patients participated in the online survey of which 22.5% were diagnosed with MF, 37.1% with PV, and 37.4% with ET. Respondents represented MPN patients from 37 countries (48.8%), United Kingdom (32.7%), Australia (6%), and Canada (3.6%). Average MPN-SAF TSS score was 33.6 (SD=17). Dietary Habits: 22.5% of the dimensions having number of meals or snacks, 31.6% having a specific diet, 26% following a specific lifestyle, 26.6% taking supplements, 16.6% took supplements with the intent of reducing inflammation. Half (47.5%) of these individuals felt that the supplements they used made them feel better. Approximately 15% of respondents had tried alternative medicine to help treat their MPN. Among these, 44.8% were under the care of a naturopath and 60.2% endorsed that their treatment plan included dietary change.

**NUTRITIONAL EDUCATION PREFERENCES: OVERALL, 34.4% OF PATIENTS ENDORSED...**

Figure 1.

**Summary/Conclusions:** The GAH scale appears to have the potential to give guidance for election of individual treatment regimens. By identifying elderly patients at high risk to develop toxicities, it may help to choose low-toxicity combinations, to avoid harmful therapies and to identify those patients that could benefit from more intensive treatment. Nonetheless prospective studies with larger populations should be performed to confirm these findings and to try to determine particular cut-off points for different diseases."
using diet to help control their symptoms or MPN disease. Patients most often utilized books (28.2%), websites (27.1%), health care providers such as physicians, NPs or naturopaths (28.2%), online forums (23.2%), friends (12.2%), nutritionists (9.5%), phone or tablet applications (9.1%), or videos (4.2%) for nutritional education. The vast majority (95.9%) of MPN patients endorsed being willing to eat only certain foods if it helped to control symptom burden and or could help their MPN to stabilize or reduce the risk of their MPN getting worse (98.0%).

Summary/Conclusions: There remains an unmet need for symptom burden improvement in low-risk MPN patients or among those who have reoccurrence of symptoms while on JAK inhibitor therapy. Nutritional interventions for MPN patients have not previously been investigated and have the potential to be paired with traditional interventions to allow MPN patients to self-manage symptom burden. This study represents the first evaluation of MPN-related nutritional habits and preferences. These results will be used to inform the creation of an MPN nutritional intervention with the goal of improving symptom burden and reducing inflammation.

P378

DO PHYSICIANS NEED HELP TO ADEQUATELY INFORM AND SUPPORT PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA? RESULTS FROM A QUALITATIVE STUDY IN GREECE

C. Karamanidou1,*, A. Xochelli1, V. Koutkias1, P. Ghia2, K. Stamatopoulos1
1Institute of Applied Biosciences, CERTH, Thessaloniki, Greece, 2Division of Experimental Oncology and Department of Onco-Hematology, Università Vita-Salute San Raffaele and IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: Despite recent progress in prognostication and management, chronic lymphocytic leukemia (CLL) remains unpredictable at diagnosis, while virtually incurable, posing challenges to physicians on how to properly communicate the actual nature of the disease. Moreover, the great majority (~85%) of patients do not need treatment at diagnosis, creating a major cognitive dissonance between the perception of leukemia diagnosis and the "wait & watch" strategy usually applied, that may become a major reason of anxiety and quality of life (QoL) impairment for patients and frustration for physicians. Evidently, both patients and physicians need parameters that would allow co-decision making tailored to each particular case.

Aims: To identify physicians’ needs in order to improve their communication skills and thus facilitate CLL patient empowerment through a patient-centered-ness model.

Methods: An in-depth qualitative study with semi-structured interviews was conducted within hematologists (n=30) all over Greece. Data collection was considered as completed when saturation was reached i.e. no new themes emerged as assessed by the investigators. Content analysis was performed separately by a hematologist and a health psychologist with 98% inter-rater reliability score.

Results: None of the participants had ever received formal communication training but rather adopted the techniques of senior physicians or developed their own through experience alone, thus frequently doubting their approaches (n=12/30, 40%). The most popular communication technique mentioned was adaptation of the quality and quantity of information provided according to each patient’s characteristics (n=29/30, 96.7%); followed by the use of caregivers as mediators for the communication of difficult issues (n=24/30, 80%); balance of realism and hope (n=21/30, 70%); careful choice of wording (e.g. lymphocytosis instead of leukemia) (n=18/30, 60%); gradual disclosure (n=17/30, 56.7%); and, descriptions through pictorial representations or metaphors (n=16/30, 53.3%). Even though physicians did not systematically assess patients’ anxiety and depression levels, they often found themselves dealing with patients’ emotions (n=29/30, 96.7%) through lengthy discussions. With regards to decision making, some mentioned that physicians should make all the decisions (n=9/30, 30%) and that patients are not always willing to take part in the decision-making process (n=8/30, 26.7%), while others were keener on stirring patients towards a decision (n=15/30, 50%), taking into account patients’ preferences (n=10/30, 33.3%). Most physicians felt uncomfortable delivering bad news such as initial diagnosis, relapse and poor prognosis (n=25/30, 83.3%). Self-reported needs included (i) communication skills training (n=20/30, 66.7%); (ii) psychological support (n=7/30, 23.3%); and, (iii) working in a multidisciplinary team (n=8/30, 26.7%).

Summary/Conclusions: In the absence of structured communication guidance there is great uncertainty among physicians concerning their skills on communicating CLL nature and handling difficult situations, leading to distress endangering their engagement in a healthy relationship with the patient. Additional studies are warranted at European level for identifying physician needs in different countries aiming at improving their communication skills to support and empower CLL patients for participating in their own care and enhance their QoL.
OUTCOME OF ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPANTATION FOR PATIENTS WITH ACUTE LEUKEMIA ABOVE 70 YEARS OF AGE: ON BEHALF OF THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

O. Ringdén1, A. Boumendil2, M. Labopin2, B. Sadeghi1, B. Savani3, M. Mohy4, A. Nagler5.

1LABMED, Translational Cell therapy Research, Karolinska Institutet, Stockholm, Sweden, 2Hôpital Saint Antoine, Paris, France, 3Division of Hematology/Oncology, Medical Center Drive, Nashville, United States, 4Hôpital Saint Antoine, Paris, France, 5Chaim Sheba Medical Center, Tel-HaShomer, Israel

Background: The average age of patients (pts) with AML is about 67 years. Historically, many of these pts were not considered as viable candidates for allo-transplantation (HCT) because of concerns about increased transplantation-related toxicity and excessive non-relapse mortality (NRM), a challenging problem especially in older individuals. However the development of reduced-intensity conditioning (RIC) regimens and the improvement in HCT supporting care allowed the successful application of HCT in older pts with AML.

Aims: Compare outcome of allo SCT in acute myeloid leukemia AML patients aged above 70 years of age with that of younger patients.

Methods: AML patients aged between 50 and 90 years old receiving a first or second allo SCT between 2004 and 2014 with MSD or UD donor were included in the study. Comparison of outcomes of patients aged above 70 with that of patients below 70 years of age were performed for the whole period and separately according to disease status at SCT (CR1, CR2, above).

Results: Altogether N=16874 pts were included in the study, N=713 were aged above 70 years old (median 72, IQR 71-73) and N=16161 between 50 and 70 (median 59, IQR 55-63). Older pts were more often male (62 vs 55%, p<0.001), had more often secondary AML (42% vs 28%, p<0.001), more advanced disease (42% vs 27%, p<0.001), more frequent peripheral blood stem cell grafts (96 vs 91%, p<0.001), more often unrelated donors (79% vs 59%, p<0.001) and poorer Karnofsky score (36% below 90, p<0.001), received more often reduced intensity conditioning (80 vs 63%, p<0.001). Incidence of acute GVHD III/IV, chronic GVHD and relapse were the same in the two groups in multivariate analyses, high pre-HSCT MN1 copy numbers were significantly associated with higher CIR (HR=1.2, Figure 1A) & high pre-HSCT BAALC copy numbers was determined using the R package "OptimalCutpoints" & defined pts with high (12%) & low (88%) pre-HSCT BAALC copy numbers. Applying these cut-offs, 71% of the pts had low BAALC & MN1 copy numbers & 10% had high BAALC & MN1 copy numbers, 2% had high MN1 but low BAALC & 17% had high BAALC but low MN1 copy numbers. Pts with high & low pre-HSCT BAALC & MN1 copy numbers did not differ significantly in pre-treatment characteristics or remission status at HSCT (CR vs CR1) while pts with high pre-HSCT BAALC copy numbers were less often in CR1 at HSCT (P=0.02). Both high pre-HSCT BAALC & MN1 copy numbers significantly associated with higher CIR (P=0.02, Figure 1C & P<0.001, Figure 1D, respectively). In multivariate analyses, high pre-HSCT BAALC ( Hazard Ratio [HR] 2.5, Confidence Interval [CI] 1.1-5.7, P<0.001) & high pre-HSCT MN1 copy numbers (HR 5.6, CI 2.6-12.2, P<0.001) retained their prognostic impact on CIR after adjustment for ELN 2010 genetic risk groups.

Summary/Conclusions: In AML with CR1, CR2 status at allo SCT, pts above 70 years of age have worse NRM, survival and LFS compared to pts 50-70 years of age. In pts above 70 years of age Karnofsky score is of significant importance for outcome.

BLOOD BAALC AND MN1 COPY NUMBER ASSESSMENT BY DIGITAL DROPLET PCR PRIOR TO ALLOGENIC TRANSPANTATION PREDICTS RELAPSE IN ACUTE MYELOID LEUKEMIA PATIENTS

M. Jentsch1, M. Bill1, J. Schulz2, J. Grimm1, J. Häntschel1, S. Beinicke1, K. Schacht1, J. B. Behre1, G. Schumacher1, G.-N. Franke1, T. Lange1, V. Vucimic1, D. Niederwieser1, S. Schwind1

1Hämatoologie und intern. Onkologie, UNIVERSITÄTSKLINIKUM LEIPZIG, Leipzig, Germany

Background: Acute myeloid leukemia (AML) patients (pts) that relapse after allogeneic stem cell transplantation (HCT) have a dismal prognosis. Identification of pts at high risk of relapse may allow preemptive therapy & improve outcomes. At diagnosis high expression of the AML associated genes BAALC (brain and acute leukemia, cytoplasmic) & MN1 (meningioma 1) adversely impact AML pts outcomes, but little is known about their usability for residual disease detection. Recently, we demonstrated a higher cumulative incidence of relapse (CIR) for pts with high pre-HSCT BAALC copy numbers in 82 AML pts (ASH 2016, #517). Until today no study assessed the prognostic impact of MN1 copy numbers prior to H SCT.

Aims: To assess the prognostic impact of peripheral blood (PB) pre-HSCT BAALC & MN1 copy numbers in an expanded set of AML pts in hematologic CR using digital droplet (dd) PCR.

Methods: We identified 118 AML pts (median age at HSCT 64 [range 31-76] years [y]) in first (55%) or second complete remission (CR; 23%) or CR with incomplete recovery (22%) with PB prior to HSCT (median 7, range 0-29 days) available. All pts received non-myeloablative (NMA) conditioning (fludarabine 3x30 mg & 200 cGy total body irradiation). At diagnosis karyotypes & NPM1, CEBPA gene mutations (mut) & presence of FLT3-TKD & FLT3-ITD were assessed. Quantification of BAALC & MN1 normalized to ABL1 copy numbers in pre-HSCT PB of the AML pts & in PB of healthy controls (n=7, median age 63 [range 40-82y]) was performed by ddPCR. Median follow up after HSCT for pts alive was 1.8y.

Results: European LeukemiaNet (ELN) 2010 classification was 20% favorable, 25% intermediate-1, 24% intermediate-2, 31% adverse. AML pts & healthy controls did not differ in age (P=1), sex (P=1) or mean BAALC (P=0.37, Figure 1A) or MN1 (P=0.96, Figure 1B) copy numbers. BAALC & MN1 copy numbers correlated well in pts (R=0.80) & healthy controls (R=0.75). The previously determined cut-off of 0.14 BAALC copy numbers (in 82 pts; ASH 2016, #517) defined pts with high (27%) & low (73%) pre-HSCT BAALC copy numbers. A cut-off of 0.74 MN1 copy numbers was determined using the R package "OptimalCutpoints" & defined pts with high (12%) & low (88%) pre-HSCT MN1 copy numbers. Applying these cut-offs, 71% of the pts had low BAALC & MN1 copy numbers & 10% had high BAALC & MN1 copy numbers, 2% had high MN1 but low BAALC & 17% had high BAALC but low MN1 copy numbers. Pts with high & low pre-HSCT MN1 copy numbers did not differ significantly in pre-treatment characteristics or remission status at HSCT (CR vs CR1) while pts with high pre-HSCT BAALC copy numbers were less often in CR1 at HSCT (P=0.02). Both high pre-HSCT BAALC & MN1 copy numbers significantly associated with higher CIR (P=0.02, Figure 1C & P<0.001, Figure 1D, respectively). In multivariate analyses, high pre-HSCT BAALC ( Hazard Ratio [HR] 2.5, Confidence Interval [CI] 1.1-5.7, P<0.001) & high pre-HSCT MN1 copy numbers (HR 5.6, CI 2.6-12.2, P<0.001) retained their prognostic impact on CIR after adjustment for ELN 2010 genetic risk groups.

Summary/Conclusions: High pre-HSCT copy numbers of BAALC & MN1 associated with higher CIR in univariate & multivariate models and might indicate residual disease burden in these AML pts. High copy number pts should be closely monitored for relapse in the post-transplant period. Prospective clinical trials are needed to validate the determined cut-offs, to evaluate if BAALC or MN1 copy numbers or a combination of the genes represents the most suitable prognosticator pre-HSCT and whether AML pts with high pre-HSCT BAALC or MN1 copy numbers benefit from additional pre- or post-HSCT treatment.

THE USE OF BPX-501 DONOR T CELL INFUSION WITH INDUCIBLE CASCADE 9 SUICIDE GENE TOGETHER WITH HLA-HAPLOIDENTICAL STEM CELL TRANSPLANTATION TO TREAT CHILDREN WITH HEMOGLOBINOPATHIES AND ERYTHROID DISORDERS

Burris not discordant; P. Merli1, M. Kocer2, P. Merli1, M. Kocer2, W. Pönisch1, C. Klaas1, F. Locatelli1

1Ospedale Pediatrico Bambino Gesù, Roma, Italy, 2Childrens Hospital at Montefiore, Bronx, NY

Background: Alogeneic HSCT from either an HLA-identical sibling or an unrelated donor is a potentially curative treatment for patients with hemoglobinopathies and erythroid disorders (ED), such as Thalassemia Major (TM),
Sickle Cell Disease (SCD) and Diamond-Blackfan Anemia (DBA). Bertain et al (Blood, 2014) have previously shown that abTcR depleted haplo-transplantation in children with multiple types of non-malignant disorders was feasible. An ongoing Phase II/III trial evaluates the safety and efficacy of post-transplant infusion of donor T-cells transduced with the iC9 suicide gene (BPX-501 cells). (ClinicalTrials.gov identifier: NCT02058869). The iC9 vector contains the sequence for the CD19 molecule, so that the BPX-501 cells (CD5+CD7+CD19+) can be tracked in peripheral blood. We report on 15 children with hemoglobinopathies and ED.

Aims: This study was performed to determine the clinical impact of infusing BPX-501 T cells post αβ T-cell depleted haplo-identical HSCT in pediatric patients with hemoglobinopathies and ED.

Methods: Fourteen patients were transplanted from a parent and one patient was transplanted from a sibling. Conditioning regimen included busulfan, thiotepa and fludarabine. Low dose ATG was administered to prevent graft-versus-host disease (GVHD) and graft failure. No post-transplantation GVHD prophylaxis was given. Median follow-up is 387 days (range 126-631 days). Six patients were males and nine females, and median age at diagnosis and at HSCT was 0.8 and 8.9 years (range 2.5-19.2), respectively. Two patients had DBA and four with SCD. All 9 TM patients were ββββ, and among the those with TM, 4 patients belonged to class I and 3 to class II of the Pesaro classification. All 15 patients were transfusion-dependent and receiving iron-chelation therapy before haplo-HSCT. 161/15 patients maintained full donor chimerism. The patients with secondary graft failure were re-transplanted from the same donor and maintained full donor chimerism.

Results: All patients are alive and well with no Treatment Related Mortality (TRM). Initial engraftment was resistant to treatment or grade IV (TRM) in 4 patients at a median of 23.5 days (range 14-55) and there were two patients re-hospitalized at 30, 163 days respectively. Grade IV skin acute GVHD occurred in four patients and one patient had acute skin GVHD Grade IV. No chronic GVHD was observed. Median time to neutrophil recovery was 14 days (range 10-32 days), while median time to platelet recovery was 11 days (range 8-12 days). Median time to last RBC transfusion was 8 days (5 - 34 days). See Figure 1 for individual Hemoglobin levels. Median time of infusion of 1x10^9 BPX-501 T cells/kg was 14 days after HSCT (range 10-26). BPX-501 cells expanded after infusion and still persist in all patients. Immune reconstitution with normal cellular and humoral immunity present at 180 days post HSCT. All patients remain transfusion-free with a median hemoglobin of 11 or greater after 6 months.

Summary/Conclusions: These data suggest that Haplo-HSCT combined with infusion of BPX-501 T cells with a suicide gene may be a safe and curative option for children with hemoglobinopathies and ED who lack a matched donor. Infusion of gene modified T cells with an inducible suicide mechanism, combined with selective αβ T-cell depletion, offers the potential to rapidly reverse GVHD and eliminate the need for the use of GVHD prophylaxis. Additionally, this approach results in rapid hematological and immune reconstitution for Haplo-HSCT recipients.

Background: All clinical data published thus far on the use of MSCs were generated using cells expanded from individual bone marrow donors hence suffer from huge inter-donor differences in MSC generation, expansion and immunomodulatory potential. To control these variables and to be able to administer to all patients highly similar MSC products, we established a proprietary pooling procedure and generated a large bank of MSC end-of-passage-1 vials from which end-of-passage-2 MSC products are expanded for clinical use. The manufacturing process is fully GMP-compliant and generates an animal serum-free, serum- and xeno-immunomodulatory agent. Importantly, they showed a significantly higher allosuppressive potential than the mean allosuppressive potential of MSCs generated from individual donors. All tested individual MSC doses were equipotent in suppression of the alloantigen-driven reaction in mixed lymphocyte reactions (Kuc1 et al. Haematologica 2016: 101 (8): 885-894).

Aims: A “hospital exemption” issued by the national regulatory authority Pau-Ehrich-Institute (Number: PEl A11748.01.1) licenses the clinical use of these products for patients with steroid refractory GVHD. On the basis of this licence patients were with severe GVHD were treated who were either non responsive or not candidates for additional treatment after treatment failures during periods after 7 days.

Methods: Using these standardised MSC products altogether 52 patients were treated between December 2014 and December 2016. Patients were male (n=31, 60%) or female (n=21, 40%) and were transplanted for leukemia (n=38, 73%), or non-malignant (n=14, 27%) diseases. Median age was 8 years (range: 0.5-58 years). 32 patients were related stem cell source (n=17, 33.3%) or MMF (n=19, 38.4%) and 10 children (n=20, 38%), four lines (n=10, 19%), 5 lines (n=7, 13%), six lines (n=4, 8%), or 7 lines (n=1, 2%) of immune suppressive drugs.

Results: Response was defined as either complete response (CR) in patients with complete resolution of all signs of GVHD, partial response (PR) in patients who showed overall GVHD grade less according to the Glucksberg criteria, or non response (NR) at day 28 after first MSC transfusion. At day ≥+28, 12 patients (23%) achieved CR, 29 patients (57%) PR (overall response= 80%), 8 patients (17%) NR, and in 2 patients (4%) no data were available at day +28. At the last follow up of GVHD, 29 patients (56%) were in CR, 13 patients (25%) in PR, 9 patients (17%) in NR, and for 1 patient (2%) no data were available. At 2 years these response rates resulted in a non-relapse mortality rate (NRM) of 27±6%, cumulative relapse incidence (CIR) of 14±5%, and OS rate of 66±6% (OS). Patients with aGVHD III and IV had an OS survival probability at 2 years of 77±12% and 59±35%, respectively. This study was performed to determine the clinical impact of infusing BPX-501 T cells post αβ T-cell depleted haplo-identical HSCT in pediatric patients with hemoglobinopathies and ED.

Response with standardised equipotent MSCs from the "FRANKFURT MSC-BANK" offers an excellent chance to overcome treatment-resistant and steroid-refractory acute GVHD.

HIGHER PEAK TACROLIMUS CONCENTRATIONS AFTER ALLOGENEIC TRANSPLANTATION INCREASE THE RISK OF ENDOTHELIAL CELL DAMAGE AND COMPLICATIONS

T. Morishita1,1, M. Ohbik1, M. Osaki1, M. Yoshino1, S. Ikeno1, M. Nakashima1, T. Sato1, Y. Kagaya1, Y. Ozawa1, K. Miyamura1

1Hematology, Japanese Red Cross Nagoya Daiichi Hospital, Nagoya, Japan

Background: Noninfectious transplantation-related complications (TRC) such as GVHD and endothelial cell damage (TRC-EC) including sinusoidal obstructive syndrome (SOS), transplant-associate microangiopathy (TAM), idiopathic pneumonia syndrome (IPS), are a major cause of treatment failure and mortality. Higher blood levels of TAC were expected to reduce the risk of GVHD, but may increase the risk of endothelial cell damage (TRC-EC) including sinusoidal obstructive syndrome (SOS), transplant-associate microangiopathy (TAM), idiopathic pneumonia syndrome (IPS).

Aims: Here we evaluated the impact of TAC blood levels upon TRC-EC occur-

Methods: Two hundred sixty-one consecutive patients (pts) who received TAC as a GVHD prophylaxis after allo-HSCT at our institute from 2009 to 2015 were candidates for this retrospective study. Pts who received haploidentical allo-HSCT

Madrid, Spain, June 22 – 25, 2017

haematologica | 2017; 102(s2) | 131

102(s2) | 131
and pts with unavailable TAC concentration data were excluded. A total of 253 pts were eligible. All pts received standard GVHD prophylaxis by continuous intravenous (iv) TAC with starting dose of 0.02 mg/kg/day from 1 day before allo-HSCT (day -1) and iv methotrexate on day 1, 3, 6 at dose of 10 mg/m2, 7 mg/m2, respectively. TAC dosage was adjusted to target the serum concentration of 8-12 ng/ml until at least day 30 and then tapered. TAC was rapidly tapered and pts with unavailable TAC concentration data were excluded. A total of 253 pts were eligible.

Background: T-cell replete haplo-identical stem cell transplantation (haplo-SCT) is a valid therapeutic option for adult patients (pts) with high risk acute myelogenous leukemia (AML) undergoing haplo-SCT. The aim of the study was to confirm the efficacy and feasibility of RIC among a population for which the choice of conditioning intensity is more related to center strategy than pts comorbidities or disease status.

Methods: We retrospectively compared the outcomes of 614 pts with de novo or secondary AML transplanted between 2007 and 2015 from an haplo-identical donor using either RIC (n=365) or MAC (n=249) regimens. Age was categorized in three subgroups (45-55 yrs, 55-60 yrs, >60 yrs). Patients receiving a previous allogeneic transplantation were excluded. RIC was defined according to EBMT definitions.

Results: The median follow up for MAC and RIC was 24 and 20 months, respectively and the median year of transplant was 2013 for both. Pts receiving a RIC were older (55 yrs in MAC vs 61 yrs in RIC, p=<10^-4). Secondary AML was more frequent in RIC vs MAC (31% vs 22%) while 77% of MAC and 68% of RIC were transplant for de novo AML, p=0.01. No differences were found on disease status and Karyoskofy performance status (KPS) at transplant: pts were in CR1 (MAC: 44%, RIC: 40.5%), CR2/3 (MAC: 17%; RIC: 17%) or had active disease (MAC: 40%; RIC: 43%), p=0.68; 12% of pts in both groups had KPS>80, p=0.95. The most frequently used MAC regimen was TBF (56%), while in RIC it was miniTBF (27%) and low dose TBI+Fludarabine (24%). RIC regimens had a more frequent use of associated drugs for GVHD prophylaxis as stem cell source (MAC 42% vs RIC 55%, p=0.002). Post-transplant cyclophosphamide was used in 69% of both RIC and MAC, p=0.39. Main outcomes were not different according to conditioning regimen: at 2 years RIC was 26% vs 32% (p=0.29), NRM 31% vs 34% (p=0.62), sGVHD grade II-IV 24% vs 31% (p=0.05), and cGVHD grade 27% vs 26% vs 39% (p=0.17), OS 46% vs 39% (p=0.15), GFRS 36% vs 28% (p=0.10) for MAC vs RIC, respectively. The results according to RIC and MAC were not different in any of the three age subgroups. 338 patients died; main causes of death were infections and GVHD to be followed by disease recurrence. In multivariate analysis, the type of conditioning regimen was not associated with risk of relapse or treatment failure: R1 (HR: 1.22, p=0.28), NRM (HR: 0.92, p=0.63), acute GVHD grade II-IV (HR: 1.14, p=0.48), chronic GVHD (HR: 1.26, p=0.30), LFS (HR: 1.03, p=0.77), GFRS (HR: 1.07, p=0.55), OS (HR: 1.05, p=0.68). Disease status was associated with outcomes (active disease vs CR): R1 (HR: 2.44, p=<10^-4), LFS (HR: 1.75, p=10^-4), GFRS (HR: 1.72, p=10^-4), OS (HR: 1.71, p=10^-4) as well as KPS>90: NRM (HR: 0.53, p=0.0002), LFS (HR: 0.67, p=0.001), GFRS (HR: 0.74, p=0.014), OS (HR: 0.62, p=0.0002).

Summary/Conclusions: In our study no differences were found between RIC and MAC regimens for haplo-SCT in adults with AML including patients with relapsed and refractory disease. Disease status and performance status were the major predictors of transplantation outcome, while conditioning intensity had no effect. These results may serve as the background for a well design randomized study comparing RIC vs MAC for haplo-SCT in adult pts with AML.
Decision analysis is a computerized modeling analysis which can simulate the clinical outcomes of different therapeutic strategies and identify an appropriate therapeutic strategy.

**Aims:** The aim of this study is to compare the life expectancy (LE) of chemotherapy followed by up-front allo-HSCT vs chemotherapy alone. The transition probabilities between each health states were calculated from the database of 1,792 patients and patients were stratified into low-, intermediate- and high-risk groups according to the risk stratification system which we developed previously (Fuji S et al. 18th International Conference on Human Retrovirology). The model simulated the LE, quality-adjusted LE (QALE) and survival curve after diagnosis of aggressive ATL. Since QoL data for patients with aggressive ATL are lacking, estimates from a similar decision analysis study of patients with acute myeloid leukemia were used. In terms of the timing of up-front allo-HSCT, it was set as all patients receive up-front allo-HSCT from 2 to 6 months if ATL did not progress before allo-HSCT. We used the TreeAge Pro 2016 software package for decision analysis (TreeAge Software Inc., Williamstown, MA).

**Results:** In all patients, up-front allo-HSCT was associated with higher LE in comparison to chemotherapy alone (2.26 years vs 1.75 years). Stratified into 3 groups according to the prognostic scoring system, LE of up-front allo-HSCT was higher compared to that of chemotherapy alone in the intermediate- (2.27 years vs 1.66 years) and high-risk groups (1.50 years vs 0.91 years). The estimated survival curve depicted by TreeAge showed the superiority of up-front allo-HSCT as shown in Figure 1A-D. The Monte Carlo simulation showed that the probability of superiority of up-front allo-HSCT was 100% in all patients, 97.1% in the low-risk group, 100% in the intermediate-risk group and 100% in the high-risk group in terms of LE, and was 99.8% in all patients, 75.2% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of QALE.

**Summary/Conclusions:** Based on decision analysis, up-front allo-HSCT was associated with higher LE and QALE in the intermediate- and high-risk groups in comparison to chemotherapy alone in patients with aggressive ATL. In the absence of prospective randomized controlled trials, our results suggest that up-front allo-HSCT for aggressive ATL is the favored treatment strategy in the intermediate- and high-risk groups.

**P386**

OUTCOMES OF THIOTEPA BASED REDUCED-INTENSITY CONDITIONING VERSUS STANDARD REDUCED-INTENSITY CONDITIONING IN ADULT PATIENTS UNDERGOING DOUBLE-UNIT CORD-BLOOD HEMATOPOIETIC STEM CELL TRANSPLANT

P. Sharma1,2, D. Poliya3, C. Smith3, E. Purev3, M. Kamdar1, B. Haverkos1, D. Sherbenou3, J. Gutman1

1Division of Hematology, University of Colorado, Denver, United States

**Background:** Cord blood transplantation (CBT) is an established alternative source for hematopoietic stem-cells in patients without matched donor. However, the most commonly used high-dose total-body-irradiation (TBI) myeloblastic conditioning (MAC) results in high treatment related mortality (TRM). Non-myeloablative and reduced-intensity conditioning (RIC) have been studied to decrease TRM and provide curative chance to the elderly and those with comorbidities. However, these strategies are associated with higher relapse-rate and graft rejection. A novel-RIC using addition of thiopeta and higher dose of TBI to standard RIC has shown to result in sustained donor engraftment. Our study compares transplant-related-outcomes in patients who underwent first double-unit CBT with standard-RIC regimen of fludarabine (Flu, 200mg/m²), cyclophosphamide (Cy, 50mg/kg), and TBI (200cGy or 300cGy) versus this standard-RIC regimen with addition of thiopeta (10mg/kg) and increased dose of TBI (60cGy).

**Aims:** 1. To compare transplant related outcomes in CBT recipients who received standard-RIC (FluCyTBI) to those who received novel-RIC (FluCy with addition of thiopeta and increased dose of TBI). 2. To identify optimal conditioning regimen in patients undergoing UCT.

**Methods:** After IRB approval, consecutive patients undergoing CBT from 08/2009 to 08/2016 were evaluated and data retrospectively abstracted. Patient selection, graft-versus-host disease prophylaxis and transfusions were per institutional standards and conditioning regimens were compared as described.

**Results:** Of the 99 patients who underwent allogeneic double-CBT, 52 received standard-RIC and 47 received novel-RIC. Median age at transplant was 67 years (range, 24-74) and 54 years (range, 25-67) in standard-RIC and novel-RIC cohort respectively. Acute myeloid leukemia was the major indication for transplant in both cohorts. Median hematopoietic stem-cell transplant comorbidity-index (HSCT-CI) was 3 (range, 0-6) and 1 (range, 0-6) in standard-RIC and novel-RIC groups respectively. Four patients suffered engraftment failure (2 in each cohort). Median neutrophil engraftment was 13 days (range, 6-42) and 21 days (range, 12-43) while median platelet engraftment was 37 days (range, 26-70) and 38 days (range, 24-74) in standard-RIC and novel-RIC groups respectively. Fifty-three suffered acute-GVHD which occurred in 21 (40%) patients (grade 2-4: n=15, 29%; grade 3-4: n=5, 4%) in standard-RIC group and in 32 (66%) patients (grade 2-4: n=29, 62%; grade 3-4: n=5, 11%) in novel-RIC group. Chronic-GVHD (cGVHD) occurred in 18 patients (n=7, 14% in standard-RIC; n=11, 23% in novel-RIC group). The one-year cumulative incidence of relapse was 36% (n=15) in standard-RIC while it was 15% (n=5) in novel-RIC cohort. Median relapse free survival (RFS) was significantly improved in novel-RIC cohort compared to standard-RIC (HR, 0.32, CI:0.11-0.76, p=0.01). Median RFS was 29 months in standard-RIC cohort while median RFS was not reached in novel-RIC cohort. The one-year cumulative incidence of transplant related mortality (TRM) was 22% (n=10) in those who received standard-RIC while it was 16% (n=7) in those who received novel-RIC. TRM was not significantly different between the standard-RIC and novel-RIC cohorts. Median follow-up in standard-RCI cohort was 9.3 months (range, 0.16-79) and 13 months (range, 1.4-36) in novel-RCI cohort. The overall survival (OS) was significantly better in novel-RCI cohort compared to standard-RIC (HR 0.49, CI: 0.25-0.94, p=0.03). Median OS was 17 months in standard-RIC cohort while median OS was not reached in novel-RIC group (Figure 1).

**Summary/Conclusions:** In our study, RIC consisting of FluCy with addition of thiopeta and increased dose of TBI in patients undergoing double-cord UCT was associated with improved OS and improved RFS without increase in TRM as compared to standard RIC. While older and more comorbid patients might experience increased TRM with the thiopeta based regimen, these data suggest that consideration of this regimen may be appropriate in fit, older patients.

INTERFERON-Α IS EFFECTIVE FOR TREATMENT OF MINIMAL RESIDUAL DISEASE IN PATIENTS WITH ACUTE LEUKEMIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

X.-D. Mo1,*, X.-H. Zhang1, L.-P. Xu1, Y. Wang1, C.-H. Yan1, H. Chen1, W. Han1, F.-R. Wang1, J.-Z. Wang1, K.-Y. Liu1, X.-J. Huang1

1Peking University People’s Hospital, Institute of Hematology, Beijing, China

**Background:** Post-transplant relapse is a major cause of transplant failure. Because impending relapse can be indicated by minimal residual disease (MRD) after allogeneic hematopoietic stem cell transplantation (allo-HCT), MRD-directed intervention may be a reasonable option for relapse prophylaxis. **Aims:** We investigated the efficacy of MRD-directed interferon-α (IFN-α) treatment in acute leukemia patients who were positive for MRD after allo-HSCT.
P388

COMPARABLE LONG-TERM OUTCOME AFTER ALLOGENEIC STEM-CELL TRANSPLANTATION FOR OLDER PATIENTS (AGE ≥50 YEARS) WITH AML FROM SIBLING AND MATCHED UNRELATED DONORS. A REPORT ON Behalf of the ALWP of EBMT

Background: Allogeneic hematopoietic stem cell transplantation (allo-SCT) is a curative therapy in AML. Most deaths after SCT occur within the first 2 years. Prior large cohort studies showed that patients (pts) surviving leukemia free 2 years after SCT have high probability of survival at 10 years. Most of these studies were done in younger pts following myeloablative conditioning (MAC). Marked improvement has been achieved in SCT from unrelated donors (UD) in recent years due to improvement in tissue typing, donor selection and supportive care. However, there is relatively limited data on the comparable long-term outcomes (beyond 10 years) of SCT in AML pts (age ≥50 years) from sibling and UD in this setting.

Aims: To compare the long-term outcomes after SCT from sibling and UD using different conditioning intensities in AML pts age ≥50 years.

Methods: We analyzed long-term outcomes in a relatively large cohort of pts with de novo AML (n=1134), age ≥50 years, who were alive and leukemia-free 2 years after SCT from matched siblings (n=848) or UD (n=286), in the years 2000–2014. Follow up was 8.6 years (2–16.4).

Results: The median patient age was 56 years (50-75) and 58 years (50-74) after SCT from siblings and UD, respectively (P=0.005). 77%, 12% and 11% in the sibling group were in CR1, CR2 and active leukemia at SCT compared to 50%, 25% and 25% in the UD group, respectively (P<0.001). 37% and 38% had reduced-intensity conditioning according to EBMT definitions (P=0.78), while 27% and 70% had in-vivo T-cell depletion (TCD), respectively (P<0.001). Chronic GVHD prior to the 2 year time point occurred in 61% and 53%, respectively (P=0.02). The 10-year leukemia-free survival (LFS) of pts surviving leukemia-free 2 years after SCT was 72% (68-75) and 62% (55-70) after SCT from sibling and UD, respectively (P=0.04). Multivariate analysis of MVAD definitions showed that disease status was the major predictor of subsequent LFS while conditioning intensity had no effect. While relapse is the major cause of late death after both donor types, NRM and in particular GVHD and infections are more common causes of late death after SCT from UD.

Summary/Conclusions: These data confirmed that MRD-directed IFN-α treatment is effective for patients who were MRD-positive after allo-SCT.

P389

IMPACT OF AZACITIDINE PRETREATMENT ON OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH-RISK MYELODYSPLASTIC SYNDROME

Background: Myelodysplastic syndrome (MDS) is a heterogeneous myeloid stem cell disorder with ineffective hematopoiesis, dysplastic cell morphology, and a propensity for progression to acute myeloid leukemia. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only curative therapy for MDS. In recent years, azacitidine (AZA) has been increasingly used as pre-transplant induction therapy in high-risk MDS patients. However, the benefits of pretransplant therapy in these patients are unclear, and the optimal therapy regimen remains unknown.

Aims: We conducted a retrospective analysis to elucidate the clinical impact of AZA pretreatment on outcomes after allo-HSCT in high-risk MDS patients.

Methods: Clinical data were collected from the registry database of the Japan Society for Hematopoietic Cell Transplantation. We selected patients with high-risk MDS at diagnosis (IPSS intermediate 2 or high), aged 16 years or older, who underwent their first transplantation between January 2009 and December 2014 and received AZA or best supportive care (BSC) before allo-HSCT. Patients who received conventional chemotherapy or immunosuppressive therapy prior to allo-HSCT were excluded. We compared overall survival (OS), relapse, non-relapse mortality (NRM), and hematopoietic recovery after allo-HSCT.

Results: Of the 485 patients, 161 patients (33.2%) received AZA and 324 patients (66.8%) received BSC before allo-HSCT. The median age was 60 (18–70) and 56 (18–74) years, respectively (P=0.002). A higher proportion of BSC patients received cord blood transplantation (P=0.005). Bone marrow transplantation (BMT) was used in 60% (P=0.02) of AZA patients and 52% (P=0.02) of BSC patients.

A total of 107 patients who were MRD-positive after allo-HSCT were enrolled. MRD-positive status was defined as positivity for leukemia-associated aberrant immune phenotypes or positivity for Wilms’ tumor gene 1 in a single bone marrow sample. Recombinant human IFN-α-2b injections were administered subcutaneously 2–3 times per week for 6 months.

Results: The 2-year cumulative incidence of severe acute and chronic graft-versus-host disease (GvHD) treated with AZA or BSC was 15% and 27% and 70% and 70% had in-vivo T-cell depletion (TCD), respectively (P<0.001). Eighty-one (75.7%) patients tolerated MRD-negative after IFN-α treatment, including 42 (39.3%), 6 (6.6%), 7 (6.5%) and 26 (24.3%) who turned MRD-negative 1, 2, 3, and >3 months after MRD-directed IFN-α treatment, respectively. Twenty patients were lost relapse after IFN-α treatment, and 4 patients died of non-relapse mortality (NRM). The 2-year cumulative incidence of relapse and NRM after IFN-α treatment was 11.5% and 4.3%, respectively. The 2-year probabilities of event-free survival and disease-free survival after IFN-α treatment were 66.5% and 82.4%, respectively. Persistent MRD after IFN-α treatment was significantly associated with higher relapse risk and poorer survival.

Summary/Conclusions: These data confirmed that MRD-directed IFN-α treatment is effective for patients who were MRD-positive after allo-SCT.

Background: Isolated thrombocytopenia is a common complication of hematopoietic stem-cell transplantation (HSCT), which was defined as consistent low platelet counts with recovery of the other two cell lines after transplantation. This status leads to an increased risk of life-threatening hemorrhage, frequent requirements of platelet transfusion and extended hospital stays, representing a challenging clinical problem. Previous studies have demonstrated that decitabine, a hypomethylating agent, may increase platelet counts by promoting megakaryocyte maturation and platelet release in mouse model.

Aims: In order to investigate the role of decitabine in patients after HSCT suffering from isolated thrombocytopenia, we conduct a clinical trial to validate this effect in post-HSCT setting.

Methods: We performed a prospective open-label study to evaluate the treatment of low-dose decitabine in patients with hematological malignancies who received allogeneic HSCT and suffered from isolated thrombocytopenia. The inclusion criteria were: (1) Platelet count ≤ 100 x 10⁹/L persistently at day 60 post-HSCT or later; (2) Recovered neutrophil and hemoglobin; (3) Full donor chimerism; and (4) No response to conventional treatments for a duration of at least 4 weeks. Patients with malignancy relapse, active infections, uncontrolled graft-versus-host disease, severe organ damage or transplant-related thrombosis were excluded. From July 2013 to July 2016, 38 patients were randomly assigned into either the control group to receive conventional treatment only, or the test group to receive additional decitabine (15mg/m², intravenously daily for 3 consecutive days).

Results: Major response was observed in 16 out of 19 patients (84.2%) in decitabine group, with a median time of 22 days to achieve platelet transfusion independence. Two patients (10.5%) showed a minor response and 1 patient (5.3%) failed. In contrast, 3 out of 19 patients in the control group (15.8%) showed a major response, 2 patients (10.5%) showed a minor response, 14 patients (73.7%) did not show any improvement, of which 1 patient died of severe hemorrhage in week 5. For bone marrow morphological analysis, all 38 patients showed low levels of megakaryocytes at week 0. However, the megakaryocyte counts in decitabine group were significantly increased at week 4, while no significant difference was recorded in control group. After decitabine treatment, we did not observe a change in anti-platelet antibodies levels and T cell subsets ratios. However, reactive oxygen species (ROS) and megakaryocyte counts increased in the test group. No considerable myelosuppression, febrile neutropenia, and nonhematologic toxicities associated with the treatment were observed.

Summary/Conclusions: Our data showed an encouraging efficacy of decitabine in patients after HSCT suffering from isolated thrombocytopenia and may lead to remarkably increased megakaryocyte counts. Decitabine may improve isolated thrombocytopenia via regulating ROS and megakaryocyte reconstitution.

QUANTITATIVE PROTEOMICS OF PLASMA EXTRACELLULAR VESICLES TO IDENTIFY NOVEL MARKERS OF CLINICAL SEVERITY FOR HBE/B-THALASSEMIC PATIENTS

K. Kittivorapart1,2,3,4, V. Karamatic Crew1, N. Siritharanarukul1, A. Mark Toye1,2,4

1Bristol Institute for Transfusion Sciences (BITS), NHS Blood and Transplant, 2School of Biochemistry, University of Bristol, Bristol, United Kingdom, 3Department of Transfusion Medicine, 4Department of Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand

Background: Hemoglobin (Hb) E/β-thalassemia has a wide spectrum of clinical manifestations that cannot be explained purely by its genetic background. Extracellular vesicles (EV) are one factor that may indicate and/or contribute to disease severity because there is an observed increase in EV release due to the enhanced oxidative stress in thalassemic erythrocytes.

Aims: This study aims to explore the differences in protein composition and abundance between circulating EV from HbE/β-thalassemic patients and normal individuals.

Methods: 15 HbE/β-thalassemia patients and 15 matched-controls from Thailand were fully consented and recruited for this study. Pooled EVs isolated from five thalassemic samples were compared to pooled EVs from five matched controls using a Duplex-Tandem Mass Tag (TMT) mass spectrometry (TMT-MS) analysis. This experiment was repeated three times in total, using different patient and control samples to identify consistent alterations of protein expression in EVs. Finally, protein differences were also confirmed using Western blotting.

Results: The total proteins identified across the three experimental TMT-MS datasets ranged from 1.764 to 2.534 proteins. When restricted to proteins that contained more than one unique peptide, the range of proteins was reduced to 685 to 1,127 proteins. Many proteins were previously reported EV constituents. 19 proteins were consistently increased in patient samples compared to controls across all data sets. The majority of these proteins were chaperone proteins and antioxidant enzymes. Alpha Hemoglobin Stabilizing Protein (AHSP) had the highest increase of between 31 to 47-fold. Other proteins that exhibited increased abundance in thalassemic circulating EV included catalase, superoxide dismutase, T-complex proteins, heat shock protein 70 and ferritin light chain. Importantly, the heme scavenger and plasma proteins – haptoglobin and hemopexin were observed to be consistently decreased in patients’ EV across all data sets. Immunoblotting results corroborated the TMT-MS findings.

Summary/Conclusions: We have successfully identified consistent alterations in protein expression levels between EV generated by HbE/β-thalassemic patients and normal individuals. These findings may potentially lead to the development of a prognostic marker, and therefore may improve the therapeutic outcome for the patients suffering from thalassemia.
and in the percent of circulating erythroblasts; (iv) the increase in β Thal red cell survival. RO4917838 induced a significant reduction in extramedullary erythropoiesis as well as in the amount of insoluble alpha chain aggregates in circulating red cells. It is of note that in β-Thal sorted erythroblasts we found a reduction in HRI and in phospho-eIF2α, indicating a reduction in free heme, which shall resulted in the activation of HRI, in RO4917838 treated β -Thal mice (10 mg/Kg/d, 6 weeks). Finally, in β-Thal mice treated with RO4917838 (4 weeks at 30 mg/kg/d) a reduction in liver and spleen iron-overload was identified, which was associated with increased hepcidin liver expression.

Summary/Conclusions: Our data suggest that RO4917838 ameliorates anemia and ineffective erythropoiesis by reduction of heme biosynthesis in a mouse model for β-thalassemia. RO4917838 is a potential, novel therapeutic approach for the treatment of anemia in patients affected by beta-thalassemia.

P393

MAY MUTATIONS IN THE KLF1 GENE HAVE WORSENING EFFECTS ON THE Beta THALASSEMIA PHENOTYPE

M.R. Storno1, M. Giuliano1, G. Fioretti2, S. Puzone1, R. Sessa1, L. Vicari1, M.P. Ottiano1, M. Caldora3, S. Costantini4, C. Matarese3, A. Sarappa3, G. Amendola3, A. Filosa3, P. Izzo1, M. Grossi1,1

1Dep. Molecular Medicine and Medical Biotechnology, University of Naples Federico II, 2UOSG Genetica Medica, AORN A. Cardarelli, 3UOC Patologia Clinica, P.O. Pellegrini, ASL NA, 4UOSS Malattie rare del globulo rosso, AORN A. Cardarelli, Naples, 5UC Pediatría-TUM, P.O. Umberto I, Nocera Int., Italy

Background: Kruppel-like factor 1 (KLF1) is a pleiotropic erythroid transcriptional factor that plays a key role in erythropoiesis (Siatecka M, Blood 2011; 118: 2044-521). Accordingly, KLF1 mutations have been found to be responsible for a variety of hematological disorders. KLF1 also contributes directly or indirectly to regulate the expression of genes in the beta-globin gene cluster and the fetal-to-adult globin gene switching (Wayne JS et al Int. J. Lab. Hem. 2015; 37: 78-84). It has been reported that mutations leading to KLF1 haploinsufficiency cause β-thalassemia major (Santoro et al. Ann. Hematol 2013; 92: 53-58) and two novel mutations (C94X and P173Pfs*236), all of them in the proline-rich domain (F182L and M39L) (Radmilovic M. et al. Ann. Hematol 2013; 92: 53-58) and 2 novel mutations (C94X and P173Pfs*236), all of them in the proline-rich domain in exon 2. Functional studies were performed in K562 cells in order to clarify the pathogenic significance of these mutations and to better define the role of KLF1 in atypical thalassemia phenotypes. Interestingly, the c.-251 C>G polymorphism was found to be associated with an increased transcriptional activity of the KLF1 promoter (Figure 1A), thus allowing us to exclude for this nucleotide variation the condition of a neutral polymorphism. Furthermore, unexpectedly, the novel F182L and M39L mutation was found to be associated with a dramatic reduction of the beta-globin mRNA expression levels (Figure 1B).

Summary/Conclusions: Our study confirmed the ameliorative effect of some KLF1 mutations on the thalassemia phenotype that were found to be associated with increased fetal- and/or beta-globin gene expression. In other cases we demonstrated that KLF1 mutations may contribute to worsen the beta-thalassemia phenotype or result in a silent beta-thalassemia trait. This study provides further insights into the multiple roles of KLF1 in erythropoiesis and highlights an intriguing effect of a subset of KLF1 mutations that may contribute to the severity of the thalassemia phenotype, thus reinforcing the relevant implications of KLF1 screening for genetic counseling and for effectiveness of preventive screening programs for hemoglobinopathies.

SECONDARY SOLID TUMORS FOLLOWING HEMATOPOIETIC CELL TRANSPLANTATION FOR THALASSEMIA MAJOR

A. Meloni1,1, A. Natale2, S. Santaroni3, M. Di Ianni1,1, S. Angelini2, L. Pistoia1,1, L. Cuccia1, A. Spasiano3, A. Pepe4, P. Di Bartolomeo2

1Fondazione G. Monasterio CNR-Regione Toscana, Pisa, 2Bone Marrow Transplant Center, Pescara, 3University of L’Aquila, L’Aquila, 4Tor Vergata University, Roma, 5ARNAS Civico “Benferratelli-Di Cristina”, Palermo, 6AORN A. Cardarelli, Napoli, Italy

Background: Secondary solid tumors (SST) have been described after HCT, in particular for patients affected by hematologic malignancies. There is limited information about the incidence of SST following HCT for thalassemia major (TM).

Aims: The aim of this study was to determine the incidence of SST in 134 patients with TM who received HCT in our Center between 1983 and 2013.

Methods: 117 patients survived more than 3 years after HCT and were enrolled in the study. Of them, 57 were males and 60 females. Their median age at time of HCT was 10 years (1-29). As conditioning regimen, they received Busulfan (14 mg/Kg) and Cyclophosphamide (200 mg/Kg). The GVHD prophylaxis included Ciclosporine and Methotrexate. All patients received bone marrow cells from an HLA identical donor.

Results: At time of this report, 112 patients were cured, whereas 5 patients rejected their graft and are now under regular transfusion treatment.

Overall, the median follow-up after HCT was 24 years (3-34). Seven patients developed a malignancy (6 males, median age 10 years at time of marrow donation) after HCT including 2 carcinomas of the tongue, 1 oral squamous cell carcinoma, 1 colorectal cancer, 1 thyroid carcinoma, 1 carcinoma of the uterine cervix, and 1 parotid carcinoma. The 30-yr cumulative incidence (CI) of developing SST was 10±0.17%. All patients underwent surgical resection of the tumor and in addition 4 of them received chemotherapy and/or radiotherapy. Of relevance, the 3 patients with cancer of the oral cavity were affected by severe chronic GVHD with buccal cavity involvement. Two patients (1 with parotid and 1 with tongue carcinoma) died of tumor progression and 5 are living. We compared these results with 2 case control populations. First of all, we investigated the occurrence of solid tumors in the 117 individuals (64 males, median age 10 years at time of marrow donation), who served as stem cell donors for HCT. One donor developed breast cancer 29 years after marrow donation at age of 38. The 30-yr CI of developing solid tumor for donors was 4,5±0.21% with a statistically significant difference (p=0.03) as compared to that of transplanted patients. The second case control population consisted of 117 transplanted patients, who were affected by cancer (4% CI). The matching technique applied was based on the variables age and sex. One control per case (transplanted patient) was randomly selected from the MIOT (Myocardial Iron Overload in Thalassemia) registry and matched by sex and age with the transplanted patient population. Two patients developed an hepatocellular carcinoma (HCC) at age of 39 and radiotherapy. respectively. Of relevance, the 3 patients with cancer of the oral cavity were affected by severe chronic GVHD with buccal cavity involvement. Two patients (1 with parotid and 1 with tongue carcinoma) died of tumor progression and 5 are living. We used the rate measure, we observed an event rate of 0.102 at 30 years for the transplant group and 0.041 for the nontransplant group (p=0.106).

Summary/Conclusions: This study shows that the magnitude of increased risk of SST is twofold to threefold for patients treated with HCT as compared with the general population. The second case control population consisted of 117 transplanted patients, who were affected by cancer (4% CI). The matching technique applied was based on the variables age and sex. One control per case (transplanted patient) was randomly selected from the MIOT (Myocardial Iron Overload in Thalassemia) registry and matched by sex and age with the transplanted patient population. Two patients developed an hepatocellular carcinoma (HCC) at age of 39 and radiotherapy. respectively. Of relevance, the 3 patients with cancer of the oral cavity were affected by severe chronic GVHD with buccal cavity involvement. Two patients (1 with parotid and 1 with tongue carcinoma) died of tumor progression and 5 are living. We used the rate measure, we observed an event rate of 0.102 at 30 years for the transplant group and 0.041 for the nontransplant group (p=0.106).

Secondary solid tumors (SST) have been described after HCT, in particular for patients affected by hematologic malignancies. There is limited information about the incidence of SST following HCT for thalassemia major (TM).
Background: Newborn screening program for thalassemia (thal) and hemoglobinopathies (NBS-Hbs) is crucial for early detecting patients with serious hemoglobinopathies (Hb variants). Sickle cell anemia (Hb SS), NTDB-NBS-Hb has been incorporated into a routine neonatal service in several developed countries. However, its role on early detection other forms of globin disorders remains unclear. Moreover, NBS-Hbs can detect several types of thalassemia and HB variants carriers. This application could be useful for the national prevention and control program for thalassemia syndromes in many developing countries including Thailand where these conditions are highly prevalent especially β-thal major, Hb E/β-thal and Hb Bart’s hydrops fetalis (caused by α+-thalassaemia). Recently, a new capillary electrophoresis (CE) has been developed specifically for NBS-Hbs. However, there is a limited data on validation of this technology on detecting several types of thalassemia and HB variants found in Southeast Asia.

Aims: To evaluate and validate a new CE system to screen globin disorders in newborn to initiate the national NBS-Hbs for Thailand.

Methods: After informed consent, 1,213 blood samples of 2 days old newborns were collected by heel prick puncture into 5-dried blood spots. After elution, dried blood samples were analyzed by Capillaries 2 NEONAT FAST® (SEbia, Evry, France). All samples were also extracted for DNA and genotyped by our extensive PCR based panel to detect >98% of abnormal globin alleles found in Thailand using o-thal GAP-PCR, α-thal ARM-PCR, β-thal ARMS-PCR, and PCR-RFLP for Hb E. We compared CE data with each globin genotypes and use a ROC curve to set up new diagnostic criteria using% Hbs from CE for future cases.

Results: Identification of Hb Bart’s provided 100% sensitivity, specificity, accuracy in most individuals with α-thal. Using ROC analysis, we proposed different cut-off values of Hb Bart’s to differentiate Hb H disease, α-thal and non-deletional α-thal traits; ≥7.40%, ≥0.85%, ≥0.45%, respectively, with excellent accuracy (Table 1). Interaction of Hb E with these α-thal genotypes has no effect on these cut-off values (Table 1). However, there was a limitation to identify deletional α-thal [Hb Bart’s ≥0.10% (detectable level)]. A cut-off level to distinguish Hb EEE from Hb E trait was suggested at ≥4.95% level. A cut-off level to distinguish Hb EE from Hb E trait was suggested at ≥0.7%. Two patients with Hb E/β-thalassemia were identified through PCR-RFLP for Hb E. We compared CE data with each globin genotypes and use a ROC curve to set up new diagnostic criteria using% Hbs from CE for future cases.

Table 1.

Summary/Conclusions: This newborn CE platform showed a high efficiency for detecting several types of thalassemia and HB variants in particular α-thal, β-thal and Hb E using cut-off levels of each Hb species described herein. Besides early detecting of HB S, we can now apply this NBS into a routine service in order to early detect HB H disease, HB E/β-thalassemia and the majority of common thalassemia carriers. This NBS-Hbs approach can reinforce and leverage our current program on prevention and control for severe thalassemia syndromes in our region. Moreover, due to population migration from The East to the West, our new diagnostic guideline by CE could be useful and applicable for existing NBS programs currently available in several European countries.

P396

TRANSIENT ELASTOGRAPHY IN NON TRANSFUSION DEPENDENT THALASSEMIA: A SUCCESSFUL TOOL TO ASSESS AND MONITOR LIVER FIBROSIS

A. Ferrant1, G. Graziadei1, M. Pennisi1, M. Migne De Amicis1, M. F Kickelli2, M.D. Cappellini3

1Rare Diseases Center, Department of Medicine and Medical Specialities, Foundation IRCCS “Ca Granda” Ospedale Maggiore Policlinico, 2Department of Pathophysiology and Organ Transplantation, 3Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy

Background: Non Transfusion Dependent Thalassemia (NTDT) patients are at risk for several complications due to chronic anemia, hypoxia and iron overload. Over the recent years hepatic complications are more frequently observed in these patients probably due to the aging and poor care: monitoring liver fibrosis is becoming part of the follow up. Liver stiffness measurement (LSM) by transient elastography (TE), a widely-used non-invasive tool, in our centre has been included in the regular follow-up of patients with NTDT.

Aims: To evaluate by TE liver fibrosis in NTDT patients, its correlation with biochemical, hematological and clinical parameters at baseline and after 5 years.

Methods: Hepatic fibrosis and siderosis were evaluated in 101 NTDT patients using respectively TE, and liver iron concentration (LIC) derived from T2 Magnetic Resonance Imaging (MRI) at baseline and, in a subset of patients, after 5 years. The following TE thresholds were taken into account: <5.0 kPa no fibrosis (F0), ≥5.1-7.9 kPa mild fibrosis (F1), ≥8.0-9.9 kPa moderate fibrosis (F2), ≥10.3 advanced fibrosis (F3), ≥11.9 kPa cirrhosis (F4). Biochemical and hematological blood test were collected too. Patients were also tested for HCV antibodies and HCV RNA. Data were analyzed retrospectively.

Results: Patient’s mean age was 46±11 years, 37/101 (36.6%) were splenectomized, 51/101 (50.5%) had never been transfused, 46/101 (45.5%) were occasionally transfused and 4/101 (3.9%) had been regularly transfused for 10+Syrs. At baseline (T0), the overall mean LSM was 5.9±2.6 kPa, mean LIC 6.68±5.37 mg/g dw, ferritin 700±596 mg/ml, Hb 9.3±1.3 g/dl, ALT GGT and ALP were normal. LSM correlate with GGT (p <0.01) and AST values (p <0.01). LIC was >10 in 6/101 (6%) patients. Two patients were on ICT, both had high LIC (≥4.95%) and LIC >10. Among patients with LIC >10, median LIC and GGT were 10.5 (5.2-17.5) and 24.8 U/L in patients with any grade of fibrosis, p <0.05). For 60 patients data at 5±1 years (T1) were available. LSM remained stable in 35/60 (58.3%): 24 patients did not show fibrosis in both T0 and T1 evaluations, 10 patients showed F1 fibrosis in both evaluations while 4 remaining patients showed F0-F3. Among these patients 13/35 (37.1%) were on ICT. A reduction in LSM was found in 21/60 (35%) patients (T0=7.09±1.63 kPa, T1=5.07±1.61 kPa, p<0.001), with a reduction trend in LIC (T0=6.79±4.9 mg/g dw, T1=5.18±3.04 mg/g dw; p=0.09 ns) and a statistical significant reduction in ferritin levels (T0=709±58 mg/ml, T1=436±280 mg/ml, p=0.005); 21/66 (31.8%) were on ICT. Our patients who were still transfused and stable with LIC at follow up, showed improved grade of fibrosis, a significant difference was found regarding the number of patients on ICT (37.1% vs 66.6% respectively, p <0.05). A worsening in LSM was observed in 4/60 (6.6%) patients: among them LSM changed from F0 to F1 in 2 patients, and from F2 to F4 in the other 2 patients. None of these patients presented HCV RNA positivity.

Summary/Conclusions: NTDT patients could benefit from regular non-invasive assessment of liver fibrosis. In our study subject who received ICT had best chance to reduce the grade of fibrosis through the reduction in iron overload. These patients, those using are HCV RNA negatively monitoring and treating iron overload is a crucial point in the prevention of hepatic fibrosis being the hepatic siderosis the primary cause of hepatic tissue damage, cirrhosis and hepatocellular carcinoma.
with malignancies were identified (incidence: 4.6%). The mean age of the diagnosis of the malignancy was 41.8 years (36.6 years for thyroid gland cancer, 45.8 years for liver, 38 years for hematologic malignancies and 46 for renal cancer). 24 patients were transfusion dependent (TD) (7% of the patients) and 3 non transfusion dependent (1.18%). Liver cancer had the highest incidence 29.6%, followed by thyroid gland cancer 25.9%, hematologic malignancies 11.1% and renal cancer 14.8%. HCV infection was found in 56.7% of the patients and a statistical significant relationship between HCV infection and cancer (p=0.001) was detected. No correlation between liver failure and cancer was detected. In the TD group, the age specific ratio of cancer increased with age with the patients >50 years having the highest ratio of 42.3, compared to 36.1% of patients in the TD group aged 40-60 years and 41-45 years age group respectively. In regards to chelation therapy, at the time of diagnosis 40.9% of the patients were receiving deferasirox (DFX), 22.7% deferiprone (DFP), 22.7% deferoxamine (DFO), 9.1% no chelation therapy and 4.5% DFO/DFP. No statistical significant difference was observed between the different chelation therapies (p<0.118). As the utilization of different types of chelation changed throughout the years, according to the availability of the chelating agents, we analyzed separately, the patients that developed malignancies in the period after 2010 when longitudinal exposure to all three chelators can be assumed. Even though the results showed a difference (p=0.027) between the different groups, with 47.1% of those patients receiving DFX at the time of the diagnosis compared to 27.1% receiving DFP and 11.8% receiving DFO, this distribution reflects the overall distribution of chelator usage during that period. Apart from the incidence, there was no statistical significant difference between TD and NTD patients with cancer regarding the gender, age and year of diagnosis. The cancer mortality rate was 48%, but varied significantly with the type of cancer with liver cancer and hematological malignancies having a mortality of 66%. Overall only 2% of the deaths occurring in our group of patients were attributed to cancer.

Summary/Conclusions: This retrospective study has confirmed the increased incidence of malignancies in thalassemia patients in Greece, which is, at least, partially related to the aging of this population. Based on these observations, adaptation of monitoring guidelines is essential for optimal management of thalassemic patients. Periodic screening for malignancies, especially hepatic, thyroid and hematologic, will allow early detection and timely, and thus, more efficacious treatment of the neoplasia.

P398
SAFETY AND EFFICACY OF EARLY START WITH SUBOPTIMAL DOSE OF DEFERIPRONE IN MINIMALLY TRANSFUSED INFANTS WITH TRANSFUSION DEPENDENT THALASSEMIA: A RANDOMIZED TRIAL

Methods: In the current trial (ClinicalTrials.gov Identifier: NCT02173951), sixty-four children recently diagnosed with thalassemia major who had begun receiving blood transfusions in first year of life to keep pre-transfusion Hb above 10 gm/dl, had not yet started iron chelation therapy and had SF ≥400 µg/L or transferrin saturation (TSAT) ≥70% or labile plasma iron (LPI) ≥0.2 µM were randomized to start deferiprone (DFP) at a sub-therapeutic dose (50 mg/kg/day) or no chelation (NC). Median age at 1st transfusion dose (50 mg/kg/day) or no chelation (NC). Median age at 1st transfusion was 8 months for both DFP-treated and for NC children. The percentage of patients with LPI ≥0.6 µM, SF ≥1000 µg/L or TSAT ≥70% in each study arm was assessed at 6, 9 and 12 months (patients confirmed SF ≥1000 ng/mL after 8-9 transfusions).

Results: Table 1. Summary of the efficacy results of SF, TSAT, and LPI.

Table 1.

All NC patients were removed from the trial prior to completing 7 months of follow-up (9-11 transfusions ) due to confirmed SF ≥1000 µg/L. Mean ± SD time of follow up was 10.4± 4.9 and 5.9 ± 2.5 months for DFP and NC respectively. Most common adverse events in patients on DFP versus NC were diarrhea (19% vs 13%, p= 0.73), vomiting (13% vs 13%, p=1.00), abdominal colic (13% vs 13%), elevated liver enzymes (6% vs 3%, p=1.00) and neutropenia (6% vs 6%). All adverse events were mild in severity and did not require interruption of DFP use. There were no cases of agranulocytosis or moderate neutropenia, no arthralgia and no serious infections in DFP-treated patients. DFP therapy was associated with a significant reduction in the rate of iron accumulation as measured by SF (P<0.0001), LPI (P<0.001)and TSAT (P<0.001) (Figure 1a, b, c). LPI≥0.6 µM appeared as early as after 5 transfusions in NC children and was delayed to at least 10 transfusions with DFP therapy. TSAT ≥70% appeared after 10 transfusions in NC children and was delayed to at least 17 transfusions with DFP therapy. The results of this study show that LPI and TSAT may reach values ≥0.6 µM and ≥70%, respectively, after 5 -10 transfusions in children with TM and all NC children had SF ≥1000 µg/L after 8-9 transfusions.

Figure 1.

Summary/Conclusions: A sub-therapeutic dose of deferiprone for a mean of 12 months in children with TM and low iron overload was not associated with safety concerns and able to significantly reduce the rate of iron accumulation as measured by SF , LPI and TSAT.

P399
LONGLITUDE PROSPECTIVE MRI STUDY IN PEDIATRIC PATIENTS WITH THALASSEMA MAJOR

Methods: We considered 68 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) project with less than 18 years at the first MRI scan and who performed a follow-up (FU) study at 18±3 months. Myocardial and hepatic iron burdens were quantified by the T2* technique. Atrial dimensions and biventricular function were quantified by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.

Results: At the baseline MRI, 16 (23.5%) patients showed myocardial iron overload (MIO; global heart T2*>20 ms) and 54 patients liver iron overload
(79%). Figure 1 shows the changes in iron levels. Twenty-five patients changed the chelation regimen after the baseline MRI. Globally, a worsening in cardiac iron was found in the 3% of the patients while a worsening in hepatic iron in the 21% of the patients (P=0.003). The LV end-diastolic volume index and all RV volumes as well as the LV mass index were significantly lower at the FU MRI. No significant improvement in left or right global systolic function was found. For 40 patients the presence of myocardial fibrosis was investigated at both baseline and FU scans. Six patients (15.0%) had myocardial fibrosis at the baseline MRI and myocardial fibrosis was detected for all of them also at the FU. The extent of myocardial fibrosis was comparable between the two scans (0.77±0.42% vs 0.79±0.51%; P=0.686). At the FU 4 new occurrences of myocardial fibrosis were detected. In patients with baseline MIO no significant correlation was found between the percentage change in cardiac iron and the changes in hepatic iron or the baseline hepatic iron.

**Methods:**

**Results:**

Dec16. MRI-R2* heart, liver and pancreas in a cohort of well treated TM patients. We report a cross-sectional and longitudinal experience with the use of multi-organ evaluation of iron overload by R2* Magnetic Resonance Imaging (MRI) in β-thalassemia major (TM) patients has improved the patient care allowing a more careful tailoring of iron chelation therapy. However pancreatic-R2* remains above the cut-off for the prediction of cardiac iron overload, so this parameter should be considered with caution in the tuning of the chelation therapy, in order to avoid over-chelation risk. Ferritin values trend agree with R2* values confirming the reliability of this parameter. These results were obtained with a prevalent use of oral chelation regiment (90% of patients).

**Summary/Conclusions:** In this experience we observed that the regular multi-organ assessment of iron overload by R2* is concomitant with a reduction of the iron burden in this cohort of well treated patients confirming that is a careful method to tailoring the iron chelation therapy. However pancreatic-R2* remains above the cut-off for the prediction of cardiac iron overload, so this parameter should be considered with caution in the tuning of the chelation therapy, in order to avoid over-chelation risk. Ferritin values trend agree with R2* values confirming the reliability of this parameter. These results were obtained with a prevalent use of oral chelation regiment (90% of patients).

---

**Table 1.**

- **Table 1. Multi-organ MRI-R2* values at baseline and at FU.**
  - **Heart**
    - Baseline: R2* > 50 Hz: 27/23 patients, FU: 21/23 patients, p=0.017.
    - **Liver**
      - Baseline: R2* > 50 Hz: 27/23 patients, FU: 21/23 patients, p=0.017.
    - **Pancreas**
      - Baseline: R2* > 50 Hz: 27/23 patients, FU: 21/23 patients, p=0.017.

**Figure 1.**

**Summary/Conclusions:** Magnetic resonance monitoring in children with TM demonstrated a good control of cardiac iron overload in terms of prevention and treatment but the need for further improvement of liver iron overload. Myocardial fibrosis appears mainly multifocal, non progressive and not reversible over a 18-month period. A prompt and aggressive approach to iron overload and a chelation regimen consistent with the high iron intake and the high rate of severe liver iron overload is recommended in children.

**LONG TERM FOLLOW-UP OF A COHORT OF WELL TREATED B-TALASSEMIA MAJOR PATIENTS BY MULTI-ORGAN R2* MAGNETIC RESONANCE IMAGING**

V.M. Pinto1, L. Bacigalupo2, B. Giansin1, M. Balocco1, M. Lamagna1, S. Quintino1, G.L. Forini1

1Haematology-Centro Microcitemia Anemie Congenite, 2Radiology Unit, Ospedale Galliera Genova, Genova, Italy

**Background:** The introduction of non-invasive multi-organ evaluation of iron overload by R2* Magnetic Resonance Imaging (MRI) in β-thalassemia major (TM) patients has improved the patient care allowing a more careful tailoring of iron chelation therapy. Aims: We report a cross-sectional and longitudinal experience with the use of MRI-R2* heart, liver and pancreas in a cohort of well treated TM patients. Methods: TM patients underwent contemporaneous assessment of pancreatic, cardiac and hepatic MRI-R2* (1.5 T GE HDx scanner) in the period Jan08-Dec16. Results: 69 TM patients: 43% male, age 38±9yrs, median number of observations/patient 6 (IQR: 5-7), median number of yrs of the follow-up (f.u.) 8 (IQR: 7-8). Iron chelation regimens included deferiprone (basal 30%-f.u.32%), deferasirox (basal 45%-f.u.52%), daily alternating deferasirox+deferiprone (basal 3%-f.u.6%), deferoxamine (basal 9%-f.u.6%) and heart (Rp=0.26, p=0.028) and pancreas (Rp=0.23, p=0.05). Moreover the variations of ferritin correlate with the variations of R2* of the liver (Rp=0.6,p<0.001), heart (Rp=0.25, p=0.04) and pancreas (Rp=0.41,p<0.001). Finally, assuming the cutoff value of 100 Hz for the pancreatic-R2* as the predictor of a cardiac R2*>50Hz, we calculated the numbers of false/true positive/negative according to the rule above. At the baseline we can observe that the number of false positive is the 14/27 (52%). The percentage increases to 91% (21/23) after f.u.: the pancreas-R2*>100Hz in 23 patients but only 2 has iron overload in the heart; the total number of patients with pancreatic-R2*>100Hz is quite the same before and after f.u. (27 compared to 23). We found no correlation between the false positive predicted and particular conditions such as impaired glucose tolerance, diabetes or adipose involution (Table 1).

DEVELOPMENT OF HTLV-1 HYPERIMMUNE GLOBULINS AGAINST HTLV-1 INFECTION
T. Mizukami1, K. Nojima1, R. Sobata2, W. Kuribayashi3, C. Matsumoto2, Y. Hiradate1, E. Sasaki1, K. Furuhata1, Y. Hiradate1, K. Ohkuma1, S. Matsuoka1, M. Satake1, I. Hamaguchi1
1Department of Safety Research on Blood and Biologicals, National Institute of Infectious Diseases, 2Central Blood Institute, Japanese Red Cross, 3Department of Cellular and Molecular Medicine, Graduate School of Medicine, Chiba University, Tokyo, Japan

Background: Adult T-cell leukemia (ATL) is a malignant disease caused by infection with human T-lymphotropic virus (HTLV-1). The prevention of HTLV-1 infection is the most effective strategy to eradicate ATL. However, there is no effective vaccine or anti-viral agent for HTLV-1.

Aims: The aim of this study was to develop an effective HTLV-1 hyperimmune globulin (HTLV-IG) isolated from HTLV-1 positive carriers screened at the Japanese Red Cross.

Methods: We developed two in vitro and in vivo screening methods to evaluate and characterize the anti-viral effect of HTLV-1 positive plasma and HTLV-IG.

Results: HTLV-1 positive plasma (PVL >4) inhibited both HTLV-1 infection and syncytia formation. We purified HTLV-IG from the HTLV-1 positive plasma (PVL >4) and evaluated its effect in a humanized mouse model. NOD.Cg-Fkdcscl:Il2tgntm1Sug/Jic mice were treated with HTLV-IG for 5 days before HTLV-1 infection. During the monitoring period up to 40 days after post-infection, HTLV-1 infection was observed in untreated infected mice, but not in HTLV-IG-treated mice. The inhibitory effect of HTLV-IG was observed at the early stage of HTLV-1 infection. Treatment with HTLV-IG at 20 days after HTLV-1 infection had a partial inhibitory effect. HTLV-1 gp46 expression in HTLV-1 infected cells was slightly reduced and the localization of these cells was changed in each tissue after the first line of treatment. These data suggest HTLV-IG is effective at the early phase of HTLV-1 infection. We also assessed the viral safety of HTLV-1 during the HTLV-IG manufacturing process. High log reduction values of HTLV-1 were observed during the Cohn fractionation process. Virus safety was assessed by PCR based assay and in vitro GP46 expression. Partial viral infectivity in HTLV-IG during the HTLV-1 manufacturing process. High log reduction values of HTLV-1 can be seen during the Cohn fractionation process. Virus safety was assessed with PCR based assay and in vitro and vivo infection assay.

Summary/Conclusions: These data suggest HTLV-IG is effective and safe for the prevention of HTLV-1 infection.

THE COMPOSITION OF TUMOR CELLS IN THE APERIPHERISATION MATERIAL DOES NOT PREDICT THE RESPONSE OF MULTIPLE MYELOMA PATIENTS TO AUTOLOGOUS TRANSPLANTATION
M.L. Lozano1, F. De Arriba1, M. Solà1, A. Sanchez-Fuentes1, N. Revilla1, F. Ortuño1, A. Jere2, I. Heras1, P. Iniesta1, O. Lopez-Godino1, M.D. Garcia-Malo1, V. Vicente1
1Hematology and Clinical Oncology, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, Spain

Background: The use of high dose of chemotherapy followed by autologous stem cell transplantation (ASCT) has improved the prognosis of patients with multiple myeloma (MM) and plasma cell dyscrasia. However, there is controversy over the effect of infusion of atypical plasma cells (PC) on the apheresis product.

Aims: To analyze whether in MM malignant plasma cell reinfusion could negatively affect responses to ASCT.

Methods: Patients (n=114) undergoing ASCT (n=120) for MM between June 2003 and February 2016 were enrolled in a retrospective study to analyze the prognostic value of aberrant (CD38++CD138+CD19-CD45weak) to normal phenotype (CD38+++CD138+CD19+CD45+) plasma cells (A:T PC ratio) in the autograft by flow cytometry. The Durie-Salmon stage at diagnosis, the detection of atypical PC in the graft (p=0.06). At day +100, 94% of patients in PR, SD or PD achieved post-ASCT CR or VGPR (p=1.24^-7). There was no association between the content of atypical PC in the graft and the response to day +100. However, the percentage of pre-ASCT PC in the bone marrow was significantly related to the response at day +100 (CR or VGPR vs PR, SD or PD), p=0.003, as well as the pre-ASCT monoclonal component (p=4.03^-7).

Table 1.

Summary/Conclusions: Infusion of PC with atypical phenotype does not appear to affect the response at day+100 following ASCT, in patients with MM or plasma cell dyscrasia. Conversely, the quality of response to induction therapy was significantly associated to 100-day outcome after transplantation. These data support that in vivo persistent residual cells, but not those being infused with the graft, are the main source of relapse in MM.

P403
EVALUATION OF THERAPEUTIC PLASMA EXCHANGE AT A TERTIARY LONDON HOSPITAL
R. Moll1,2, D. Warcel3, S. Clark1, M. Sekhar1
1Haematology, Royal Free Hospital, London, United Kingdom

Background: Therapeutic plasma exchange (TPE) is used to treat a number of haematological, renal and neurological conditions. Pathogenic antibodies or other plasma molecules are removed, and plasma volume is replaced with plasma substitute. Albumin solution (HAS) is usually preferred, except in cases of Thrombotic Thrombocytopenic Purpura (TTP) and related conditions. TPE may result in dilutional coagulopathy, and reactions such as hypersensitivity can occur. The British Society for Haematology (BSH) published a 2015 guideline to assist the use of TPE in UK clinical practice, providing evidence-based indications and recommendations.

Aims: To evaluate the use of elective TPE at a large tertiary London hospital, compare clinical practice against BSH guideline recommendations, and explore the effect of TPE on coagulation test results.

Methods: Data was collected prospectively over a 2 month period, using patient notes and electronic transfusion records. A data collection form recorded the indication, treatment schedule, replacement fluid, complications, the presence of a written treatment plan, and frequency and results of coagulation testing.

Results: 24 plasma exchanges took place over the period of data collection; there were no cases of TTP. Adherence to BSH guidelines was variable; although most cases (88%) had an evidence-based clinical indication for TPE, just 4% had a full written treatment plan, and only 17% of courses followed recommended scheduling. 75% of patients had received at least one prior course, some outside guideline indications for repeat courses. Most patients (83%) initially received appropriate replacement fluid (HAS), however 87% received FFP at some point during TPE, with 42% receiving Solvent Detergent FFP. In 17% of patients this fluid change was due to a reaction, but for the remainder it was due to dilutional coagulopathy. The guidelines recommend fibrinogen monitoring, and although most patients had baseline measurement (75%), subsequent testing showed wide variation. Despite this, 71% had a fibrinogen of ≥1 g/l measured during TPE. Fibrinogen levels showed some correction by the next day but usually still abnormal. A prolonged APTT and TT was also seen in most patients immediately following TPE, which almost always corrected by the next day.

Table 1.

Median age, yr (range) 60 (36-70)

Male (%) 55 (45.8)

Plasma cell dyscrasia, n (%) 66 (55.0)
Multiple myeloma, IgG 28 (23.3)
Multiple myeloma, IgA 15 (12.5)
Bence-Jones multiple myeloma 5 (4.2)
Other: Non-secretory myeloma 6 (5.0)

Salmon-Durie staging, n (%) 10 (8.3)
Stage I 36 (30.0)
Stage II 46 (35.3)
Stage III 44 (36.7)
Other: plasma cell leukemia or plasmacytoma 10 (8.3)

Response to induction treatment before ASCT, n (%) 30 (25.0)
Complete response 30 (25.0)
Very good partial response 19 (15.8)
Partial response 55 (45.8)
Satisfactory response 12 (10.0)
Progressive disease 1 (0.8)

Mobilization regimen, n (%) 87 (72.5)
G-CSF 33 (27.5)
Chemotherapy and G-CSF 54 (44.8)

Summary/Conclusions: Summary/Conclusions: Infusion of PC with atypical phenotype does not appear to affect the response at day+100 following ASCT, in patients with MM or plasma cell dyscrasia. Conversely, the quality of response to induction therapy was significantly associated to 100-day outcome after transplantation. These data support that in vivo persistent residual cells, but not those being infused with the graft, are the main source of relapse in MM.
Summary/Conclusions: TPE use was generally compliant with BSH guidelines regarding clinical indication and initial replacement fluid. However many patients were changed from HAS to FFP due to measured or predicted coagulopathy. This is a recognised complication of TPE, and the guidelines suggest that if possible, TPE can take place on alternate days to ameliorate this. Fluid change to FFP is recommended only for those at increased haemorrhagic risk. Almost all the TPE transfusions in our study took place over 3 to 5 subsequent days, reflected in the high frequency of fibrinogen monitoring, and the level that should prompt change to the TPE schedule, require further exploration. The following are planned to enhance adherence to BSH guidelines and improve patient care. 1. Documented treatment plans with clinical indication, proposed treatment schedule, replacement fluid. 2. Local trust guidelines to include recommended TPE schedules, agreed parameters to monitor response, frequency of fibrinogen monitoring, common complications and their management. Where possible, TPE should take place on alternate days to reduce dilutional coagulopathy. 3. Education of staff involved with service provision, and strengthening of the role of apheresis nurse as lead.

A COMPREHENSIVE PROTEOMICS STUDY ON PLATELET CONCENTRATES: PLATELET PROTEOME, STORAGE TIME AND MIRASOL PATHOGEN REDUCTION TECHNOLOGY
V. Saji1, J.F. van Alphen2, I.M. De Cuyper1, B. Nota1, C. van der Zwaan1, P.F. van der Meer3, B.D. Baal3, D. De Korte1, A.B. Meijer1, T.K. van den Berg1, L. Gutierrez2.
1Blood Cell Research, 2Plasma Proteins, Sanquin Research, 3Product and Process Development, Sanquin Blood Bank, Amsterdam, Netherlands, 1Hema-

Background: Platelet concentrates (PCs) represent a blood transfusion product with a major concern for safety as their storage temperature (20-24°C) allows bacteri- al growth, protein oxidation and change in storage time (less than a week) results in complete microbiological testing. Pathogen reduction technologies (PRTs) provide an additional layer of safety to the blood transfusion products from known and unknown pathogens (such as bacteria, viruses and parasites). In this context, PRTs (such as Mirasol technology) have been developed and are implemented in many countries. However, several studies have shown in vitro that Mirasol PRT induces a certain level of platelet shape change, hyperactivation, basal degranulation and increased oxidative damage during storage. It has been suggested that Mirasol PRT might accelerate what has been described as the platelet storage lesion (PSL), but supportive molecular signatures have not been obtained.

Aims: We aimed at dissecting the influence of both variables, i.e. Mirasol PRT and storage time, at the proteome level.

Methods: We present comprehensive proteomics data analysis of control PCs and PCs treated with Mirasol PRT at storage day 2, 6 and 8. Our workflow was set to perform proteomics analysis using a gel-free and label-free quantification (LFQ) approach. The first step in our workflow was to identify the expressed proteins using MaxQuant/Perseus software platform. Then we set to perform proteomics analysis using a gel-free and label-free quantification strategy. For PCs treated with Mirasol PRT at storage day 2, 6 and 8. Our workflow was set to perform proteomics analysis using a gel-free and label-free quantification strategy. For PCs treated with Mirasol PRT at storage day 2, 6 and 8. Our workflow was set to perform proteomics analysis using a gel-free and label-free quantification strategy. For PCs treated with Mirasol PRT at storage day 2, 6 and 8. Our workflow was set to perform proteomics analysis using a gel-free and label-free quantification strategy.

Results: We identified marginal differences between Mirasol PRT and untreated PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to affect PCs upon Mirasol PRT, and in addition, the effect of Mirasol PRT on the platelet proteome appeared not to be exclusively related to proteomic changes due to PSL.

Summary/Conclusions: In summary, semi-quantitative proteomics allows to discern between storage changes due to Mirasol PRT or PSL, and proves to be a methodology suitable to phenotype platelets in an unbiased manner, in various physiological contexts.

USE OF A SURVEY TO ASSESS AND IMPROVE ADHERENCE TO UK BLOOD TRANSFUSION GUIDELINES IN A HOSPITAL SETTING
D. Warcel1,*, R. Mol1, A. L1.
1Haematology, Royal Free Hospital, London, United Kingdom

Background: UK guidelines to provide evidence-based support for decisions to transfuse young red cells were published in 2015 by NICE (National Institute for Health and Care Excellence). The guidelines specified hemoglobin (Hb) targets for transfusion, use of single unit transfusion to avoid over-transfusion, information provision to patients for informed consent, and avoidance of pre-operative transfusion by timely identification of iron deficiency for referral through an anemia clinic and providing patients with iron supplementation. An additional layer of safety to the blood transfusion products from known and unknown pathogens (such as bacteria, viruses and parasites). In this context, PRTs (such as Mirasol technology) have been developed and are implemented in many countries. However, several studies have shown in vitro that Mirasol PRT induces a certain level of platelet shape change, hyperactivation, basal degranulation and increased oxidative damage during storage. It has been suggested that Mirasol PRT might accelerate what has been described as the platelet storage lesion (PSL), but supportive molecular signatures have not been obtained.

Aims: We aimed at dissecting the influence of both variables, i.e. Mirasol PRT and storage time, at the proteome level.

SCREENING OF TRANSFUSION PRODUCTS FOR PRION DISEASES USING APATAMERS AND TUNABLE RESISTIVE PULSE SENSING
M. Healey1,*, M. Sivakumaran2, M. Platt1
1Chemistry, Loughborough University, Loughborough, 2Haematology, Peterborough City Hospital, Peterborough, United Kingdom

Background: Prion diseases are a group of fatal transmissible neurological conditions whose disease etiology is characterised by the change in conformation of the normal intrinsic cellular prion protein (PrPc) in to the highly ordered insoluble amyloid state conformer (PrPSc). The significant event fundamental to the progression of these diseases is the self-catalytic, and perpetuating, nature of the conversion of PrPc in the presence of PrPSc aggregates. The PrPSc aggregates (PrP^sc) are capable of infecting normal prion disease in humans in the United Kingdom during the 1990s, is considered to be an effect of dietary exposure to the bovine spongiform encephalopathy (BSE) agent through contaminated meat products. To date, the widely accepted estimate for the prevalence of vCJD in the UK puts the number of potential car- riers at 1 in 2000. Since the disease is known to be infectious and transmissible, the iatrogenic ability of this disease is a significant risk to public health through transfusion products and surgical procedures.

Aims: We aim to develop a reliable and robust assay that can be used as a screening tool to detect the infectious PrPSc protein at low levels in human blood with high selectivity and high sensitivity.

Methods: Here we use a technique based on the Coulter Counter principle that uses tunable elastomeric nanopores termed Tunable Resistive Pulse Sensing (TRPS) to detect the prion protein without an amplification step. The first stage optimizes the grafting of an ssDNA aptamer onto nanoparticle. In proof of concept work, the functionalized nanoparticles were added to the cellular prion protein in phosphate buffered saline by monitoring the relative change in velocity through the nanopore, which is then converted to zeta po- tential. The method was then applied to protein rich samples and serum.

Results: By varying the concentration of aptamer relative to the binding capacity of the nanoparticles, a sensitivity to change (p<0.05) was observed. Here mean zeta values were -1.94 mV for 0%, -4.43 mV for 33%; and -7.30 mV for 100%. The assay was further developed by monitoring the functionalized particle’s translocation velocity as a function of prion protein concentration. Increasing the concentration of the protein caused shielding of the polyionic DNA by the positive protein at pH 7.4, therefore the velocity of the nanoparticle conjugate decreased. The lowest concentration to have a significant change (p<0.05) in velocity distribution was 1 nM, with a 2.5% decrease relative to 0 nM. The higher concentration of 50 nM had a bigger effect of 24% decrease.

Summary/Conclusions: TRPS technology presented here offers the ability to detect infectious prion protein in the circulation without the need for particle assay design. Any relative change to the functionalized particle’s signal could be observed, demonstrating its capability and suitability to detect biological targets.
Front-line combinations in multiple myeloma and amyloidosis

QUADRUPLET VS SEQUENTIAL TRIPLET INDUCTION THERAPY FOR MYELOMA PATIENTS: RESULTS OF THE MYELOMA XI STUDY
1The Institute of Cancer Research, London, United Kingdom, 2Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, United States, 3Clinical Trials Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 4Heart of England NHS Foundation Trust, Birmingham, 5Leicester Royal Infirmary, Leicester, 6Centre for Clinical Haematology, Nottingham University Hospital, Nottingham, 7University Hospitals of North Midlands, Stoke-on-Trent, 8Kant and Canterbury NHS Trust, Canterbury, 9Southampton Hospital, Southampton, 10University of Leeds, Leeds, 11The Royal Marsden Hospital, London, 12Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, 13Haematological Malignancy Diagnostic Service (HMDS), St James’s University Hospital, 14Clinical Trial Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 15Department of Haematology, Newcastle University, Newcastle, United Kingdom

Background: Combining anti-myeloma induction therapies limits the impact of clonal heterogeneity on resistance to therapy, maximising response and associated clinical outcomes. Triplet combinations induce deeper, longer remissions than doublets and those containing an immunomodulatory agent, a proteasome inhibitor (PI) or both are the current standard of care in Europe/US. Potential approaches to further improve outcomes include response-adapted induction, treating suboptimal responders with sequential treatment using an agent with a different mechanism of action, or intensifying therapy for all patients by the use of quadruplet combinations up-front.

Aims: The UK NCRI Myeloma XI trial is a large, phase III study comparing, in transplant eligible (TE) patients, the induction quadruplet carfilzomib, cyclophosphamide, lenalidomide and dexamethasone (KCRD) to the sequential strategy of triplet immunomodulatory combinations (with thalidomide or lenalidomide) followed by additional pre-transplant consolidation with PI triplet therapy for those with a suboptimal response.

Methods: In 2013, the TE pathway of the Myeloma XI study was amended to include KCRD given in 28 day cycles (carfilzomib 36mg/m² IV d1-2,8-9,15-16 (20mg/m² #1d-2), cyclophosphamide (cyclo) 500mg PO d1,8, lenalidomide (len) 25mg PO d1-21, dexamethasone (dex) 40mg PO d1-4,8,9,15-16). Patients were randomised to this up-front quadruplet or the sequential strategy of CRD (cyclo 500mg PO d1,8, len 25mg PO d1-21 PO daily, dex 40mg PO d1-4,12-15) or CTD (cyclo 500mg PO d1,8,15 thalidomide 200mg PO daily, dex 40mg PO d1-4,12-15) given to max. response. Patients with VGPR/CPR proceeded straight to ASCT, those with PR/MR were randomised to pre-transplant consolidation for suboptimal responders to triplet induction, treating suboptimal responders with sequential treatment using an agent with a different mechanism of action, or intensifying immunomodulatory therapy.

Results: 2568 TE patients underwent induction randomisation (CTD 1021, CRD 1021, KCRD 526). Patients were comparable with respect to age (median 59 years), sex and other key laboratory parameters. Patients were mandated to receive a minimum of 4 cycles of initial induction with therapy continued to maximum response. The median number of cycles delivered was CTD: 5, CRD: 5, KCRD: 4. Grade ≥3 haematological toxicities differed between the groups. (Neutropenia CTD: 12%, CRD: 22%, KCRD: 16%; Thrombocytopenia CTD: 3.4%, CRD: 4.5%, KCRD: 8.1%; Anaemia CTD: 6.7%, CRD: 9.6%, KCRD 10%). Grade ≥3 neurological toxicity was greater with the thalidomide-containing regimen (Sensory neuropathy CTD: 9.5%, CRD: 3.4%, KCRD: 2.3%). There was no statistically significant difference in rates of investigator reported, all-grade, thromboembolic events between regimens (CTD: 11.8%, CRD 11.1%, KCRD 14.7%). Response to initial induction and following ASCT is shown in Table 1 indicating deeper responses with the quadruplet compared to triplets both at the end of first induction regimen (p<0.0001) and, importantly, post-ASCT (p<0.0001). These differences were observed despite the use of randomised pre-transplant consolidation for suboptimal responders to triplet immunomodulatory therapy.

Summary/Conclusions: Induction therapy with KCRD, an outpatient delivered quadruplet regimen, was associated with deeper responses than immunomodulatory triplet therapy (CRD/CTD) and was well tolerated. Deeper responses persisted after ASCT, with an impressive response rate ≥VGPR of 92% with KCRD.

Background: Triplet combinations that include a proteasome inhibitor (PI) have been proven superior to doublets in newly diagnosed multiple myeloma (NDMM) (San Miguel et al, N Engl J Med 2008, Durie et al, Lancet 2017). The all-oral combination of the novel PI ixazomib plus lenalidomide-dexamethasone (IRd) was evaluated as an induction regimen in NDMM patients, followed by single-agent ixazomib maintenance.

Aims: Here we report updated efficacy and long-term safety data for patients who did not withdraw from the study in order to receive stem cell transplantation (SCT).

Table 1.

| Table 1. | Treatment exposure and safety data. | All pts who did not withdraw to receive SCT (n=420) | Maintenance subset (n=229) | AE's with onset during induction (cycles 1-12) | AE’s with onset during maintenance (cycles 13+)

</table>
Methods: In this phase 1/2 study (NCT01217957), patients with NDMM received weekly oral ixazomib (1.88-3.5mg/m²; days 1, 8, 15) plus lenalidomide (25mg, days 1-21) and dexamethasone (40mg, days 1, 8, 15, and 22) for up to twelve 28-day induction cycles, followed by maintenance therapy with weekly single-agent ixazomib, at the last tolerated dose given during induction, until disease progression or toxicity.

Results: Of the 42 enrolled patients, 42 continued on study treatment without early withdrawal for SCT; the long-term follow-up of these 42 patients is reported here. Baseline patient characteristics included: median age, 68 years (range 34-86); ISS stage I/II/III in 40%/4%/17%. As of October 18, 2016, with median follow-up of 56 months, the confirmed overall response rate (ORR; partial response [PR] in, was 80%, complete plus very good partial response [CR+VGP] rate was 63%, and CR rate was 32%. Median time to first response was rapid (0.95 months), while median time to CR was 5.6 months. Median progression-free survival (PFS) in these patients not receiving SCT was 25.3 months. Median overall survival (OS) has not been reached at a median follow-up of 3 years and OS rate at 17 months was 87%. Safety findings are summarized in the Table; 74% of patients had grade 3 treatment-related adverse events (AEs), and 26% of the patients had treatment-related serious AEs. Among treatment-related AEs of interest, grade 3 rash and peripheral neuropathy were infrequent. There was one treatment-related death due to respiratory syncytial viral pneumonia. After completing 12 cycles of induction therapy with IRd, 25 patients went on to receive maintenance single-agent ixazomib. In these 25 patients, at the end of the induction period ORR was 100%, including 44% VGPR and 32% CR. Responses deepened during maintenance; at data cut-off, the response rates in this maintenance therapy population were 73% VGPR, 32%, and 20% CR. Median PFS for patients who received maintenance therapy was 24 months. The occurrence of the most common treatment-related grade ≥3 AEs (neutropenia, thrombocytopenia, and fatigue) was confined almost exclusively to the induction period. During the maintenance period no patients reported onset of grade ≥3 peripheral neuropathy or rash.

Summary/Conclusions: In patients with NDMM, weekly ixazomib plus Rd, followed by single-agent ixazomib maintenance, was highly active, resulting in deep and durable responses, long PFS, and a high 3-year OS estimate. IRd followed by single-agent ixazomib maintenance also showed an acceptable safety profile, with less toxicity reported during the maintenance (single-agent ixazomib) vs induction (IRd) periods, with no evidence of cumulative toxicities.

Background: Bortezomib plus melphalan and prednisone (VMP) and lenalidomide plus low-dose dexamethasone (Rd) are two standards of care for elderly patients with newly diagnosed multiple myeloma (MM). The FORTE trial compared KCd (cyclophosphamide and dexamethasone) induction followed by single-agent Rd maintenance therapy with IRd, 25 patients went on to receive maintenance single-agent ixazomib. In these 25 patients, at the end of the induction period ORR was 100%, including 44% VGPR and 32% CR. Responses deepened during maintenance; at data cut-off, the response rates in this maintenance therapy population were 73% VGPR, 32%, and 20% CR. Median PFS for patients who received maintenance therapy was 24 months. The occurrence of the most common treatment-related grade ≥3 AEs (neutropenia, thrombocytopenia, and fatigue) was confined almost exclusively to the induction period. During the maintenance period no patients reported onset of grade ≥3 peripheral neuropathy or rash.

Summary/Conclusions: In patients with NDMM, weekly ixazomib plus Rd, followed by single-agent ixazomib maintenance, was highly active, resulting in deep and durable responses, long PFS, and a high 3-year OS estimate. IRd followed by single-agent ixazomib maintenance also showed an acceptable safety profile, with less toxicity reported during the maintenance (single-agent ixazomib) vs induction (IRd) periods, with no evidence of cumulative toxicities.

Background: Bortezomib plus melphalan and prednisone (VMP) and lenalidomide plus low-dose dexamethasone (Rd) are two standards of care for elderly untreated MM patients. In order to improve its outcome, we decided to use the present therapeutic approach, based on VMP and Rd for 18 cycles. In a sequential, alternating scheme. After a median flu of 27 months, both regimens (sequential and alternating) showed similar efficacy with an acceptable toxicity profile.

Aims: To consolidate data, we have updated the outcome with long flu (51 months), evaluating the role of Complete Response and Minimal Residual Disease (MRD) level on PFS and OS.

Methods: 242 pts were randomized to receive 9 cycles of VMP followed by 9 cycles of Rd or the same regimens in an alternating approach (one cycle of VMP alternating with one Rd, up to 18 cycles). VMP included iv administration of weekly bortezomib (except in the first cycle that was given twice weekly) at a dose of 1.3mg/m². Oral lenalidomide 10mg/m² daily on days 1-21 plus dexamethasone 40mg weekly. MRD was evaluated by second generation flow (sensitivity level of 10⁻⁵).

Results: 233 pts were evaluable for efficacy. Baseline characteristics of the pts were similar between the 2 arms. Median age was 64.6 (range 41-86). Median overall survival (OS) was 26 months in the sequential arm and 26.2 in the alternating arm (p=0.5). The median overall survival (OS) has been reached in the sequential arm (64m) whilst has not been reached yet in the alternating arm (63% at 5y) (p=0.95, 95 patients (41%) achieved >CR (49 and 46 patients in the sequential and alternating arms, respectively). Pts who achieved >CR had a significantly longer PFS (median of 45m) as compared with pts who didn’t achieve >CR (median of 22.3 m) (HR: 0.32; p<0.0001). This translated into a benefit in OS: 73% of pts that achieved >CR remain alive at 5 years whilst the median OS was of 49m for patients that didn’t achieve CR (HR: 0.34; p<0.0001). No differences were observed between the sequential and alternating arms. Minimal residual disease MRD was evaluated in 83 out of the 95 pts who achieved >CR. In 46 of them (55%) cells were undetectable with a sensitivity threshold of 10⁻⁵, and were considered as MRD-ve patients. These pts displayed a significantly longer PFS (median not reached as compared to MRD+ve pts (median PFS of 40m) (HR: 0.32; p=0.006) as well as a significantly longer OS (median 22.6 vs 14.3; p<0.001). DFS was available in 174 patients: 32 (18%) were considered high-risk (t14, t14;16 or del 17p). Outcomes were inferior but not significantly different between the high- and standard-risk groups in terms of DFS (26m vs. 33 months (p<0.1)).

The achievement of >CR completely overcame the adverse prognosis of the minimal risk, as CR + VGPR rate was 63% receiving a median PFS of 40m, and 50m in the high and standard-risk subgroup, respectively (p=0.5). This effect was also evident when MRD negativity was achieved. In terms of OS, the outcome for both high and standard risk subgroup of pts was superimposable during the first 20 months but the curves separated since this point, resulting in a median OS of 40m and 63m (p=0.001), respectively. This effect was maintained for pts that achieved >CR including MRD negativity.

Summary/Conclusions: The present therapeutic approach, based on VMP and Rd for newly diagnosed elderly MM pts represents an acceptable therapeutic option for fit elderly patients. Pts who achieved >CR and MRD-flow had significantly longer PFS and OS. The achievement of >CR and MRD negativity is likely to become the predictor of the probability of high risk cytogenetic abnormalities in terms of PFS but continuous therapy is probably required for high risk patients in order to maintain the benefit in OS.
Summary/Conclusions: Safety profile was acceptable; more patients required plerixafor in the KRd arm. Rate of VGPR was higher with KRd. Updated data on a higher number of patients will be presented at the meeting. The trial is registered at Clinicaltrials.gov: NCT02203643.

S411

HOVON 104; FINAL RESULTS FROM A MULTICENTER, PROSPECTIVE PHASE II STUDY OF BORTEZOMIB BASED INDUCTION TREATMENT FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH DE NOVO AL AMYLOIDOSIS

M. Minnema1,*, K. Nasserinejad2, B. Hazenberg3, U. Hegenbart4, L. Noens5, P. Ypma6, S. Zweegman7, L. Tick8, A. Broijl9, H. Koene10, G. Bos11, N. Thuss2, P. Sonneveld9, S. Schonland4
1Haematology, UMC UTRECHT, Utrecht, 2HOVON data center, ErasmusMC, Rotterdam, 3Rheumatology, UMCG, Groningen, Netherlands, 4Amyloidosis Center, University of Heidelberg, Heidelberg, Germany, 5Haematology, UZ Gent, Gent, Belgium, 6Internal Medicine, HAGA hospitals, the Hague, 7Haematology, VU medical center, Amsterdam, 8Internal Medicine, Maxima Medical Center, Eindhoven, 9Haematology, ErasmusMC, Rotterdam, 10Internal Medicine, st Antonius Hospital, Nieuwegein, 11Haematology, University Hospital Maastricht, Maastricht, Netherlands

Background: Bortezomib (B) has been reported to be very effective in AL amyloidosis with overall response rates (ORR) varying between 50-80%. However, there are no prospective data from multicenter studies on B treatment in de novo patients. We investigated the efficacy and safety of B-Dexamethasone (BD) induction treatment followed by HDM+SCT in de novo AL amyloidosis patients.

Aims: The primary aim was to improve the hematological CR rate at 6 months after SCT on intention to treat analysis from 30 to 50%. Secondary aims were OS, PFS, hematological response rate after BD treatment, organ responses, safety and prognostic factors for survival.

Methods: Patients with biopsy proven AL amyloidosis, aged between 18-70 years, with detectable M-protein and/or level of involved FLC >50mg/L, WHO performance status 0-2, NYHA stage 1-2 and ejection fraction >45% were included. Major exclusion criteria were symptomatic orthostatic hypotension, NT proBNP level >5000 pg/ml, Troponin T> 0.06 ug/l, Bilirubin >2x ULN, eGFR<30 ml/min, CTCAE grade peripheral sensory neuropathy > grade 2 or > grade 1 with pain. Inclusion and exclusion criteria were installed both at entry and before stem cell mobilization (SCM). B was given subcutaneously 1.3mg/m² twice a week in a 21-day cycle, D 20mg orally on each B day and the following day. HDM dosage was 200mg/m². Hematological responses were defined according to consensus criteria with the addition of very good partial response (VGPR), defined as the difference between involved and uninvolved FLC<40mg/L. Cardiac, renal and liver response and progression criteria were defined according to consensus criteria with addition of NT proBNP.

Results: Median age was 59 years (range 26-70) and 60% were male. NYHA stage was 1 in 56% and 2 in 42% of patients. Mayo cardiac risk score was 1 (30%), II (36%), III (34%). Organ involvement was 82% renal, 66% heart, 28% liver, 14% neurological, 8% gastrointestinal and 38% of patients had 3 or more organs involved. Bone marrow plasmacellular were >10% in 28% of patients. The median FU for patients alive is 24 (10-55) months. Twelve of 50 (24%) patients could not proceed to SCM. Four patients due to B related toxicity, 3 patients died (both amyloidosis related) and 3 miscellaneous. Of these 38 patients, 3 went subsequently off protocol because of ineligibility for HDM. Thirty-five out of 50 patients (70%) received HDM + SCT, one patient died of a cardiac arrest after the SCT procedure. The ORR after induction was 80%, ≥VGPR in 54% and CR in 6% of patients. The ORR in the 35 patients at 6 months after SCT was 80%, ≥VGPR in 51% and CR in 43% of patients. On intention to treat analysis the CR rate at 6 months after SCT was 30%. Organ responses at 6 months after SCT were 16/29 renal, 2/8 liver and 13/23 heart. No baseline characteristics were identified to be predictive for OS or PFS. BD doses were reduced and delayed after 2 cycles in almost half of patients, mostly because of neurotoxicity, Sensory neuropathy grade 2 or higher was seen in 36% of patients and autonomic neuropathy, mostly dizziness and collapse, in 22%.

Summary/Conclusions: This final analysis demonstrates that the primary aim of improving CR rate at 6 months after SCT from 30 to 50% was not met. This was mainly caused by the high dropout rate before SCT. This may be due to patient selection, but we also demonstrate that BD, given twice weekly sc, despite good efficacy, cannot prevent early amyloidosis related toxicity and can induce grade 2 or higher neurotoxicity.

Trial registration www.trialregister.nl (NTR 3220), EudraCT 2010-021445-42, supported by the Dutch Cancer Society (UU 2010-4884) and by an unrestricted grant from Janssen-Cilag.
**Results:** In total, 243 pts were treated: 63 in Cohort A (BV-naïve), 80 in Cohort B (BV after ASCT), and 100 in Cohort C (BV before and/or after ASCT). The most common cause of death was progression (28%), followed by second malignancy (25%), neurologic (17%), and infection (7%). Median (95% CI) OS was 37 (32, 41) mo in Cohort A, 31 (27, 35) mo in Cohort B, and 37 (33, 41) mo in Cohort C, respectively. DOR for patients with progressive disease after failure of ASCT was 16 (9, 23) mo in Cohort A, 15 (9, 19) mo in Cohort B, and 17 (11, 23) mo in Cohort C, respectively. CR rate was 77%, 53%, and 51%, respectively. Median (range) age was 34 (18-72) y. Of 35 pts receiving nivolumab, 21 (60%) pts had prior BV and 14 (40%) pts had prior ASCT. BV only after ASCT; Cohort C: BV before and/or after ASCT). All pts received nivolumab 3 mg/kg every 3 wk until disease progression or unacceptable toxicity. Pts in Cohort D with a persistent complete response (CR) for 1 y were to discontinue nivolumab and could resume at relapse. Primary endpoint was ORR per Independent Radiology Review Committee. Secondary endpoints included DOR, progression-free survival (PFS), overall survival (OS), and safety were exploratory endpoints. All pts provided written informed consent.

**Aims:** To confirm in a prospective setting the favorable prognosis of advanced-stage PET2 negative patients treated with ABVD, as well as the safety and efficacy of escalated BEACOPP given to PET2 positive patients.

**Methods:** We conducted a prospective clinical trial (HD0607 ClinicalTrials.gov identifier:00795613), in which advanced-stage (IIB-IVB) CHL pts were treated with 2 ABVD courses, and PET2 performed afterwards. The latter was blindly and independently reviewed by a panel of nuclear medicine experts, using the Deauville 5-point scale (5-PS). PET2+ patients (5-PS = 3-5) were randomized to continue nivolumab and could resume at relapse. Primary endpoint was ORR, encouraging duration of response (DOR) and an acceptable safety profile.

**Results:** Of 35 pts receiving nivolumab, 21 (60%) pts had prior BV and 14 (40%) pts had prior ASCT. BV only after ASCT; Cohort C: BV before and/or after ASCT). All pts received nivolumab 3 mg/kg every 3 wk until disease progression or unacceptable toxicity. Pts in Cohort D with a persistent complete response (CR) for 1 y were to discontinue nivolumab and could resume at relapse. Primary endpoint was ORR per Independent Radiology Review Committee. Secondary endpoints included DOR, progression-free survival (PFS), overall survival (OS), and safety were exploratory endpoints. All pts provided written informed consent.

**Aims:** To confirm in a prospective setting the favorable prognosis of advanced-stage PET2 negative patients treated with ABVD, as well as the safety and efficacy of escalated BEACOPP given to PET2 positive patients.

**Methods:** We conducted a prospective clinical trial (HD0607 ClinicalTrials.gov identifier:00795613), in which advanced-stage (IIB-IVB) CHL pts were treated with 2 ABVD courses, and PET2 performed afterwards. The latter was blindly and independently reviewed by a panel of nuclear medicine experts, using the Deauville 5-point scale (5-PS). PET2+ patients (5-PS = 3-5) were randomized to continue nivolumab and could resume at relapse. Primary endpoint was ORR, encouraging duration of response (DOR) and an acceptable safety profile. All pts received nivolumab 3 mg/kg every 3 wk until disease progression or unacceptable toxicity. Pts in Cohort D with a persistent complete response (CR) for 1 y were to discontinue nivolumab and could resume at relapse. Primary endpoint was ORR per Independent Radiology Review Committee. Secondary endpoints included DOR, progression-free survival (PFS), overall survival (OS), and safety were exploratory endpoints. All pts provided written informed consent.
Overall, 150 (19.2%) proved PET2+ (97 score 4, 53 score 5) and 630 (80.5%) PET2-. PET2+ patients were more frequently male (56.7% vs 47.1%, p<0.03), had higher IPS score (P=0.0002) and bulky disease (28.0% vs 17.9%; p=0.0002). Out of 149 PET2+ patients randomized to Be+Bb (76) or Be+Bb+R (73), 136 were evaluable for response: 93 obtained CR and 43 had a treatment failure. Of the remaining 13 patients, 3 died, 7 withdrew their consent and 3 stopped treatment for toxicity. As per study protocol, 627 out of 630 PET2- patients continued with 4 ABVD cycles and 3 withdrew their consent. Overall, 30 patients (3.8%) died, due to early death (n=2), resistant disease (n=18; 12 with a positive and 6 with a negative PET2), transplant related toxicity (n=5), infections (n=4) and pulmonary fibrosis (n=1). After a median follow-up of 1303 days (2-2857), the 4-Y PFS and OS for all 782 patients was 83% (95% CI 80%>86%) and 96% (95% CI 94%>97%), respectively. For PET2+ and PET2- patients, the 4-Y PFS was 69% (95% CI 60%>76%) and 87% (95% CI 84%>89%), while the 4-Y OS was 89% (95% CI 82%>93%) and 97% (95% CI 95%>98%) (Figure 1, Panel A and B). No outcome difference was observed for Be+Bb vs Be+Bb+R patients, with a 4-Y PFS of 69% (95% CI 57%>79%) and 68% (95% CI 55%>78%), respectively (p=0.9731). Consolidation RxT in PET2- patients in CR after 6 ABVD and LNM did not translate in to a significant benefit, with a 4-Y PFS of 98% (95% CI 91%>98%) for RxT and 93% (95% CI 87%>96%) for NFT (p=0.2882).

Summary/Conclusions: These data suggest that 1) an early switch from ABVD to escalated BEACOPP can be safely done in PET2+ advanced-stage cHL; 2) the long-term outcome for the entire patient cohort is superior to standard ABVD; 3) no clinical benefit is associated with post ABVD RxT in PET2- patients presenting with large nodal mass; 4) the addition of Rituximab does not increase the effectiveness of Be+Bb in PET2+ patients.

S414
DISEASE CHARACTERISTICS AND SURVIVAL AFTER 3RD RECURRENT OF CLASSICAL HODGKIN LYMPHOMA: AN ANALYSIS OF THE GERMAN HODGKIN STUDY GROUP
P.J. Bröckelmann1, H. Müller1, E. Küüksanoglan1, A. Engert1, B. von Tresckow1
1Department of Internal Medicine and German Hodgkin Study Group (GHSG), University Hospital of Cologne, Cologne, Germany

Background: Data on disease presentation, therapeutic options and survival after 3rd or higher relapse of classical Hodgkin lymphoma (cHL) are sparse. Therefore the additional benefit of new agents, which are currently initially investigated after several relapses of cHL, is difficult to estimate.

Aims: The aim of this study was to define and describe a historical control group in European patients from the German Hodgkin Study Group (GHSG) data for comparison of safety and efficacy of novel therapeutic agents.

Methods: Cases with at least three consecutive tumor-related events or progressive refractory or relapsed disease, were identified in the GHSG database. Detailed information was added from case report forms and physician’s letters. Overall survival (OS) was the main and progression free survival (PFS), response to therapy, adverse events, disease and treatment characteristics as secondary endpoints.

Results: Among 12,584 HL patients in the GHSG first-line trials HD7 to HD15 and 449 HL patients in the trials HDR1 and HDR2 a total of 69 cHL patients with ≥3 tumor events were identified. The dates of occurrence of 3rd relapse ranged between 15th of January 1993 and 21th of June 2013. The sample consisted of 51 male (74%) and 18 female (26%) patients. At time of 3rd relapse the age of the patients ranged from 20 to 79 years (mean 39.2 years, standard deviation (SD) 14.0 years) and the majority of patients presented with stage III or IV disease (67%). Time from end of 3rd-line treatment to 3rd relapse was ≤3 months (i.e. GHSG definition of refractory disease) in 15 cases (22%), ≤12 months (early relapse) in 19 cases (28%) and >12 months (late relapse) in 35 cases (51%). All 69 patients were pretreated with chemotherapy, 35 (50.7%) with BEACOPP, 30 (43.5%) with ABVD and no BEACOPP, and 32 (46.6%) with another type of chemotherapy. The number of prior chemotherapies ranged from one to three median 3). Pretreatment with radiotherapy was observed in 57 (82.6%) patients, with salvage chemotherapy aimed to induce a remission prior to a stem-cell transplantation (SCT) in 58 (84.1%), and with high dose chemotherapy followed by autologous SCT in 50 (72.5%) patients. Four patients (5.8%) had received allogeneic SCT as 3rd-line treatment. None of the patients had received brentuximab vedotin or anti-PD1 antibodies before 3rd relapse. With a median observation time of 63.3 months for OS after 3rd relapse, 45 patients (65.2%) had died and 60 (87.0%) had another PFS event. Twelve months after the 3rd relapse OS was 73.2% (95%CI 62.6% to 83.8%) and PFS 50.8% (95%CI 38.9% to 62.8%, Table 1).

Summary/Conclusions: Patients with a 3rd relapse or progression of cHL have a dismal, mostly palliative prognosis due to frequent tumor progression. Within one year half of the patients have a PFS event and one fourth die.

Background: Waldenström’s macroglobulinemia (WM) is a rare low-grade B-cell lymphoma characterized by the lymphoplasmacytic bone marrow infiltration and a monoclonal IgM immunoglobulin in the serum. The indolent lymphoma that has heterogeneous clinical manifestations and patients with this disease may have a prolonged disease course; however, there are groups of patients with poor outcomes after a relatively short disease course. In order to develop a robust staging system a collaborative effort resulted in the formulation of the International Prognostic Scoring System for WM (IPSS-WM) which was developed in 2009 based on data of patients that were treated primarily without rituximab and mainly with alkylators and nucleoside analogues. IPSSWM is based on five covariates (age, hemoglobin, platelet counts, IgM levels and b2 microglobulin) and stratifies WM patients into 3 broad risk groups. IPSSWM does not take into account non-WM related mortality, which is common and quite different among patients over the age of 75 year and the presence of monoclonal IgM immunoglobulin in the serum. WM is an indolent lymphoma characterized by the lymphoplasmacytic bone marrow infiltration and a monoclonal IgM immunoglobulin in the serum. WM is a rare low-grade B-cell lymphoma characterized by the lymphoplasmacytic bone marrow infiltration and a monoclonal IgM immunoglobulin in the serum. WM is a rare low-grade B-cell lymphoma characterized by the lymphoplasmacytic bone marrow infiltration and a monoclonal IgM immunoglobulin in the serum. WM is an indolent lymphoma characterized by the lymphoplasmacytic bone marrow infiltration and a monoclonal IgM immunoglobulin in the serum. WM is a rare low-grade B-cell lymphoma characterized by the lymphoplasmacytic bone marrow infiltration and a monoclonal IgM immunoglobulin in the serum.
Aims: The aim of the current study was to revise the current IPSSWM by using a large dataset of symptomatic WM patients treated with different types of primary therapy that included rituximab and other new agents.

Methods: The analysis included 492 patients from the prospectively maintained database of the Greek Myeloma Study Group with a median follow up of 10 years. All patients fulfilled criteria for diagnosis and for treatment initiation according to Consensus Recommendations.

Results: In univariate analysis factors such as age, beta-2 microglobulin, serum albumin and LDH were all associated with poor outcome. The IPSSWM includes age and b2 microglobulin but not serum albumin, or LDH, while the presence of very high IgM (>7 gr/dl) was quite rare and of limited prognostic value. The presence of anemia <11.5 gr/dl was common across all subgroups while low platelet counts <100 x 10^9/L was found in relatively few patients and had no prognostic significance. Based on ROC analysis for early death (within 3 years), serum albumin <3.5 gr/dl and b2microglobulin >4 mg/L were the two most important prognostic factors of early WM-related death. Age >65 years was associated with increased risk of death, however, age >75 years conferred additional risk (double hazard of death compared to those 65-75 years and fourfold compared to patients <65 years). Thus, we formulated a score in which high b2 microglobulin, elevated LDH and low serum albumin are scored with 1 point each, age 66-75 years is scored with 1 point but age >75 years is scored with 2. As a result, patients with scores 0, 1, 2, 3 or 4-5 had 3-year WM-related death rate of 3%, 7%, 14%, 19% and 48% (chi-square: 80.7, p<0.001). Regarding overall survival, 10-year survival rate was 85%, 59%, 39%, 28% and 12% (p=0.001) (Figure 1). Because age is a major determinant of disposition we also evaluated this staging system in patients >65 years and retained it prognostic significance. Compared to IPSSWM, this new staging system outperformed ISSWM: c-statistics, a measure of performance of a prognostic tool, was 0.652 for IPSSWM (95% CI 0.627-0.677) vs 0.711 (95% CI 0.659-0.763) for the new staging system.

Summary/Conclusions: A revised staging system, based on b2 microglobulin, elevated LDH, low serum albumin and age identifies groups with very different outcomes among patients with symptomatic WM treated with contemporary regimens and may outperform IPSSWM.

Table. Baseline characteristics and outcome of 104 SMZL pts treated with R monotherapy

S416 SPLENIC MARGINAL ZONE LYMPHOMA (SMZL) TREATED WITH RITUXIMAB (R) MONOTHERAPY: A LONG TERM FOLLOW-UP STUDY ON 104 PATIENTS

1Department of Haematology, University Hospital, University of Crete, Heraklion, 2Department of Haematology, Athens Medical Center-Psychikon Branch, 3Department of Haematology, University of Athens, Laikon General Hospital, 4Department of Anatomic Pathology, Evangelismos General Hospital, University of Athens, 52nd Department of Internal Medicine, University of Athens, 6Department of Immunology Laboratory, Laikon General Hospital, 71st Department of Propedeutics, University of Athens, Laikon General Hospital, 8First Department of Internal Medicine, 9Department of Pathology, University of Athens, Athens, Greece

Background: Rituximab monotherapy has been used successfully in the treatment of SMZL and it can replace splenectomy, at least in 1st line.

Methods: The diagnosis of SMZL was based on the WHO criteria. Criteria for treatment initiation included: bulky/symptomatic splenomegaly, cytopenias or presence of B-symptoms. All pts received 6 weekly cycles of R as 1st line therapy at a dose of 375 mg/m² (induction phase). None of the pts had been splenectomised before R treatment. Maintenance with R at a dose of 375 mg/m² every 2 months for 1-2 years was given according to physician’s discretion. Response assessment was based on the SLSG consensus criteria. Survival curves were estimated using the Kaplan Meier method and compared by log-rank test.

Results: 104 pts with SMZL were included. 45% were males with a median age of 66 y (41-91). At diagnosis all pts had bone marrow infiltration with a median % of infiltration of 40 (10-85). Anemia and thrombocytopenia were present in 30% and 19%, respectively. 40% had absolute lymphocytosis. LDH was elevated in 43%. According to the SLSG prognostic system, 39% were classified in group A, 56% in group B and 5% in group C. The median time from diagnosis to treatment initiation was 2 months (0-203). 71 pts received R maintenance. The overall response rate 2 months after the end of induction treatment was 93% (CR, CRu and PR in 42%, 21% and 30%, respectively). Maintenance therapy improved the quality of response in 19 of them, 52 pts maintained their initial response and one relapsed during maintenance phase. The 5- and 10-year PFS, OS and CSS were 70% and 64%, 93% and 88%, 99% and 93%, respectively. Maintenance therapy was associated with better PFS (p=0.008). 22 pts relapsed (6 of them with histologic transformation to DLBCL). 11/22 were retreated with R and 9/11 responded. 8 deaths were recorded: 3 of them disease related. R therapy was well tolerated. Only one pt could not complete treatment due to intolerance.

Summary/Conclusions: The present study, includes a large number of pts with a long follow-up, confirms that R monotherapy is very effective in SMZL with minimal toxicity and is recommended as the treatment of choice for this disease.
Biology of MPN: JAK2 and beyond

S417

YOU DON'T KNOW JAK: A PROGRAMMED RIBOSOMAL FRAMESHIFTING DEFECT POTENTIATES THE TRANSFORMING ACTIVITY OF THE JAK2-V617F MUTATION

S. Sulima1,*, Y. Khan2, J. Briggs2, S. Vereecke1, J. Jones2, V. Advani2, J. Verbeeck1, K. De Keersmaecker1, J. Dinman2
1Department of Oncology, LKI, KU Leuven, Leuven, Belgium, 2Department of Cell Biology and Molecular Genetics, University of Maryland, College Park, United States

Background: The JAK-STAT pathway is a critical controller of cellular proliferation, differentiation, survival and apoptosis in response to external stimuli. Promiscuous activation of this pathway is an important driver in the pathogenesis of BCR/ABL-negative chronic myeloproliferative neoplasms. The JAK2-V617F allele is the most common and characterized mutation linked to this class of leukemia. The increased activation of JAK-STAT signaling in JAK2-V617F cells can be partially explained by increased JAK2 autophosphorylation. It is unclear however if these effects are sufficient to fully account for the strong activation of the JAK-STAT pathway induced by JAK2-V617F. We recently described programmed -1 ribosomal frameshifting (-1 PRF) as a novel mechanism regulating the expression of ~10% of human genes, including cytokine receptors (Belew AT et al, Nature, 2014). In this process, cis-acting mRNA elements (-1 PRF signals, which consist of a slippery site followed by a pseudoknot) direct translating ribosomes to slip by one base in the 5' direction, establishing a new reading frame. This directs ribosomes towards premature termination codons, resulting in destabilization of the -1 PRF signal-containing mRNA via nonsense-mediated mRNA decay (Figure 1). There is thus an inverse relationship between -1 PRF efficiency and mRNA stability.

Aims: To investigate whether the JAK2-V617F mutation, shown here to be located in the pseudoknot of a -1 PRF signal in the JAK2 mRNA, impacts disease progression through ablation of -1 PRF.

Methods: Computationally predicted -1 PRF signals were validated using dual luciferase reporters and proteomic analysis of a -1 PRF fusion protein. -1 PRF was silenced using RNAi and its consequences on JAK2 expression, contributing to its transforming activity in vitro and disease onset in vivo. We suggest that -1 PRF normally provides a layer of control by limiting JAK2 translation. Defective -1 PRF synergizes with the transforming activity of the JAK2-V617F protein by causing its overexpression, explaining why this particular mutation causes such aggressive malignancies. In support of this, the combination of rucozolitinib and an HSP-90 inhibitor, which reduce kinase activity and JAK2 expression respectively, leads to increased therapeutic efficacy in myeloproliferative neoplasms (Bhagat N et al, Blood, 2014).

Results: We demonstrate in human cell lines that the JAK2-V617F mutation structurally disrupts the -1 PRF signal in the JAK2 mRNA, leading to ~2-fold lower rates of -1 PRF and increased abundance of the JAK2 mRNA and protein. The transforming potential of a series of mutants designed to manipulate -1 PRF independent of V617F was assayed in a Ba/F3 cell model. Silent protein coding changes in the pseudoknot of the -1 PRF signal at position V617 (V617m) or the slippery site (SSm), both of which drastically reduced frameshifting, increased JAK2 expression and led to transforming activity, albeit less than V617F. Importantly, the V617F+SSm combination conferred an additive effect on cellular transformation. Ba/F3 cells expressing these JAK2 variants were also introduced into mice. Whereas mice injected with wild type JAK2 remained healthy, both V617m and SSm induced similar leukemia phenotypes as V617F and V617F+SSm, with a ~2-fold longer disease latency of 8-10 weeks. Increased JAK2 mRNA abundance in JAK2-V617F homozygous patients as well as the presence of three additional -1 PRF signals in the JAK2 mRNA further suggest a prominent role for -1 PRF in controlling JAK2 production.

Conclusions: We demonstrate that the JAK2-V617F mutation diminishes -1 PRF on the JAK2 transcript, stabilizing the mRNA and increasing JAK2 expression, contributing to its transforming activity in vitro and disease onset in vivo. We suggest that -1 PRF normally provides a layer of control by limiting JAK2 translation. Defective -1 PRF synergizes with the transforming activity of the JAK2-V617F protein by causing its overexpression, explaining why this particular mutation causes such aggressive malignancies. In support of this, the combination of rucozolitinib and an HSP-90 inhibitor, which reduce kinase activity and JAK2 expression respectively, leads to increased therapeutic efficacy in myeloproliferative neoplasms (Bhagat N et al, Blood, 2014).

Background: Chronic myelomonocytic leukemia (CMML) is characterized by increased proliferation and myelomonocytic lineage commitment of hematopoietic and monocytic cells in the bone marrow and peripheral blood. CMML patients and to a CMML-like myeloproliferative disorder (CML-MPD) in mice via causing hypersensitivity to GM-CSF. Loss of RAF kinase inhibitor protein (RKIP), a negative regulator of Ras signaling, is frequent in myelomonocytic and monocytic subtypes of acute myeloid leukemia (AML) and is often associated with Ras mutations. Moreover, RKIP loss has recently been shown to increase the proliferation of AML cell lines.

Aims: In this work, we aimed at investigating the role of RKIP in the development of CMML.

Methods: RKIP expression was measured by immunoblot and quantitative real-time PCR in 23 primary CMML patient samples as well as in CD34+ HSCs, B-lymphocytes, granulocytes and monocytes of four healthy donors. Sequence analysis of CMML samples was done with an Ion Torrent Next Generation Sequencing platform using an amplicon panel covering 39 genes recurrently mutated in myeloid neoplasms. Effects of RKIP on GM-CSF-induced myelomonocytic differentiation were studied in human CD34+ HSCs transiently transduced with RKIP shRNA, as well as in a genetic mouse model for RKIP deletion (RKIP-/-). Effects of RKIP on CML-MPD development were initially studied in the same RKIP-/- model. Additionally, these mice were crossed with animals exhibiting a somatically inducible mutation in NRAS (RKIP-/-;Myxl-Cre;NRASG12D) and the severity of CML-MPD onset was studied at an age of six months.

Results: Loss of RKIP protein expression was observed in 6/23 (26%) CMML patient specimens and was associated with decreased mRNA levels as well (P<0.001). Patients with RKIP loss exhibited an increased percentage of myelomonocytic cells in the peripheral blood (56% vs 75%, P=0.0226). One or more mutations affecting the Ras signaling pathway were detected in all specimens with RKIP loss. In addition to the previously demonstrated induction of proliferation, we then aimed to delineate a role of RKIP loss in myeloid lineage commitment. When studying healthy donors, we observed that RKIP expression was high in HSCs and lymphoid cells, but significantly decreased in cells belonging to the myeloid lineage (monocytes, P=0.001 and granulocytes, P<0.001). In functional experiments, knockdown of RKIP increased the GM-CSF-induced myelomonocytic lineage commitment of both, human and murine HSCs (P<0.05 and P=0.0295, respectively). These results could be corroborated in vivo, as intraperitoneal injection of GM-CSF caused a significant increase of myelomonocytic cells in the intraperitoneal cavity (P=0.006, bone marrow (P=0.007) and peripheral blood (P=0.027) in RKIP-/- mice when compared to their wildtype littermates. In a final step, we evaluated the potential of RKIP loss to cause CML-MPD in mice. While it proved to be insufficient to cause the disease as a single event in RKIP-/- mice, it aggravated the CMML-MPD phenotype in animals carrying an additional mutation in NRAS. In this case, deletion caused worsening of leucocytosis (P=0.036) and splenomegaly (P=0.035), which was associated with increased levels of myelomonocytic cells in the bone marrow (P=0.028), peripheral blood (P=0.002) and spleen (P=0.025).

Summary/Conclusions: RKIP loss is a frequent event in CMML and is associated with mutations affecting the Ras signaling cascade. Loss of RKIP is functionally involved in myelomonocytic lineage commitment of HSCs and aggravates CML-MPD development in mice carrying an additional mutation in NRAS.

S420 JAK2 V617F HAEMATOPOIETIC CLONES WITH DIFFERENT EXPANSION KINETICS ARE DETECTABLE SEVERAL YEARS PRIOR TO MPN DIAGNOSIS

T. Mckerrell1,2, N. Park1, J. Chi3, G. Collord2, T. Moreno4, H. Ponstingl5, J. Dias2, P. Gerasimou3, K. Melanthyou6, C. Prokopiou6, M. Antoniades7, I. Varela8, P. Costeas8, G. Vassilioul1,2
1Department of Haematology, University of Cambridge, 2Wellcome Trust Sanger Institute, Cambridge, United Kingdom, 3The Center for the study of haematological malignancies (CSHM)/Karaskiakio Foundation, Nicosia, Cyprus, 4Instituto de Biomedicina y Biotecnología de Cantabria (UC-CSIC), Cantabria, Spain, 5Cancer Molecular Diagnosis Laboratory, University of Cambridge, 6Cambridge Biomedical Research Centre, UK, 7Haematology, Nicosia General Hospital, Nicosia, Cyprus

Background: JAK2 V617F is the most common somatic mutation in the classical myeloproliferative neoplasms (MPNs) and is also frequent amongst healthy individuals with age-related clonal haemopoiesis (ARCH).

Aims: To investigate the pre-clinical clonal evolution of MPNs.

Methods: We identified 12 individuals with JAK2 V617F mutant MPN from whom blood DNA was available from the time of MPN diagnosis and also from an earlier time point of between 4.5-15.2 years previously (median 10.2 years) when blood was donated for registration to the Cyprus Bone Marrow Donor Registry. We used deep DNA sequencing to interrogate all 24 samples at 15 myeloid mutation hotspots including JAK2 V617F, using an established multiplex PCR/MiSeq sequencing protocol that reliably detects nucleotide substitutions present at a variant allele fraction (VAF) ≥0.008. Additionally, for 12 samples with sufficient DNA available, we performed targeted DNA capture for all exons of 41 genes recurrently mutated in myeloid neoplasms using a custom RNA bait library followed by sequencing on Illumina HiSeq 2500. Finally, we genotyped archived Registry samples for the rs12343867 single nucleotide polymorphism (SNP) (G>T) linked to the JAK2 46/1 haplotype.

Results: Amplicon sequencing returned a median coverage of 6641 reads per nucleotide (nt) at the studied hotspots. This confirmed the presence of JAK2 V617F in all 12 diagnostic and 9 of 12 archival samples. The remaining 3 samples were JAK2 V617F negative at the sensitivity of our assay (VAF<0.008). The only other hotspot mutation identified was SRSF2 P95R in one patient, P3, whom had a diagnosis of myelofibrosis. Pulldown sequencing of all exons of 41 genes from 12 samples with sufficient DNA returned an average coverage of 1978 reads per nt and showed a close correlation in JAK2 V617F and SRSF2 P95R VAF quantitations with amplicon sequencing. The JAK2 V617F VAF at JAK2 V617F was absent/undetectable at the sensitivity of our method (VAF≥0.008). One or more mutations affecting the RAS signaling pathway were detected in all specimens with JAK2 V617F loss. In functional experiments, knockdown of JAK2 increased the GM-CSF-induced myelomonocytic lineage commitment of both, human and murine HSCs (P<0.05 and P=0.0295, respectively). These results could be corroborated in vivo, as intraperitoneal injection of GM-CSF caused a significant increase of myelomonocytic cells in the intraperitoneal cavity (P=0.006, bone marrow (P=0.007) and peripheral blood (P=0.027) in RKIP-/- mice when compared to their wildtype littermates. In a final step, we evaluated the potential of RKIP loss to cause CML-MPD in mice. While it proved to be insufficient to cause the disease as a single event in RKIP-/- mice, it aggravated the CMML-MPD phenotype in animals carrying an additional mutation in NRAS. In this case, deletion caused worsening of leucocytosis (P=0.036) and splenomegaly (P=0.035), which was associated with increased levels of myelomonocytic cells in the bone marrow (P=0.028), peripheral blood (P=0.002) and spleen (P=0.025).

Summary/Conclusions: RKIP loss is a frequent event in CMML and is associated with mutations affecting the Ras signaling cascade. Loss of RKIP is functionally involved in myelomonocytic lineage commitment of HSCs and aggravates CML-MPD development in mice carrying an additional mutation in NRAS.

S421 DISRUPTION OF HAEMATOPOIETIC STEM CELL HETEROGENEITY IN A MOUSE MODEL OF MYELOPROLIFERATIVE NEOPLASM

Figure 1.
Background: The hematopoietic stem cell (HSC) compartment in mice encompasses a broad range of heterogeneous cell types including highly lineage-biased HSCs, such as platelet-biased HSCs (PMID:23934107). Myeloproliferative neoplasms (MPNs) are a heterogeneous spectrum of clonal hematopoietic disorders, that includes essential thrombocythemia (ET), a MPN-subtype usually presenting with isolated thrombocytosis. Most ET patients carry a gain-of-function point mutation in JAK2 (JAK2V617F), with several other collaborating hits reported to co-occur with JAK2V617F at lower frequencies, including thrombocytosis-associated gene expression in EZH2, which are more frequent in advanced MPN.

Aims: Although it is generally accepted that MPNs are propagated by counterparts of HSCs, the impact of collaborating MPN-associated mutations arising in different HSC subsets remains unclear. We aimed to explore the possibility that platelet-biased HSCs might selectively promote development of an ET phenotype.

Methods: We generated a novel mouse model of MPN that carries a conditional knock-in of heterozygous human JAK2V617F (hJAK2V617F) and the conditional knock-out (KO) of EZH2 together with an inducible Mx1-Cre transgene. To analyse platelet-biased HSC subsets upon onset of the mutation(s), we also crossed in the vwf-eGFP transgene, which is selectively expressed in the vwf-eGFP+ve HSCs.

Results: Compared to wild-type and single mutant mice, EZH2-KO hJAK2V617F mice showed increased platelet counts, including a subset of mice which became acutely unwell with an extreme thrombocytosis. Strikingly, in serial bone marrow (BM) transplantation assays, EZH2-KO fully rescued the previously described hJAK2V617F-associated transplantation defect (PMID:20489053). EZH2-KO hJAK2V617F BM recipients showed long-term serial engraftment that was fully restricted to the platelet and myeloid lineages with a persistent thrombocytosis and absence of lymphoid reconstitution. RNA-sequencing revealed upregulation of several signaling pathways, including Hedgehog, and increased inflammation associated gene expression in EZH2-KO hJAK2V617F HSCs. Unexpectedly in this mouse model of thrombocytosis, phenotypic analysis of the HSC compartment in the BM showed that vwf-eGFP+ve HSCs were selectively lost (fold change[FC]=0.12 p=0.009), while vwf-eGFP-ve HSCs in the ability to propagate MPN, we sorted HSCs according to vwf-eGFP expression, and transplanted them into recipient mice. Unlike their normal counterparts, which showed lymphoid-biased reconstitution, vwf-eGFP+ve HSCs from EZH2-KO hJAK2V617F mice primarily gave rise to platelets and myeloid cells. In contrast, vwf-eGFP+ve HSCs from EZH2-KO hJAK2V617F mice engrafted poorly without recapitulating the disease in recipients.

Summary/Conclusions: In this novel Ezh2-KO hJAK2V617F mouse model, EZH2 loss collaborates to worsen thrombocytosis and rescue the HSC function defect in hJAK2V617F mice. We also observed a striking disruption of phenotypic and functional HSC heterogeneity in Ezh2-KO hJAK2V617F mice with an unexpected and selective loss of vwf-eGFP+ve HSCs together with subversion of vwf-eGFP-ve HSCs towards platelet-myeloid lineage commitment. This previously undescribed disruption of HSC heterogeneity in myeloid malignancy together with the clonal advantage conferred to HSCs by EZH2-KO helps to explain how this collaborating mutation might promote the development of more advanced MPN.

Clinical trials including treatment discontinuation in CML

S422

DASATINIB IN CHILDREN AND ADOLESCENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) FROM A PHASE 2 TRIAL

1Erasmus MC-Sophia Children’s Hospital, Rotterdam, Netherlands, 2University of Birmingham, Birmingham, West Midlands, United Kingdom, 3Support Group for Children and Adolescents with Cancer, 4University of Campinas, São Paulo, Brazil, 5Institut d’Hematologie et d’Onco logie Pédiatrique, Lyon, France, 6Ann and Robert H. Lurie Children’s Hospital of Chicago, Northwestern University Feinberg School of Medicine, Chicago, 7Oregon Health & Science University, Portland, United States, 8The Catholic University of Korea, Seoul St. Mary’s Hospital, Seoul, Korea, Republic Of, 9Instituto Nacional De Pediatría, Mexico City, Mexico, 10Prince Aly Khan Hospital, Mumbai, India, 11Regina Margherita Hospital, Turin, Italy, 12University of Olsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic Of, 13Hôpital Enfants Armand-Trousseau, Paris, France, 14Royal Marsden Hospital, Sutton, Surrey, United Kingdom, 15Dana-Farber Cancer Institute, Boston, 16Texas Children’s Cancer Center, Baylor College of Medicine, Houston, 17Bristol-Myers Squibb, Princeton, 18University of Colorado School of Medicine/Children’s Hospital Colorado, Aurora, United States

Background: As safe and effective frontline treatment options for children and adolescents with CML are limited, and no approved therapies exist for patients (pts) resistant/intolerant to imatinib (IM), additional treatment options and alternative formulations are greatly needed for this younger population. Dasatinib (DAS) has proven efficacy in adults with newly diagnosed CML-CP, as well as those resistant/intolerant to IM (Cortes JCO 2016, Shah AJH 2016). Results of a phase 1 study confirmed its dosing and safety in pediatric pts (Zwaan JCO 2013); however, a larger prospective study is necessary to further support the use of DAS in pediatric pts with newly diagnosed or IM-resistant/intolerant CML-CP.

Aims: To determine whether DAS is safe and effective in pediatric pts with CML-CP newly diagnosed or resistant/intolerant to IM enrolled in a phase 2, open-label, nonrandomized prospective clinical trial (CA180-226/NCT00777036).

**INITIAL REDUCTION OF THERAPY BEFORE COMPLETE WITHDRAWAL IMPROVES THE CHANCE OF SUCCESSFUL TREATMENT DISCONTINUATION IN CHRONIC MYELOID LEUKAEMIA (CML): YEAR 2 RESULTS IN THE BRITISH DESTINY STUDY**

1Haematology, Royal Liverpool University Hospital, Liverpool, UK; 2Liverpool Cancer Trials Unit, University of Liverpool, Liverpool, UK; 3Centre for Haematology, Imperial College at Hammersmith Hospital, London, UK; 4Haematology, East Kent Hospitals University NHS Foundation Trust, Canterbury, UK; 5Haematology, St James University Hospital, Leeds, UK; 6Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, UK; 7Haematology, Kings College Hospital, London, UK; 8Paul O’Gorman Leukaemia Research Centre, University of Glasgow, Glasgow, UK

**Background:** In CML, there is considerable current interest in whether some patients can safely discontinue tyrosine kinase inhibitor (TKI) therapy. However, all studies so far have examined patients in stable MR4 at entry, i.e. BCRABL/ABL1 ratio ≤0.01%. Patients in stable major molecular response (MMR) but not MR4 (<0.1 but >0.01%) have not been formally studied, neither have the effects of stepwise TKI withdrawal.

**Aims:** The present British De-Escalation and Stopping Therapy with Imatinib, Nilotinib or Sprycel (DESTINY) study examines treatment de-escalation as a precaution to complete cessation, in patients in not only stable MR4 but also those in MMR but not MR4.

**Methods:** Trial entry required first chronic phase of CML, TKI treatment for ≥3 years, and either the same TKI (imatinib, dasatinib or nilotinib) since diagnosis or only one switch for intolerance. All PCR tests (minimum of 3) in the 12 months before trial entry must have been ≤0.1% (i.e. MMR), each with ≥10,000 ABL1/ABL1 ratio. Patients in stable MR4 but not MR4 were also separately eligible. TKI treatment was reduced to half dose in patients in both stable MR4 and those in MMR but not MR4.

**Results:** From 145 pts enrolled, 130 were treated; 54% were aged ≥12-<18 years. Within the institutional imatinib group, 25 were resistant, 2 were intolerant, and 2 were undetermined. For pts with CML-MP (n=113), 48% of pts with imatinib-resistant/imatinib-CML and 73% with newly diagnosed CML-MP remained on treatment at the time of this analysis (table 1). Cumulative rate of MMR was reached as early as 3 months for imatinib-resistant/imatinib-CML, and a cumulative rate of CCyR >55% was reached as early as 6 months for newly diagnosed CML-MP. The estimated progression-free survival (PFS) was 48 months for imatinib-resistant/imatinib-CML and 93% for newly diagnosed CML-MP (table). Reasons for progression were loss of MCR (n=3 imatinib-resistant/imatinet; n=6 newly diagnosed), loss of complete hematologic response (n=2 each), and development of CML-BP (n=2 imatinib-resistant/imatinet; n=1 newly diagnosed). One death was reported in the imatinib-resistant/imatinet-CML-MP cohort 1 year after stopping DAS (gastrointestinal bleeding). Adverse events (AEs) were consistent with reports in DAS-treated adults, except no DAS-related pleural/pericardial effusion, pulmonary edema/hypertension, or pulmonary arterial hypertension were reported here. Hypersensitivity in a newly diagnosed pt was the only DAS-related AE that led to discontinuation.

**Summary/Conclusions:** Results from the largest prospective and registration trial of pediatric pts with CML-MP demonstrate that DAS is a safe and effective treatment for pediatric CML-MP. Target responses to first- or second-line that DAS were met as early as 3 and 6 months, respectively, and deep responses were observed. Efficacy and safety of DAS in pediatric pts were similar to those observed in adults; however, unlike in adults, no cases of pleural/pericardial effusion were reported.

**Figure 1.**

**Summary/Conclusions:** The present 24 month RFS of 77% for the overall 24 months in patients in stable MR4 appears better than in any comparable study to date, and implies that the initial 12 months of dose reduction may be respon-sible, perhaps via improved compliance in the few months prior to stopping or through an as yet undefined mechanism.

**Results:** The objective of this study was to assess the efficacy and safety of imatinib 400 mg as first-line treatment of chronic myeloid leukemia (CML). The study was a randomized phase III trial comparing imatinib 400 mg daily with imatinib 800 mg daily. The primary endpoint was complete cytogenetic response (CCyR) at 12 months. Secondary endpoints included molecular response, survival, and safety. The study enrolled 2051 patients with newly diagnosed CML-CP (n=113) and advanced phase (n=2 each), and development of CML-BP (n=2 IM-resistant/imatinet; n=1 newly diagnosed). One death was reported in the IM-resistant/imatinet-CML-MP cohort 1 year after stopping DAS (gastrointestinal bleeding). Adverse events (AEs) were consistent with reports in DAS-treated adults, except no DAS-related pleural/pericardial effusion, pulmonary edema/hypertension, or pulmonary arterial hypertension were reported here. Hypersensitivity in a newly diagnosed pt was the only DAS-related AE that led to discontinuation.

**Summary/Conclusions:** Results from the largest prospective and registration trial of pediatric pts with CML-MP demonstrate that DAS is a safe and effective treatment for pediatric CML-MP. Target responses to first- or second-line that DAS were met as early as 3 and 6 months, respectively, and deep responses were observed. Efficacy and safety of DAS in pediatric pts were similar to those observed in adults; however, unlike in adults, no cases of pleural/pericardial effusion were reported.

Background: The optimum initial treatment of chronic myeloid leukemia (CML) is unknown.

Aims: CML-study IV was designed to confirm the International Randomized Study on Interferon (IFN) and STI571 (IRIS) and to explore whether treatment with imatinib (IM) at 400mg/day could be optimized.

Methods: From July 2002 to March 2012, 1551 newly diagnosed patients in chronic phase (CP) were randomized into a 1:1 arm study. 1536 patients were evaluable, 400 for IM400mg, 430 for IM + IFN, 420 for IM800mg, 156 for IM + cytarabine and 128 for IM after IFN failure. Recruitment to the latter two arms was stopped after a pilot-phase.

Results: After a median observation time of 9.5 years, 10-year overall survival (OS) of all patients was 82%, 10-year progression free survival (PFS) 80%, and 10-year relative survival 92%. 10-year OS of patients with IM400mg, IM + IFN, 79% with IM800mg, 84% with IM + cytarabine and 79% with IM after IFN (Figure 1). The differences were not significant in spite of faster response with IM800mg. In a multivariate analysis, risk group, comorbidities, major route chromosomal aberrations, smoking and type of treatment center (academic vs others) influenced survival, but not gender, transcript type or any form of treatment optimization. Patients reaching the molecular response milestones at 3, 6 and 12 months had a significantly better survival, the faster response of a treatment group (IM800mg) did not translate into a detectable survival advantage.

Figure 1.

Summary/Conclusions: Monotherapy with IM400mg provides a close to normal life expectancy. Faster response does not necessarily translate into better survival. Outcome of CML is currently more determined by disease biology and demographics than by treatment optimization.

S425
BOSUTINIB VS IMATINIB FOR NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA: INITIAL RESULTS FROM THE BFORE TRIAL
T.H. Brümmendorf1, C. Gambacorti-Passerini2, M. Deininger3, M.J. Mauro4, LEUKEMIA: INITIAL RESULTS FROM THE BFORE TRIAL

Bosutinib (BOS) is a potent, dual SRC/ABL tyrosine kinase inhibitor approved for treatment of adults with Philadelphia chromosome-posit (Ph+) chronic myeloid leukemia (CML) resistant or intolerant to prior therapy.

Aims: To assess the efficacy and safety of BOS versus imatinib (IM) for first-line treatment of chronic phase (CP) CML in the BFORE trial (NCT02130557). Methods: In this ongoing, multinational, phase 3, open-label study, 536 patients with newly diagnosed CP CML were randomized 1:1 to BOS 400mg once daily (n=268) or IM 400mg once daily (n=268 [3 not treated]). Informed consent was obtained from all patients. Per protocol, efficacy was assessed in a modified intent-to-treat (mITT) population of 487 Ph+ patients (BOS, n=246; IM, n=241) with the last 14-day administration of Ph+ patients and those with a known Ph status and/or BCR-ABL transcript type were excluded from this population.

Results: After ≥12 months of follow-up, 78.0% of BOS and 73.2% of IM patients remain on treatment with median treatment durations of 14.1 months and 13.8 months, respectively. Major molecular response (MRM) rate at 12 months (primary endpoint) was significantly higher with BOS versus IM in the mITT population (74.2% vs 63.9%; P<0.02) as well as in the ITT population of all randomized patients (46.6% vs 36.2%; P<0.02). In the mITT population, time to MMR was shorter for BOS (median 2.4 months vs 3.4 months for IM; P<0.05). Rate of complete cytogenetic response (CCyR) by 12 months was also significantly higher with BOS versus IM (77.2% vs 66.4%; P=0.038), with time to CCyR shorter for BOS (median 2.8 months vs 5.6 months for IM; P=0.001). Rate of BCR-ABL transcripts ≤1% (Int'l Scale) at 3 months was higher with BOS versus IM (75.2% vs 57.3%; P=0.001); rates of deep molecular response over time were also generally higher with BOS (Table). Results for molecular endpoints were similar in the ITT population. The only baseline characteristic identified as a significant predictor of MMR at 12 months besides treatment arm was Sokal risk group (high vs low; P=0.0001 and intermediate vs low; P=0.05 [mITT]).

On-treatment progression to accelerated or blast phase occurred in 4 patients (1.6%) receiving BOS and 6 patients (2.5%) receiving IM in the mITT population. One BOS-treated and 4 IM-treated patients discontinued treatment due to progression to accelerated or blast phase. Among all treated patients, there were no deaths within 28 days of last dose of BOS and 4 with IM. Safety data for treated patients were consistent with the known safety profiles of BOS and IM. Discontinuation due to drug-related toxicity occurred with 12.7% of BOS patients and 6.7% of IM patients. Grade ≥3 neutropenia (7.8% vs 2.5% BOS vs IM); grade ≥3 anemia (19.0% vs 0% BOS vs IM; grade ≥3 thrombocytopenia (10% vs 0% BOS vs IM) and grade ≥3 gastrointestinal events were infrequent in both groups (all grades: 3.0%, 1.5%, and 0% BOS vs 0.4%, 1.1%, and 0.4% IM; grade ≥3: 1.5%, 0%, and 0% BOS vs 0%, 0%, and 0% IM).

Table 1.

Summary/Conclusions: Patients on BOS had significantly higher rates of 12-month MMR and CCyR and achieved responses faster than those on IM. Consistent with the known safety profile, higher incidences of gastrointestinal events and transaminase elevations were observed with BOS. Primary results from this study suggest BOS may be an important treatment option for patients with newly diagnosed CP CML.
chronic myeloid leukemia patients were not different in molecular relapse after stopping imatinib in Mr4 whether relapse was detected or not - when adjusting for number of control transcripts

Background: With imatinib (IM), most patients with chronic myeloid leukemia (CML) achieve deep molecular responses. Six months after stopping tyrosine kinase inhibitor in deep response in the EURO-SKI trial, 61% of the patients were in molecular relapse-free survival (RFS). Here we present survival data of patients in major molecular remission (3-log reduction in BCR-ABL1 levels) (Mahon ASH 2016). Between patients with and without BCR-ABL1, the difference in RFS at 6 months was not significant when assessing BCR-ABL1 detectability at the MR4.5 level (at least 0.976 log reduction in BCR-ABL1) (Pfirrmann ASH 2016). Aims: For 91 of 448 patients of the EURO-SKI trial samples, the sensitivity to claim undetectable disease at the MR4.5 level was not given. Aim was to investigate whether RFS probabilities would be different when comparing detectable and undetectable disease at the MR4 level.

Methods: Detectability of BCR-ABL1 depends on the number of control gene transcripts. To reduce bias when comparing “MR4 detectable disease” (MR4 but still detectable BCR-ABL1 transcripts; i.e. 0.01 - 0.0033% IS) and “MR4 undetectable disease” (MR4 without detectable BCR-ABL1; based on 10,000-31,999 ABL1 or 24,000-76,999 GUSB copies), two samples with similar sensitivity of identifying BCR-ABL1 were to be identified using propensity score (PS) matching (Rosenbaum, Rubin 1983). Apart from type (ABL1 or GUSB) and number of control gene transcripts, matching variables were interferon alpha pre-treatment, duration of MR4, and the IM treatment time before observation of MR4. Logistic regression was used to compare RFS at 6 months. Significance level was 0.05.

Results: A total of 448 patients had eligible, complete, and sufficient molecular data prior to and within the first 6 months after stopping IM treatment. All molecular results had sensitivity at the MR4 level with yet detectable disease in 196 patients (44%). With small differences in GUSB copy numbers (used in 96 of 448 cases, U test (detectable vs undetectable): P>0.5), prior to PS matching, median numbers of ABL1 transcripts were higher with MR4 detectable disease (78,975 vs 68,925 with undetectable disease; P=0.0511, not significant (n.s.)). In 196 patients with detectable disease, RFS at 6 months was 52% (95% confidence interval (CI): 43-60%) with patients with undetectable disease 63% (95% CI: 53-72%) and RFS at 12 months was 39% (95% CI: 29-50%) with patients with undetectable disease 54% (95% CI: 46-62%). In the logistic model stratified for the matched pairs, for relapse at 6 months, the odds ratio for MR4 with detectable to undetectable disease was 1.308 (CI: 0.862-1.984, n.s.).

Summary and Conclusions: Using the MR4 threshold, after matching on number of control transcripts and other factors, results suggest little or no impact of detectability of BCR-ABL1 on RFS. Time in deep response seems to be more important. In daily routine, many labs produce reliable outcome at the MR4 but not always at the MR4.5 level. Discontinuation at the MR4 level, irrespective of detectability of BCR-ABL1 residual disease, appears safe, with a good chance of success when performed as in EURO-SKI. With PS matching, bias and differences but also power was reduced. To judge whether molecular response on the MR4 level is sufficient, further data is welcome.

AML Biology II: Epigenetic targets

ETO2-GLIS2 RECRUTIS ET ORGANES IN AML COMPLEX AT SUPER-ENHANCERS TO CONTROL TRANSCRIPTION AND DRIVE LEUKEMIC PROPERTIES IN PEDIATRIC ACUTE MEGAKARYOBLASTIC LEUKEMIA

ETO2-GLIS2 recruits ETO2/ERG complex at super-enhancers to control transcription and drive leukemic properties in pediatric acute megakaryoblastic leukemia (AML) (Martineau et al. Blood 2015). ETO2-GLIS2 contains the self-renewal-associated transcriptional regulator ERG, and its deregulation is an essential node for the transcriptional control by the fusion at enhancer super-enhancers, so called super-enhancers, to control transcription of associated genes. To reduce bias when comparing “MR4 detectable disease” (MR4 but still detectable BCR-ABL1) to “MR4 undetectable disease” (MR4 without detectable BCR-ABL1; based on 10,000-31,999 ABL1 or 24,000-76,999 GUSB copies), two samples with similar sensitivity of identifying BCR-ABL1 were to be identified using propensity score (PS) matching (Rosenbaum, Rubin 1983). Apart from type (ABL1 or GUSB) and number of control gene transcripts, matching variables were interferon alpha pre-treatment, duration of MR4, and the IM treatment time before observation of MR4. Logistic regression was used to compare RFS at 6 months. Significance level was 0.05.

Results: A total of 448 patients had eligible, complete, and sufficient molecular data prior to and within the first 6 months after stopping IM treatment. All molecular results had sensitivity at the MR4 level with yet detectable disease in 196 patients (44%). With small differences in GUSB copy numbers (used in 96 of 448 cases, U test (detectable vs undetectable): P>0.5), prior to PS matching, median numbers of ABL1 transcripts were higher with MR4 detectable disease (78,975 vs 68,925 with undetectable disease; P=0.0511, not significant (n.s.)). In 196 patients with detectable disease, RFS at 6 months was 52% (95% confidence interval (CI): 43-60%) with patients with undetectable disease 63% (95% CI: 53-72%) and RFS at 12 months was 39% (95% CI: 29-50%) with patients with undetectable disease 54% (95% CI: 46-62%). In the logistic model stratified for the matched pairs, for relapse at 6 months, the odds ratio for MR4 with detectable to undetectable disease was 1.308 (CI: 0.862-1.984, n.s.).

Summary and Conclusions: Using the MR4 threshold, after matching on number of control transcripts and other factors, results suggest little or no impact of detectability of BCR-ABL1 on RFS. Time in deep response seems to be more important. In daily routine, many labs produce reliable outcome at the MR4 but not always at the MR4.5 level. Discontinuation at the MR4 level, irrespective of detectability of BCR-ABL1 residual disease, appears safe, with a good chance of success when performed as in EURO-SKI. With PS matching, bias and differences but also power was reduced. To judge whether molecular response on the MR4 level is sufficient, further data is welcome.

Nucleosome Binding Protein HMGN1 Blocks MyeloidDiffer-Enation and Promotes Clonal Dominance Via Ablarent Histone Histon

1Dana Farber Cancer Institute/ Harvard Medical School, Boston, 2Broad Institute, Cambridge, 3Massachusetts General Hospital, 4Harvard Medical School, Boston, United States
Background: Acute myeloid leukemia (AML) is characterized by rapid growth and block in differentiation of myeloid progenitors. The AML blast is defined by having "open" chromatin. We hypothesized that alterations of chromatin composition may promote AML. Reversing those changes could represent a novel therapeutic approach.

Aims: Gain of chr21q22 is the most common focal amplification in complex karyotype AML. HMGN1 is a chromatin-remodeling protein on 21q22 known to affect lymphoid development, and our preliminary data suggested that HMGN1 could directly mediate a myeloid differentiation block. Since HMGN1 is known to decompact chromatin and alter histone marks, our goal was to define and therapeutically target the mechanisms by which HMGN1 overexpression disrupts myeloid differentiation and promotes clonal dominance.

Methods: We immortalized bone marrow progenitors from wild-type (WT) or OE-HMGN1 mice (transgenic overexpressing HMGN1) with an estrogen receptor-HoxB8 fusion protein. Using exogenous estrogen to control nuclear translocation of HoxB8, we analyzed synchronized myeloid differentiation by flow cytometry, RNAseq, and TMT proteomic analysis. We performed MINT-ChIP-seq (MNase Indexed T7-chromatin IP) to measure the histone marks H3K27ac, H3K27me3, H3K4me3 and total Histone H3. We also measured histone marks in hematopoietic stem and progenitor subpopulations in vivo. We performed competitive bone marrow transplantation with CD45.1 WT and OE-HMGN1 donors and measured the relative contribution to hematopoiesis over time.

Results: Synchronized differentiation in WT cells progressed over 6 days from myeloid progenitors to mature neutrophils and monocytes, analyzed by cell surface markers, morphology, and gene and protein expression. OE-HMGN1 cells proliferated faster and remained as undifferentiated myeloblasts (84% Cd11b+Gr1+ in WT vs 4% in OE-HMGN1, p<0.002; Fig A). Gene set enrichment analysis revealed more similarity to undifferentiated hematopoiesis and leukemia signatures in OE-HMGN1 cells. MINT-ChIP indicated higher global and locus-specific levels of H3K27ac in OE-HMGN1 cells (Fig B, upper panel), consistent with an increase in gene transcription confirmed by RNA-seq. We found a specific increase in HoxA cluster expression in OE-HMGN1 cells, highly impaired proliferation and clonogenic growth (n=3; p<0.001) in OE-HMGN1, p=NS). Knockdown (KD) of PIWIL4 in AML cell lines resulted in over 4000 differentially expressed genes upon PIWIL4 depletion. 30% of the loci that lost expression of AML specific oncogenes in murine stem progenitors, within 96h post-transduction, induced a 6 to 8 fold increase in PIWIL expression compared to GFP control (n=3, p<0.0001). Knockdown (KD) of PIWIL4 in AML cell lines significantly impaired proliferation and clonogenic growth in vitro (n=3, p<0.001) and delayed onset of leukemia in NSG mice (n=8; p<0.0001). PIWIL4 KD in primary AML patient BM cells lead to 5-fold decrease in clonogenicity (n=3, p<0.01). Thus, collectively, we could show for the first time that PIWIL4 expression is deregulated in human AML and acts as a piRNA binding, epigenetically active and growth regulatory protein in human AML.

Figure 1. Summary/Conclusions: Our study suggests that HMGN1 overexpression blocks myeloid differentiation and promotes proliferation in hematopoietic progenitors via increased H3K27 acetylation. Targeting epigenetic changes downstream of HMGN1 or interfering with HMGN1 itself may represent a novel therapeutic strategy in AML.
Aims: To identify novel therapeutic vulnerabilities of AML.

Methods: A CRISPR-Cas9 drop-out screen was used to identify genetic vulnerabilities of AML. Downstream, we study the function of the RNA methyltransferase METTL3, a novel therapeutic vulnerability of AML. These included in-vitro and in-vivo validation of METTL3 as a therapeutic target using CRISPR/gRNA or shRNA, and investigation of its function using ChIP-seq, RNA-IP-seq, ribosome footprinting (RFP) and bioinformatic analyses.

Results: We performed a genome-wide CRISPR screen on AML cells from Ft3+TdT+/–RosaCas9/− mice transformed with MLL-AF9 lentivirus and identified >1500 cell-essential genes of which ~250 were AML-specific and included many MLL-AF9 interactors and several putative RNA methyltransferase genes: METTL1, METTL3, METTL14 and METTL16 (Fig 1A). Focusing on METTL3, we show that its disruption with Cas9/gRNA promoted differential counting of mifepristone and human MLL-AF9 AML cells and inhibited their growth in vitro and in vivo (Fig 1B), but did not affect primary murine haematopoietic stem/progenitor cells.

To invest METTL3 function we performed chromatin immunoprecipitation (ChIP) for METTL3 and H3K4me3 and identified 126 METTL3 peaks, localized many mifepristone promoters with bimodal H3K4me3. METTL3 binding was highest at transcription start sites (TSS) (Fig 1C) and the most enriched transcription factor motif at METTL3 sites was that for the NFY complex. Using available ChIP-seq datasets we found that NFYA, NFYB, H3R2me2s, WDR5 and KLF9 showed strong co-binding with METTL3. Also shRNA knock-down (KD) of WDR5 led to reduced METTL3 binding to target genes SP1 and SP2.

To investigate if/how METTL3 controls expression of target genes we first noted that their mRNA levels were unaffected by METTL3 KD. As METTL3 is an N6-methyladenosine (m6A) methyltransferase, we then performed RNAseA treatment on IP with an m6A-specific antibody (m6A-IP). This identified >4000 METTL3-dependent m6A peaks on poly-A+ RNA. m6A peaks were seen on 72±% of METTL3-binding gene transcripts and were located in the coding region (CDS) in contrast to stop codon enrichment in the general transcriptome (Fig 1D). Also, METTL3-bound gene transcripts and were located in the coding region (CDS) in contrast to stop codon enrichment in the general transcriptome (Fig 1D). Also, METTL3-bound gene transcripts and were located in the coding region (CDS) in contrast to stop codon enrichment in the general transcriptome (Fig 1D). Also, METTL3-bound gene transcripts and were located in the coding region (CDS) in contrast to stop codon enrichment in the general transcriptome (Fig 1D). Also, METTL3-bound gene transcripts and were located in the coding region (CDS) in contrast to stop codon enrichment in the general transcriptome (Fig 1D). Also, METTL3-bound gene transcripts and were located in the coding region (CDS) in contrast to stop codon enrichment in the general transcriptome (Fig 1D).

Figure 1.

Summary/Conclusions: Our results show that METTL3 controls translation of specific mRNA's by binding their TSS and introducing m6A at [GAG] motifs within their CDS, in turn increasing their TE. These mRNAs code for proteins essential for AML cell survival, making METTL3 a novel therapeutic vulnerability of AML.

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by increased platelet destruction and impaired platelet production. Despite decades of basic and clinical research, the understanding of severe, corticosteroid-resistant or relapsed disease remains a challenge. Our preliminary study indicated the effectiveness of all-trans retinoid acid (ATRA) for ITP (Wang M, et al. ASH 2012, Abstract #3338). This has been coupled with previous discoveries of an immune-modulation effect of ATRA in ITP, including its role in the regulation of platelet progenitor cells, the NFκB complex, and the inhibition of the NFκB signaling pathway. Our previous study showed that the combination of ATRA and danazol may work synergistically based on the mechanism of action targeting both increased platelet destruction and insufficient platelet production.

Aims: To investigate the efficacy and safety of ATRA plus danazol in patients with corticosteroid-resistant or relapsed ITP.

Methods: A multicentre prospective study was performed in non-splenectomized corticosteroid-resistant or relapsed ITP patients. Participants were at least 18 years of age, had a platelet count of less than 30×109/L at enrolment, and did not achieve a sustained response to treatment with full-dose corticosteroids for a minimum duration of 4 weeks or relapsed during steroid-tapering or after its discontinuation. Written informed consents were obtained from all of the participants. The primary endpoint was a sustained response. The secondary endpoints included overall response, time of response, duration of response, incidence of bleeding symptoms and safety.

Results: From 2012 to 2016, 130 consecutive patients were enrolled from 5 different tertiary medical centres in China. Thirty-seven patients were ineligible and excluded, leaving 93 patients randomized to the ATRA+danazol group (n=45) and the danazol group (n=48). At 12 months follow-up, sustained partial or complete response was achieved in 71.6% of patients in the danazol+ATRA group, significantly higher than 47.2% for danazol monotherapy (<0.001). Additionally, 92.5% and 42.5% of patients receiving ATRA+danazol achieved at least one response (R), while only 58.3% and 11.1% of patients with danazol monotherapy achieved the same. In patients achieving CR or R, the time to treatment response was 30.5 days with a peak platelet count of 155×109/L in the danazol+ATRA group compared with 49 days with a peak platelet count of 155×109/L in the danazol group. Multivariate analysis revealed that the initial response at day 28 and the median ITP duration were the potential variables associated with a sustained response. There was no treatment-related death due to adverse events. One patient receiving danazol monotherapy died from intracranial haemorrhage 4 weeks after study enrollment.

Summary/Conclusions: Our findings demonstrate that the combination of ATRA and danazol is safe and effective in achieving a rapid and long-lasting response, making it a potential promising therapeutic option for patients with severe, corticosteroid-resistant or relapsed ITP.

NOVEL PERSPECTIVES IN GENOTYPE-PHENOTYPE CORRELATIONS IN MYH9-RELATED DISEASE: NO LONGER JUST A MATTER OF HEAD OR TAIL

C. Zaninetti1,2, D. De Rocco2, A. Pastore2, V. Bozzi1, S. Barozzi1, F. Melazzini1, A. Savoia1, P. Noris1, C.L. Baldini1, A. Pecci1

1Department of Internal Medicine, IRCCS Policlinico San Matteo Foundation, and University of Pavia, Pavia, 2Institute for Maternal and Child Health, IRCCS Burlo Garofolo, and University of Trieste, Trieste, Italy

Background: MYH9-related disease (MYH9-RD) is an autosomal-dominant disorder caused by mutations in MYH9, the gene for non-muscle myosin heavy chain.

haematologica | 2017; 102(s2) | 155
chain II (NMMHC-IIA), and represents the most frequent inherited thrombocyto-
penia worldwide. NMMHC-IIA comprises two discrete domains, the N-termi-
nal globular head domain (HD) and the C-terminal tail domain (TD), and
causative mutations hit either the HD or the TD. All patients present at birth
with macrothrombocytopenia and only some of them develop during life addi-
tional manifestations, including nephropathy often leading to end-stage renal
disease (ESRD), sensorineural deafness, and/or cataract. Thus, the search
for genotype-phenotype correlations in MYH9-RD has been an important
research topic since the identification of the disorder. In 2008, the analysis of
108 patients allowed to conclude that the mutations affecting the HD were
associated with evolution to early-onset ESRD and deafness, whereas the risk
of the TD mutations was much lower for patients carrying mutations of the TD. In 2014, raising to 255 the number of patients, we sug-
gested that evolution to juvenile ESRD associated only with the most frequent
among HD mutations, i.e. substitution of the arginine 702 (R702). Conversely,
the mutations that affected the TD were almost exclusively found in a distinc-
tic region at the interface between the SH3 subdomain and the motor domain
(SH3/MD interface), may be associated with a much less severe evolution.

**Aims:** To improve prognostic assessment of patients with MYH9-RD.

**Methods:** All the consecutive patients enrolled in the Italian registry for MYH9-
RD until June 2016 were included. The association of MYH9 genotype
with phenotype was assessed by a generalized linear regression model (event-free
survival analysis).

**Results:** We enrolled 350 patients belonging to 199 MYH9-RD pedigrees.
Mutilational screening allowed us to identify 6 novel causative mutations in the HD
or 6 different pedigrees. Interestingly all of these variants were localized in the
hydrophobic region at the SH3/MD interface. By raising the number of
patients with mutations in this region from 14 to 26, and increasing the obser-
vation time, we could demonstrate that the mutations in the SH3/MD interface are
associated with an earlier and more severe disease onset compared to mutations
in the HD. These findings suggest to perform genetic analysis in all subjects with autosomal
dominant form of mild, non-syndromic thrombocytopenia. This innocuous
disease is relatively rare (1.3% of families of our case series) but it has to be
 distinguished from the more severe autosomal dominant ITPs with normal platelet
size deriving from mutations in ETv6, ANKRD26 and RUNX1, since they predis-
pose to the development of hematological malignancies. Because of the
similarity of the clinical features and the lack of reliable laboratory markers, we
suggest to perform genetic analysis in all subjects with autosomal dominant
thrombocytopenia and normal platelet size in order to identify their disorders,
define prognosis and organize an appropriate follow-up regimen.

**S433**

**A MONOALLELIC LOSS-OF-FUNCTION MUTATION IN THE THROMBOPOIETIN
(THPO) GENE IS RESPONSIBLE FOR A NEW FORM OF INHERITED
THROMBOCYTOPENIA**

P. Norris1, C. Marconi2, D. De Rocco3, F. Melazzini1, T. Pippucci2, G. Loffredo2, T. Giangregorio3, E. Cigalini1, A. Pecci1, M. Seri2, A. Savoia1

**Background:** The THPO-MPL axis plays a central role in platelet biogenesis:
the signaling cascade inducing megakaryocytes (MKs) differentia-
tion from progenitor cells and regulates MK maturation, proplatelet
extension, and nascent platelets release into the bloodstream. Different diseases are
known to be derived from abnormal MK differentiation: thrombocyto-
topenia, myelodysplastic syndromes (MDS), and thrombosis. Gain-of-
function mutations in both genes cause congenital thrombocytosis, while loss-of-
function mutations in MPL result in congenital amegakaryocytic thrombocy-
topenia: patients affected by this form of inherited thrombocytopenia (ITP) pres-
ent at birth with isolated thrombocytopenia, which always evolves into severe
bone marrow aplasia. Similarly, a homoygous loss-of-function variant in
THPO gene was found to be responsible for recessive aplastic anemia in
a Micronesian family.

**Aims:** To unravel the molecular basis of ITs and to improve the clinical and
laboratory diagnostic algorithms for the new ITs described.

**Methods:** Whole exome sequencing (WES) was performed in 86 proposi-
tions with unknown IT identified 2 unrelated individuals (Family A and B) carrying the heterozygous variant c.391G>A, Arg131Glu which
is expected to result in a mutant protein degradation and THPO haploinsuf-
ciency. In each family the segregation with the disorder was confirmed ana-
lyzing one affected relative. Bleeding tendency was absent in all cases.
All patients with mild thrombocytopenia; blood film examination did not identify any
morphological abnormalities. A panel of platelet function tests in both families revealed
the consistently increased size in patients of family A. In vitro platelet aggregation and
surface expression of GPIb/IIa and GPIb/IX were investigated in the two
patients of Family B and gave normal results. The mild severity of thrombo-
cytopeinia and the absence of qualitative platelet defects, at least in the two
subjects of family B, are consistent with the absence of bleeding tendency
in affected subjects. THPO serum level was at the lower limit of the normal range
in the two subjects of family B, the only available for this assay. This result
was in agreement with our hypothesis that THPO mutations were expected to
result in haploinsufficiency.

**Summary/Conclusions:** The Arg131Glu mutation in THPO causes a new autosomal
dominant form of mild, non-syndromic thrombocytopenia. This innocuous
disease is relatively rare (1.3% of families of our case series) but it has to be
distinguished from the more severe autosomal dominant ITPs with normal platelet
size deriving from mutations in ETv6, ANKRD26 and RUNX1, since they predis-
pose to the development of hematological malignancies. Because of the
similarity of the clinical features and the lack of reliable laboratory markers, we
suggest to perform genetic analysis in all subjects with autosomal dominant
thrombocytopenia and normal platelet size in order to identify their disorders,
define prognosis and organize an appropriate follow-up regimen.

**POSITION OF THE GFI1B ZINC FINGER MUTATION DECOUPLES CD34
EXPRESSION FROM ALPHA-GRANULE DEFICIENCY IN GFI1B-RELATED
PLATELET DISORDERS**

W. Stevenson1, D. Rabbolini2, M.-C. Morel-Kopp1, Q. Chen1, S. Gabrielli1, C. Ward1

**Haematology, University of Sydney, Sydney, Australia**

**Background:** GFI1B is a transcription factor that plays an important role in
haematopoiesis. Families with a mutation of the fifth DNA-binding zinc-finger
domain of GFI1B experience bleeding and have a platelet phenotype charac-
terised by macrothrombocytopenia, increased CD34 expression and alpha-
granule deficiency.

**Aims:** To explore the function of other zinc finger domains of GFI1B we have
characterised two unrelated families with a GFI1B variant, C166F, predicted to
disrupt the first Zn-finger domain and compared the phenotype with a previously
described pedigree with the H294fs mutation that disrupts the fifth Zn-
finger domain.

**Methods:** Clinical platelet phenotypes were determined by light and transmis-
sion electron microscopy and functional studies performed by light transmission
and whole blood impedance cytometry. Platelet protein expression was measured
by flow cytometry and western blotting. DNA-binding of variants was
determined by gel mobility shift assays (EMSA) and changes in gene trans-
scription by luciferase assays. Cellular phenotypes were then studied in patient
specific iPSC derived megakaryocytes.

**Results:** Individuals with both C166F and H294fs are thrombocytopenic (mean platelet
count =107 x109/L, n=8) but lack the collagen induced aggregation defects
and bleeding symptoms observed in individuals with H294fs (ISTH BAT,
P=0.015). Alpha granule content observed by microscopy and quantitated by
western blotting of granule related proteins, P-selectin and fibrinogen, were
similar between C166F and control platelets and this was significantly greater
than that observed for the H294fs mutation (P<0.01). EMSA studies indicate
that the C166F variant retains the ability to bind DNA whereas the H294fs
mutation altering GFI1B Zn finberg 5 abrogates DNA binding. Despite retaining the ability
to bind DNA, the C166F variant de-represses gene transcription at 7UBB1,
Megakaryocyte CD34 expres-
tion was increased in cells derived from individuals with both C166F and
H294fs variants but alpha granule deficiency was only observed in cells
containing the non-DNA-binding H294fs mutation.

**Summary/Conclusions:** Mutations altering GFI1B zinc finger 5 cause throm-
boocytopoiesis and increased CD34 expression but these platelets retain
alpha-granule deficiency and clinical bleeding.

**TREATMENT OF PRIMARY ADULT CHRONIC IMMUNE THROMBOCYTOPENIA (CITP) WITH FOSTAMATINIB, AN ORAL SYK INHIBITOR: RESULTS OF TWO RANDOMIZED, PLACEBO-CONTROLLED PHASE 3 STUDIES**

Jussel1,2, Mayer1, Cervinka1, K. Chojnowska3, W. Homand1, A. Hellmann1, J. Windyga4, E. Grossbard5, A. Duliege6

1Division of Pediatric Hematology/Oncology, Department of Pediatrics, Weill Cornell Medicine, New York, NY, United States; 2Fakultät Nemocnice Brno, Brno, Czech Republic; 3Wojewódzki Szpital Specjalistyczny im. M. Kopernika w Łodzi, Łódź, Wojewódzki Szpital Specjalistyczny im. J. Konczaka, Słupsk, Polsland; 4Rigel Pharmaceuticals Inc., South San Francisco, CA, United States

**Background:** ITP is characterized by autoantibody-directed platelet destruction mediated by activated monocyte Fc receptors which signal via spleen tyrosine kinase (syk). A Phase 2 trial of the oral syk inhibitor Fostamatinib (FOSTA) in 16 patients (pts) with refractory ITP provided preliminary efficacy and safety data (Podolanczuk et al., 2009).

**Aims:** To evaluate the efficacy and safety of FOSTA in adult CITP in 2 parallel, identical, multi-center, randomized, double-blind phase 3 studies (S047 and S048) of 24 weeks duration, followed by an open label study (S049).

**Methods:** 150 pts with 3 platelet (pt) counts (ct) <30K/µL were enrolled (76 in S047, 74 in S048) with a 1:1 randomization to FOSTA 100mg or placebo bid, and stratification by prior splenectomy and baseline pt ct ≤15K/µL. Sixty-one % of pts were female; median age was 54 (20-88); 93% were Caucasian; 93% had cITP; median disease duration: 8.5 y; median baseline pt ct: 16K/µL. Prior therapies received by pts included 94% steroids, 47% TPO-RAs, 35% TPO-RAs, 37% rituximab. Stable response (SR) was defined as a pt ct ≥50K/µL at 14 of 4 biweekly visits over Weeks 12-14; immediate intermediate response (IR) as at least 2 consecutive bi-weekly pt cts ≥50K/µL, both without rescue splenectomy, and 32% rituximab. SR and IR, consistent with S047 and S048. Fifty-four of 101 (54%) FOSTA pts and 21% placebo pts. The number of pts with ≥1 adverse event (AE) was similar in FOSTA vs placebo (83% vs 75%). The majority AEs on FOSTA were mild or moderate; all resolved over time. Most common AEs were: diarrhea (15% vs 17%), nausea (19% vs 20%), hypertension (20% vs 3%), ALT/AST increase (10% vs 0%). Serious AEs were reported in 13% FOSTA vs 21% placebo pts.

**Summary/Conclusions:** Fostamatinib substantially improves pt cts in certain pts with heavily pre-treated, severe cITP of long disease duration. AEs are mostly mild or moderate in severity. Given its unique mechanism of action based on inhibition of syk, FOSTA could, if approved, be an important alternative as single agent and be a useful component of combination therapy for pts with difficult cITP.

TNF RECEPTOR 2 IS REQUIRED FOR RIP1-DEPENDENT CELL DEATH IN LEUKEMIA

J. Aguadé-Gorgorí1,*, S. McComb1,2, M.P. Dobay3, C. Mezzatesta1, G. Carlo4, C. Eckert5, A. von Stackelberg5, M. Starullia6, M. Schrappe4, J.-P. Bourquin1, B. Bornhauser1

Background: Persistence of residual leukemia cells, due to deficiencies in apoptotic programs, is a major driver of relapse. Activation of alternative non-apoptotic cell death pathways such as necroptosis represents an attractive strategy to eliminate residual leukemia cells and prevent relapse. We have previously shown that SMAC-mimetics (SM) potently induce cell death by simultaneous RIP1-dependent apoptosis and necroptosis in a subset of refractory acute lymphoblastic leukemia (B-ALL) patient-derived samples. The molecular signals that drive sensitivity to RIP1-dependent cell death remained elusive so far.

Aims: The aim of this project was to understand the mechanisms that determine the specific vulnerability to necroptosis in ALL.

Methods: To identify molecular determinants of sensitivity to SM, we correlated the gene expression profiles of 17 primary samples with high and low sensitivity to SM with the IC50 in response to two SM compounds, birinapant and LCL161. We confirmed the top scoring genes including TNF receptor 1 (TNFR1) and TNFR2 by quantitative RT-PCR in patient-derived xenografts. We further validated our results by quantifying the expression of the candidate genes in an independent cohort of relapsed primary B-ALL and by screening samples with different expression levels of TNFR1 and 2 for their response to SM in vitro.

To assess the mechanistic role of TNFR1 and 2 in the response to SM, we generated patient-derived TNFR1 and TNFR2 knockout cells using the CRISPR/Cas9 model of the bone marrow. Deletion of either TNFR1 or TNFR2 using CRISPR/Cas9 gene editing technology, and evaluated their response to SM in vitro and in vivo using a CRISPR selection model. Additionally, we overexpressed TNFR2 and evaluated the cell death phenotype. To determine the mechanism of TNFR2-mediated sensitization to SM, we investigated the formation of the pro-death RIP1-TNFR1 complex in wild type versus TNFR2ko and in SM sensitive and resistant ALL by immunoprecipitation in primary ALL samples.

Results: Comparative gene expression profiling indicated a correlation of the expression of TNFR2 with sensitivity to SM in primary ALL. Using an independent cohort of relapsed ALL samples, we found that high TNFR2 expression predicted sensitivity to SM in an ex vivo model of the bone marrow. Deletion of either TNFR1 or TNFR2 using CRISPR/Cas9 in patient-derived ALL conferred resistance to treatment with SM in vivo in the xenograft model, indicating that TNFR1 and 2 are both functionally required for cell death. In agreement with an important role for TNFR2 in the response to SM, the overexpression of TNFR2 leads to increased sensitivity to the TNFR1/RIP1 death axis. On the mechanistic level, recruitment of RIP1 to TNFR1 is a key event in the activation of cell death, which is abolished in TNFR2-deficient leukemia and does not occur in SM resistant cases.

Summary/Conclusions: Taken together, our data reveal a novel function of TNFR2 in cell death signaling, as TNFR2 predicts sensitivity to SMAC mimetics and plays a key role in activating the TNFR1/RIP1 cell death pathway, which underlies the switch from RIP1-controlled cell survival to cell death and characterizes a distinct vulnerability in ALL.

THERAPEUTIC TARGETING OF ONCOGENIC MYB ACTIVITY IN T-ALL

T. Pieters1,*, S. T’Sas1, J. Morsci1, F. Matthijssens2, K. Lemeire2, T. Hochepied2, B. Lintemans1, L. Reunis1, J. Haigh3, G. Berx4, S. Goossens1, P. Van Vlierberghe1

1Center for Medical Genetics, Ghent University, 2Ghent University, Ghent, Belgium, 3Monash University and Alfred Health Centre, Melbourne, Australia

Background: T-lineage acute lymphoblastic leukemia (T-ALL) is an aggressive hematologic malignancy that accounts for 10–15% of pediatric and 25% of adult ALL cases. The prognosis of T-ALL has gradually improved, however, the outcome of T-ALL patients with primary resistant or relapsed leukemia remains poor. Thus, further advances in the treatment of T-ALL require the development of effective and highly specific molecularly targeted antileukemic drugs. The proto-oncogene MYB (encodes c-MYB) is aberrantly activated in a subset of T-ALL patients through T-cell receptor driven translocations or genomic duplications of the MYB locus itself. Recently, a new genetic mechanism for the generation of oncogenic super-enhancers in malignant T cells was identified, and suggests a general role for MYB in the regulation of T-cell specific super-enhancer activity.

Aims: We want to identify the role of enhanced MYB activity in super-enhancer driven oncogenic transcription in the context of malignant T-cell development and investigate the in vivo role of cMYB in the initiation and maintenance of T-ALL.

Methods: To evaluate if cMYB could act as a bona fide oncogene in the pathogenesis of T-ALL, we developed a conditional R26-driven cMyb overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the cmyb gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs using recombinase-mediated cassette exchange (RMCE).

Results: Here, we report a novel conditional Myb knockin mouse model (R26-Myb). To study the in vivo oncogenic capacity of Myb, we initially crossed this conditional Myb knockin model with Vav1Cre mice, in order to obtain hematopoietic specific expression of Myb and the EGFP/luciferase from the ROSA26-promoter. Notably, Vav1-Cre+/R26-Myb+/ mice developed T-cell lymphomas with a median latency of 77 weeks, suggesting that Myb can act as a bona fide oncogene in malignant T-cell transformation (Figure 1A). Next, we crossed our Myb transgenic model with Pten conditional knockout mice, to allow comparative analysis of tumors with and without T-cell specific Myb expression. Genetic inactivation of Pten is frequently observed in human T-lymphomas with a median latency of 77 weeks, suggesting that Myb can act as a bona fide oncogene in malignant T-cell transformation (Figure 1A). Next, we crossed our Myb transgenic model with Pten conditional knockout mice, to allow comparative analysis of tumors with and without T-cell specific Myb expression. Genetic inactivation of Pten is frequently observed in human T-lymphomas with a median latency of 77 weeks, suggesting that Myb can act as a bona fide oncogene in malignant T-cell transformation (Figure 1A). Next, we crossed our Myb transgenic model with Pten conditional knockout mice, to allow comparative analysis of tumors with and without T-cell specific Myb expression. Genetic inactivation of Pten is frequently observed in human T-lymphomas with a median latency of 77 weeks, suggesting that Myb can act as a bona fide oncogene in malignant T-cell transformation (Figure 1A). Next, we crossed our Myb transgenic model with Pten conditional knockout mice, to allow comparative analysis of tumors with and without T-cell specific Myb expression. Genetic inactivation of Pten is frequently observed in human T-lymphomas with a median latency of 77 weeks, suggesting that Myb can act as a bona fide oncogene in malignant T-cell transformation (Figure 1A). Next, we crossed our Myb transgenic model with Pten conditional knockout mice, to allow comparative analysis of tumors with and without T-cell specific Myb expression. Genetic inactivation of Pten is frequently observed in human T-lymphomas with a median latency of 77 weeks, suggesting that Myb can act as a bona fide oncogene in malignant T-cell transformation (Figure 1A).

Summary/Conclusions: We developed a novel Myb-driven T-ALL mouse model and could demonstrate a pathogenic role for cMYB in T-cell leukemia. In addition, the Myb-driven preclinical mouse model will open new avenues for therapeutic intervention in T-ALL.

Figure 1.

Summary/Conclusions: Taken together, our data reveal a novel function of TNFR2 in cell death signaling, as TNFR2 predicts sensitivity to SMAC mimetics and plays a key role in activating the TNFR1/RIP1 cell death pathway, which underlies the switch from RIP1-controlled cell survival to cell death and characterizes a distinct vulnerability in ALL.

Figure 1.

Summary/Conclusions: We developed a novel Myb-driven T-ALL mouse model and could demonstrate a pathogenic role for cMYB in T-cell leukemia. In addition, the Myb-driven preclinical mouse model will open new avenues for therapeutic intervention in T-ALL.
THE T-CELL LEUKEMIA ASSOCIATED RIBOSOMAL RPL10 R98S MUTATION ENHANCES JAK-STAT SIGNALING

1Department of Oncology, LKI, KU Leuven, Leuven, Belgium, 2Department of Cell Biology and Molecular Genetics, University of Maryland, College Park, United States, 3Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle-upon-Tyne, United Kingdom, 4Center for Human Genetics, LKI, KU Leuven, 5Center for Cancer Biology, VIB, Leuven, Belgium, 6Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle-upon-Tyne, United Kingdom, 7Department of Pediatric Oncology/Hematology, Erasmus Medical Center, Rotterdam, Netherlands

Alterations in ribosomal protein genes RPL5, RPL10, and RPL22 have been described in ~20% of T-cell acute lymphoblastic leukemia (T-ALL) cases. Whereas RPL5 and RPL22 show heterozygous inactivating mutations and deletions, RPL10 contains a clear mutational hotspot at residue arginine 98 (R98), with 8% of pediatric T-ALL patients harboring this RPL10 R98S missense mutation.

Aims: Investigating the pathogenic role of the recurrent R98S mutation in ribosomal protein L10 (RPL10) in T-ALL.

Methods: A label-free quantitative proteomics experiment was performed to screen for differentially expressed proteins in engineered mouse lymphoid Ba/F3 cells expressing RPL10 WT or RPL10 R98S. Differences in protein expression were further validated in hematopoietic cells derived from a transgenic RPL10 R98S knock-in mouse model and in material derived from xenografted T-ALL patient samples.

Results: The differential proteome screen revealed overexpression of several Jak-Stat signaling components (Csf2rb/2, Jak1, Stat1, Stat3, Stat5a/b and Stat6) in engineered RPL10 R98S mouse lymphoid cells, which we confirmed in hematopoietic cells derived from a transgenic RPL10 R98S mouse model. The relevance of this overexpression was illustrated by enhanced Jak-Stat pathway activation upon cytokine stimulation in RPL10 R98S lymphoid cells, as well as increased sensitivity of these cells to clinically used JAK-STAT inhibitors ruxolitinib and pimozone. RPL10 R98S positive leukemia patients likewise showed overexpression of IL7RA, Jak1 and Stat5, increased sensitivity to pimozone, as well as a mutually exclusive mutation pattern between RPL10 R98S and JAK-STAT lesions, suggesting that RPL10-R98S also modulates the cascade in human T-ALL. Programmed -1 ribosomal frameshifting (-1 PRF) recently emerged as a post-transcriptional mechanism regulating expression of cytokine receptors. We identified -1 PRF signals in mouse and human Jak-Stat and observed RPL10 R98S associated frameshifting reduction in several of these, which may contribute to their overexpression. Altered levels of -1 PRF can however only partially explain observed JAK-STAT protein expression changes, and transcriptional changes and altered protein stability are also involved. Indeed, our data point to altered proteasome activity and composition in RPL10 R98S cells, with upregulation of immunoproteasome specific catalytic subunits, which may explain the increased stability of particular proteins such as Jak1. Of further medical interest, RPL10 R98S cells showed reduced proteasome activity and enhanced sensitivity to the clinically used proteasome inhibitors bortezomib and carfilzomib.

Summary/Conclusions: We explored the molecular mechanism by which the RPL10 R98S mutation contributes to the pathogenesis of T-ALL. We propose a model in which R98S associated decreases in -1 PRF levels, combined with changes in the degradation of particular proteins and potential other mechanisms such as transcriptional regulation, leads to selective upregulation of the JAK-STAT cascade (Figure 1). Besides expanding the relevance of the JAK-STAT cascade in T-ALL and leukemia in general, our results have therapeutic potential since cells harboring the RPL10 R98S mutation are sensitized towards clinically used JAK-STAT and proteasome inhibitors.

NFATC3-PLA2G15 is a novel intergenically spliced chimera that is associated with aggressive T-acute lymphoblastic leukemia biology

Background: Several somatic ribosomal defects have recently been discovered in cancer, yet their underlying oncogenic mechanisms remain poorly understood. Alterations in ribosomal protein genes RPL10, RPL11, and RPL22 have been described in ~20% of T-cell acute lymphoblastic leukemia (T-ALL) cases. Where- as RPL5 and RPL22 show heterozygous inactivating mutations and deletions, RPL10 contains a clear mutational hotspot at residue arginine 98 (R98), with 8% of pediatric T-ALL patients harboring this RPL10 R98S missense mutation.

Aims: Investigating the pathogenic role of the recurrent R98S mutation in ribosomal protein L10 (RPL10) in T-ALL.

Methods: A label-free quantitative proteomics experiment was performed to screen for differentially expressed proteins in engineered mouse lymphoid Ba/F3 cells expressing RPL10 WT or RPL10 R98S. Differences in protein expression were further validated in hematopoietic cells derived from a transgenic RPL10 R98S knock-in mouse model and in material derived from xenografted T-ALL patient samples.

Results: The differential proteome screen revealed overexpression of several Jak-Stat signaling components (Csf2rb/2, Jak1, Stat1, Stat3, Stat5a/b and Stat6) in engineered RPL10 R98S mouse lymphoid cells, which we confirmed in hematopoietic cells derived from a transgenic RPL10 R98S mouse model. The relevance of this overexpression was illustrated by enhanced Jak-Stat pathway activation upon cytokine stimulation in RPL10 R98S lymphoid cells, as well as increased sensitivity of these cells to clinically used JAK-STAT inhibitors ruxolitinib and pimozone. RPL10 R98S positive leukemia patients likewise showed overexpression of IL7RA, Jak1 and Stat5, increased sensitivity to pimozone, as well as a mutually exclusive mutation pattern between RPL10 R98S and JAK-STAT lesions, suggesting that RPL10-R98S also modulates the cascade in human T-ALL. Programmed -1 ribosomal frameshifting (-1 PRF) recently emerged as a post-transcriptional mechanism regulating expression of cytokine receptors. We identified -1 PRF signals in mouse and human Jak-Stat and observed RPL10 R98S associated frameshifting reduction in several of these, which may contribute to their overexpression. Altered levels of -1 PRF can however only partially explain observed JAK-STAT protein expression changes, and transcriptional changes and altered protein stability are also involved. Indeed, our data point to altered proteasome activity and composition in RPL10 R98S cells, with upregulation of immunoproteasome specific catalytic subunits, which may explain the increased stability of particular proteins such as Jak1. Of further medical interest, RPL10 R98S cells showed reduced proteasome activity and enhanced sensitivity to the clinically used proteasome inhibitors bortezomib and carfilzomib.

Summary/Conclusions: We explored the molecular mechanism by which the RPL10 R98S mutation contributes to the pathogenesis of T-ALL. We propose a model in which R98S associated decreases in -1 PRF levels, combined with changes in the degradation of particular proteins and potential other mechanisms such as transcriptional regulation, leads to selective upregulation of the JAK-STAT cascade (Figure 1). Besides expanding the relevance of the JAK-STAT cascade in T-ALL and leukemia in general, our results have therapeutic potential since cells harboring the RPL10 R98S mutation are sensitized towards clinically used JAK-STAT and proteasome inhibitors.
Thrombotic disorders

ASSESSING THE RISK-BENEFIT OF ANTICOAGULANTS IN ELDERLY PATIENTS WITH CANCER-ASSOCIATED VENOUS THROMBOEMBOLISM: A POPULATION-BASED STUDY

A. Gart unsustainable
A. Garg1,1.2, 3, M. McCallum3, S. Dixon3
1Epidemiology and Biostatistics, 2Medicine, Western University, 3Institute for Clinical Evaluative Sciences, London, Canada

Background: Cancer patients have a higher risk of venous thromboembolism (VTE) which conveys a higher subsequent mortality risk; conversely, they also have a higher risk for bleeding due to many factors including abnormal tumor anatomy and the use of chemotherapy agents with the associated risk for thrombocytopenia. However, the consequences of a recurrent VTE or a major bleeding event (MB) might be different in terms of mortality. As a result, the risk of VTE recurrence or a MB event might bear different weights. A previous systematic review has suggested that the case fatality rates of VTE recurrence and MB are similar. However, heterogeneity in study design, outcomes and in particular the types of populations included, limited the interpretation and applicability of the results. Clinical decision making uses estimations of risk and benefit for any given intervention. In the case of VTE, anticoagulants are the cornerstone of treatment having a proven benefit in reducing the risk of recurrent VTE events with an associated increase in the risk of bleeding. Therefore, determining the risk-benefit of anticoagulants might allow for better informed treatment decisions, in particular in a population at high risk for both ends of the spectrum. Therefore, herein we sought to estimate the risk and benefit of anticoagulant therapy in cancer patients developing a VTE using data from administrative databases.

Aims: To provide empirical case fatality rates of VTE recurrence and MB, as well as the case fatality rate-ratio for MB and VTE recurrence in cancer patients developing a VTE treated with anticoagulants.

Methods: We conducted a retrospective population-based cohort study in Ontario, Canada using de-identified linked administrative healthcare databases housed at the Institute for Clinical Evaluative Sciences (ICES). We included patients over 65 years of age with a diagnosis of cancer defined using provincial, ICD-9 and ICD-10 codes for major malignancies and who developed a VTE event within 6 months of the initial cancer diagnosis. VTE was identified through a previously validated algorithm using a combination of diagnostic codes for deep vein thrombosis (DVT) and pulmonary embolism (PE) and codes identifying diagnostic procedures for VTE (i.e. ultrasound, CT pulmonary angiography, lung scintigraphy) within 7 days of each other. Recurrent VTE and MB events were assessed within 180 days from the index date. MB was identified using a previously validated algorithm and included upper and lower gastrointestinal and intracranial bleeding events. Treatment was classified based on the first available prescription within 7 days of the index VTE. We estimated mortality within 7 days of the VTE recurrence or MB events using an unadjusted Cox proportional hazards model and competing risk analysis. Ratios of the mortality for MB compared to VTE recurrence were calculated and 95% confidence intervals were estimated using non-parametric models.

Results: Between 2004 and 2014 there were 6967 VTE events identified in cancer patients over 65 years of age and treated with an anticoagulant. Mean age was 75 years, and 47.6% patients were women. Of all patients, 59.9% received prescriptions for LMWH alone, 15.3% for LMWH followed by warfarin, 22.1% for warfarin and 2.7% for rivaroxaban. At 180 days after the index VTE event there were 235 (3%) MB events and 1184 (17%) VTE recurrences. Within 7 days of the outcome event there were 26 (11%) deaths after MB and 6 (0.5%) after VTE. The mortality ratio for MB versus VTE was 21.8 (95% CI 9.5-53). In exploratory analyses we did not find differences according to type of anticoagulant prescription.

Summary/Conclusions: In this large, population-based, study based on more than 40,000 patients with NHL and almost 116,000 controls, we demonstrated that there is an increased risk of thrombosis in patients with NHL when compared to controls. This is true for all types of thrombosis. We therefore conclude that hypercoagulability seems to increase with diagnosis of NHL. Several factors may contribute to this prothrombotic state, including chemotherapy and other treatment related factors as well as the disease itself. Considering that the increase in the incidence of thrombosis was highest before and around the time of diagnosis for NHL patients, that indicates that the tumor itself may have a great impact on the hypercoagulability of these patients.

COMPARATIVE ANALYSIS OF PREDICTIVE MODELS FOR THROMBOEMBOLIC EVENTS IN LYMPHOMA PATIENTS

D. Antic1, 2, N. Milic2, S. Nikolovski1, M. Todorovic1, J. Bilaj1, P. Djurdjevic1, B. Andjelic1, V. Djurasinovic1, A. Sretenovic1, M. Smiljanic1, V. Vukovic1, J. Jelicic1, B. Mihailjevic1
1Clinic for hematology, Clinical Center of Serbia, 2Medical school Belgrade, Belgrade, Serbia

Background: Actual guidelines recommend Padua and Khorana score for thromboembolic (TE) risk estimation for cancer patients in general. These existing models are quite limited for designation of lymphoma patients for TE events, as their development is not based on features specific for hematomatological patients.

Aims: The aim of this study was to compare diagnostic performance of these suggested predictive models, as well as Thrombosis lymphoma (Thyro) score, developed by our group, which is more specific for lymphoma patients.

Methods: The study population included all consecutive patients with a confirmed diagnosis of non-Hodgkin lymphoma (NHL), Hodgkin lymphoma (HL), and chronic lymphocytic leukemia (CLL) who were treated in the Lymphoma Departments of Clinical Center Serbia and Clinical Center Kragujevac in period from 2006 to 2012. Data for newly diagnosed and relapsed patients who had completed a minimum of one chemotherapy cycle were prospectively collected for all venous and arterial TE events from time of diagnosis to 3 months after the last cycle of therapy. Data for specific thrombosis, clinical, and laboratory scoring systems were also collected. The Venous Padua and Khorana scores were also calculated. Moreover, potential disease-related risk factors were gathered. The study population was divided based on a split-sample random method into the model developing
and validation cohorts. The ThroLy model was developed using data solely from a derivation cohort, which included 1236 patients. Variables were evaluated by univariate logistic regression analysis, while the model was developed using a stepwise multivariate logistic regression analysis. Once a final model was defined, patients were divided into low risk and at risk groups. The final model was assessed in the validation cohort (584 patients). The studied population was also divided, based on Khorana and Padua score, into low risk and at risk groups.

Results: The study population included 1820 eligible lymphoma patients. The mean patient’s age was 53.1 years (range, 15–87 years). Most patients (83%) were newly diagnosed and had advanced stage disease: Ann Arbor stage III, 14.7% and stage IV, 44%. A total of 778 patients (42.7%) had high-grade lymphoma; 351 (19.3%) had low-grade lymphoma; 266 (14.6%) had HL; 156 (8.6%) had other forms; and 269 (14.8%) had CLL/SLL. Of all the patients included in the study, 99 (5.4%) developed at least one TE during the follow-up period. There were 73 patients with venous TE (73.7%), and 25 with arterial TE (25.3%), while 1 patient had both. Patients with aggressive NHL had significantly higher odds of developing TE compared to patients with any other lymphoma type (RR=1.5; 95% CI for RR 1.1–2.4; p=0.027). The incidence of thromboembolism was 81 (5.3%) in the newly diagnosed patients and 18 (6.2%) in relapsed patients. Overall, 35.4% (35/99) of the patients with thromboembolism experienced the event before the start of chemotherapy. The majority of patients (64.6%) had TE events during chemotherapy or within 3 months after chemotherapy. For patients classified at risk according to ThroLy score in derivation cohort, the model produced negative predictive value (NPV) of 98.5%, positive predictive value (PPV) of 25.1%, sensitivity of 75.4%, and specificity of 87.5%. In validation cohort PPV for Throly score was 28.9%. Padua and Khorana score had PPV of 15.5% and 14.8% in derivation, and 11.5% and 14.8% in validation cohort, respectively.

Summary/Conclusions: Lymphoma patients are at increased risk of thromboembolic events but thromboprophylaxis in these patients is largely underused. ThroLy score is more specific for lymphoma patients than suggested Padua and Khorana score, but external validation in large prospective cohort studies is required.

IDENTIFICATION OF A NEW AND RELATIVELY FREQUENT SERPINC1 GENE DEFECT CAUSING ANTITHROMBIN DEFICIENCY HARDLY DETECTED BY CURRENT MOLECULAR METHODS: DUPLICATION OF EXON 6

M.E. De La Morena-Barrio1,2, S. Blanco, M. Rueda, J. Padilla1, T. Blasco, M. Noriega, J. Corral1,2, J. Corral1,2
1Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arraxaca, 2Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII), Murcia, 3Servicio de Hematología, Hospital Clínico San Carlos, Madrid, Spain, 4The John Paul II Hospital, Krakow, Poland; 5Institute of Cardiology, Jagiellonian University Medical College, Krakow, Poland

Background: Antithrombin (AT) deficiency was the first thrombophilia described 50 years ago and so far the strongest one. Up to 78% of cases are explained by point mutations or small deletion/insertions in exons or flanking regions of SERPINC1 that are easily detected by sequencing analysis. A low proportion of cases (2%) is explained by gross gene defects, mainly deletions, which are detected by multiplex ligation-dependent probe amplification (MLPA) analysis. However, the molecular base of AT deficiency is unknown using current methods in 20% of cases.

Aims: To identify new SERPINC1 defects causing AT deficiency.

Methods: We studied 271 unrelated cases with AT deficiency. Functional and biochemical assays characterized plasma AT. Genetic analyses involved Sanger and Next Generation Sequencing (NGS) (PGM, Ion Torrent), MLPA and specific PCR designs.

Results: Sanger sequencing of PCR amplicons with primers flanking the 7 exons and further analysis with SeqscapeTM detected pathogenic mutations in 173 cases. Whole gene sequencing identified 5 mutations in regulatory regions. MLPA analysis revealed 5 cases with whole or partial deletion of the gene. Moreover, 13 cases had disorders of glycosylation. Interestingly, the analysis of the PCR product and the electropherogram of exon 6 of a 42 year-old male patient (P1) with deep vein thrombosis and 75% of anti-FXa activity
with no apparent gene defect by either Sanger sequencing of 7 exons or by NGS analysis of the whole gene using the Ion Torrent platform, revealed a 193 bp insertion, which corresponded to a tandem duplication involving exon 6. Family studies revealed the same duplication in 5 relatives, all with AT deficiency (60-75%). The first MLPA analysis of this case failed to detect the duplication and only after a fine readjustment, it was detected. MLPA analysis under the new conditions of the remaining 59 cases with unique molecular base for their AT deficiency identified one additional case, P2, with potential duplication of exon 6. P2 was a 17 year-old female with 41% of anti-FXa activity, who developed deep venous thrombosis. Sanger and NGS sequencing also failed to detect any genetic defect in P2. A set of primers specific to detect tandem duplications of exon 6 was designed with forward primer from 3’ end of exon 6, and reverse primer from 5’ of exon 6. This set of primers only rendered amplification in the two cases with exon 6 duplication. The second patient (P2) had a new 863 bp duplication in tandem of exon 6. Sanger sequencing of the specific amplicons in the two cases with tandem duplication of exon 6 revealed Alu sequences surrounding these duplications. Finally, one out of 5 cases with gene deletions involved breakpoints affecting intron 5 (deletion of exons 2-5).

Summary/Conclusions: Our study identified a new and relatively frequent SERPIN1 gene defect causing AT deficiency that is hardly identified by current molecular methods: duplication of exon 6. This genetic defect was detected in 1% of our cohort, and represents nearly half of the total gross gene defects causing AT deficiency. The small size of this exon makes difficult the identification of this defect by MLPA. The presence of 6 Alu elements up and downstream exon 6 makes this region a hotspot for unequal recombination that may cause deletions, tandem duplications and potentially transpositions, which may produce AT deficiency (both severe and mild) by an aberrant splicing. We also developed a simple and specific method to detect duplications in tandem of exon 6.

Stem cell transplantation - Experimental

CYTOSOLIC NUCLEIC ACID SENSORS PROMOTE INTESTINAL EPITHELIAL INTEGRITY DURING ACUTE TISSUE DAMAGE AND PROTECT FROM GRAFT-VERSUS-HOST DISEASE

Background: The epithelial lining of the gastrointestinal (GI) tract represents the first line of defense mediating protection from microbial challenge. Next to producing antimicrobial molecules, Paneth cells contribute to this defense by providing a supportive niche for intestinal stem cells (ISCs) maintaining the epithelium. Loss of intestinal barrier function by total body irradiation (TBI) or chemotherapy (CTX) is an essential step in enhancing the development of enteropathy, intestinal inflammation and GVHD. Antigen-presenting cells like dendritic cells, which sense microbial pathogens or engage the STING pathway also protect from loss of barrier function and GVHD and are involved in the development of GVHD, and (iii) for the regenerative response of other tissues.

Methods: We used an integrated approach with pathophysiologic mechanistic studies on IECs in experimental mouse models (MHC-mismatched and minor histocompatibility antigen (miHA)-mismatched transplants to model highly aggressive GVHD; genotoxic stress induced by TBI and CTX) and evaluation of immune-mediated regenerative strategies to promote epithelial barrier function (organoid cultures, barrier function test).

Results: Mice lacking MAVS were more sensitive to total body irradiation (TBI)- and chemotherapy induced intestinal barrier damage, and, like RIG-I-deficient mice, developed worse graft transplantation (allog- HSCT). This phenotype was not associated with changes in the intestinal microbiota, but with reduced epithelial integrity and regeneration. Conversely, targeted activation of the RIG-I pathway during damage promoted these processes and ameliorated GVHD. Mechanistically, IFN-1 (RIG-I-induced or recombinant) could promote growth of intestinal organoids cultures and production of Regifill. Importantly, our findings were not confined to RIG-1/MAVS signaling, as interventional engagement of the STING pathway also protected from loss of barrier function and GVHD and led to IFN-1-dependent intestinal organoid growth. Consistent with this, STING-deficient animals suffered from worse GVHD.

Summary/Conclusions: Our studies may have the potential to develop novel targeted therapies (i) to promote intestinal barrier integrity, (ii) to prevent the development of GVHD, and (iii) for the regenerative response of other tissues.
T cells were isolated, again with different tissue specificities. Could be isolated which all recognized biliary epithelial cells with or without co-variation of various tissue specificities. From patient 4, 26 HLA-DPB1*01:01 reactive T cells recognized only hematopoietic target cells, whereas other clones again showed recognition which 27 recognized only hematopoietic target cells and 96 clones also recognized colon derived cells only. None of the T cell clones recognized biliary epithelial cells. From patient 2 total of 230 HLA-DPB1*03:01 reactive CD4 T cell clones were isolated, of which 27 recognized only hematopoietic target cells and 96 clones also recognized GVHD target cells with differences in tissue specificity. 32 HLA-DPB1*03:01 reactive T cell clones were found from patient 3, of which 6 recognized only hematopoietic target cells, whereas other clones again showed various tissue specificities. From patient 4, 26 HLA-DPB1*01:01 reactive T cells could be isolated which all recognized biliary epithelial cells with or without co-recognition of other target cells. In addition, also 11 HLA-DPB1*03:01 reactive T cells were isolated, again with different tissue specificities.

**Summary/Conclusions:** These results illustrate that donor CD4 T cells directed against mismatched HLA- DP show differential recognition of target cells. Furthermore, it is possible that these mismatched HLA-DP alleles can be used to mediate tumor specific immune responses after HLA 10/10 matched unrelated stem cell transplantation.

**Aims:** To investigate if IL-33 can contribute to the therapeutic effect of MSCs, we studied the interaction between MSCs and IL-33 in vitro.

**Methods:** IL-33 isolated from human tonsils was CellTrace-labeled and cocultured with bone-marrow derived MSCs for 5 days in the presence of IL-2.

**Results:** Co-culture with MSCs significantly enhanced the proliferation of IL33 and their IL-22 production. Reciprocally, IL33 promoted ICAM-1 and VCAM-1 expression on MSCs. Transwell experiments revealed that, in the interaction is mainly dependent on cell-cell contact and close proximity of MSCs and IL33. Addition of blocking antibodies against ICAM-1, VCAM-1, or their integrin ligands, did not affect IL33 proliferation, suggesting that IL33 stimulation is ICAM/VCAM independent. Soluble factors also contributed to the interaction, as IL-33 proliferated slightly better in the presence of MSC culture supernatant compared to IL-2 only. Based on experiments with blocking antibodies, we found IL-2 to be the likely candidate for this effect.

**Summary/Conclusions:** We show that via cell-cell contact and IL-7, MSCs promote the proliferation and IL-22 production by IL33 in vitro, suggesting that IL-33 may play a role in the control of GVHD upon MSC therapy.
Background: Aberrant B-cell homeostasis has been described in patients (pts) with chronic graft-versus-host disease (cGVHD) following allogeneic stem cell transplantation (allo-SCT). However, there is no information on the predictive value of specific B-cell subsets of the incidence of cGVHD.

Aims: We sought to determine if B-cell subsets measured around day 100 after allo-SCT predict the subsequent occurrence of cGVHD in a prospective clinical study.

Methods: Peripheral blood (PB) samples were obtained from consented patients (pts) between day 80 and 110 (D100) after allo-SCT at The University of Texas MD Anderson Cancer Center from 2012 to 2015. Only pts who had not been diagnosed with cGVHD or progression of underlying malignancy by D100 were eligible for this study. We analyzed CD19+CD20+ B cell subsets by flow cytometry. Subsets were defined as naïve (CD27+IgD+), unswitched (CD27+IgD-), and switched (CD27+IgD-) memory cells. Receiver Operating Characteristic (ROC) curve was used to identify threshold levels of B cell % and numbers that predict the incidence of cGVHD. cGVHD diagnosis was based on the 2014 National Institutes of Health guidelines.

Results: A total of 80 pts were enrolled in the study. The median age at SCT was 49 years (range 21-75). The majority (80%) of pts received myeloablative conditioning, and 75% received tacrolimus with mycophenolate or mycophenolate mofetil for GVHD prophylaxis. Diagnosis was myeloid (61%) or lymphoid (34%) malignancy in the majority of pts. Grafts source was primarily PB or bone marrow from matched-unrelated (61%) or related (24%) donors. Grade 3-4 acute GVHD had occurred in 45% of pts before D100. Thirty-six percent of pts had undetectable B cells were significantly more likely to have an underlying malignancy with <90% naïve and >5% switched B cells (HR=7, p<0.001) with a 1-year value of specific B-cell subsets of the incidence of cGVHD.

Conclusions: In conclusion, D100 frequency of naïve and switched B cells predicts the subsequent development of cGVHD. Lymphoid malignancies and older age may be associated with aberrant B-cell reconstitution. Consideration of D100 B-cell subsets may improve risk stratification models for the development of cGVHD.
been treated by stem cell transplantation. Eight patients were treated in the EU at the Instituto Universitario Niño Jesús, 18 Differentiation and Cytometry Unit. Energéticas, Medioambientales y Tecnológicas (CIEMAT), Centro de Investigación Hematopoietic Innovative Therapies Division, Centro de Investigaciones Biomédicas en Red de Enfermedades Raras (CIBERER), Madrid, Spain.

Background: Pyruvate kinase deficiency (PKD) is the most common glycolytic enzyme defect causing hereditary non-spherocytic hemolytic anemia. PKD does not have a specific curative treatment. Therefore treatment is mainly supportive, consisting of regular red blood cell transfusions, splenectomy and chelation therapy for iron overload. This does not improve patient quality of life for affected patients. Hematopoietic allogeneic stem cell transplantation (HSCT) has the potential to cure the disease. However, there is little experience in applying HSCT in PKD and guidelines are not available. To date, only four cases of HSCT have been published. Thus, additional data are required to help the establishment of HSCT guidelines and support future strategies, such as gene therapy.

Aims: The aim of this study was to make a worldwide inventory of all cases of PKD that have been treated by HSCT, and to evaluate indication, procedures employed, and outcome.

Methods: This is an international case series. Queries were sent to national and international databases and to physicians involved in HSCT on PKD patients. The latter were asked to complete a questionnaire on disease characteristics, pre-transplant condition, transplant regimen and post-transplant outcome. Two additional cases were derived from a recently published report (Kim. 2016. Bone Marrow Transplantation).

Results: From 1996 to 2016 a total of 16 PKD-patients were reported to have been treated by stem cell transplantation. Eight patients were treated in the EU and eight in Asian centres, respectively. No patient resulted to be transplanted in the US. Median age at transplantation was 6.5 years. (10 patients (62.5%) were <10 years; 6 (37.5%) >10 years), seven patients (43.8%) were splenectomized at the time of HSCT. Fifteen patients (94%) reached engraftment. The sixteenth patient showed mixed chimerism followed by spontaneous transition to full donor chimerism after splenectomy six months post transplantation. Two patients suffered from secondary graft loss. One of these had recovery of 91% donor chimerism after donor lymphocyte infusion. Outcome in the other patient is unknown. GVHD grade 4 was reported in 6/16 cases (38%). There was no obvious relation between GVHD prophylaxis or any other clinical factors and the occurrence of GVHD grade 2-4 in our patients. Two-year cumulative survival was 74%. Seven patients did not reach the two-year milestone yet. All five patients who did not survive died of transplant-related causes. Patients who did not sur-

Summary/Conclusions: This is the first study on outcome of HSCT in PKD patients. Due to the still relatively small number of cases no definite conclusions on the safety of HSCT in PKD can be drawn. However, we observed a better survival for patients transplanted before the age of ten. This difference could also explain difference in survival between patients transplanted in Europe versus Asia. The high rate of severe GVHD in this cohort is a reason for concern. The strong decline in survival of patients older than ten years of age indicates the need for very careful selection of HSCT-candidates.

S453 HEREDITARY XEROCYTOSIS: CLINICAL AND BIOLOGICAL PRESENTATION AT DIAGNOSIS IN A RETROSPECTIVE SERIES OF 103 PATIENTS

1Laboratoire d’Hématologie, 2Service de Pédiatr. Générale, CHU Biécor, Le Kremlin-Bicêtre, 3Laboratoire d’Hématologie, CHU Rouen, Rouen, 4Hematologie, CHU Saint Eloi, Montpellier, 5Service de Médecine Interne, CHU Estang, Clermont-Ferrand, 6Service d’Onco-Oncologie et d’Hémato, Hôpital Saint Vincent de Paul, Lille, 7Laboratoire d’Hématologie, CHRU Nancy, Nancy, 8Héma
tologie Biologique, CHU Grenoble, Grenoble, 9Médecine interne, CH-Dax, Dax, 10Hématologie, Hôpital d’Enfants, Toulouse, 11Hémologie, CHU Jean Minjoz, Besançon, 12Genétique Médicale, CHU Nantes, Nantes, 13Service de Biochimie, Hôpitaux Universitaires Paris Nord Val de Seine, Colombes, 14Hématologie Pédiatrique, CHU Sud, Rennes, 15Hématologie, Hôpital du Scorff, Lorient, 16Hématologie Pédiatrique, CHU, Saint-Etienne, France, 17Département d’Hématologie, Université Cottet, Switzerland, 18Médicine interne, CHU Henri Mondor, Creteil, 19University Picardie Jules Verne, CHU Amiens CEDEX1, France.

Background: Dehydrated hereditary stomatocytosis, also called hereditary xeroeytosis (HX), is a dominantly inherited hemolytic anemia characterized by an increased leak of monovalent cations through the red cell membrane leading to dehydration and a shortened red cell survival. HX is difficult to diagnose because of its rarity and the heterogeneity in its clinical presentation.

Aims: Our study aims to characterize the clinical and biological features at HX diagnosis in a retrospective diagnostic series of 103 patients.

Methods: HX diagnosis was based on the typical left-shifted curve of osmolar gradient ectocytometry performed at CHU Biécor from 1993 to 2016. All patients were from European origin. They were referred to our center for: chronic non-spherocytic hemolysis (30), thrombotic events after splenectomy (8), hyperferritinemia and/or a chelation therapy were noticed for 26 patients among the 55 for which this data was available (47%). 19 patients were treated for iron overload: phlebotomy (14) and/or Deferasirox (6) and/or Deferoxamine (6) and/or Deferriferone (1). A perinatal edema history was noted in 17 (16.5%) patients. A history of thrombosis or arterial events (3), pulmonary embolism (4), portal thrombosis (4), splenic infarcts (2) and deep vein thrombosis (2) was noted in the 55 for which this data was available (47%).
Sickle Cell Center, Medical College of Georgia, Augusta University, Augusta, This and was well tolerated in the 52-week SUSTAIN study (Ataga KI and was shown to significantly reduce the frequency of SCPC events after loading, was presented a totally compensated hemolysis with a hemoglobin level above 115g/L. MCHC was in the normal range (median 35±1.3g/dL) but was above 36 g/dL for 28 (27.1%) patients. Stomatocyties were noticed on the blood smear in 42 patients over 70 available, numbered as rare (19%), few (60%) or numerous (21%). Genotypes could be performed in 45 subjects from 22 distinct families. At least one PIEZO1 mutation was identified in very affected subjects. No KCNN4 mutations were found in these typical ektacytometric forms of HX.

Summary/Conclusions: This work represents the largest HX series and highlights the important heterogeneity in the clinical features at diagnosis. One important finding is that most patients were not anemic and presented a compensated hemolysis. In a significant percentage of cases, diagnosis was made in the exploration of extra hematological features including perinatal edema or hemochromatosis occurring despite the absence of any red blood cells transfusion. Moreover, we confirmed the very high risk of thrombotic events after splenectomy, underlining the absolute necessity of formally eliminating HX in any unexplained chronic hemolysis each time splenectomy is considered.

S454
CRIZANLIZUMAB, A P-SELECTIN INHIBITOR, INCREASES THE LIKELIHOOD OF NOT EXPERIENCING A SICKLE CELL-RELATED PAIN CRISIS WHILE ON TREATMENT: RESULTS FROM THE PHASE II SUSTAIN STUDY

Aims: This post-hoc analysis evaluated patients who did not experience a SCPC for the duration of the trial.

Methods: SUSTAIN was a randomized, double-blind, placebo-controlled, Phase II study (NCT01895361). Patients aged 16–65 years with SCD (including HbSS, HbSC, HbSβ0–thalassemia, and HbSβ+–thalassemia genotypes) and ≥2 SCPC events in the previous 12 months were included. Concomitant use of hydroxyurea (HU) was permitted if the patient had been using it for ≥6 months and at a stable dose for ≥3 months. Patients were randomized 1:1:1 to receive crizanlizumab 5.0mg/kg, 2.5mg/kg or placebo. Dosing loads were administered on days 1 and 15, followed by routine treatment every 4 weeks for the duration of the study, based on the intent-to-treat (ITT) population overall and by prior SCPC events, SCD genotype and HU use at baseline.

Results: Among the 198 patients included in the study (ITT population), 62.6% and 37.4% had experienced 2–4 and 5–10 SCPC events in the previous year, respectively, and 62.1% were taking HU at baseline. HbSS was the most common genotype (71.2%, HbSC: 16.2%, HbSβ0–thalassemia: 6.1%, HbSβ+–thalassemia: 5.1%, other: 1.5%). Overall, more patients in the crizanlizumab 5.0mg/kg group (n=24/67; 35.8%) were SCPC event-free than in the 2.5mg/kg group (n=12/66; 18.2%) and placebo (n=11/65; 16.9%) groups. In each of the prior SCPC events, SCD genotype and HU use subgroups, a greater proportion of patients treated with crizanlizumab 5.0mg/kg were SCPC event-free compared with those in the crizanlizumab 2.5mg/kg or placebo arms (Table 1). In subpopulations considered to be at increased risk of experiencing a SCPC (patients with 5–10 SCPC events in the previous year and/or with the homozygous HbSS genotype), a higher proportion of patients treated with crizanlizumab 5.0mg/kg were SCPC event-free compared with those in the placebo arm (28.0% vs 4.2% and 31.9% vs 17.0%, respectively). Additionally, 33.3% of patients who were taking HU and treated with crizanlizumab 5.0mg/kg were SCPC event-free during the study, compared with 17.5% in the placebo arm, possibly suggesting an additive effect.

Summary/Conclusions: Treatment with crizanlizumab 5.0mg/kg appears to increase the likelihood of adult patients with SCD being SCPC event-free while on treatment, even in high-risk subpopulations. Crizanlizumab 5.0mg/kg was also effective in those who had experienced at least two SCPCs in the previous year despite taking HU, suggesting that this dose is effective as a disease-modifying agent that meets an unmet medical need.

S455
FREE IRON IN SERA OF PATIENTS WITH SICKLE CELL DISEASE CONTRIBUTES TO THE RELEASE OF NEUTROPHIL EXTRACELLULAR TRAPS

Aims: To verify the potential therapeutic use of Hpx administration to block NET formation and the occurrence of VOC in human SCD, we aimed to deter-
mine whether ex vivo Hpx addition to human SCD sera would prevent NET formation.

Methods: Patient serum and plasma samples were obtained from 32 incidents of VOC in 24 adult SCD patients, with informed consent. Moreover, steady state samples were obtained at least 4 weeks after discharge from the hospital. Patients having had a blood transfusion in the 3 months prior to admission were excluded. NET formation by human neutrophils from healthy donors was studied using confocal fluorescence microscopy and staining for extracellular DNA with the cell nonpermeable dye Sytox Green. The presence of extracellular DNA that stains positive for citrullinated histone H3 confirmed the formation of NETs (Figure 1A).

Results: Indeed, we found that hemin (ferriprotoporphyrin IX) activated neutrophils to generate reactive oxygen species and release NETs, which was prevented by addition of plasma-derived Hpx. Moreover, exposure of neutrophils to sera from patients with SCD promoted NET formation, which was significantly enhanced during VOC. However, we observed that circulating free heme levels were elevated in SCD patient serum irrespective of disease state, and serum concentrations of Hpx were reduced in both VOC and steady state compared to healthy donor serum. Strikingly, addition of Hpx in supraphysiological concentrations of Hpx were reduced in both VOC and steady state compared to sera from patients with SCD promoted NET formation, which was significantly enhanced during VOC. However, we observed that circulating free heme levels were elevated in SCD patient serum irrespective of disease state, and serum concentrations of Hpx were reduced in both VOC and steady state compared to healthy donor serum. Strikingly, addition of Hpx in supraphysiological concentrations failed to prevent the formation of NETs in all SCD sera tested. We and others (Chen et al. Blood 2014) have found that, in contrast to hemo, protoporphyrin IX does not trigger NET formation, revealing that the iron atom is required for the release of NETs. This observation led us to investigate whether free iron may directly induce NET formation. When neutrophils were exposed to Fe-NTA or serum from a thalassemia patient with iron overload, NETs were formed. Scavenging of free iron by addition of the iron-chelator deferoxamine or the specific iron-binding protein apotransferrin prevented NET release (Figure 1B). Moreover, we found that sequestration of free iron prevented NET formation induced by a subset (6 out of 11 tested), but not all, sera of patients with VOC (Figure 1C and D). In addition, sickled red blood cells (RBCs) are known to bind to neutrophils in vivo. Here, we found that neutrophils released NETs in response to sickled RBCs, even in the presence of Hpx. By contrast, blocking of complement C5 activation completely prevented the formation of NETs when neutrophils were exposed to sickled RBCs (Figure 1E).

Summary/Conclusions: In summary, we observed that sequestration of free iron with these iron binding compounds may be explored therapeutically to prevent or treat VOC development in SCD. Finally, complement activation in the presence of sickled RBCs activates neutrophils to release NETs, which may also contribute to VOC and SCD pathogenesis. Therefore, anti-CS IgG may represent an alternative therapeutic strategy to prevent VOC in SCD.

**PHASE 3 ELOQUENT-2 STUDY: EXTENDED 4-YEAR FOLLOW-UP OF ELOTUZUMAB PLUS LENALIDOMIDE/DEXAMETHASONE VS LENALIDOMIDE/DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA**

1National and Kapodistrian University of Athens School of Medicine, Athens, Greece, 2Winship Cancer Institute, Emory University, Atlanta, United States, 3Queen Elizabeth II Health Sciences Centre and Dalhousie University, Halifax, Canada, 4University Hospital, Nantes, France, 5University Hospital of Salamanca–Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, 6Clínica Universidad de Navarra, Centro de Investigación Médica Aplicada, IDISNA, CIBERONC, Pamplona, Spain, 7Dana-Farber Cancer Institute, Boston, United States, 8Institute of Haematology, Assuta Medical Centers, Tel Aviv, Israel, 9Medical University of Silesia, Katowice, Poland, 10Charles University in Prague and General Teaching Hospital, Prague, Czech Republic, 11Medical University of Lublin, Lublin, Poland, 12Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel, 13CROSS Cancer Institute and University of Alberta, Edmonton, 14Princess Margaret Hospital, Toronto, Canada, 15Ankara University, Ankara, Turkey, 16Bristol-Myers Squibb, Lawrenceville, 17AbbVie Bioresearch-epueics Inc. (ABR), Redwood City, United States, 18University of Tübingen, Tübingen, Germany

Background: Elotuzumab is an immunostimulatory monoclonal antibody that targets SLAMF7, a glycoprotein highly expressed on multiple myeloma (MM) cells and natural killer cells. Elotuzumab exerts a dual effect, directly activating natural killer cells and mediating MM cell death via antibody-dependent cell-mediated cytotoxicity. In a 3-year follow-up of ELOQUENT-2 (NCT01239797), elotuzumab plus lenalidomide/dexamethasone (ELd) demonstrated a sustained 27% reduction in the risk of disease progression/death and an overall survival (OS) trend towards benefit compared with lenalidomide/dexamethasone (Ld) alone in patients with relapsed/refractory (RR) MM (Dimopoulos et al, ASH 2015).

Aims: To evaluate the long-term efficacy and safety of ELd following extended 4-year follow-up (median 46 months).

Methods: RRMM patients with 1-3 prior lines of therapy randomized 1:1 received ELd or Ld in 28-day cycles until disease progression/ unacceptable toxicity or consent withdrawal. Co-primary endpoints were progression-free survival (PFS) and overall response rate (ORR); OS was a secondary endpoint (analysis not prespecified for this data cut) and safety an exploratory endpoint. Written informed consent was obtained for all patients.

Results: In total, 646 RRMM patients were randomized: 321 to ELd and 325 to Ld. At 4-year follow-up (data cut-off: Oct 18, 2016), nearly twice as many patients remained on ELd therapy vs Ld (17% vs 9%). With the extended follow-up, ELd demonstrated a sustained relative improvement of 50% in PFS rates vs Ld (21% vs 14%) and maintained reduction in the risk of progression/death of 29% for ELd vs Ld (all randomized patients: HR 0.71; 95% CI 0.59, 0.86). Patients with terry good partial response (VGPR) (ELd 95 [29%]) had the greatest reduction (35%) in risk of progression/death (HR 0.65; 95% CI 0.46, 0.94). ORR was greater with ELd vs Ld (79% vs 66%) and the duration of response benefit was maintained over time (HR 0.77; 95% CI 0.62, 0.95). Early separation of the Kaplan–Meier survival curves, which remained consistently separated over time, supports a sustained OS benefit in favor of ELd vs Ld (Figure). Grade 3-4 adverse events in ≥5% of patients were generally comparable between ELd and Ld arms–vascular diseases (10% vs 8%; mostly venous-related), second primary malignancies (SPMs; 9% vs 6%) and cardiac disorders (5% vs 8%); the exception was a

Figure 1. OS Kaplan-Meyer Curve (all randomized patients).
slightly higher incidence of infection with ELd (33% vs 26%). Overall rate (any grade) of infection (84% vs 75%) and SPMs (17% vs 11%) was higher for ELd vs Ld. However, exposure to ELd was longer than to Ld (median [Q1, Q3] treatment cycles: 19 [9, 42] vs 14 [6, 25]). Disease progression and infection were major causes of mortality in both arms; however, fewer deaths were reported with ELd vs Ld (165 vs 186).

Summary/Conclusions: At 4 years, ELd has the longest median follow-up of an immuno-oncology agent in MM. The data continue to show that adding elotuzumab to Ld results in durable long-term responses, clinically relevant improvement in PFS, sustained reduction in risk of progression/death, and a survival trend in favor of ELd. Overall, these data continue to support the durability and efficacy of ELd. Updated safety and tolerability, including rate of SPMs, was consistent with previous findings despite longer exposure, with minimal incremental AEs compared with Ld therapy.

S457
A PHASE IB STUDY OF ISATUXIMAB PLUS POMALIDOMIDE (POM) AND DEXAMETHASONE (DEX) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM)

1Mayo Clinic, Phoenix, Arizona, 2Medical Oncology, Dana-Farber Cancer Institute, Boston, 3Levine Cancer Institute, Charlotte, 4Massachusetts General Hospital, Boston, 5Myeloma & Transplant Program, Swedish Cancer Institute, Seattle, United States, 6Sanofi, Vitry-Alfortville, France, 7Sanofi Oncology, Cambridge, United States

Background: Isatuximab (ISA) is an anti-CD38 monoclonal antibody, which kills tumor cells via multiple mechanisms. Here, we report preliminary data from the dose-escalation cohort, and the first 3 patients (pts) of the expansion cohort, of a Phase 1b study of ISA plus Pom/Dex in pts with RRMM (NCT02283775).

Aims: To evaluate combination therapy with ISA plus Pom/Dex in pts with RRMM.

Methods: Pts with RRMM (≥2 prior MM therapies, including lenalidomide and a proteasome inhibitor) were sequentially enrolled to ISA 5 mg/kg, 10 mg/kg, 20 mg/kg (weekly doses, then every 2 wks until disease progression or intolerable toxicity) with Pom 4 mg (Days 1–2, 8, 9, 15, and 22; 20 mg if ≥75 yrs old), in 28-day cycles. An expansion cohort was initiated at ISA 10 mg/kg (plus Pom/Dex) based on preliminary safety, efficacy, and PK data. Primary objective: determine maximum tolerated dose (MTD). All patients were required to provide informed consent.

Results: 26 pts were analyzed (5 mg/kg [n=8]; 10 mg/kg [n=12]; 20 mg/kg [n=6]), median age 65 yrs (42–80 yrs). Median 4.0 (2-11) prior treatment regimens, with 20 (77%) pts refractory to prior immunomodulatory drug therapy. At data cut-off (Nov 8, 2016), median duration of ISA treatment was 19.0 wks and 16 pts remained on treatment. 15 pts at 10 mg/kg discontinued therapy due to adverse events (AEs) (grade [Gr] 5 perforated bowel; Gr 3 infusion-associated reaction [IAR]). Dose-limiting toxicities reported in 1 pt at each dose level (Gr 4 neutropenia; Gr 4 neutropenic infection; Gr 3 confusional state), and MTD has not been reached. Most common TEAEs, besides IARs, were fatigue (62%), diarrhea (54%), constipation (46%), neutropenia (46%), pyrexia (46%), and hypokalemia (44%). Most frequent hematologic toxicity (laboratory assessment) was neutropenia (Gr 3, 40%; Gr 4, 52%), and Gr 3/4 thrombocytopenia was reported in 8 (32%) pts (Gr 3, 16%; Gr 4, 16%). IARs occurred in 12 (46%) pts (Gr ≥3 in 1 pt); only with 1st infusion in 9/12 pts. 16 (62%) pts remained on treatment. 2 pts at 10 mg/kg discontinued therapy due to adverse events (AEs), and 1 pt at 20 mg/kg discontinued due to disease progression or intolerable toxicity. Median time to first response, 4.2 wks; median duration of response, 25.6 wks. The PK parameters of ISA were not affected by co-administration with Pom/Dex.

Summary/Conclusions: The combination of ISA and Pom/Dex was manageable and clinically active in heavily pretreated RRMM. A Phase III trial of this combination is ongoing.

S458
OVERALL SURVIVAL OF PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA TREATED WITH CARFILZOMIB AND DEXAMETHASONE VERSUS BORTEZOMIB AND DEXAMETHASONE IN THE RandONIZED PHASE 3 ENDEAVOR TRIAL

1MRC Clinical Trials Unit, London, United Kingdom, 2Sanofi, Vitry-Alfortville, France, 3Institut Català d'Oncologia, Institut Josep Carreras, Hospital Germans Trias i Pujol, Barcelona, Spain, 4Irmandade Da Santa Casa De Misericordia de São Paulo, São Paulo, Brazil, 5University Medical Center of the Johannes Gutenberg-University, Mainz, Germany, 6Winship Cancer Institute, Emory University, Atlanta, GA, 7Weill Cornell Medical College, New York, NY, United States, 8University of Melbourne, St. Vincent's Hospital, Melbourne, Australia, 9Janssen Research & Development, Raritan, NJ, United States

Background: Daratumumab is a human monoclonal antibody targeting CD38 that induces deep and durable responses with significant clinical benefit and is well tolerated as monotherapy and in combination with established standard-of-care regimens in patients with RRMM. Here, we provide updated safety data from CASTOR, a multicenter, phase 3, randomized, active-controlled study of Daratumumab in combination with pomalidomide and dexamethasone in patients with relapsed or refractory multiple myeloma (NCT02707478) that met its primary endpoint of significantly longer median progression-free survival (PFS) with Daratumumab plus Pom/dex (Daratumumab plus Pom/dex vs Pom/dex; HR 0.648-0.964; 1-sided P<0.0001; Dimopoulos MA et al. Lancet Oncol. 2016;17:27-38).

Methods: Eligible patients with ≥2 prior lines of therapy were randomly assigned to 8 cycles (every 3 weeks) of Vd (1.3mg/m2 SC bortezomib on Days 1, 4, 8, 11)
and 11; 20mg PO/IV dexamethasone on Days 1-2, 4-5, 8-9, and 11-12) with or without daratumumab (18mg/kg IV once weekly in Cycles 1-3, every 3 weeks for Cycles 4-8, then every 4 weeks until progression). Patients who were refractory to bortezomib were excluded. Progression-free survival (PFS) was the primary endpoint. Minimal residual disease (MRD) was assessed at suspected complete response (CR) and at 6 and 12 months after first dose at 3 sensitivity thresholds (10^{-4}, 10^{-5}, and 10^{-6}) using the ClonoSEQ™ next-generation sequencing (NGS)-based assay (Adaptive Biotechnologies, Seattle, WA).

**Results:** A total of 498 patients were randomized with median (range) age of 64 (30-88) years. Patients received a median (range) of 2 (1-10) prior lines of therapy; 66% of patients previously received bortezomib, and 21% were refractory to lenalidomide in their last prior line of therapy. After median follow-up of 13.0 months, DVD significantly prolonged PFS compared with Vd alone (median: not reached vs 7.1 months; hazard ratio [HR], 0.33; 95% confidence interval [CI], 0.26-0.43; P<0.0001). Twelve-month PFS rates were 60% versus 22%, respectively. Signicant PFS benefit was observed with DVD over Vd regardless of the number of prior lines of therapy, although the greatest benefit was seen in patients with 1 prior line of therapy (median: not reached vs 7.9 months; HR, 0.22; 95% CI, 0.14-0.34; P=0.0001). Overall response rate (ORR; 84% vs 63%) and rates of very good partial response (VGPR) or better (62% vs 29%) were grade 3 or 4 treatment-emergent adverse events. The most common grade 3 or 4 AEs in ≥2 pts were febrile neutropenia, thrombocytopenia, cardiac failure, pneumonia, sepsis, acute kidney injury, respiratory failure, embolism, and hypotension. Dose-limiting toxicities were grade 3 cardiac failure in the 300mg cohort (possibly related to dexamethasone) and grade 3 thrombocytopenia during the first cycle in the safety expansion. No events of laboratory or clinical TLS were reported. Four deaths were due to PD and 1 due to respiratory syncytial virus infection. Overall response rate (ORR) for all pts was 67% (44/66); 28% (42%) achieved very good partial response (VGPR) or better (3 stringent complete response [sCR], 10 CR, 15 VGPR). Pts non-refractory to prior proteasome inhibitors (PI) or immunomodulatory drugs (IMiDs) had higher ORR than refractory pts (PI, 92% vs 72%; IMiDs, 82% vs 57%). Among pts refractory to any 2 or more (n=15), 3 or more (n=7), or all 4 (n=4) prior therapies (bortezomib, carfilzomib, lenalidomide, pomalidomide), ORR was 40%, 43%, and 25%, respectively. Median time to progression (~10 vs 3 months) and duration of response (~10 vs 7 months) were longer for pts not refractory to any of these therapies versus refractory pts. ORR for pts with or without cytogenetic abnormalities, respectively, was as follows: 78% vs 65% for t(11;14), 60% vs 67% for t(4;14), 47% vs 73% for del(17p), and 63% vs 69% for del(13q).

**Summary/Conclusions:** VEN combined with bortezomib and dexamethasone has an acceptable safety profile with promising anti-myeloma activity, and the highest response rates were observed in R/R MM pts who were not refractory to PI or IMiDs. These data support the ongoing phase 3 trial with this regimen in R/R MM.

---

**Aims:** The objectives of the study are to evaluate safety and preliminary efficacy of VEN with bortezomib and dexamethasone in relapsed/refractory (RR) MM.

**Methods:** Phase 1b study of patients (pts) with R/R MM who received daily VEN (50-1200mg for dose escalation cohorts; 800mg in safety expansion) with standard bortezomib (1.3mg/m² SC) and dexamethasone (20mg PO).

**Results:** As of 19Aug2016, 86 pts were enrolled. Median age was 64 years; 9 (14%) pts had t(11;14), 5 (8%) had t(4;14), 15 (23%) had del(17p), and 30 (45%) had del(13q) abnormalities. Median number of prior therapies was 3 (range: 1-13), with 39% of pts refractory to prior bortezomib, 14% to carfilzomib, 53% to lenalidomide, and 21% to pomalidomide. Median time on study was 5.9 months (range: 0.3–29.8). Forty-six (70%) pts discontinued, with 36 due to disease progression (PD). Common AEs in ≥30% of pts were diarrhea (46%), constipation (41%), thrombocytopenia (39%), nausea (38%), peripheral neuropathy (33%), and insomnia (32%). Common grade 3/4 AEs in ≥10% of pts were thrombocytopenia (29%), anemia (15%) and neutropenia (14%). Serious AEs in ≥2 pts were febrile neutropenia, thrombocytopenia, cardiac failure, pyrexia, influenza, lower respiratory tract infection, pneumonia, sepsis, acute kidney injury, respiratory failure, embolism, and hypotension.

**Background:** Venetoclax (VEN) is a potent, selective, orally bioavailable small-molecular inhibitor of BCL-2. When combined, VEN can enhance the activity of bortezomib in multiple myeloma (MM) cell lines and xenograft models.
Improving prognostication and front-line therapy in chronic lymphocytic leukemia

**S461**

CYTOSTEGENIC COMPLEXITY IN CHRONIC LYMPHOCYTIC LEUKEMIA: DEFINITIONS, ASSOCIATIONS WITH OTHER BIOMARKERS AND CLINICAL IMPACT: A RETROSPECTIVE STUDY ON BEHALF OF ERIC V. B. F. PILLOWS

department of internal medicine - hematology and oncology, University Hospital, Brno and faculty of medicine, Masaryk University, Brno, Czech Republic, Institute of applied biology, cytogenetics and pathology, science for life laboratory, uppsala university, uppsala, Sweden, & Institute of applied biology - hematology and oncology, Masaryk university, Brno, Czech republic.

**Methods**: 3580 CLL and monoclonal B-cell lymphocytosis (MBL) patients (CLL=3322, 93% and MBL=258, 7%, respectively) were analysed with CpG-oligodeoxynucleotides/interleukin 2 (CpG/IL2, n=379, 11%), phorbol-12-myristate-13-acetate (TPA, n=1846, 52%) or both (n=1355, 37%). CBA was mostly performed within the first year from diagnosis and before treatment administration (79% and 88%, respectively). Main features of the studied cohort: median age: 65.6 years/male: 2252 (63%)/Binet A/B/C: 2356/357/258.

**Results**: Following the current definition for CK and no unfavorable cytogenetics (79% and 57%, respectively). The median OS was 5.1 years for the high-CK vs intermediate-CK', n=82, 22% and ≥5 (high-CK', n=99, 29% abberations). High-CK cases were stratified into those with 3 (low-CK, n=200, 52%), 4 (intermediate-CK', n=82, 22%) and ≥5 (high-CK', n=99, 29%) aberrations.

**Background**: Recent evidence suggests that complex karyotype (CK) identified by chromosome banding analysis (CBA) may be a relevant biomarker for treatment decisions in CLL, especially regarding the response to signaling inhibitors. However, many challenges towards routine clinical application of CBA still need to be overcome.

**Aims**: The aim of this study was to analyse the outcome of M-CLL patients with no unfavorable cytogenetics CBA according to the type of therapy.

**Methods**: We analysed 816 CLL patients from Sant Pau Hospital, Barcelona, Spain; Uppsala University Hospital, Sweden and IRCCS San Raffaele Scientific Institute, Milan, Italy for whom IGHV mutational status was available. Endpoints were OS and TFS.

**Table 1.**

<table>
<thead>
<tr>
<th>Table 1.</th>
<th>Clinical and biological characteristics of patients with mutated or unmutated IGHV by CK</th>
</tr>
</thead>
<tbody>
<tr>
<td>CK</td>
<td>(n=98)</td>
</tr>
<tr>
<td>No CK</td>
<td>(n=228)</td>
</tr>
</tbody>
</table>

**Results**: 488 patients had mutated IGHV genes (400 without unfavorable FISH cytogenetics; 26 had either del(11q) and/or del(17p), and in 62 cases FISH was not available) and 328 patients carried unmutated IGHV genes. The main clinical and biological characteristics at diagnosis are shown in Table 1. OS at 5 and 10 years was 93% (CI, 95-91) and 81% (CI, 85-77) for M-CLL cases and 78% (CI, 83-73) and 65% (CI, 52-38) for U-CLL cases (p<0.05). TFS at 5 and 10 years was 78% (CI, 83-73) and 72% (CI, 61-66) and 28% (CI, 33-23) and 10% (CI, 14-6) for M-CLL and U-CLL, respectively (p<0.05). After a median follow-up of 8 years (range, 1-26), 424 patients [161 M-CLL (136 without poor-prognostic FISH cytogenetics, 13 with either del(11q) and/or del(17p) and 12 cases in whom FISH information was not available) and 263 U-CLL] required therapy. Front-line treatment consisted of purine analogues (PA)-based therapy (n=85), alkylating agents (n=212), anti-CD20 moAbs with PA or bendamustine (n=75), anti-CD20 moAbs with alkylating agents (n=21), BCR-signal inhibitors or BCL2 antiapoptotic agents (n=9), others (n=23), and unknown (n=1).
median duration of response to first therapy was 42 months (range, 33-52) in M-CLL cases vs 24 months (range, 18-30) in U-CLL patients (p<0.001). 282 patients received a second line of therapy: PA-based therapy (n=95), alkylating agents (n=82), anti-CD20 MoAbs with PA or bendamustine (n=33), anti-CD20 MoAbs with alkylating agents (n=16), BCR-signal inhibitors or BCL2 antiprototic agents (n=12), others (n=59), and unknown (n=5). In 481 of 816 patients in whom detailed information on treatment regimens beyond second-line was available, 99 patients received a third-line treatment including PA-based therapy (n=15), alkylating regimens (n=20), anti-CD20 MoAbs with PA or bendamustine (n=15), anti-CD20 MoAbs with alkylating agents (n=8), BCR or BCL2 inhibitors (n=11), others (n=28) and unknown (n=2); 49 patients received four or more lines of therapy. In M-CLL patients with poor FISH cytogenetics (n=136) the type of therapy for 1st primary endpoint patients’ outcome. Thus, the median survival was not reached in patients treated with CIT as first-line (i.e FCR, BR) as compared to 202 months in those not having received CIT (p=0.317). In contrast, in U-CLL patients the OS was highly dependent on the type of therapy. In detail, U-CLL patients who received anti-CD20 MoAbs with PA or bendamustine either as first line or subsequent lines (60 of 120 patients) showed significantly longer survival than those who did not receive these therapeutic regimens (median survival: 173 vs 103 months, p=0.001). On the contrary, in M-CLL cases no differences in survival were observed in those receiving anti-CD20 MoAbs with PA or bendamustine vs who did not (p=0.358).

Summary/Conclusions: This retrospective study suggests that OS of CLL patients with mutated IGHV genes and no unfavorable FISH cytogenetics do not depend on the type of therapy. This has important clinical implications and provides background for randomized studies aimed at identifying the optimal treatment strategy for this group of patients.

IBRUTINIB IN CLL PATIENTS WITH CHRONIC LYMOPHOCYTIC LEUKAEMIA (CLL) MUTATED IGHV AND NON-DEL(17P)

N. Jain1,2, P. Thompson1, J. Burger1, G. Borthakur1, P. Bose1, Z. Estrov1, A. Ferrajoli1, V. Gandhi1, W. Plunkett2, W. Lopez1, H. Kantarjian3, S. O’Brien3, M. Keating1, W. Wierda1

Leukaemia, Experimental Therapeutics, MD Anderson Cancer Center, Houston, Texas, United States

Background: Patients with mutated IGHV (IGHV-M) have favorable long-term outcomes (10-year PFS of >60%) after receiving first-line FCR. Aims: To develop an FC-based chemoimmunotherapy regimen of finite duration that included ibritinib and obinutuzumab (iFCG) for previously untreated CLL patients. Methods: We designed an investigator-initiated phase II trial with ibritinib, fludarabine, cyclophosphamide, and obinutuzumab (iFCG) for previously untreated CLL patients (NCT02629809). The intent was to limit FC to 3 courses, potentially reducing short- and long-term toxicity, while maintaining efficacy through the addition of ibritinib and a more potent antibody (obinutuzumab). Primary endpoint analysis is based on uncleaned data, the final analysis will be presented at the EHA meeting. Results: Between May 2015 and January 2016, 66 pts were enrolled. Two (29%) pts immediately started with the induction. 60 pts completed 6 induction courses. Pt enrollment continues, and updated results will be presented at the EHA meeting.

</table>

Summary/Conclusions: iFCG achieves high rate of MRD-neg remission after 3 courses. Pt enrollment continues, and updated results will be presented at the EHA meeting.
ed (table 1); with an ORR of 97%, at the end of induction, the primary endpoint was met. MRD negativity (<10^-4) by flow cytometry in peripheral blood (pB) was achieved in 56 pts (89%); MRD assessment from bone marrow was available in 8 pts (4 TN and 4 R/R, among them 4 with a CR and 4 with a PR) and were all negative. As of January 9th 2017, 83 serious adverse events (SAEs) were reported in 37 pts, including 69 SAEs (83%) related to study treatment. 66 pts (80%) were GCT3-4 and 1 had a fatal AEs (related to disease progression (DR)). Most SAEs occurred in the R/R cohort (61 SAEs, 74%) and during the induction phase (63 SAEs, 76%). Most common SAEs were infections (27 in 16 pts; including 13 CTC°3-5) and hematological disorders (18 in 10 pts; CTC°3-4), followed by infusion-related reactions (6 in 6 pts), laboratory TLS in 5 pts, during debulking. 1 in induction cycle 1 with G, 2 in cycle 3 and 1 in cycle 4 with G and A) and ischemic coronary artery disorders (5 in 4 pts). No clinical TLS occurred.

Summary/Conclusions: With an ORR of 97% and a MRD negativity rate of 89%, at the end of induction, the primary endpoint of B de
dubling, followed by G and A was very efficacious in a heterogeneous study population and well tolerated excepted for 3 fatal septicamias in R/R pts.

SAFETY RESULTS OF TERMINATED PHASE 2 STUDY OF IDELISIB PLUS CHROMOPLASMONIC CAR T CELLS FOR NON-HODGKIN Lymphoma (TCL) WITH DEL(17P) in 8 pts of the study. The study was terminated in March 2017, leaving 8 pts after dosing of the last enrolled pt. 77 pts (75.5%) remained on study at the time of study termination. The reasons for discontinuation from study were death (4 in 4 pts), investigator discretion (3 in 3 pts), and unplanned withdrawal of consent (2.9%), other anticancer therapy (2.0%), and lost to follow up (1.0%). The investigator assessed response rate was 79%. 101 pts (99%) had adverse events (AEs); Gr ≥ 3 occurred in 80.4%, the most frequent Gr ≥3 AEs were neutropenia (27.5%), diarrhea (20.6%), infections (18.6%), and diarrhea (14.7%). Laboratory Gr ≥ 3 ALT and/or AST elevations were seen in 41.2%, with med time of onset of 8.1 wks (range 4.1-24.1). The med age of pts both with and without Gr ≥ 3 ALT/AST was 66 years, and the incidence of Gr ≥ 3 ALT/AST was similar in younger (43.9%, <65yr) and older (39.3%, ≥65yr) pts. Gr ≥3 diarrhea/collitis occurred in 17.1% of pts <65yr and in 14.8% of pts ≥65yr. Gr ≥3 fatigue occurred in 19% of pts, 1 fatality was reported and 1 discontinuation due to fatigue (1.2%). Other frequent AEs were febrile neutropenia (2.9%), and encephalopathy (2.1%), Gr ≥ 3 cytokine release syndrome ( CRS) and neurologic events (NE) occurred in 13% and 28% of pts, respectively. All CRS and all NE resolved except 1 Gr 1 memory impairment. As previously reported, there were 3 Gr 5 AEs (3%). Peak CAR T levels and AUC respectively. All CRS and all NE resolved except 1 (Gr 1 memory impairment). As previously reported, there were 3 Gr 5 AEs (3%). Peak CAR T levels and AUC post-axi-cel were associated with durable responses. Additionally, this pres-entation will include an expanded analysis of efficacy outcomes by novel bio-
logic and clinical covariates including key molecular phenotypes and tlocizum-
ab/corticosteroid interventions used for management of adverse events.

Summary/Conclusions: Axi-cell significantly improved ORR in patients with refractory aggressive NHL. The CR rate was 7-fold higher compared to histor-
cal controls (Crump, ASCO 2016) and nearly half the patients had an ongoing response. Axi-cell demonstrated significant clinical benefit with a manageable se-
riety profile in pts lacking curative treatment options.

1In Lee Moffitt Cancer Center & Research Institute, Tampa. 2The University of Texas MD Anderson Cancer Center, Houston, 3St. Louis. 4University of Miami, Miami, 5Stanford University, Stanford, 6Dana-Farber Cancer Institute, Boston, 7Montefiore Medical Center, Bronx, 8Vanderbilt University Medical Center, Nashville, 9City of Hope, Duarte, 10Mayo Clinic, Rochester, 11University of California at Los Angeles, Los Angeles, 12University of Rochester School of Medicine, Rochester, 13Kite Pharma, Santa Monica, United States

Background: Outcomes for pts with refractory aggressive NHL are poor with current therapies (Crump, ASCO 2016). Results from the interim analysis of (n=62) patients with refractory aggressive NHL, showed a median PFS of 13.8 months (95% CI 8.7-23.7). The CR rate was 7-fold higher compared to historical controls (Crump, ASCO 2016) and nearly half the patients had an ongoing response. Axi-cell demonstrated significant clinical benefit with a manageable safety profile in pts lacking curative treatment options.

CC-122 IN COMBINATION WITH OBINUTUZUMAB (GA101): PHASE IB STUDY IN RELAPSED OR REFRACTORY PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA, FOLLICULAR LYMPHOMA, OR MARGINAL ZONE LYMPHOMA

1Institut Gustave Roussy, Villejuif, 2Institut Paoli-Calmettes, Marseille, France, 3Erasmus MC Cancer Institute, Rotterdam, 4On behalf of the LLPC (Lunenburg
Background: CC-122 is a cereblon modulating agent that degrades Aiolos and Ikaros, resulting in potent anti-lymphoma and immunomodulatory effects on T- and NK-cell function. Phase I clinical data revealed promising activity of CC-122 against follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL). Preclinical combination of CC-122 with obinutuzumab has shown synergism in FL and additive effects in DLBCL vs either single agent (Chiu. ASH 2015), supporting further study of this combination’s therapeutic potential.

Aims: To best response was 57 d, and median duration of response was not yet reached. In evaluable patients, 6-mo progression-free survival (PFS) was 63%.

Table 1.

Summary/Conclusions: The combination of CC-122 and obinutuzumab was well tolerated and demonstrates promising response rates and durable remissions in R/R patients with B-cell NHL. CC-122 doses of ≥3mg and obinutuzumab were neutropenia (50%) and thrombocytopenia (21%). Fifteen patients (44%) had ≥1 serious TEAE. The most common (≥10%) grade 3/4 treatment-emergent AEs (TEAEs) were neutropenia (50%) and thrombocytopenia (21%). Fifteen patients (44%) had ≥1 serious TEAE, including 2 each of febrile neutropenia (related to CC-122), cytokine release syndrome (related to obinutuzumab), and pneumonia. Three deaths occurred during the study (2 PD; 1 AE-related). Overall response rate (ORR) was 59%, including 26% CR and 32% PR (Table 1). Median time to best response was 57 d, and median duration of response was not yet reached. In evaluable patients, 6-mo progression-free survival (PFS) was 63%.

Table 1.

Summary/Conclusions: The combination of CC-122 and obinutuzumab was well tolerated and demonstrates promising response rates and durable remissions in R/R patients with B-cell NHL. CC-122 doses of ≥3mg and obinutuzumab have shown best response rates to date. The study is ongoing to establish the phase II recommended dose.

Table 1.  

Summary/Conclusions: Updated evaluation of pola + BR shows promising durable responses and an acceptable safety profile in heavily pre-treated R/R FL and DLBCL pts. Safety and efficacy data will be updated at the time of presentation.

**POLATUZUMAB VEDOTIN PLUS BENDAMUSTINE AND RITUXIMAB OR OBINUTUZUMAB IN RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA OR DIFFUSE LARGE B-CELL LYMPHOMA: UPDATED RESULTS OF A PHASE 1B/2 STUDY**

1Memorial Sloan Kettering Cancer Center, New York, 2City of Hope, Duarte, 3University of Colorado, Denver, 4Department of Medicine, University of Birmingham, Birmingham, United States, 5Jewish General Hospital, 6Department of Hematology, Maisonneuve-Rosemont Hospital and University of Montreal, Montreal, Canada, 7Seoul National University Hospital, 8Samsung Medical Center, Seoul, Korea, Republic Of, 9Hospital Universitari Vall d’Hebron, Barcelona, Spain, 10Manchester Academic Health Science Centre, The University of Manchester and the Christie NHS Foundation Trust, Manchester, United Kingdom, 11Winship Cancer Institute of Emory University, Atlanta, United States, 12Roche, Shanghai, China, 13Genentech Inc., South San Francisco, United States, 14BC Cancer Agency, Vancouver, Canada

Background: Transplant ineligible patients (pts) with relapsed/refractory (R/R) FL or DLBCL have poor outcomes. Polatuzumab vedotin (pola) is an antibody drug conjugate that targets delivery of the microtubule inhibitor MMAE to cells expressing CD79b. Pola + rituximab (R) previously showed promising responses in R/R FL and DLBCL. Aims: The primary aim is to assess safety and tolerability of pola + BR/BG in R/R FL and DLBCL. Secondary aims include assessing safety and efficacy of pola + BG in an expansion cohort.

Methods: All pts provided informed consent to participate in the study and were treated with pola (1.5mg/kg) + B (90mg/m2) and R (375mg/m2) or G (1000mg) every 28 days (FL) or 21 days (DLBCL) for 6 cycles. Responses were assessed by modified Lugano criteria after 3 cycles, end of treatment (tx), and every 6 months for 2 years during follow-up (fu).

Results: As of 14 Nov 2016, 65 pts were enrolled: 24 pts (12 FL, 12 DLBCL) in P1b and 41 pts (20 FL and 21 DLBCL) in P2. In safety evaluable pts, FL pts (N=32) were median age of 63 yr (37-86), 82% ECOG 0-1 and 3% 1-2. In DLBCL, pts (N=32) were median age 66 (30-86), 88% ECOG 0-1 and 12% ECOG 2-3, 73% Stage III/IV, 5% 1-2. In FL pts, ORR was 65%, including 26% CR and 39% PR. Median time to best response was 57 d, and median duration of response was not yet reached. In evaluable patients, 6-mo progression-free survival (PFS) was 63%.

**POLATUZUMAB VEDOTIN PLUS BENDAMUSTINE AND RITUXIMAB OR OBINUTUZUMAB IN RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA OR DIFFUSE LARGE B-CELL LYMPHOMA: UPDATED RESULTS OF A PHASE 1B/2 STUDY**

1Memorial Sloan Kettering Cancer Center, New York, 2City of Hope, Duarte, 3University of Colorado, Denver, 4Department of Medicine, University of Birmingham, Birmingham, United States, 5Jewish General Hospital, 6Department of Hematology, Maisonneuve-Rosemont Hospital and University of Montreal, Montreal, Canada, 7Seoul National University Hospital, 8Samsung Medical Center, Seoul, Korea, Republic Of, 9Hospital Universitari Vall d’Hebron, Barcelona, Spain, 10Manchester Academic Health Science Centre, The University of Manchester and the Christie NHS Foundation Trust, Manchester, United Kingdom, 11Winship Cancer Institute of Emory University, Atlanta, United States, 12Roche, Shanghai, China, 13Genentech Inc., South San Francisco, United States, 14BC Cancer Agency, Vancouver, Canada

Background: Transplant ineligible patients (pts) with relapsed/refractory (R/R) FL or DLBCL have poor outcomes. Polatuzumab vedotin (pola) is an antibody drug conjugate that targets delivery of the microtubule inhibitor MMAE to cells expressing CD79b. Pola + rituximab (R) previously showed promising responses in R/R FL and DLBCL. Aims: The primary aim is to assess safety and tolerability of pola + BR/BG in R/R FL and DLBCL. Secondary aims include assessing safety and efficacy of pola + BG in an expansion cohort.

Methods: All pts provided informed consent to participate in the study and were treated with pola (1.5mg/kg) + B (90mg/m2) and R (375mg/m2) or G (1000mg) every 28 days (FL) or 21 days (DLBCL) for 6 cycles. Responses were assessed by modified Lugano criteria after 3 cycles, end of treatment (tx), and every 6 months for 2 years during follow-up (fu).

Results: As of 14 Nov 2016, 65 pts were enrolled: 24 pts (12 FL, 12 DLBCL) in P1b and 41 pts (20 FL and 21 DLBCL) in P2. In safety evaluable pts, FL pts (N=32) were median age of 63 yr (37-86), 82% ECOG 0-1 and 6% ECOG 2-3, 84% Stage III/IV, 2% 1-2. In DLBCL, pts (N=32) were median age 66 (30-86), 88% ECOG 0-1 and 12% ECOG 2-3, 73% Stage III/IV, 5% 1-2. In FL pts, ORR was 65%, including 26% CR and 39% PR. Median time to best response was 57 d, and median duration of response was not yet reached. In evaluable patients, 6-mo progression-free survival (PFS) was 63%.

Table 1.
Background: Patients (pts) with persistent DLBCL after two or more lines of therapy have limited effective treatment options. The nuclear export protein exportin 1 (XPO1) is upregulated in hematologic malignancies, including DLBCL, and has pleiotropic effects on tumorigenesis including functional downregulation of tumor suppressor proteins (TSPs) and increased export and translation of mRNAs for oncoproteins c-Myc and key survival proteins such as Bcl-2. Selinexor (SEL), an oral XPO1 inhibitor, causes sequestration of TSPs including p53, p21, and IkBα, the latter of which serves to suppress NF-κB driven transcription, along with reductions in c-Myc and Bcl-2 family proteins. In a Phase I clinical study, pts with relapsed/refractory (R/R) DLBCL treated with SEL biweekly doses of 60 or 100mg demonstrated promising efficacy and safety. Herein, we report an update from this ongoing phase II study.

Methods: Pts with R/R DLBCL were randomized to 60 or 100mg of SEL twice weekly (8 doses) per 28-day cycle. Cycles were stratified by prior lines of therapy; 23% had rituximab refractory disease; 74% had Ann Arbor stage III/IV disease; 65% had elevated lactate dehydrogenase level, and 52% had a poor revised International Prognostic Index (3–5).

Results: 72 pts were enrolled: 37 pts on 60mg (24 M/13 F, median age 71 yrs) and 35 pts on 100mg (23 M/12 F, median age 68 yrs). Both groups had a median of 3 prior treatment regimens.

Summary/Conclusions: The combination of MOR208 plus LEN is well tolerated and shows promising activity in patients with R-R DLBCL. Accrual and follow-up of patients is ongoing, as are cell of origin and other biomarker analyses.
Targeted treatment of AML

S471

ENASIDENIB (AG-221) IN MUTANT-IDH2 RELAPSED OR REFRACTORY ACUTE MYELOID LEUKAEMIA (R/R AML): RESULTS OF A PHASE 1 DOSE-ESCALATION AND EXPANSION STUDY

1Memorial Sloan Kettering Cancer Center, 2Weill Cornell Medical College, New York, 3University of Texas MD Anderson Cancer Center, Houston, 4University of Colorado School of Medicine, Aurora, 5Massachusetts General Hospital Cancer Center, 6Harvard Medical School, Boston, 7New York Presbyterian Hospital, New York, 8Robert H. Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, 9Dana-Farber Cancer Institute, Boston, 10Sarah Cannon Research Institute, Nashville, 11University of Texas Southwestern Medical Center, Dallas, 12Florida Cancer Specialists and Sarah Cannon Research Institute, Sarasota, 13City of Hope Comprehensive Cancer Center, Duarte, 14Cleveland Clinic Taussig Cancer Institute, Cleveland, 15Sylvester Comprehensive Cancer Center, University of Miami, Miami, 16Stanford Comprehensive Cancer Center, Stanford University, Stanford, 17Celgene Corporation, Summit, 18Agios Pharmaceuticals, Inc., Cambridge, United States, 19Institut Gustave Roussy, Villejuif, France

Background: Recurrent mutations in isocitrate dehydrogenase 2 (mIDH2) occur in ~12% of AML patients (pts), mIDH2 proteins synthesize an oncometabolite, 2-hydroxylutarate (2HG), causing DNA and histone hypermethylation and blocked myeloid differentiation. Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of mIDH2 proteins. Differentiation of myeloblasts, not cytotoxicity, appears to drive the clinical efficacy of enasidenib. In preclinical studies, bone marrow blasts from pts with mIDH2 exposed to enasidenib ex vivo were shown to produce mature, fully functioning neutrophils with conserved mIDH2 allele frequency, indicating differentiation of mature cells from the mIDH2 blasts (Yen et al, Cancer Discov, 2017). Additionally, no apoptosis was observed in mIDH2-R140 erythroleukemia (TF-1) cells treated with enasidenib for 7 days in vitro.

Aims: Evaluate the maximum tolerated dose (MTD), pharmacokinetic (PK) and pharmacodynamic (PD) profiles, safety, and clinical activity of enasidenib in pts with mIDH2 defined AML, or with mIDH2 M5 with refractory anemia with excess blasts, and ECOG PS scores ≤2. Pts were relapsed or refractory (R/R) to prior anti-cancer therapy, or had untreated AML if aged ≥60 years and not eligible for standard-of-care treatment (Tx). Safety for all pts and clinical efficacy in the largest pt subgroup, those with R/R AML, from the phase 1 dose-escalation and expansion phases are reported.

Results: In all, 239 pts received enasidenib. Median age was 70 ys. In the dose-escalation phase (n=113), pts received daily enasidenib doses of 50-650mg. The MTD was not reached. Median 2HG reductions from baseline at cycle 2 day 1 were 92%, 90%, and 93% for pts receiving <100mg, 100mg, and >100mg/day, respectively. Enasidenib 100mg QD was chosen for the expansion phase (n=126) based on PK/PD profiles and demonstrated efficacy. Median number of enasidenib cycles was 5 (range 1-25). Grade 3-4 investigator-reported Tx-related adverse events included indirect hyperbilirubinemia (12%) and IDH-inhibitor-associated differentiation syndrome (IDH-DS; ie, retinoic acid syndrome) (7%). Of 176 R/R AML pts, 94 (53%) had received ≥2 prior AML-directed therapy. Overall response rate (ORR; complete remission [CR] + CR with incomplete response [CRi] + complete remission-remission with incomplete counts restoration in R/R AML pts was 40.3%, including 34 pts (19.3%) who attained CR (Table). Median time to 1st response was 1.9 months (mos); 87.3% of responding pts attained a 1st response by cycle 5. Median response duration was 5.8 mos. Of pts who achieved CR, 7 pts (21%) did so by cycle 3, 23 (88%) by cycle 5, and 28 (82%) by cycle 7. Median duration of CR was 8.8 mos. ORR with enasidenib 100mg/day was 38.5% (Table). Seventeen pts (11%) proceeded to stem cell transplant. Response was associated with cellular differentiation, typically with no evidence of aplasia. Median overall survival (OS) of R/R AML pts was 9.3 mos. For pts who attained CR, OS was 19.7 mos. Pts who had received ≥2 prior AML Tx had a median OS of 8.0 mos.

Summary/Conclusions: Enasidenib was well tolerated, induced CRs in R/R AML pts, and was associated with OS of >9 mos in pts who had failed prior AML Tx. A randomized phase 3 study of enasidenib vs conventional care in older pts with late-stage R/R AML is ongoing (NCT02577406).

S472

SAFETY AND EFFICACY OF VENETOCLAX (VEN) IN COMBINATION WITH DECITABINE OR AZACITIDINE IN TREATMENT-NAIVE, ELDERLY PATIENTS (≥26 YEARS) WITH ACUTE MYELOID LEUKAEMIA (AML)

1Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, 2University of Colorado School of Medicine, Aurora, 3UC Davis Comprehensive Cancer Center, Sacramento, 4Department of Hematology and Hematopoietic Cell Transplantation and Gehr Family Center for Leukemia Research, City of Hope National Medical Center, Duarte, United States, 5The Alfred Hospital, and Monash University, Melbourne, Australia, 6Emory University, Atlanta, 7Division of Hematology, University of Washington and Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, 8Northwestern University Feinberg School of Medicine, 9University of Chicago Medical Center, Chicago, United States, 10Centre Hospitalier Universitaire (CHU) de Bordeaux, INSERM U1035, University of Bordeaux, Bordeaux, 11Institut Universitaire de Cancer de Toulouse Oncopole, CHU de Toulouse and Université de Toulouse III, Toulouse, France, 12Peter MacCallum Cancer Centre, Melbourne, Australia, 13AbVie Inc., North Chicago, 14Dana-Farber Cancer Institute, Boston, 15University of Texas MD Anderson Cancer Center, Houston, United States

Background: Newly diagnosed patients (pts) with AML aged ≥65 years and ineligible for standard induction therapy have limited treatment options, and low overall survival. VEN is an orally bioavailable, selective BCL-2 inhibitor that has displayed single-agent activity in pts with relapsed/refractory AML. VEN at escalating doses combined with low-dose ara-C demonstrated antileukemic activity, with an overall response rate (ORR) including complete remission (CR), and CR with incomplete marrow recovery of 60%. Combining VEN with HMAs, such as decitabine (DEC) or azacitidine (AZA), may provide a novel low-intensity approach for treating AML. Preliminary results from the expansion stage of a phase 1b trial comparing 2 doses of VEN plus either DEC or AZA (NCT02203773) are reported.

Aims: To evaluate the safety and efficacy of VEN at 400-mg vs 800-mg doses plus DEC or AZA.

Methods: This open-label, nonrandomized, two-stage phase 1b study evaluated the safety and efficacy of VEN plus DEC or AZA in treatment-naive pts aged ≥65 years with AML. Eligibility included: ECOG PS ≤2; eligible for standard induction therapy; intermediate- or poor-risk karyotype. Pts received DEC (Arm D, 20mg/m²/day [d]; intravenous [IV]) on d 1–5, or AZA (Arm E, 75mg/m²/d; subcutaneous or IV) on d 1–7 of each 28-d cycle (C) in combination with once-daily oral VEN. The dose-expansion stage consisted of 2 VEN dose cohorts (continuous 400-mg and interrupted 800-mg dosing) in each arm (D1, D2, E1, and E2, respectively) to determine optimal dose. Tumor lysis syndrome (TLS) prophylaxis was administered in C to all pts during VEN dose-ramp up until final dose was reached. All pts provided informed consent.
Results: As of 13/09/16, 100 pts were enrolled in the expansion stage; 25 pts in each arm. Overall, 61% pts were male, 59% had ECOG PS 1 and 15% ECOG PS 2; mean age was 73.9 (range 65–86); 53% had adverse karyotype; and 22% had secondary AML. Median time on study was 6 (4–9), 6 (0.2–9), 5 (0.5–9), and 4 (1–8) mo for arms D1, D2, E1, and E2, respectively. The incidence of adverse events (AEs) was generally comparable between the 4 arms. Overall, the most common treatment-emergent AEs (TEAEs; in ≥30% of pts) were nausea (59%), diarrhea (42%), febrile neutropenia (FN; 41%), constipation (39%), fatigue, and decreased white blood cell count (31% each). The most frequent grade 3/4 TEAE and serious AE was FN (41% and 29%, respectively).

No TLS was observed. Overall, 29 pts discontinued the study for ≥1 reason, including progressive disease (PD) per protocol (n=10), “other” (n=10; 9/10 proceeded to stem cell transplantation) and AEs not related to progression (n=10). A total of 16 deaths occurred; 12 pts died within 30 d of initiating VEN and HMA due to AEs (n=12) and PD (n=4). The ORR was 68%, with rates of 76% (19/25), 71% (17/24), 68% (17/25), and 60% (15/25) observed in arms D1, D2, E1, and E2, respectively. The Kaplan-Meier survival curve for all pts with a median follow-up time of 5.4 mo is shown.

Figure 1.

Summary/Conclusions: Overall, the safety profile was favorable when combining VEN at either dose with DEC or AZA in treatment-naïve elderly AML pts. Promising activity with high ORRs was observed at the lower 400-mg VEN dose in both HMA arms. A Phase 3 study of VEN plus AZA is planned.

Aims: Evaluate the safety and efficacy of VEN+LDAC in older pts with untreated

AML.

Methods: In this open-label phase 1/2 study, pts ≥65 years with untreated AML, ineligible for standard induction chemotherapy, with an ECOG performance status of 0–2 received oral VEN QD on days (d) 1–28 and subcutaneous LDAC 20mg/m2 QD on d 1–10 of each 28-d cycle. VEN target dose evaluation followed a 3+3 design, ranging from 600–800mg; 18 pts were enrolled and the RP2D was established as 600mg. Safety and efficacy of VEN at RP2D were evaluated in the expansion phase. All pts were hospitalized and received prophylaxis before a dose ramp-up of VEN during cycle 1 to mitigate the risk of tumor lysis syndrome (TLS). Adverse events (AEs) were graded by NC1 CTCAE V4.0. Pts enrolled as of May 2016 are included in this analysis; data cutoff was August 2016. All pts provided informed consent.

Results: In total, 61 pts, including 8 from phase 1, were treated at the RP2D of 600mg (median age 74 years; ECOG 1–2 70%; adverse karyotypes 31%; secondary AML 44%; prior hypomethylating agent [HMA] 28%). AEs (all grade; serious AEs) across the 3 arms were nausea (72%), hypokalemia (46%), diarrhea (44%), fatigue (43%), and decreased appetite (41%). Grade 3/4 AEs (≥10% pts) were febrile neutropenia (34%), hypokalemia (15%), hypophosphatemia (13%), and hypertension (10%). No pts had clinical TLS; 1 pt had laboratory TLS, which was managed. The 30-d and 60-d mortality rates were 3% and 15%, respectively. The CR/CRi rate was 54% (33/61; 21% CR and 33% CRi). The overall response rate (ORR; CR+CRi+partial remission) was 61% (37/61). VEN+LDAC was shown to be active across a wide range of cytogenetic mutations and pt profiles (ORR: 70% in pts ≥75 years; 52% in second-line AML; 47% in pts with adverse karyotypes; 53% in pts with prior HMA).

Among response-evaluable pts, those achieving an objective response have longer survival than pts who do not achieve an objective response (Figure 1).

Figure 1.

Summary/Conclusions: VEN (RP2D 600mg) and LDAC exhibited an acceptable safety profile and durable efficacy in pts aged ≥65 years with untreated AML who are ineligible for or unable to receive intensive induction chemotherapy. ORR highly correlated with overall survival, with better survival observed in responders compared with nonresponders. A planned phase 3 randomized trial has commenced.

Aims: To assess the best response to Aza+Nivo at the end of 3 courses of combination therapy.

Methods: Pts were eligible if they had AML and failed prior therapy, had adequate performance status (ECOG ≤2), and organ function. The first six pts
received AZA 75mg/m² Days 1-7 with nivolumab 3mg/kg on Day 1 and 14. Courses were repeated every 4-5 weeks indefinitely. Only one of six pts had a dose limiting toxicity (grade 3 pneumonitis) and this dose was RP2D. 60 additional pts have been treated at the RP2D.

Results: 66 pts with a median age of 71 years (range, 44-90), secondary AML (39%), poor risk cytogenetics (35%), median number of prior regimens 2 (range, 1-7) have been enrolled. All 66 pts had baseline next-generation sequencing: TP53 (n=11), DNMT3A (n=12), ASXL1 (n=10), TET2 (N=9), and RAS (n=9), IDH2 (n=9), IDH1 (n=6), CEBPA (n=7). 63 pts are evaluable for response: 14 (22%) achieved complete remission (CR)/complete remission with insufficient recovery of counts (CRi) (3 CR, 11 CRi), 7 (11%) had hematologic improvement (HI) (3 CRi, 4 HI). 5 pts (8%) had stable disease >6 months, and 24 (38%) had progression. 3 pts are too early for response assessment (<3 courses). The median number of courses to CR/CRi/HI was 2 (range, 1-4+). The med OS among the CR/CRi pts was 15.3 months (range, 2-27.14+ months). The nivo pts was 7 months (range, 4.67-17.45+), and NR was 5.0 months (range, 0.29-16.16). The 4- and 8-week mortality were 5% and 11%, respectively. The median OS for the 63 evaluable pts on Aza+Nivo compares favorably to historical median OS with AZA-based salvage protocols in similar pts treated at MDACC (P=0.10) (Fig 1A and Fig 1B). Grade 3/4 and Grade 2 immune toxicities were observed in 8 (12%) and 7 (11%) pts, respectively. The most common Grade 3/4 AEs on treatment included pneumonitis, colitis, nephritis, skin rash, and hypophysitis. One pt died from grade 4 pneumonitis/epiglottitis. In the remaining 14 cases the toxicities responded rapidly to steroids and 13 of these pts were successfully rechallenged with nivolumab. Time to onset of toxicities ranged from 4 days to 3.5 months. Multicolor flow-cytometry studies and mass-cytometry (CyTOF) studies are conducted by the Immunotherapy Platform on baseline and on-treatment BM aspirate (end of cycle 1, 2, 4, 8). Baseline and end of cycle (EOC) 1 and 2 BM was evaluated in 6 responders and 19 non-responders. Pts who achieved a response had a baseline higher live total CD3 (P=0.10), CD8+ T-cells (P=0.02), and lower live CD4+ Foxp3+ PD1+ T-regulatory (T-reg) cells (P=0.01) infiltrate in BM. Patients who had a response had progressive increase in BM CD3+ cells and BM CD8+ cells, with increased ICOS (activation) marker on BM CD4 effector cells at EOC 1 and EOC 2 as compared to those who had no response. The CTLA4 on CD8 T-cells went up in both responders and non-responders after PD1 based therapy.

Summary/Conclusions: Full dose AZA and nivolumab are tolerable and produce an encouraging response rate with durable responses in relapsed AML with poor risk features. Immune mediated toxicities occur and may be adequately managed with early recognition and systemic steroids. Up-regulation of CTLA4 may be a mechanism of resistance to PD1 based therapies in AML and suggest role for combination therapy.

QUIZARTINIB AND BRIDGE TO TRANSPLANT IN FLT3-ITD AML PATIENTS AFTER FAILURE OF SALVAGE CHEMOTHERAPY: A HISTORICAL COMPARISON WITH UK NATIONAL CANCER RESEARCH INSTITUTE (NCRI) DATA

R. Hills1,*, G. Gammon2, D. Trone3, A. Burnett4
1Centre for Trials Research, Cardiff University, Cardiff, United Kingdom, 2formerly Daichi Sankyo, 3Daichi Sankyo, San Diego, United States, 4Blackwaterfoot, Isle of Arran, United Kingdom

Background: The presence of a FMS-like tyrosine kinase 3 (FLT3) Internal tandem duplication (ITD) mutation in pts with AML is associated with an increased early relapse rate and a dismal prognosis. Quizartinib is a potent, selective, oral FLT3 receptor tyrosine kinase inhibitor with confirmed activity (mOS) of 23 weeks and remission rate of 46% in a single-arm phase 2 study (AC220-002) in pts with AML with a FLT3-ITD mutation who were relapsed or refractory (R/R) to second line therapy. (Levis, et al. ASH 2012) As context, a study of AML pts, regardless of FLT3 mutation status, receiving second-salvage therapy reported mOS of only 1.5 months. (Giles F, et al. Cancer 104 (3), 2005).

Purpose: The primary aim was to compare SCT rates and outcomes of pts on quizartinib from an exploratory selected cohort in the AC220-002 study with those from a historical cohort of 1388 AML pts with confirmed FLT3-ITD mutations in the UK NCRI database.

Methods: Within AC220-002, 58 pts with a FLT3-ITD mutation were identified who had received intensive chemotherapy, and were relapsed (n=53), or refractory (n=5) to salvage therapy prior to entry. Applying the same entry criteria to the NCRI database, we identified 118 pts who received only recognized chemotherapy regimens prior to eligibility (relapsed n=99; refractory n=19). To avoid biases where those dying early would predominantly contribute to the NCRI group (reflecting that pts in AC220-002 had to be fit enough to be enrolled), pts in this cohort entered analysis 14 days following being identified as R/R. Multivariable Cox/logistic regression was used to compare remission rates and survival stratified for known prognostic factors. A landmark analysis excluding deaths before day 90 (allowing for those too unfit for SCT) was performed on the pooled sample (n=176) of the AC220-002 and NCRI cohorts to compare survival between transplanted and non-transplanted pts.

Results: Overall, quizartinib-treated pts had significantly greater remission rates, consisting mainly of complete remission without normal blood counts (CRI), vs NCRI pts (40% vs 3%, adjusted OR 0.05 (0.01-0.21), p<0.0001) and improved mOS (140d vs 54d, adjusted HR 0.38 (0.25-0.58) p<0.0001). A greater proportion of pts in AC220-002 proceeded to SCT: 23/58 (40%) vs 9/118 (8%). Comparing survival in SCT vs no-SCT in a landmark analysis, 18-month survival was significantly greater in the SCT group (29% vs 7%, adjusted HR 0.36 (0.20-0.65) p<0.0005). Significance persisted in sensitivity analyses with the landmark set at 120 or 150 days indicating an association between long-term survival and SCT. A similar analysis in an unmatched cohort consisting of SCT-naive pts in first relapse also found better survival for SCT vs no-SCT, confirming a potential benefit of SCT in this poor risk population.

Summary/Conclusions: When compared to a large historical cohort, quizartinib was associated with greater remission rates and opportunity to receive SCT in pts who relapsed after salvage therapy. While varying practice patterns and patient factors obviously influence treatment choices and outcomes, pts with AML with FLT3-ITD mutation appeared to benefit with longer survival than pts with AML with FLT3-ITD mutation who were relapsed or refractory to salvage chemotherapy regimens prior to eligibility. Quizartinib was associated with greater remission rates and opportunity to receive SCT in pts who relapsed after salvage therapy. While varying practice patterns and patient factors obviously influence treatment choices and outcomes, pts with AML with FLT3-ITD mutation appeared to benefit with longer survival than pts with AML with FLT3-ITD mutation who were relapsed or refractory to salvage chemotherapy regimens prior to eligibility.

GLOBAL REGISTRATION TRIAL OF EFFICACY AND SAFETY OF CTL019 IN PEDIATRIC AND YOUNG ADULT PATIENTS WITH RELAPSED/REFRACTORY (R/R) ACUTE LYMPHOCYTIC LEUKEMIA (ALL): UPDATE TO THE INTERIM ANALYSIS

1Oslo University Hospital Rikshospitalet, Oslo, Norway, 2Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, 3Department of Internal Medicine, University of Utah, Salt Lake City, Utah, United States, 4Department of Pediatrics, Faculty of Medicine, University of Montreal, Montreal, Canada, 5Hematology Oncology Division, CHU Sainte-Justine, 6Charles-Bruneau Cancer Center, CHU Sainte-Justine Research Center, Montreal, Canada, 7Department of Pediatrics, The University of Texas Southwestern Medical Center, Dallas, United States, 8Division for Stem Cell Transplantation and Immunology, Hospital for Children and Adolescents, University Hospital Frankfurt, Frankfurt, Germany, 9Adult and Pediatric Blood and Marrow Transplant Program, University of Minnesota, Minneapolis, 10Children’s Mercy Hospital and Clinics, Kansas City, 11Aflac Cancer and Blood Disorders Center, Emory University, Atlanta, 12Division of Hematology Oncology/Blood and Marrow Transplant, Children’s Hospital Los Angeles, USC Keck School of Medicine, Los Angeles, United States, 13Department of Pediatric Hematology-Oncology and Stem Cell Transplantation, Ghent University Hospital, 14Cancer Research Institute Ghent (CRIG), Ghent University, 15Graduate School of Medicine Kyoto University, Kyoto, Japan, 16Department of Pediatrics, Stanford University School of Medicine, Stanford, 17Lucile Packard Children's Hospital, Palo Alto, 18Division of Pediatric Blood and Marrow Transplant, Duke University Medical Center, Durham, 19Oregon Health & Science University, Portland, OR, 20Division of Hematology/Oncology/Blood and Marrow Transplant, Children’s Hospital Los Angeles, USC Keck School of Medicine, Los Angeles, United States, 21Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, 22Stem Cell Transplantation Unit, St. Anna Children’s Hospital, Vienna, Austria, 23Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, United States, 24Hospital Sant Joan de Déu, Barcelona, Spain

Background: The CD19-targeted chimeric antigen receptor (CAR) T-cell therapy CTL019, an investigational therapy that reprograms cytotoxic T cells to eliminate target cells, resulted in high response rates and a manageable safety profile in pediatric/young adult patients (pts) with R/R B-cell ALL in a single-center trial. Aims: We report an updated interim analysis from the first multicenter global pivotal phase 2 trial of the CD19-targeted CAR T-cell therapy (ELIANA; NCT02435849 and ENSIGN; NCT02228096) in pediatric and young adult R/R B-cell ALL. Methods: This is a single-arm, open-label, multicenter, global, phase 2 study of CTL019 in pediatric/young adult pts with CD19+ R/R B-cell ALL with ≥5% bone marrow lymphoblasts by morphology. CTL019 was manufactured from leukapheresis collected from pts and infused with a single dose of CTL019, median dose 3.0×10^6/kg (range 0.2-6.4×10^6/kg) following a protocol-confirmed algorithm. Results: As of November 2016, 88 pts were enrolled. There were 7 (8%) manufacturing failures, 9 (10%) pts were not infused due to death or adverse events (AEs), and 4 pts (5%) were pending infusion at the time of data cutoff. Following lymphodepleting chemotherapy in most pts (fludarabine/cyclophosphamide [n=64] or other [n=11], 68 pts were infused with a single dose of CTL019 (median dose 3.0×10^6/kg, range 0.2-6.4×10^6/kg) using a protocol (protocol)-confirmed algorithm. AUC0-28d increased with pres

Figure 1. Results: Data from 79 pts (ELIANA, n=50; ENSIGN, n=29) were pooled for analysis. Using qPCR, pts with CR/CRi (n=62) had 2-fold higher CTL019 expansion than pts with NR (n=7) (Cmax, 73.5% higher geometric [geo] mean; AUC0-28d, 104% higher geo mean). Table 1. Pts with NR had delayed Tmax compared with pts with CR/CRi (20 vs 10 days). Intrinsic pt factors including baseline cytogenetics, disease characteristics, and disease status did not appear to affect Cmax or AUC0-28d with the exception that pts with a higher tumor burden at enrollment generally had higher expansion, based on box plots. In summary statistics, Extrinsic factors (prior lines of therapy, stem cell transplant) and parameters related to the manufactured product (% T cells, transduction efficiency, cell viability, total cell count), did not appear to impact cellular kinetics, based on graphical analysis. AUC0-28d increased with pres.
enence and severity of CRS. Pts who received anti-cytokine agents for grade 3/4 CRS also had higher expansion. CR/CRI pts treated with tocilizumab and steroids (n=17) had 89% higher AUC0-28d than CR pts who did not receive tocilizumab and steroids (n=45). Experience is limited in NR pts with (n=4) and without (n=4) tocilizumab. Moderate correlation was observed between transgene levels and CAR surface expression in peripheral blood (r=0.592) by qPCR and flow cytometry, respectively, when matched by time points from the cellular kinetic profile. Slower B-cell recovery was observed in pts with AUC0-28d above the median. Post-dose anti-CAR19 antibody responses were determined from the fold change of anti-CAR19 antibodies above the baseline pre-dose value. Pts with treatment-induced or boosted anti-CAR19 antibody responses generally had lower expansion, based on box plots, compared with pts with treatment-unaﬀected anti-CAR19 antibody responses, although AUC0-28d was variable. The boosted levels of anti-CAR19 did not impact clinical response or relapse.

**Summary/Conclusions:** There was increased expansion of CTL019 in pts with higher tumor burden at enrollment, which correlated with higher CRS grade. There was no relationship between dose and expansion, supporting the wide dose range used. Expansion was not attenuated by tocilizumab or steroids, indicating therapies for CRS do not abortegrate CAR19 proliferation. Cellular kinetics are important to understand the determinants of tumor response with CAR T-cell therapy.

**Background:** Adults with B-cell precursor (BCP) acute lymphoblastic leukemia (ALL) often relapse following standard induction/consolidation chemotherapy (CIT). The selection of second and subsequent CTX salvage regimens (S2+) is poor compared with first salvage (S1) or frontline therapy, with less favorable outcomes among patients with shorter CR duration. Blinatumomab links cytotoxic CD3-positive T cells and CD19-positive B cells to induce tumor cell lysis. In a randomized phase 2 trial of blinatumomab vs investigator’s choice of 4 standard of care CTX (SOC) regimens, median OS was 7.7 months in the blinatumomab group vs 4.0 months with SOC (Kantarjian H, et al. NEJM 2017). Here, we evaluate outcomes by salvage status for patients in this study (NCT02013167).

**Aims:** To evaluate responses to blinatumomab vs SOC in patients with relapsed/refractory ALL by prior salvage therapy status. **Methods:** Patients with relapsed/refractory (R/R) BCP-ALL in this international multicenter trial were randomized 2:1 to blinatumomab (n=271) or SOC (n=134). For this analysis, salvage status was adjudicated separately from prior randomization. Blinatumomab was given by continuous IV infusion (9 µg/d in week 1 of cycle 1, then 28 µg/d) in cycles of 4 weeks on, 2 weeks off. The primary endpoint was overall survival (OS), determined from time of randomization until death due to any cause. Adverse events (AE) of interest were coded according to MedDRA version 16.0. Results: At baseline, patient characteristics were balanced between groups within salvage designations. The rate of complete remission, with or without full hematologic recovery (CR/CRI) in both the S1 and S2+ groups was higher in the blinatumomab arm compared with the SOC arm (Table 1). Patients randomized to blinatumomab had a median (95% CI) of 11.1 (8.2, NR) months vs 5.1 (3.2, 7.1) months overall survival for S1 vs S2+ subgroup, compared with 5.5 (3.7, 9.0) months vs 3.0 (2.1, 4.0) months in the SOC arm (Figure 1). For both S1 and S2+ subgroups, blinatumomab patients had longer median survival time. Grade 3 or worse AEs were experienced by 61% and 83% of S1 patients in the blinatumomab and SOC group, respectively. These percentages were 68% and 75%, respectively, in S2+ patients. Grade 4 or worse AEs occurred in 34% and 51% S1 patients, and in 36% and 54% S2+ patients. Neurologic events of grade ≥3 occurred in 9% and 9% of S1 patients, and in 10% and 9% S2+ patients, respectively. Grade ≥3 cytokine release syndrome (CRS) was observed in 4% S1 and 5% S2+ patients receiving blinatumomab, and in no SOC patients.

**Summary/Conclusions:** Patients in this trial receiving blinatumomab for R/R ALL achieved improved OS and remission rates compared with SOC regardless of prior salvage therapy. Improved OS compared with SOC in S1 patients supports earlier use of blinatumomab.

**DURABLE LONG-TERM SURVIVAL OF ADULT PATIENTS WITH B-ALL AFTER CD19 CAR (19-28Z) T CELL THERAPY**

J. Park1,*, I. Riviere 1, X. Wang 1, B. Senechal 1, Y. Wang 1, T. Purdon 1, R. Brentjens1, M. Sadelain1

1Memorial Sloan-Kettering Cancer Center, New York, United States

**Background:** CD19-specific chimeric antigen receptor (CAR) T cells have demonstrated high initial responses in patients with relapsed B-ALL. However, clinical characteristics associated with the durability of response remain undefined. **Aims:** We performed a retrospective analysis of our phase I clinical trial of 19-28z CAR T cells in adult patients with relapsed B-ALL (NCT01044069) with a focus to identify those patients who optimally benefit from 19-28z CAR T cell therapy with durable long-term survival and reduced toxicities. **Methods:** Adults with relapsed B-ALL were infused with autologous T cells expressing the 19-28z CAR following conditioning chemotherapy. Disease burden was assessed by bone marrow biopsy immediately prior to T cell infusion; patients with ≥5% blasts were classified as minimal residual disease (MRD) cohort vs patients <5% blasts as morphologic disease cohort. Response assessment occurred at 4 weeks. Median follow-up duration was 18 months (range, 0.2-57.3).

**Results:** 51 adults received 19-28z CAR T cells; 20 in the MRD and 31 in the therapy, with a duration of 17 months (95% CI: 4.2-28.2 months) vs 6.3 months (95% CI, 4.8-8.0) (p=0.0005), and NR (95% CI, 15.3-NR) vs 17 months (95% CI, 8.5-36.2) (p=0.0189), in the MRD and morphologic disease cohort, respectively. Subsequent allogeneic HSCT in either cohort did not improve survival (p=0.8). MRD cohort patients developed substantially less severe cytokine release syndrome (CRS) and neurotoxicity, and both toxicities significantly correlated with peak
STANDARD-RISK RANDOMIZATION OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA IN TRIAL AIEOP-BFM ALL 2000 INDICATES EQUILIBRATED OUTCOME WITH REDUCED-INTENSITY DELAYED INTENSIFICATION IN ETV6-RUNX1-POSITIVE PATIENTS

Gerardo, Monza, Italy

Background: ETV6-RUNX1 fusion is a common genetic aberration in childhood acute lymphoblastic leukemia (ALL) and is associated with good prognosis in the context of contemporary treatment regimens. The required treatment intensity for this well-described biologic subgroup with low risk of relapse is not known so far. In trial AIEOP-BFM ALL 2000, feasibility of reduced delay of intensified treatment to reduce the burden of chemotherapy was tested in a randomized approach in the standard-risk group. Treatment reduction was not successful in the total cohort (8-year probability of disease-free survival 89.2±1.3% for reduced intensified treatment, 92.3±1.2% for the standard treatment (log-rank P=0.04) due to evidence of more relapses observed in patients treated less intensively. Aims: The retrospective subgroup analysis presented here focuses on the ETV6-RUNX1-positive patients included in the group of randomized standard-risk patients. Methods: From 07/2000 to 06/2006, 4741 eligible patients with ALL (age range 1-17 years) were enrolled in the trial AIEOP-BFM ALL 2000 (NCT 00430188 (BFM) and NCT 00613457 (AIEOP)). Of those, 1164 patients were considered at standard risk of relapse, defined by lack of genetic high-risk criteria and absence of minimal residual disease at day 33 and week 12 of treatment (tested by immunoglobulin/T-cell receptor gene rearrangement polymerase chain reaction). They were randomly assigned to either receive the reduced-intensity protocol (P-II) or the standard intensified protocol (P-I) for delayed intensified treatment. P-III is shorter than P-II (duration 29 vs 49 days), the dose of dexamethasone in P-III is 30% lower, and the dose of vincristine, doxorubicin, and cyclophosphamide are reduced by 50% as compared to P-II. The intention was to prove non-inferiority of the reduced-intensity treatment compared to standard treatment. Results: ETV6-RUNX1-positive patients (n=367) accounted for 34% of randomized standard-risk patients (Age: <8 years n=260, 8 to <10 years n=79, ≥10 years n=28; early cytologic response evaluation in bone marrow on day 15 of induction treatment: M1 n=218, M2 n=74). Of those, 188 were treated with the experimental P III, 179 received the standard P-II. With a median follow-up of 6.8 years, the as-treated analysis showed an 8-year DFS of 94.4±1.8% for patients treated with P-II (log-rank P=0.74). Cumulative incidence of relapse at 8 years was 3.2±1.3% and 4.3±1.6% (Gray P=0.09), and 8-year overall survival was 96.9±1.4% and 98.8±0.9% (P=0.27) for P III and P II, respectively. Analysis of ETV6-RUNX1-positive patients by age groups or treatment response on day 15 allowed no further refinement of prognostic subgroups. Summary/Conclusions: There was no evidence of prognostic disadvantage in ETV6-RUNX1-positive standard-risk patients when treated with the reduced-intensity experimental arm. No clear age- or response-dependent differences could be revealed for this group, which is in line with the biologic understanding of this genetic subgroup. Hence, it might be postulated that treatment reduction might be feasible in this defined biologic subgroup. However, the present data is not result of a sufficiently powered non-inferiority study question focused on the subgroup of ETV6-RUNX1-positive patients, but reflects a subgroup analysis with descriptive character. Therefore, any decision for treatment reduction should be considered carefully.
mal transcription (t9;22) that gives rise to the oncogenic tyrosine kinase Bcr-Abl. Implementation of tyrosine kinase inhibitor (TKI) therapy resulted in significant clinical success but with TKIs failing to eradicate the disease initiating leukemic stem cell population (LSC), this treatment is not curative in the vast majority of patients. By using a transgenic CML mouse model, we previously showed that LSC persist despite complete Bcr-Abl kinase inhibition due to a lack of an adequate stem cell depletion. Subsequently, we identified the ITIM carrying Fc gamma receptor IIb (FcyRllb; CD32) to be 2.8-fold upregulated in Bcr-Abl+ versus control LSK (Lin;ScA-1; c-kit+) cells using microarray and qRT-PCR.

Aims: In this study, we first aimed to validate Bcr-Abl mediated FcyRllb upregulation on mRNA and protein level in leukemic cells. Next, we tested the effect of shRNA mediated FcyRllb knock-down and depletion on CFU (Colony forming unit) capacity, proliferation and leukemic signaling in vitro. Finally, we studied the disease-initiating potential of primitive CML stem and progenitor cells upon FcyRllb knock down.

Methods: qRT-PCR and western blot analyses were applied using cell lines, primary murine cells and HoxB8 immortalized murine bone marrow (BM) cells for studying FcyRllb expression and signaling. In order to test the biology of CML cells in vitro, we performed CFU and proliferation assays. Moreover, we performed viral infection of S-FU treated SCLTITA/Bcr-Abl BM using FcyRllb:shRNA or scrambled control and subsequent transplantation, followed by analyses of the disease, including immune-phenotyping, RNAseq and protein expression as well as histological analysis.

Results: Bcr-Abl increased FcyRllb mRNA (13.2-fold, p<0.001) and protein expression in primary murine lineage negative (lin-) BM cells. Reduction of FcyRllb in immortalized SCLTITA/Bcr-Abl progenitor cells significantly reduced CFU capacity and proliferation (p<0.01) and impaired CFU (Colony forming unit) capacity, proliferation and leukemic signaling in these cells (2.27-fold, p<0.01). Moreover, transplantation of SCLTITA/Bcr-Abl shRNA:FcyRllb BM cells (CD45.1+) into FVB/N wildtype (WT) CD45.2+ recipients reduced spleen weight (352 ± 59.13mg), as compared to scrambled shRNA (509 ± 81.32mg). Flow-cytometric analysis of the stem cell compartment revealed Gr-1+ cells (Gr-1+;CD45.1+;GFP+) were reduced in the BM (1.28-fold, p<0.01) of these mice. Flow-cytometric analysis of the stem cell compartment revealed decreased leukemic BM LSK cells (lin-; c-kit-; Sca-1-; CD45.1-; GFP-), 1.38-fold, p<0.05) in mice transplanted with shRNA:FcyRllb-vs scrambled control. We previously observed similar effects upon FcyRllb depletion (FcyRllb-/-) vs wildtype (FcyRllb+/+), combined with virally induced Bcr-Abl expression. Interestingly, Bcr-Abl signaling induces FcyRllb phosphorylation in leukemic cells. Analysis of downstream signal pathways showed decreased levels of p-ERK, p-STAT5, p-PLCγ1 in FcyRllb+/+, compared to FcyRllb+/+ Bcr-Abl transduced immortalized primary murine BM cells.

Summary/Conclusions: FcyRllb is upregulated in LSC derived from transgenic CML mice upon Bcr-Abl expression. Complete depletion or knock down of the receptor reduces CFU capacity and cell growth in CML cells and significantly impairs CML development and LSC burden in vivo, presumably due to impaired leukemic downstream signaling. Our data demonstrate that FcyRllb is critical and disease specific making it a potential novel therapeutic target in CML stem cells.

MYC-DEPENDENT REPRESSION MECHANISM OF THE MIR-150 TRANSCRIPTIONAL REGULATION IN CHRONIC MYELOID LEUKEMIA
P. Burda1,2, N. Čuřík1,2,*, K. Šrůtová1, F. Savvulidi2, G. Silvestri3, H. Klamová1,4, K. Kiss1,5, I. S. Pagani1, P. Dang1, I.O. Kommers2, J. Goyne1, V.A. Saunders1, J.A. Prime3, D.W. White1, S. Branford1, T.P. Hughes1, D.M. Ross1.
1Cancer Theme, South Australian Health and Medical Research Institute (saamri), Adelaide, Australia, 2School of Medicine, Vrije Universiteit Medical Center, Amsterdam, Netherlands, 3Department of Genetics and Molecular Pathology, Centre for Cancer Biology,SA Pathology, 4Department of Haematology, Royal Adelaide Hospital and SA Pathology, Adelaide, Australia

Background: Real-time reverse transcription quantitative PCR (RQ-PCR) for BCR-ABL1 mRNA is widely used for the monitoring of chronic myeloid leukaemia (CML). Pre-analytical factors, such as the rate of degradation of the target mRNA, and methodological factors, such as the choice of control gene, can impact the accuracy of data interpretation. The number of copies of BCR-ABL1 mRNA is directly proportional to the number of CML cells. Measuring both DNA and RNA may enable us to understand the contribution of expression and cell number to the RQ-PCR response.

Aims: To compare BCR-ABL1 DNA Q-PCR and routine RQ-PCR monitoring of CML.

Methods: Fifty-nine newly diagnosed chronic phase CML patients from the ALLG CML9 (TIDEII II) trial were included in this sub-study. Samples were tested prior to commencing TKI treatment (baseline), at 1, 2, and 3 months, and every 3 months to 24 months (total 568 samples). Since we wanted to compare the accuracy of the Q-PCR methods we selected patients that had achieved undetectable minimal residual disease (UMRD) by RQ-PCR within 24 months, and an additional 40 patients unsuitable for response. RQ-PCR results were expressed on the International Scale (IS), whereas DNA results were expressed relative to the individual patient’s baseline. Quantification of BCR-ABL1 DNA of the currently used control gene (GUSB) was performed using Q-PCR methods (dPCR or by digital PCR), dPCR (dPCR, n=19) using the Fluidigm BioMark HD System. The mean detection limit of RQ-PCR was 4.5-log, and 5.4-log for DNA methods.

Results: We first demonstrated that DNA dPCR and real-time Q-PCR gave comparable results: 45 samples from 6 patients were quantified by both methods and showed comparable results: 45 samples from 6 patients were quantified by both methods and showed comparable results; 45 samples from 6 patients were quantified by both methods and showed comparable results: 45 samples from 6 patients were quantified by both methods and showed comparable results: 45 samples from 6 patients were quantified by both methods and showed comparable results: 45 samples from 6 patients were quantified by both methods and showed comparable results: 45 samples from 6 patients were quantified by both methods and showed comparable results. The median BCR-ABL1
dPCR of BCR-ABL1 mRNA at 1, 2, and 3 months (Figure). There was good agreement between DNA and RNA may enable us to understand the contribution of expression and cell number to the RQ-PCR response.

Background: Real-time reverse transcription quantitative PCR (RQ-PCR) for BCR-ABL1 mRNA is widely used for the monitoring of chronic myeloid leukaemia (CML). Pre-analytical factors, such as the rate of degradation of the target mRNA, and methodological factors, such as the choice of control gene, can impact the accuracy of data interpretation. The number of copies of BCR-ABL1 DNA is directly proportional to the number of CML cells. Measuring both DNA and RNA may enable us to understand the contribution of expression and cell number to the RQ-PCR response.

Aims: To compare BCR-ABL1 DNA Q-PCR and routine RQ-PCR monitoring of CML.

Methods: Fifty-nine newly diagnosed chronic phase CML patients from the ALLG CML9 (TIDEII II) trial were included in this sub-study. Samples were tested prior to commencing TKI treatment (baseline), at 1, 2, and 3 months, and every 3 months to 24 months (total 568 samples). Since we wanted to compare the accuracy of the Q-PCR methods we selected patients that had achieved undetectable minimal residual disease (UMRD) by RQ-PCR within 24 months, and an additional 40 patients unsuitable for response. RQ-PCR results were expressed on the International Scale (IS), whereas DNA results were expressed relative to the individual patient’s baseline. Quantification of BCR-ABL1 DNA of the currently used control gene (GUSB) was performed using Q-PCR methods (dPCR or by digital PCR), dPCR (dPCR, n=19) using the Fluidigm BioMark HD System. The mean detection limit of RQ-PCR was 4.5-log, and 5.4-log for DNA methods.

Results: We first demonstrated that DNA dPCR and real-time Q-PCR gave comparable results: 45 samples from 6 patients were quantified by both methods and showed comparable results: 45 samples from 6 patients were quantified by both methods and showed comparable results: 45 samples from 6 patients were quantified by both methods and showed comparable results: 45 samples from 6 patients were quantified by both methods and showed comparable results: 45 samples from 6 patients were quantified by both methods and showed comparable results: 45 samples from 6 patients were quantified by both methods and showed comparable results.
and ii) verify accuracy and inter-laboratory reproducibility of results. The second phase of the study, involving 39 Italian Hematology Units, was meant to storage and a common pipeline of data analysis, interpretation and reporting, Aims: BCR-ABL1 KD mutation screening. conducted to assess the feasibility, cost, turnaround times and clinical utility of Sanger sequencers in diagnostics labs because of greater throughput, better E. Calistri19, G. Spinosa20, M. D’Adda21, I. Capodanno22, M. Baccarani23, F. Albano7, F. Ciceri8, F. Lunghi8, F. Castagnetti1, G. Gugliotta1, E. Tenti1, F. Carnuccio10, F. Pane12, S. Errichiello12, M. Annunziata13, M. Breccia14, M. Cavo1, G. Martinelli1

Background: Establishing a national network of laboratories using next generation amplicon deep sequencing for BCR-ABL1 kinase domain mutation screening: the ‘NEXT-IN-CML’ study

Methods: In the first phase, centrally prepared identical batches of 32 blinded samples (24 clinical samples with known mutation status/load as assessed by Sanger Seq plus 8 T315I BaF3 cell line dilutions simulating mutation loads between 20% and 1%) were distributed and analyzed in parallel by each of the 4 participating labs. In the second phase, 159 consecutive CML pts were prospectively studied in parallel by Sanger Seq and by Deep Seq: 101 Failures (57 pts on 1st-line TKI [IM, n=38; DAS, n=12; N1, n=7] therapy; 35 pts on 2nd-line TKI [DAS, n=14; NIL, n=17; IM, n=2; BOS, n=1; PON, n=1] therapy; 5 pts on 3rd-line TKI [DAS, n=4; NIL, n=1] therapy and 4 pts on 4th-line TKI [BOS, n=1; DAS, n=4; NIL, n=5; BOS, n=1] therapy and 20 on 2nd-line TKI [NIL, n=10; DAS, n=9; PON, n=1] therapy).

Results: In the first phase, 504/512 amplicons were successfully generated and sequenced, with a median number of forward and reverse reads of 1,757 (range 544-5,838). In the 128 samples analyzed, 51/52 expected mutations were consistently detected by all 4 labs and quantitation of mutation load was highly reproducible across a wide range of frequencies (2%>100%). Three out of 4 labs failed to detect the 1% T315I+ dilution. In clinical samples, additional low burden mutations <3% were occasionally called by one or two labs only, suggesting that this value should be taken as a threshold below which mutation detection is not reproducible and sequencing artifacts and errors cannot be ruled out. In the second phase of the study, pts positive for mutations were 25/159 (16%; 23 Failures and 2 Warnings) by Sanger Seq and 52/159 (33%; 44 Failures and 8 Warnings) by Deep Seq. Among the pts with low burden mutations detectable by Deep Seq, 4 had a T315I; 34 had other known TKI-resistant mutations; 14 had only mutations with unknown clinical significance.

Summary/Conclusions: 1) Results of the ‘NEXT-IN-CML’, the first prospective study evaluating the routine diagnostic use of Deep Seq of BCR-ABL1, show that this technology can successfully be implemented in national lab networks and is feasible, robust and reproducible; 2) in a relatively large, nonselected cohort of CML pts analyzed for mutations because of a Failure or Warning response, Deep Seq confirmed that enhancing sensitivity enables to detect BCR-ABL1 KD mutations in twice as many pts as compared to Sanger Seq (33% vs 16%); 3) all the pts who need to be switched to another TKI would benefit from sensitive BCR-ABL1 KD mutation screening by Deep Seq.
Prognostic markers and new treatment in MDS

PATIENTS WITH IDIOPATHIC CYTOPENIA OF UNDETERMINED SIGNIFICANCE SHOW SIMILAR SURVIVAL PATTERNS AS LOW RISK MDS PATIENTS

J.W. Hansen1, M. Westman2, A.D. Ørskov1, L. Sbj3, L. Salf4, M.S. Holm2, C. Claus Marcher2, M. Karimi7, E. Hellstrom-Lindberg2, M.K. Andersen2, K. GRENBAEK1

1Hematology, Aarhus University Hospital, Aarhus, 6Hematology, Odense University Hospital, Odense, Denmark, 7Center for Hematology and Regenerative Medicine, Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden

Background: Cytopenia is a hallmark in myelodysplastic syndrome (MDS), however, many patients with persistent cytopenia do not fulfill the criteria for MDS. These patients are now classified as idiopathic cytopenia of undetermined significance (ICUS) or if a mutation is detected as clonal cytopenia of undetermined significance (CCUS). Little is known about these new entities in regards to survival and prognostication.

Aims: In this study we want to compare ICUS patients with MDS patients having low- or very low-risk disease according to the IPSS-R. We also wanted to investigate if sequencing of the cohort could bring additional information in regards to overall survival.

Methods: All patients underwent a bone marrow biopsy, cytogenetics and a broad range of blood tests. Furthermore, all ICUS patients underwent a blinded morphology review by two experienced pathologists; these review data will be ready for presentation at EHA. ICUS was defined as persistent cytopenia for more than six months, no chromosomal aberrations and common causes of cytopenia were ruled out. The patients were sequenced with a targeted sequencing panel, either using a customized Haloplex panel or a customized sequencing panel for the Ion Torrent platform. We analyzed 20 genes which are the most commonly mutated genes in MDS.

Results: So far we included 157 patients, 122 were classified as ICUS and 35 as MDS and the median age is 65 and 69 years, respectively (p=0.27). We have sequenced 78% of the ICUS patients and 74% of the MDS patients. In total 53% and 73% of the ICUS and MDS patients had at least one mutation detected, respectively. If the patients carried a mutation, the median number of mutations was two in both the CCUS and the MDS group. The most commonly mutated genes were TET2, SRSF2, DNMT3A and ASXL1 in 38 patients (31%), n=16 (13%), n=10 (8%), n=10 (8%), respectively. There were no significant differences in the distribution between the two groups. Mutations in NRAS, KRAS, TP53 were only identified in one patient each. The overall survival between the ICUS and the low-risk MDS patients did not differ (p=0.18) (figure 1). We also subdivided the ICUS patients into non-clonal ICUS and CCUS, but observed no difference between these two groups (p=0.355).

Eight of the patients categorized as ICUS progressed to a myeloid neoplasm during the follow up, and of these seven had a detectable mutation at time of enrollment, only one ICUS patient without a detectable mutation progressed (p=0.06).

Summary/Conclusions: We here demonstrate that low-risk MDS and ICUS patients share similar survival patterns, however, larger studies with longer follow up are needed. Mutations are most commonly found in the epigenetic regulators in this cohort of ICUS and low-risk MDS, while mutations in classical tumor suppressors and oncogenes such as TP53 and NRAS are rare. Mutational screening seems promising in detecting patients at risk of progression, however, other biomarkers for prognostication are warranted.

1Leukemia, 2Biostatistics, 3Hematopathology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Outcomes of pts with MDS after hypomethylating agent (HMA) failure remain poor. Upregulation of PD-1, PD-L1 and CTLA-4 in MDS CD34+ cells after exposure and loss of response to HMA have been reported. Nivo and Ipi have single-agent activity in MDS, however, other biomarkers for prognostication are warranted.

Methods: We designed a phase II study of Nivo Ipi in monotherapy or combination for pts with MDS. Pts with prior therapy with HMA were to be treated in 1 of 3 consecutive cohorts combining Nivo and Ipi. The study design allowed for AZA add-back after 6 cycles of therapy if there was no response or progression. Pts with previously untreated MDS were to be treated in 1 of 3 consecutive cohorts combining AZA and Nivo. The study was subdivided into 6 consecutive cohorts following the revised 2006 IWG criteria. The study included stopping rules for response and toxicity.

Results: A total of 63 pts have been enrolled, 54 (86%) are evaluable for response and toxicity. Outcomes of pts with MDS after hypomethylating agent (HMA) failure remain poor. Upregulation of PD-1, PD-L1 and CTLA-4 in MDS CD34+ cells after exposure and loss of response to HMA have been reported. Nivo and Ipi have single-agent activity in MDS, however, other biomarkers for prognostication are warranted.

Figure 1.
Hypomethylating agents (HMA) such as azacitidine and decitabine remain the standard of care for the treatment of myelodysplastic syndromes (MDS) however, loss of response to therapy is associated with poor outcomes. Multiple studies have tried to identify biomarkers of response but the impact of the mutational architecture present at the time of diagnosis in response outcomes is unclear.

**Aims:** To evaluate the impact of the mutational architecture present at the time of diagnosis in response outcomes is unclear.

**Methods:** We evaluated 222 previously untreated patients with MDS or CMML that received HMA therapy at The University of Texas MD Anderson Cancer Center. Next generation sequencing analyzing a panel of 28 genes was performed prior to therapy with HMA. VAF estimates were used to evaluate clonal and subclonal relationships within each individual sample with clonal heterogeneity being defined in cases with Pearson goodness-of-fit p-values <0.05. Generalized linear models were used to study association of response rates (ORR=overall and CR=complete) and risk factors. Response was defined following 2006 IWG criteria.

**Results:** A total of 143 patients (79%) had MDS and 43 (19%) had CMML, including 108 (49%) with lower-risk based on IPSS and 114 (51%) with higher-risk disease. Therapy consisted in azacitidine monotherapy in 60 (27%) patients, decitabine monotherapy in 57 (28%), and decitabine in 46 (21) and combinations in 59 (27%). The ORR was 61% (135/222) with 80 (36%) patients achieving CR. A total of 161 (73%) patients had at least one detectable mutation. Median number of mutations was 1 (range 0-5). Frequencies of detected mutations are shown in Figure 1A. Among 70 (32%) patients evaluable for clonal heterogeneity, 38 (55%) were clonally heterogeneous and carried at least 1 subclone. Pairwise associations of mutations revealed distinct and significant co-mutation patterns (Figure 1B). Within these co-mutation associations, there were no clear hierarchical patterns of clonality in patients evaluable for clonal heterogeneity, as indicated in Figure 1B. By univariate analysis, presence of mutations in ASXL1 (OR 0.45, CI 0.22-0.93, p=0.03) and RUNX1 (0.44, CI 0.20-0.96, p=0.038) as well as that of TP53 mutations with VAF ≥0.31 (OR 0.21, CI 0.05-0.8, p=0.024) predicted for a lower likelihood of response. Analysis of clonal evolution revealed that patients with mutations in chromatin (OR 0.43, CI 0.21-0.86, p=0.017) and signaling genes (OR 0.48, CI 0.23-1.00, p=0.049) had lower likelihood of achieving response. Additionally, patients with ASXL1 mutations (OR 0.24, CI 0.09-0.64, p=0.005) particularly in the absence of co-occurring TET2, as well as those with increased number of mutations, particularly if more than 3 (OR 0.21, CI 0.06-0.73, p=0.014), or signaling gene mutations (OR 0.32, CI 0.13-0.80, p=0.016), had a lower likelihood of achieving a CR. Among patients who achieved CR, presence of 3 or more mutations (2.6 vs 1.3 months, OR 1.35, CI 1.00-1.83, p=0.049) and TP53 mutations with VAF ≥0.31 (0 vs 3.7 months, OR 2.03, CI 1.03-3.98, p=0.040) predicted for shorter CR duration. Presence of clonal heterogeneity, as well as the identified pairwise co-mutation patterns did not predict for any of the response outcomes.

**Figure 1.**

**Summary/Conclusions:** The type, number and burden of mutations at the time of diagnosis may predict response to therapy with HMA in patients with MDS and CMML.
STUDY OF THE EFFECT OF miRNAs TARGETING RPS14 ON CELLULAR BIOLOGICAL BEHAVIOR OF MYELODYSPLASTIC SYNDROMES

Y. Nie¹,², B. Xiong¹, X. Zuo¹, S. Wang²
¹Zongnan Hospital of Wuhan University, Wuhan, ²Institute of Hematology & Blood Disease Hospital, CAMS & PUMC, Tianjin, China

Background: As key factors in gene post-transcriptional regulation, microRNAs (miRNAs) have been identified to play important roles in carcinogenesis in various tumors. Myelodysplastic syndrome (MDS) is a group of clonal myeloid disorders characterized by refractory quantitative and qualitative abnormalities of hemocytes and its pathogenesis is poorly understood. Some studies have shown that abnormal expressions of some miRNAs have close relationship with the pathogenesis of MDS. Recently, low RPS14 expression is found common in all kinds of myelodysplastic syndromes including patients without 5q deletion, but its mechanism remains unclear.

Aims: To determine the cause of RPS14 reduction in MDS except 5q-syndrome, influence of miRNAs on RPS14 expression was analyzed, and the role of specific miRNA on proliferation, differentiation and apoptosis of hematopoieticstem cells were evaluated. This research will help reveal the pathogenesis of MDS from a new angle and provide new ideas for the diagnosis, treatment and prognosis evaluation of MDS.

Methods: Firstly, we predicted that miR-223 may target 3’UTR of RPS14 by bioinformatics software, then verified if the special miRNA could target RPS14 by assay of luciferase activity. Secondly, the miRNA expression level of miR223 were detected in the bone marrow BM selected from 28 MDS patients including ten RCUD patients, ten RCMD patients, four RAEB-1 patients and four RAEB-2 patients, meanwhile, the miR223 expression status were tested in four kinds cell lines including SKM-1, HL-60, K562 and THP-1 cell lines through qRT-PCR and RPS14 expression was detected by means of immunofluorescence(IF).

Thirdly, constructing lentivirus which carried miR223 overexpression vector and inhibitor were infected to the SKM-1 cell line and K562 cell line which had the highest level of RPS14, then apoptotic analysis was detected by flow cytometry method and proliferation was tested by CCK-8 assay. Fourthly, hemin (50μM,) was used to induce erythroid differentiation of K562 cells which carried miR223 overexpression We used flow cytometry method CD71 and CD235a makers and qRT-PCR(CD235 and r-globin) to detect the erythroid proliferation.

Results: 1.We verified miR-223 could target RPS14 by assay of luciferase activity. 2. MDS patients had higher miR-223 expression compared with health controls especially the types of RAEB-1 and RAEB-2 (P < 0.05). In MDS patients, RAEB patients expressed higher level of miR223 than other types of MDS. Meanwhile, in cell lines, K562 cell line showed the highest level of RPS14 and lowest level of miR223. 3. Infecting miR223 overexpression lentivirus could promote cell proliferation and inhibit cell apoptosis while infecting miR223 inhibitor lentivirus had the opposite effect in SKM-1 and K562 cell lines. 4. We found that forced expression of miR-223 suppresses commitment of r-globin, CD235a and CD71 labeling, in contrast, underexpression of miR-223 promoted terminal erythropoiesis in K562 cell line.

Summary/Conclusions: MDS patients had higher miR-223 expression compared with health controls. We demonstrated that miR223 could promote cell proliferation, inhibit cell apoptosis and suppress terminal erythropoiesis through target RPS14.

Background: Clinical applications of next generation sequencing (NGS) in allogeneic hematopoietic stem cell transplantation are a topic of interest. Mutation dynamics post-HCT using longitudinal NGS have not been thoroughly examined. We hypothesized that serial sequencing of pre-HCT and post-HCT in AML patients could provide a much deeper and broader understanding of clonal origin/hierarchy of relapse after allogeneic HCT. The present study aimed to evaluate mutation dynamics in AML using serial samples from pre- and post-HCT with respect to transplant outcomes, particularly overall survival (OS) and relapse.

Aims: To track origins of post-HCT relapse in AML using serial sequencing

Methods: 88 AML patients were enrolled and sequenced using an Illumina HiSeq 2000 sequencer (84 myeloid custom gene panel) on 419 bone marrow samples at diagnosis (n=88), pre-HCT (n=88), 21 days after HCT (n=88), and at relapse (n=20). Two patients relapsed by day 21. T-cell (n=80) and donor samples (n=57) were also sequenced. All computational and statistical analyses were performed using Python and R.

Results: The mean on-target coverage in 419 samples was 1773.7x. In total, we detected 217 mutations throughout the course of treatment in 79/88 patients (89.8%). NPM1 (26.1%), DNMT3A (26.1%), CEBPA (13.6%), IDH2 (13.6%), FLT3 (12.5%), and PTPN11 (11.4%) were commonly mutated at diagnosis. Unsurprisingly, most mutations appeared at initial diagnosis (200/217, 92.1%). Only 1, and 14 mutations were acquired/selected at post-HCT (0.5%), day 21 (9.9%), and (6.5%), respectively. Most mutations were cleared at pre-HCT (mean mutation allele frequency (VAF) from 27.4% to 2.9%) and were further reduced after HCT (mean VAF from 2.9% to 0.7%) (Fig A). Leveraging
IBRUTINIB FOR CHRONIC GRAFT-VERSUS-HOST DISEASE AFTER FAILURE OF FRONTLINE CORTICOSTEROIDS: RESULTS OF A MULTICENTER OPEN-LABEL PHASE 2 STUDY

Background: There are no approved therapies for chronic GVHD (cGVHD) after failure of steroids. Both B and T cells play a role in the pathophysiologic process of GVHD. In preclinical models, ibritinib (ibr) reduced the severity of cGVHD by inhibition of Bruton's tyrosine kinase (BTK) and interleukin-2-inducible T-cell kinase (ITK).

Aims: This phase 2 study evaluated the efficacy and safety of ibr in patients (pts) with steroid dependent/refractory cGVHD in need of additional therapy.

Methods: Eligible pts had ≤3 prior regimens for cGVHD and either >25% body surface area erythematous rash or a NIH mouth score ≥4. Informed consent was obtained from all pts. Pts were treated with ibr 420mg/d until cGVHD progression or unacceptable toxicity. The primary end point was cGVHD response based on 2005 NIH consensus response criteria. Secondary end points included rate of sustained response, change in Lee cGVHD symptom scale, change in steroid dose over time, and safety. The pharmacodynamics (PD) of ibr and its effects on biomarkers associated with GVHD, inflammation, and fibrosis were evaluated.

Results: A recommended phase 2 dose of 420mg was identified in phase 1b (n=6). For 42 pts in phase 2, the median number of prior cGVHD regimens was 2 (range, 1–3). At a median follow-up of 13.9 mo, overall response rate (ORR) was 67% (CR, 21%), with 71% of responders showing a sustained response ≥20 weeks, 79% responding by the first response assessment. Median time to response in responders from 0.29mg/kg to 0.12mg/kg was ≥29 weeks. Overall, 62% of pts achieved steroid doses <0.15mg/kg/d while on ibr; 5 responders discontinued steroids. Organs with cGVHD involvement including skin, mouth, and gastrointestinal system showed similar responses (>90%). Of 25 responders with ≥2 involved organs, 20 (80%) showed a response in ≥2 organs and 14 (56%) showed a sustained response > ≥20 weeks. Among 61 pts treated, overall improvement was reported for 43% of responders by month 6 and 61% overall, compared with 11% of nonresponders by month 6 and overall. Ibr blocked BTK-driven basophil activation in an ex vivo IgE stimulation assay and ITK-mediated activation of PLCγ1-1-Y783 in CD4 T-cells. Analysis of soluble plasma factors associated with inflammation, fibrosis, and cGVHD from all treated pts showed a significant decrease over time with ibr. Adverse events (AEs) were largely grade 1 or 2 events; AEs occurring in ≥20% of pts were fatigue, diarrhea, muscle spasms, nausea, and bruising. Grade 3 AEs occurring in ≥10% of pts were pneumonia, fatigue, and diarrhea. Serious AEs (SAEs) occurred in 52% of pts; grade 3 SAEs were reported in 46% of pts and included pulmonary, septic, and pyrexia. Two fatal events (multilobular pneumonia and bronchopulmonary aspergillosis) were reported. Fourteen pts discontinued ibr for AEs, 5 pts for progressive cGVHD, and 2 pts after resolution of cGVHD symptoms; 29% continued ibr.

Summary Conclusions: With an ORR of 67% and a sustained response rate of ≥20 weeks of 71%, treatment with ibr resulted in clinically meaningful and durable responses in pts who failed at least 1 prior treatment for cGVHD. Most responders were able to reduce steroid dose. PD and biomarker changes support a beneficial effect of ibr on immune cell subsets in pts with cGVHD. The safety profile of ibr was consistent with those previously reported for pts with B cell malignancies and those seen in cGVHD pts on concomitant steroids. Responses in this pretreated, high-risk population support study of ibr for frontline treatment of cGVHD.

OUTCOMES OF NON T-CELL-DEPLETED HAPLOIDENTICAL HSCT VS HAPLOIDENTICAL HSCT FROM MATCHED SIBLING DONORS IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA IN FIRST COMPLETE REMISSION, AN ALWP-EBMT STUDY

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is the standard of care for patients (pts) with intermediate- and high-risk AML. In pts lacking matched sibling (MSD), HSCT from haploidential donors (HAPLO) is an emerging option.

Aims: The aim of the study was to compare outcomes of non T-cell-depleted HAPLO HSCT to those from MSD HSCT.

Methods: Eligible pts included were adults with AML in first CR undergoing transplantation from HAPLO vs MSD from 2007-2015. Due to significant interaction between karyotype and donor type, int- and high-risk AML were studied separately. In addition because of some characteristic differences between the 2 groups the propensity score technique was used: 2 MSD were matched with each haplo. The following factors were included in the propensity score model: patient, year of HSCT, time from diagnosis to HSCT, conditioning (RIC), source of stem cells (BM/BP), cytogenetic group, patient and donor CMV serology status.

Results: We identified 2654 pts (HAPLO=185; MSD=2469) for int-AML (HAPLO=122; MSD=1888) or high-risk AML (HAPLO=63; MSD=581). Median follow-up of surviving pts was 116 months (1-251). Among 185 HAPLO recipients, 74% received PTCY and 26% ATG. Conditioning regimen was myeloablative in 50% vs 52% (p=0.52) of HAPLO and MSD pts, respectively. HAPLO pts had a longer interval from diagnosis to HSCT (6 vs 4 months; p<0.01), had more often high-risk AML (34% vs 23%; p<0.01), bone marrow as stem cell source (49% vs 19%; p<0.01) and CMV positive donors (72% vs 61%; p<0.01). Graft failure occurred more frequently after HAPLO (3% vs 1%; p=0.002). For pts with int-AML CI of aGVHD and cGVHD was 29% vs 20% (p=0.03) and 30% vs 36% (p=0.02) in HAPLO and MSD pts, respectively. At 2 years, NRM and RI were 26% vs 10% (p<0.01) and 17% vs 20% (p=0.52) in HAPLO vs MSD, respectively. Among surviving pts, OS was 49% at 4 years (p=0.01) and 69% at 7 years (p=0.01) in HAPLO and MSD pts, and GRFS was 45% vs 53% (p=0.05), respectively. In multivariate analysis HAPLO was associated with reduced LFS (HR 1.74; 95% CI 1.30-2.33; p<0.01), OS (HR 1.86; 95% CI 1.32-2.45; p<0.01) and GRFS (HR 1.32; 95% CI 1.01-1.72; p<0.05) and higher NRM (HR 3.03; 95% CI 1.98-4.42; p<0.001). Incremental age was independently associated to lower LFS, OS, GRFS and higher NRM and cGVHD. MAC was associated with lower RI and higher GVHD. A female donor into male recipient was associated to higher GVHD and lower GRFS. A longer interval from diagnosis to HSCT was associated with decreased risk of OS.
ciliated to lower LFS. Donor CMV seropositivity was associated with lower GRFS and higher NRM and aGVHD. In high risk-AML, aGVHD and cGVHD were 36% vs 24% (p=0.03) and 39% vs 33% (p=0.80) for HAPLO and MSD pts, respectively. At two years, NRM and RI were 18% vs 10% (p=0.16) and 21% vs 36% (p=0.02) while LFS and OS were 61% vs 55% (p=0.14) and 67% vs 66% (p=0.26) in HAPLO and MSD pts; GRFS was 42% vs 40% (p=0.17). In multivariate analysis risk of grade IV aGVHD (HR: 2.20; 95% CI: 1.20-3.74; p<0.01) was increased after Haplo as compared to MSD and no difference was observed in LFS, OS and GRFS, respectively. Conditioning regimen was associated with lower NRM and higher GRFS, while younger age and donor CMV status were associated with lower RI, higher LFS and OS. Results were confirmed in the analysis comparing with the the propensity score technique as for RI, NRM, LFS, OS and GRFS.

Summary/Conclusions: As per our registry based study in intermediate risk AML results of HSCT from matched sibling donor are superior to those of HAPLO-HSCT, while in high risk-AML relapse is lower in the HAPLO transplants and NRM, LFS and OS is similar.

S495

IMPACT OF POST-TRANSPLANT INFUSION OF DONOR T CELLS GENETICALLY MODIFIED WITH INDUCIBLE CASPASE 9 SUICIDE GENE (BPX-501 CELLS) ON CHILDREN WITH LEUKEMIA GIVEN ALPHA-BETA T-CELL DEPLETED HAPLO-HSCT

P. Merli1, A. Bertaina1, F. Galaverna1, M. Aigen1, D. Pagliara1, G. Li Pira1, J. Weinberg2, A. Moseley2, F. Locatelli1, Ospedale Pediatrico Bambino Gesu, Rome, Italy, 2Bellum Pharmaceuticals Inc., Houston, United States

Background: HLA-haploidentical allogeneic hematopoietic stem cell transplant (haplo-HSCT) offers an option for children with acute leukemia in need of a transplant and lacking an acceptable HLA-identical donor. However, performing haplo-identical-HSCT without any graft manipulation has historically been associated with a high risk of acute and chronic graft-versus-host disease (GVHD). T cell depletion reduces the risk of GVHD, but leads to delayed immune reconstitution, predisposing to serious infection and leukemia relapse due to the lack of a T-cell mediated graft-versus-leukemia (GvL). To address these challenges, we have infused mature BPX-501 T cells (donor peripheral lymphocytes which have been modified with the iCasp9 suicide gene) after αβ T-cell depleted haplo HSCT to facilitate immune reconstitution and GvL effect. BPX-501 T-cells are genetically modified with the iCasp9 suicide safety switch and a truncated CD19 marker. In the event of GVHD, the switch is activated by an infusion of the drug rimiducid (AP1903) resulting in rapid T cell apoptosis and GVHD reversal.

Aims: This study was performed to evaluate both safety and efficacy of BPX-501 T-cell infusion post αβ T-cell depleted haplo HSCT in pediatric patients with high risk ALL and AML in CR1 and CR2.

Methods: A prospective Phase II study enrolling children with hematopoietic disorder who lack a matched donor. 38 patients have been enrolled and treated with αβ TCR depleted haplo HSCT after a myeloablative preparative regimen followed by BPX-T cell infusion to date; of them, 24 had ALL and 14 AML (21% CR1, 79% CR2). Median follow-up is 11 months (range 3-24).

Results: All patients engrafted and no secondary graft failure was recorded. Median time to neutrophil and platelet recovery was 16 days (range 8-33) and 11 days (range 7-19), respectively. With a median follow-up of 11 months (range 3-24 months), the cumulative incidence of NRM and relapse was 3.7% and 12.0%, respectively, while the disease-free survival probability was 84.2% (Fig 1). All aGVHD resolved (5 Grade I skin, 5 Grade II skin, 2 Grade III GI). One child received rimiducid to treat steroid-resistant grade II skin with complete resolution in 24 hours (Fig 2). There were 3 cases of chronic GVHD, 2 were mild, 1 severe and fatal in a patient whose donor had VZV reactivation during mobilization. CD3+ T cells reached 500 cells/μl by day 90, with normalized CD4/CD8 T cell ratio by day 180.

Summary/Conclusions: Engraftment was brisk and T cell recovery normalized within 6 months. Overall incidence of severe aGVHD was low and the safety switch was successfully activated with rimiducid infusion. Cumulative incidence of NRM compares favorably to historic controls at the lead center, where a value of 0.24% for matched related donors (MR), 11.8% for matched unrelated donors (MUD) and 5% for αβ T cell depletion haplo HSCT (Haplo αβ) without BPX-501 infusion was recorded (Bertaina, 2015 ASH). The cumulative incidence of relapse was 12.0% for BPX-501, 32.3% for MR, 22.2% for MUDs and 21.9% Haplo-αβ. Disease-free survival in the BPX-501 treated patients was 84.2% compared to 65.4% for MR, 66.1% for MUDs and 73.1% for Haplo-αβ. However, length of follow-up on the control cohorts differed from that of BPX-501 treated patients. These data suggest that BPX-501 T cells modified with the iCasp9 safety switch, infused after selective αβ T-cell depletion, are safe and result in a rapid immune reconstitution and a potentially stronger GvL effect in children with high-risk leukemia who lack a matched donor.

HEREDITARY HEMATOLOGIC MALIGNANCIES: GENETIC COUNSELING IMPLEMENTATION IN A LARGE LEUKEMIA CENTER
C. Dimaro1, S. Bannen2, K. Takahashi1, C. Benton1, M. Routbort3, N. Pettmaraju1, N. Daver1, T. Kadil1, G. Garcia-Manero3, K. Patel3, H. Kantarjian1, A. Niedobite4,5
1Leukemia, 2Clinical Cancer Genetics, 3Hematopathology, 4Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Hematologic malignancies have rarely been targets for genetic evaluation, even in familial cases. Over the past decade, more than 12 genes have been identified to cause inherited predispositions to hematologic malignancies. Genetic counseling, testing, and surveillance protocols for these families are not well-established. Additionally, many families with high incidence of blood cancers do not have described syndromes suggesting additional genes remain to be identified.

Aims: To identify individuals with inherited susceptibilities to hematologic malignancies, the Hereditary Hematologic Malignancy Clinic (HHMC) was established in April 2014 at The University of Texas M. D. Anderson Cancer Center. The clinic (HHMC) and ancillary departments provide clinical and research testing for patients with congenital neutropenia who have been identified to have inherited predisposition syndromes.

Methods: Individuals were referred to the HHMC for several indications: (1) bone marrow failure/aplastic anemia/hypocellular MDS, (2) personal history of hematologic malignancy with ≥1 first-degree relative or ≥2 second-degree relatives with hematologic malignancy, (3) personal history of multiple primary cancers, (4) germline evaluation of presumed somatic mutations identified on next-generation leukemia prognostication panels, (5) management and/or surveillance of a previously-identified genetic syndrome, or (6) solid tumor hereditary syndromes with active hematologic malignancy. Over the past 3 years, 152 probands were evaluated (n=152). Skin biopsies were performed to obtain germline DNA, and next-generation sequencing approaches on both a clinical and research basis were utilized.

Results: Clinical genetic testing was performed in 97/152 individuals (64%). Research testing was performed in 46/152 (30%), particularly in patients negative for known susceptibility genes or without features suggestive of a clinical syndrome. Nine (6%) individuals did not undergo genetic testing. Clinical testing identified 23/97 (24%) individuals with a germline susceptibility to hematologic malignancy. Seven probands (7%) were identified to have RUNX1 mutations associated with the diagnosis of a familial platelet disorder with myeloid malignancy (FPD-AML). Six (6%) were identified to have the telomere disorder dyskeratosis congenita; only one of them met clinical diagnostic criteria with the “classic triad” of symptoms. Three (3%) patients were identified to have Li-Fraumeni syndrome due to constitutional TP53 mutations. Two adults (2%) were diagnosed with Diamond-Blackfan anemia and two (2%) had constitutional myelodysplastic syndrome after a long latency period and prior spontaneous remission of their childhood anemia. Two young adults (2%) with Fanconi anemia were diagnosed, and one patient each with DDX47 mutation and CBL (Noo- nan-like syndrome with JMM) were identified. Counseling, testing, and surveillance of identified mutation carriers in many affected families is ongoing.

Summary/Conclusions: Individuals with hereditary susceptibilities to hematologic malignancies are not as rare as previously thought. Clinical evaluation of these patients through genetic counseling and testing is high yield for identifying at-risk families. Research-based sequencing for novel mutations is indicated and ongoing.

S497
SECONDARY LEUKEMIAS IN GENETIC SUBTYPES OF CONGENITAL NEUTROPENIA (ELANE, HAX1, WASP, G6PC3, ETC.): A LONG-TERM ANALYSIS OF THE SCNIR EUROPE
C. Zeidler1, M. Klmiankou1, A. Nickel1, S. Mellor-Heineke1, J. Skokowa2, K. Welte2
1Leukemia, 2Clinical Cancer Genetics, 3Hematopathology, 4Genomic Medicine, Medicine, University of Texas MD Anderson Cancer Center, Houston, United States

Background: Leukemia predisposition is well known in congenital neutropenia (CN) subtypes. By taking all patients with known and unclassified CN together the incidence of secondary leukemia accounts for more than 10 percent. Advanced molecular diagnostics and the identification of inherited and acquired gene mutations have improved our understanding of leukemic transformation in CN patients.

Aims: In the European SCNIR 449 patients with congenital neutropenia and 91 patients with cyclic neutropenia (CyN) have been enrolled since 1994. These 449 patients were diagnosed by classified and unclassified genetic subtypes: ELANE, HAX1, G6PT, G6PC3, WAS, SBDS, TA2 and p14 or no identified mutation, respectively. Our aim is to assess the risk of leukemic transformation within these genetic subgroups.

Methods: Here we report the leukemia incidence of genetic subtypes analyzing all available long-term data from the European Branch of the Severe Chronic Neutropenia Registry (SCNIR). In addition, we analyzed 91 patients with CyN with or without ELANE mutations.

Results: Results from genetic testing were available for 314 of 449 CN patients, of whom 118 patients revealed ELANE, 48 HAX1, 71 SBDS, 28 G6PT, 9 G6PC3, 7 WAS, 5 TA2 mutations and 27 other rare gene mutations (e.g. p14, CXCR4), 135 patients remain unclassified. In addition, 48 of 91 patients with CyN revealed ELANE mutations. Secondary myelodysplastic syndrome (MDS) or leukemia occurred in 49 of the 449 CN patients and in 1 of the 48 ELANE-CyN patients. Acquired CSF3R nonsense truncating mutations have been detected in the bone marrow cells of about 80% of CN patients who progress to MDS or acute myeloid leukemia (AML) and around 30-35% of non-leukemic CN patients, supporting the association between the acquisition of CSF3R mutations and leukemic transformation. These mutations have been shown to be acquired in hematopoietic cells only and therefore are not the primary cause of transformation. At the time of first detection of CSF3R mutations, and of malign transformation is highly variable. Some patients progressed to MDS/AML within a few months. In others, CSF3R mutant clones persisted for many years without progression to leukemia. The distribution by genetic subtypes and the frequency of CSF3R mutations is shown in the table below.

Summary/Conclusions: The incidence of secondary AML reflects the genetic heterogeneity of CN.

EFFECT OF ECULIZUMAB IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) PATIENTS WITH OR WITHOUT HIGH DISEASE ACTIVITY: RESULTS FROM THE INTERNATIONAL PNH REGISTRY
B. Höchsmann1, S. Bannon2, K. Takahashi1, C. Benton1, M. Routbort3, A. Kulagin4, P. Hillmen5, A. Wilson5,6, M. Marantz2, H. Schrezenmeier7,8
1Institute for Clinical Transfusion Medicine and Immunogenetics, University Hospital Ulm, Ulm, Germany, 2Hôpital Saint Louis, Paris, France, 3Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of, 4Pavlov First Saint Petersburg State Medical University, St. Petersburg, Russian Federation, 5St. James’s University Hospital, Leeds, United Kingdom, 6Alexion Pharmaceuticals, Inc., Lexington, MA, United States

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, progressive, life-threatening disease caused by somatic phosphatidylinositol glycan class A (PIGA) gene mutation in bone marrow stem cells. The International PNH Registry (NCT01374360) is a prospective, multinational, observational study to record the natural history of PNH and collect data on long-term efficacy and safety of treatment with eculizumab (ecu), a humanized monoclonal antibody approved for treatment of PNH.

Aims: Evaluate the effect of eculizumab in PNH patients with or without high disease activity (HDA).

Methods: Patients enrolled in the Registry as of December 5, 2016, were stratified by HDA and ecu treatment status into 4 groups: HDA/ecu-treated; HDA/never ecu-treated; no-HDA/ecu-treated; no-HDA/never ecu-treated. HDA is defined as lactate dehydrogenase (LDH) ratio ≥1.5x upper limit of normal within 6 months of baseline and history of any of the following: fatigue, hemoglobinuria, abdominal pain, dyspnea, anemia (hemoglobin <10 g/dL), major adverse vascular event (MAVE; including thromboembolism [TE]), dysphagia, or erectile dysfunction. Patients were assessed at baseline (date of enrollment in never ecu-treated patients; date of initiation of ecu in ecu-treated patients) and at last follow-up. Outcomes include changes from baseline to last follow-up in LDH ratio, GPI-deficient granulocytes, red blood cell transfusions received, MAVE, and Functional Assessment of Chronic Illness Therapy (FAC-IT)-Fatigue score in patients with at least 6 months of follow-up.
Results: 4717 patients were enrolled; of these, 2670 had non-missing data on euc and HDA status, and were included in the current analysis (HDA/euc-treated, n=785; HDA/never euc-treated, n=636; no-HDA/euc-treated, n=111; no-HDA/never euc-treated, n=1138). Median (min, max) duration of follow-up after baseline was longer for the euc-treated patients compared with the never euc-treated patients for both the HDA and no-HDA groups (see Table). Results for changes from baseline to last follow-up in outcomes of interest are summarized in the Table. Data show that patients in the euc-treated cohort had high burden of disease at baseline. Specifically, in the HDA population, a higher proportion of euc-treated patients had a history of MAVE (33.3% vs never euc-treated patients (13.7%)). A similar disparity at baseline was also observed in the no-HDA population (33.0% vs 11.0%, respectively).

Following euc treatment, the divergence in the proportion of patients with MAVE has substantially narrowed for the HDA patients (3.9% for euc-treated vs 3.3% for never euc-treated) despite longer follow-up for the treated patients. Similar findings were seen in no-HDA patients (5.3% vs 2.1% respectively). In patients with MAVE, treatment with euc was associated with meaningful improvement in mean (standard deviation (SD)) reduction from baseline in LDH ratio (-5.0 [3.7] vs -0.4 [2.3]) and proportion of red blood cell transfusion-free patients (37.6% vs 15.8%). The FACIT-Fatigue data, while limited, showed the HDA/euc-treated group experienced a meaningful greater mean (SD) score improvement than the HDA/never euc-treated group (4.1 [10.3] vs 0.5 [6.8] points).

Table 1.

Summary/Conclusions: Our analysis of real-world data from the International PNH Registry has demonstrated that treatment with eculizumab was associated with improved outcomes in patients with HDA. Our findings are consistent with the notion that patients with HDA, including those with a history of MAVE, should be treated with eculizumab.

S499

CONGENITAL AMEGAKARYOCYTIC THROMBOCYTOPENIA: FUNCTIONAL RESCUE OF A NOVEL MPL MUTANT IN PRIMARY HEMATOPOIETIC CELLS USING CRISPR-Cas9

C. Clegge1, R. Girard1, E.H. Choi1, É. Jeziorski2, T. Lavabre-Bertrand3, C. Cleyrat1,*, R. Girard 1, E.H. Choi 1, É. Jeziorski 2, T. Lavabre-Bertrand 3, S. Hermesouñ4, S. Carrillo5, B.S. Wilson1

1Pathology, University of New Mexico Cancer Center, Albuquerque, United States, 2Service de Pédiatrie III, Hôpital Arnaud de Villeneuve, Montpellier, France, 3Laboratory of Clinical Cytology and Cytogenetics, University Hospital of Nîmes, Nîmes, 4Inserm UMRS892/CNRS UMR6299, Centre de Recherche en Cancérologie Nantes-Angers (CRCNA) and Institut de Recherche en Santé - 2, Nantes, France

Background: Thrombopoietin (Tpo) and its receptor, MPL, are the principal regulators of early/late thrombopoiesis and hematopoietic stem cells maintenance. Mutations in MPL can drastically impair its function and be a contributing factor in multiple hematologic malignancies, including congenital amegakaryocytic thrombocytopenia (CAMT). CAMT is a rare inherited syndrome characterized by thrombocytopenia at birth, progressing to bone marrow failure and pancytopenia. The functional impact of CAMT mutations on MPL is yet to be determined. Here we report unique familial cases of CAMT presenting with a previously unreported MPL mutation: T814C (W272R) in the background of the activating MPL G117T (K39N or Baltimore) mutation.

Aims: To determine the characterization of this novel MPL mutant and the use of genome editing as a novel therapeutic option for CAMT.

Methods: Human megakaryoblastic UT-7 and murine Ba/F3 cells stably expressing human wild-type (WT) MPL or mutant MPL fused to mNeonGreen were used as models. Confocal microscopy, proliferation and surface biotinylation assays, as well as co-immunoprecipitation and western blotting analysis, were used to elucidate the function and trafficking of MPL mutants. Multiplex, flow-based, CRISPR-Cas9 gene editing was used to repair mutant MPL and rescue its function. Cord blood from the younger male sibling was used as a source of primary homogeneous MPL K39N/W272R CD34+ cells. CD34+ cells were edited using ribonucleoproteins electroporation followed by sequencing and functional assays such as flow cytometry and single colony assays.

Results: Consanguineous parents and their eldest daughter, all heterozygous for MPL K39N/W272R, do not present any signs of disease. Their monozygotic twin daughters presented at birth with severe thrombocytopenia leading to a diagnosis of CAMT type I. Whole blood sequencing revealed a novel homozygous double MPL K39N/W272R mutation, as their younger male sibling. One of the twins died after bone marrow transplant. Confocal microscopy shows that a significant fraction of chimeric WT MPL protein reaches the cell surface. Significant surface expression is also noted for MPL K39N. In contrast, the chimeric MPL protein bearing the W272R mutation, alone or together with the K39N mutation, showed no detectable surface expression of the Tpo receptor while being strongly co-localized with ER marker calnexin. Both WT and K39N-mutated MPL were found signaling competent, while single or double mutants bearing W272R were unresponsive to Tpo. Tpo-induced signaling was partially rescued by overexpression of GRASP55 (forcing ER-MTOC interaction and traffic to the cell surface). Genome editing performed on cells carrying the W272R mutation restored the WT sequence and the response to Tpo, with similar cell proliferation as WT MPL cells. Finally, when applied to primary MPL K39N/W272R CD34+ cells, CRISPR-based gene editing rescued surface expression of MPL and response to Tpo, as assessed by flow cytometry. Primary MPL K39N/W272R CD34+ cells were able to generate a similar number of megakaryocytic colonies as control CD34+ cells in a single colony assay. Non-edited cells failed to do so.

Summary/Conclusions: We report a new double in cis mutation of MPL (K39N/W272R) in the context of CAMT. Function of the deficient MPL receptor could be rescued using two characterized approaches: genome editing and CRISPR-Cas9 genome engineering. Successful editing of primary hematopoietic stem cells indicates direct therapeutic applications for gene editing in this disease.

DISCOVERY OF ORALLY AVAILABLE SMALL MOLECULES FOR INHIBITION OF COMPLEMENT C5

A. Ricardo1, M.D. Hoarty1, J.C. Blain1, S.J. DeMarco1, V. Galullo1, M.R. Hale1, E. de Koning1, D. LaPlaca1, K. Seyb1, J.R. Stringer1, G.-Q. Tang1, J. Tikhe1, D. Vadyasilack1, R. Vyasamneni1, D. Vadysirisack1, R. Vyasamneni1

1Ra Pharmaceuticals, Inc., CAMBRIDGE, United States

Background: Paroxysmal nocturnal hemoglobinuria (PNH) and atypical hemolytic uremic syndrome (aHUS) are well-characterized diseases of complement dysregulation. The only approved therapeutic for these diseases is Soliris® (Eculizumab, Alexion), a monoclonal antibody that binds and inhibits the cleavage of complement C5. Soliris® requires lifelong intravenous administration by a medical professional every two weeks. An orally bioavailable small molecule inhibitor of complement C5 to treat these and other complement-mediated diseases represents a potential paradigm shift in the treatment of diseases of complement dysregulation.

Aims: To demonstrate the utility of an orally available, small molecule Complement C5 inhibitor for the treatment of complement mediated disorders.

Methods: Surface Plasmon Resonance (SPR) and Fluorescent Polarization assays (FP) were used to evaluate the affinity and specificity of the binding interaction between complement C5 and small molecule inhibitors. Determination of binding site, mechanism of action and potency were achieved by X-ray crystallography studies, Wieslab ELISA, and a sheep erythrocyte hemolysis based assay. The ability of the small molecules to prevent the hemolysis of PNH erythrocytes was evaluated using a modified Ham test. Pharmacokinetic studies were performed in rodents.

Results: Here we describe a series of first in class, orally bioavailable small molecules that bind to C5 with high affinity and inhibit its cleavage into C5a and C5b. These molecules demonstrate desirable drug-like properties with molecular weights under 500 amu and tPSA<100 Å2. A high-resolution co-crystal structure of complement C5 shows a unique binding site on the 188 kDa C5 protein, and specific binding of these molecules to C5 has been demonstrated by surface plasmon resonance (SPR) and fluorescence polarization (FP) assays. The position of the binding site suggests that these molecules will inhibit C5 cleavage in patients with the R885H/C polymorphism, which confers resistance to eculizumab. The position of the binding site suggests that these molecules will inhibit C5 cleavage in patients with the R885H/C polymorphism, which confers resistance to eculizumab. The position of the binding site suggests that these molecules will inhibit C5 cleavage in patients with the R885H/C polymorphism, which confers resistance to eculizumab. The position of the binding site suggests that these molecules will inhibit C5 cleavage in patients with the R885H/C polymorphism, which confers resistance to eculizumab. The position of the binding site suggests that these molecules will inhibit C5 cleavage in patients with the R885H/C polymorphism, which confers resistance to eculizumab.

Summary/Conclusions: The results presented here highlight, for the first time, the results of a clinical trial of an orally active, potent small molecule inhibitor of C5. The development of an orally available complement C5 inhibitor has the potential to provide a new therapeutic modality to treat both rare and common conditions where terminal complement cascade inhibition is desired.
Quality of life, palliative care, ethics and health economics

SS01 QUALITY OF LIFE WITH MELPHALAN/PREDNISONE PLUS EITHER THALIDOMIDE (MPT-T) OR LENALIDOMIDE (MPR-R) IN NON-TRANSPLANT ELIGIBLE NEWLY DIAGNOSED MULTIPLE MYELOMA; RESULTS OF THE HOVON87/NMSG18 STUDY

Background: We recently reported the results of the phase III randomized HOVON87/NMSG18 study showing comparable efficacy of treatment with melphalan, prednisolone and thalidomide following by thalidomide maintenance (MPT-T) versus melphalan, prednisolone and lenalidomide followed by lenalidomide maintenance (MPR-R) (Zweegman S et al. Blood 2016;127(9):1109-1116). As not only efficacy but also potential toxicity affecting quality of life (QoL) guides the choice of treatment, health-related (HR) QoL is important. Aims: To evaluate the HRQoL results of the HOVON87/NMSG18 study. Methods: Two validated HRQoL instruments (EORTC QLQ-C30 and MY20) were completed at baseline, after 3 and 9 induction cycles (3ID and 9ID) and after 6 and 12 months of maintenance therapy (6MT and 12MT). The subscales global QoL, physical functioning, pain, fatigue, constipation, diarrhea, nausea/vomiting, insomnia, disease symptoms, side effects of treatment, and neuropathy were analysed. Change in HRQoL score over time between treatment arms was assessed by linear mixed models. Independent sample t-tests were used to determine differences from baseline. Minimal important difference (MID) was defined in a difference in score of ≥5 points (mean difference (MD) ≥5 points or, if a subscale consisted of one parameter only, MID-0.5). To determine clinically relevant superiority of one arm, a difference in score of ≥5 was used and in addition significance level was calculated.

Results: From 553 (90.2%) of the 613 patients who participated in the HRQoL part of the study a baseline questionnaire was available. Forty (15%) of patients randomized to MPT-T versus 88 (24%) of patients randomized to MPR-R completed the study until 12 months of maintenance therapy. Change in HRQoL between arms over time: in MPT-T improvement of HRQoL over time as compared to MPR-R was found for the subscales diarrhea and insomnia. In contrast, MPR-R showed improvement over time for the subscales pain, constipation, and disease symptoms. As compared to MPT-T, Change in HRQoL per arm: In MPT-T HRQoL was reduced for the following subscales: global QoL increased after 9ID until 12MT (MID range 7-13), pain decreased at every time point (MID range -21 to -23), disease symptoms decreased after 9ID (MID -12), fatigue decreased during MT (MID 12) and insomnia decreased at each time point (MID range -11 to -23). In MPR-R the MID was reached for the following subscales: global QoL increased after 9ID until 12MT (MID range 8-14), physical functioning increased at 12MT (MID 13), pain decreased at every time point (MID range -14 to -26) and insomnia decreased at 6MT (MID -10). Difference between MPT-T and MPR-R: In the MPT-T arm significantly (p<0.05) and/or clinically (mean score difference (MSD) ≥5 points) less pain and disease symptoms at 3ID, less fatigue at 3ID and 9ID, less diarrhea and less insomnia at all time points were observed. In contrast, patients on MPR-R reported better global QoL, better physical functioning and less pain at 12MT, in general less side effects of treatment, and less constipation and neuropathy separately, at all time points than patients treated with MPT-T.

Summary/Conclusions: Both treatment with MPT-T and MPR-R controlled pain and resulted in an improvement in global QoL, as compared to baseline after 9ID and during maintenance. Treatment with thalidomide initially resulted in less pain and disease symptoms. At all treatment stages thalidomide caused less diarrhea, fatigue and insomnia as compared to treatment with lenalidomide. In contrast, therapy with lenalidomide resulted in less side effects of treatment, less constipation and less neuropathy as compared to thalidomide at all stages of treatment. In addition, long term maintenance therapy with lenalidomide resulted in better global QoL, better physical functioning and less pain.

SS02 HEALTH-RELATED QUALITY OF LIFE RESULTS FROM THE PHASE III GALLIUM STUDY OF OBINUTUZUMAB-BASED AND RITUXIMAB-BASED THERAPY IN PATIENTS WITH PREVIOUSLY UNTREATED ADVANCED INDOLENT NON-HODGKIN LYMPHOMA

1Cancer Research UK Centre, University of Southampton, Southampton, United Kingdom. 2Genentech Inc., South San Francisco, United States. 3Simmelweis University, Budapest, Hungary. 4Städtisches Klinikum Dessau, Dessau, Germany. 5Department of Hematology, Shanghai Cancer Center, Shangai, China. 6Aichi Cancer Center Hospital, Aichi, Japan. 7St George’s University, London, United Kingdom. 8St Vincent’s Hospital, Sydney, Australia. 9Bristol Haematology and Oncology Centre, Bristol, United Kingdom. 10University of Melbourne, Melbourne, Australia. 11Bristol Haematology and Oncology Centre, Bristol, United Kingdom. 12University of Melbourne, Melbourne, Australia. 13University of Manchester, United Kingdom. 14University of Tübingen, Germany. 15University of Tübingen, Germany. 16University of Genoa, Italy. 17University of Genoa, Italy. 18University of Genoa, Italy. 19University of Genoa, Italy. 20University of Genoa, Italy. 21University of Genoa, Italy. 22University of Genoa, Italy. 23University of Genoa, Italy. 24University of Genoa, Italy. 25University of Genoa, Italy. 26University of Genoa, Italy.

Background: Maintenance of pretreatment health-related quality of life (HRQoL) and/or meaningful improvements in HRQoL are important for previously untreated indolent non-Hodgkin lymphoma (iNHL) patients (pts). GALLI-
UM (NCT01332968) is an open-label, randomized Phase III study of obinutuzumab (GA101; G) plus chemotherapy (chemo) followed by G maintenance (G-chemo) compared with rituximab (R) plus chemo followed by R maintenance (R-chemo) in pts with previously untreated iNHL. In GALLIUM, G-chemo produced a clinically meaningful improvement in investigator-assessed progression-free survival (PFS) among follicular lymphoma (FL) pts (34% reduction in risk of a PFS event relative to R-chemo). Grade 3–5 and serious adverse events were more common with G-chemo.

**Aims:** To compare changes in HRQoL in FL pts receiving G-chemo and R-chemo during GALLIUM.

**Summary/Conclusions:**
- There were no clear differences between arms in the incidence of physical function, functional wellbeing, emotional and social function. Over the course of treatment, mean HRQoL was maintained in both arms. At baseline, mean HRQoL scores were similar in the two treatment arms, with all pts having some impairment of physical function, functional wellbeing, emotional and social function.
- The results suggest that lymphoma-related symptoms were reduced by both treatments and that HRQoL scores over the course of therapy.
- There were no clear differences between arms in the incidence of physical function, functional wellbeing, emotional and social function. Over the course of treatment, mean HRQoL was maintained in both arms. At baseline, mean HRQoL scores were similar in the two treatment arms, with all pts having some impairment of physical function, functional wellbeing, emotional and social function.
- The results suggest that lymphoma-related symptoms were reduced by both treatments and that HRQoL scores over the course of therapy.

**Results:** Of 1202 FL pts randomized (median age, 59 yrs; 53.2% female; median observation time, 34.5 mo [range 0–54.5]), 856/601 (92.5%; G-chemo) and 550/601 (91.5%; R-chemo) completed all FACT-Lym scales at baseline. Baseline demographics and disease characteristics were balanced between arms. At baseline, mean HRQoL scores were similar in the two treatment arms, with all pts having some impairment of physical function, functional wellbeing, emotional and social function. Over the course of treatment, mean HRQoL was similar in the two treatment arms. From end of induction onwards, pts in both arms experienced clinically meaningful improvements from baseline in LYMS scores (Figure), and the summary scales that included this subscale (TOI; Lym-Tot). On each summary scale, >50% of patients in each arm reported clinically meaningful improvements. There were no clear differences between arms in HRQoL scores over the course of therapy.

**Summary/Conclusions:** In previously untreated FL pts in GALLIUM, G-chemo and R-chemo produced similar improvements in HRQoL. These results suggest that lymphoma-related symptoms were reduced by both treatments and that the resulting improvements in well-being were not abrogated by treatment-related side effects. When viewed in the context of longer PFS, these results further support the relative benefit of G-chemo over R-chemo in GALLIUM.

**Figure 1.**

**Methods:** Enrolled pts were aged ≥18 years with documented, previously untreated FL (grades 1-3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7cm), ECOG performance status 0-2, and requiring treatment according to GELF criteria. Pts were randomized 1:1 to R 375mg/m² on day (D) 1 of each cycle (C) or G 1000mg on D1, 8, and 15 of C1 and D1 of C2-8, for 6 or 8 cycles depending on chemo (CHOP, CVP or bendamustine). Responders continued to receive R or G every 2 months (mo) for 2 years or until progression. The Functional Assessment of Cancer Treatment-Lymphoma (FACT-Lym) questionnaire (Webster et al. 2005) was used to assess overall HRQoL, physical and functional well-being, and disease- and treatment-related symptoms. FACT-Lym was administered on D1 of C1 and C3 during induction, at the end of induction, and at mo 2 and 12 during maintenance/overlap. For each FACT-Lym scale, mean and 95% confidence interval (CI) were derived for recorded scores at each visit and changes from baseline. Minimally important differences (MIDs) were used to calculate the proportion of pts reporting improvement on the FACT-Lym lymphoma subscale (LYMS; ≥3 points). All pts gave informed consent.

**Results:** Of 277 responses were returned with 1 response excluded (non-haematological malignancy). Haematological diagnoses included acute leukaemia (n=40), chronic leukaemia (n=35), lymphoma (n=62), myeloma (n=102), MDS (n=15), MPD (n=12), other (n=2) and not specified (n=7). 257 (93.1%) patients had received anticancer therapy, 218 (78%) were receiving treatment at the time of survey and 54% had ongoing symptoms related to their treatment or cancer. 197 (71.4%) patients did not want access to a support group, 23 (19%) wanted access, 51 (8.3%) were not aware of the possibility and 6 (1.8%) did not respond. 51.8% of patients were aware of the existing support groups, 38.8% were not sure, 2.9% were not aware and 1.8% did not respond. The cohort of patients who did or did not want access to a support group was another 88% were satisfied and 1% were partly satisfied with the support they had received with 11% not responding. 93% (n=231) of patients were satisfied with the information they had received at diagnosis and 90% (n=224) felt the diagnosis had been given sensitively. Only 20% of patients currently on treatment wanted access to a support group and 24% not on treatment wanted access to a support group. Date of diagnosis was divided into three groups.

**Summary/Conclusions:** Our results suggest that a large majority of patients with haematological malignancy do not want access to a cancer support group but providing satisfactory support through key workers and other health care professionals is likely to achieve better patient experiences.

**Acknowledgements:** We would like to acknowledge the members of the GMPB and patients for their contribution to the survey.

**FRONT-LINE VASCULAR ACCESS DEVICES IN ACUTE LEUKEMIAS-PERIPHERALLY INSERTED CENTRAL CATHETER (PICC) VERSUS TRADITIONAL CENTRAL VENOUS CATHETER (CVC): A PHASE IV RANDOMIZED TRIAL (NCT02405728)**

C. Cerchione1,*, M. Di Perna1, R. Della Pepa1, N. Pugliese1, F. Pane1, M. Picardi1, K. Bolton5, M. Dennis1, N. Remmington6

**Background:** The use of PICC as an alternative to other CVC devices, particularly for prolonged infusions of cytotoxic agents, blood products and/or other supportive therapy, is becoming very frequent in cancer patients. PICCs are easier to insert, and associated to a lower rate of severe complications than traditional CVCs. However, there is limited information on the feasibility and safety of PICC as primary vascular access device in the setting of high-risk hematological patients.

**Aims:** Our Hematology Department is conducting a Phase IV randomized trial on this topic. We compare PICCs versus traditional CVCs as front-line vascular access device in patients with acute leukemias undergoing intensive chemotherapy for remission induction (NCT02405728; ongoing). Primary endpoint is the occurrence of catheter-related bloodstream infections and/or thrombosis. Secondary endpoints are the occurrence of other complications, such as pneumothorax or catheter occlusion, and patients’ quality of life. Questionnaire covering functional status, sleep and hygiene disturbance had been given to assess patients’ quality of life.
Methods: From April 2015 to February 2017, 152 consecutive patients with acute leukemia planned for remission induction chemotherapy were randomly assigned (1:1) to PICC (Arm A) or traditional CVC (Arm B) (Table 1). Inclusion criteria were age >18 years, expected survival >4 weeks, and need of central venous access (long-term >4 weeks). Exclusion criteria were ongoing uncontrollable systemic infection, presence of significant thrombosis/stenosis in arm or central veins, and inability to communicate and/or to sign informed consent. All insertions were followed by ultrasonography assessments and chest X-ray. Results: 152 patients (130 AML and 22 ALL) with a median age of 47 years (range, 13-82), were randomized in the two arms. In the Arm A, 76 PICCs (power injectable PICCs, in new generation polyurethane, open-ended) were inserted in 76 patients. Double lumen PICCs (5 Fr) were inserted in 70 patients, single lumen PICCs (4 Fr) were inserted in 5 patients, and triple lumen PICC (6 Fr) was inserted in 1 patient. 68 PICCs were inserted in the right basilica vein, 5 PICCs were inserted in the left basilica vein and 3 PICCs were inserted in the left brachial vein. In Arm B, 76 traditional CVCs (ununteneed heparin-coated Vitalon CVC, Becton-Dickinson) were inserted by the Seldinger technique in other 76 patients. 45 CVCs were inserted in subclavian vein and 31 CVCs were inserted in internal jugular vein. Overall, the median duration of in situ catheter placement was 5 months: 6 months (range, 3-12) in the Arm A vs. 3 months (range, 1-10) in the Arm B. In the Arm A, catheter-related thrombosis occurred in 5 patients (2 coagulase-negative staphylococci of them, 2 meticillin-resistants). In the Arm B, 20 cases of catheter-related thrombosis (7 subclavian veins, 13 internal jugular veins) and 15 cases of catheter-related bloodstream infections (10 enterobacteriaceae; 5 coagulase-negative staphylococci, and, of them, 3 meticillin-resistants) were observed. Thus, PICCs were significantly associated with fewer major complications than traditional CVCs (catheter-related thrombosis: 10.5% in the Arm A vs. 26% in the Arm B, p=0.01 by x2 test; catheter-related bloodstream infections: 5% in the Arm A vs. 19% in the Arm B, p=0.007 by x2 test) (Figure 1). Questionnaire covering activities of daily living confirmed improvement of quality of life.

Results: Patients: A total of 1087 patient surveys were consented. Of these, 888 had 10 or more responses. There were 338 essential thrombocytosis (ET), 188 myelofibrosis (MF), 315 polychromatia vera (PV), and 17 other. In MF, DIPSS risk categories included low (8%), Int-1 (19%), Int-2 (29%), high (12%), and unknown (32%). Symptom association: Overall, patients had lower MPN related symptoms when participating in aerobic activity (p=0.001), massage (p=0.001), yoga (p=0.02), strength training (p=0.001), breathing exercises (p=0.001), and support groups (p=0.001). Overall quality of life was higher with aerobic activity (p<0.001), massage (p=0.02), yoga (p=0.02), strength training (p<0.001), breathing exercises (p<0.001), and support groups (p<0.001). Depression (PHQ-9 total >3 category) was lower in aerobic activity group (p=0.001), yoga (p=0.001), strength training (p=0.001), and meditation (p<0.001). Fatigue was lower in aerobic activity (p<0.001), massage (p=0.04), strength training (p<0.001), breathing exercises (p<0.001), and support groups (p=0.001). In subgroup analysis, ET and PV patients had lower symptom burden (MPN-SAF TSS) with aerobic activity (p<0.001, >0.001), massage (p=0.01, 0.02), and strength training (p=0.03, 0.02). Support groups were found to be associated with lower symptoms in ET patients (p=0.03). In MF, breathing exercises (p<0.001) and support groups (p=0.03) were associated with lower symptom burden. See Table #1.

Summary/Conclusions: Integrative therapies are associated with improved symptom burden, quality of life, depression, and fatigue in MPN patients. Interestingly, unique patterns were associated within MPN subtypes. Further studies are needed to understand the benefits of integrative therapies in MPN patients.

Figure 1.

Summary/Conclusions: The preliminary observations of this ongoing Phase IV randomized study, focusing on front-line use of central venous access device in a high risk hematological population, suggest that the use of PICC represents an advance in terms of decrease of complication rate and improvement of quality of life for patients with acute leukemia.

T CELL EXHAUSTION CHARACTERIZED BY COMPROMISED MHC CLASS I AND II RESTRICTED CYTOTOXIC ACTIVITY ASSOCIATES WITH ACUTE B LYMPHOBlastic LEUKEMIA RELAPSe AFTER ALLo-HSCT

L. Liu1,*, Y. Chang1, L. Xu1, X. Zhang1, Y. Wang1, K. Liu1, X. Huang1

1Peking University People’s Hospital & Peking University Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: B cell acute lymphoblastic leukemia (B-ALL) relapse contributes to the predominant mortality after allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, the mechanism of B-ALL relapse after allo-HSCT remains unknown. Eradication of leukemia in allo-HSCT settings largely relies on graft-versus-leukemia (GVL) effects mediated by donor T cells. T cell exhaustion characterized by increased expression of inhibitory receptors including PD-1 and Tim-3 and impaired function may blunt the GVL effects and was reported in acute myeloid leukemia relapse after allo-HSCT, whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT remains unknown.

Aims: To evaluate whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT.

Methods: Our study enrolled 18 B-ALL patients who underwent first hematological relapse after allo-HSCT and 18 matched B-ALL patients in remission (without minimal residual disease MRD) and 14 healthy donors from April 2016 to November 2016 at the Peking University People’s Hospital, Institute of Hematology. Transplant protocol and post-transplant time were matched in relapsed and non-relapsed patients. Post-transplant time were matched as follows: ±14 days within 12 months ±1months from 12 to18months, ±3months from 18 to 36 months, ±12months over 3 years. Extra-medullary relapse were excluded in our study. All patients had achieved full donor chimeraism before relapse or bone marrow collection. Peripheral blood (PB) were collected at the same day of bone marrow collection in relapsed patients. For patients who received induction therapy, we prospectively collected BM at least once after therapy. Sample collection was performed after patients was informed consent and approval by the institutional Human Ethics Review Committee of Peking University People’s Hospital in accordance with the Declaration of Helsinki.

Results: In the current study, we observed that increased co-expression of PD-1 and Tim-3 was observed in both CD4+ and CD8+ T cells in relapse settings. Moreover, both CD4+ and CD8+ T cells exhibited compromised proliferative capacity, cytokine production and cytotoxic potentials such as downregulation and granzym B production (preferentially on CD4+ T cells) in relapsed patients. In addition, T cell death and tumor bulk were more easily exhausted than those in peripheral blood. Reversal of T cell exhaustion was associated with effective anti-leukemic response in relapsed patients who underwent re-induction therapy.

Summary/Conclusions: In conclusion, our study suggested that T cells experienced an exhaustion and comprehensive functional impairment in B-ALL relapse settings after allo-HSCT and reversal of T cell exhaustion was associated with effective anti-leukemic responses. These results also provide a foundation for the development of novel effective leukemia therapeutics, such as anti-PD-1 or PD-1L-1 therapy, by targeting T cell exhaustion.

RUXOLITINIB/NILOTINib COTREATMENT BETTER INHIBITS LEUKEMIA- PROPAGATING CELLS IN PHILADELPHIA CHROMOSOME-POSITIVE ALL

Y. Kong1,*, Y.-L. Wu1, Y. Song1, M.-M. Shi1, X.-N. Cao1, H.-Y. Zhao1, Y.-Z. Qiu1, Y.-Y. Lai1, H. Jiang1, Q. Jiang1, J.-J. Huang1

1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Relapse remains the major cause of treatment failure in patients with acute lymphoblastic leukemia (Ph-ALL), even in the modern era of tyrosine kinase inhibitors (TKIs). Relapse of Ph-ALL may result from the persistence of leukemia-propagating cells (LPCs), which are defined by their ability to initiate human leukemia and self-renew in immunocompromised mice. Using an anti-CD122-conditioned NOD/SCID xenograft mouse assay, LPCs were enriched in the CD34+CD38-CD58- fraction in human Ph+ALL (YK,.....,XJH, Leukemia, 2014). Furthermore, a cohort study demonstrated that Ph+ALL patients with LPCs phenotype at diagnosis exhibited a significantly higher cumulative incidence of relapse than did the group with other phenotypes, even when receiving uniform front-line imatinib-based therapy pre- and post-allo-transplant (YK,.....,XJH, BMT, 2015). Therefore, it is imperative to identify novel therapeutic strategies based on LPCs to improve the prognosis of Ph+ALL patients.

Aims: To identify the potential molecular basis of LPC-mediated relapse, RNA sequencing(RNA-seq) and real-time reverse transcription-PCR (qRT-PCR) were performed to analyze the gene expression profiles and the gene expression of cells of other phenotypes from patients with de novo Ph+ALL. In order to assess the effects of the selective BCR-ABL and/or JAK2 inhibition therapy by the treatment with single agents or a combination of ruxolitinib and imatinib or nilotinib on Ph+ALL LPCs, drug-induced apoptosis of LPCs was investigated in vitro, as well as in vivo using sublethally irradiated and anti-CD122-conditioned NOD/SCID xenograft mouse assay. Moreover, western blot analyses were performed on the BM cells harvested from the different groups of recipient mice.

Methods: RNA-seq and qRT-PCR, we found that JAK2 was more highly expressed in the sorted LPCs than in the cells of other phenotypes in patients with de novo Ph+ALL. Treatment with anti-tauropininib and ruxolitinib induced significantly higher levels of apoptosis in LPCs. In human Ph+ALL mouse model, treatment with the nilotinib and ruxolitinib combination, compared with either ruxolitinib or TKIs alone, led to the most significant reduction in human Ph+ALL engraftment in the recipients. Further evidence that the most effective anti-LPCs effect occurred with the combination treatment was derived by the engraftment analysis of BCR/ABL-expressing cells using a qRT-PCR assay and HE and IHC with anti-hCD19 staining. Moreover, the combination of nilotinib and ruxolitinib more effectively reduced the LPCs capacity through a dramatic decrease of cell expression of phospho-CrKL, JAK2 and STAT5 activities at the molecular level.

Summary/Conclusions: JAK2 was more highly expressed in the sorted LPCs than in other cell phenotypes in patients with de novo Ph+ALL. Furthermore, selective BCR-ABL/JAK2 dual inhibition with nilotinib/ruxolitinib more effectively eliminated LPCs than either ruxolitinib or TKIs alone. Therefore, this pre-clinical study appears to provide scientific rationale for simultaneously targeting BCR-ABL and JAK2 activities, which represents a promising anti-LPCs therapeutic approach for patients with de novo Ph+ALL.

P508

PREDICTING ANTI-LEUKEMIA ACTIVITY OF THE B-2-SELECTIVE INHIBITOR ABT-199 IN BCP-ALL BY FUNCTIONAL ASSESSMENT OF APOPTOSIS SIGNALING

F. Seyfried1,*, S. Demiri1, R. Hörl1, J. Ryan1, A. Scheffold2, M. Villalobos-Ortiz2, S. Köhler1, J. Zirngiebel1, S. Stilgenbauer1, A. Letai1, K.-M. Debam1, L. H. Meyer1

1Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany, 2Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, 3Department of Internal Medicine III, Ulm University Medical Center, Ulm, Germany

Background: Although survival rates of pediatric BCP-ALL patients have continuously improved during the past decades, therapy-related toxicity and relapse occurring in 10-20 % of patients are associated with poor outcome, clearly emphasizing the need of novel, targeted treatment strategies. Deregulated survival pathways and cell death resistance contribute to treatment failure and reoccurrence of the disease. ABT-199 (venetoclax) is a small molecule inhibitor of BCL-2 demonstrating anti-cancer activity among different malignancies. However, predictive biomarkers are required for up-front identification of patients who would benefit from BCL-2 directed therapies.

Aims: The aims of this study were to assess the efficacy of ABT-199 in BCP-ALL, to functionally evaluate factors mediating ABT-199 susceptibility or resistance and to identify markers indicative of successful anti-leukemia activity.

Methods: The activity of ABT-199 was assessed by cell viability assays in BCP-ALL cell lines (N=6) and patient-derived xenograft (pdx) samples (N=27), analyzing half maximal effective concentrations (EC50). Expression of apopto-sis regulators was detected by western blot analysis. MCL-1 deficient cell lines were generated by CRISPR/Cas9 gene editing. B3H profiling was used to measure the mitochondrial dependence of leukemia cells on anti-apoptotic BCL-2 family proteins. In vivo treatment of ABT-199 was performed in a set of three distinct ALL rdxs.

Results: Different sensitivities of ABT-199 were observed in a series of BCP-ALL rdxs and cell lines with heterogeneous anti-leukemia activities upon drug exposure. The majority of BCP-ALL samples showed sensitivity to ABT-199-induced cell death in the nanomolar range (EC50 <1µM) with four out of six cell lines and 20 of 27 rdxs, while ABT-199 insensitivities with EC50s of more than 1µM were identified in 26% of pdx leukemias. ABT-199 induces apoptosis by selectively inhibiting BCL-2, the largest sub-nM binding-affinity thereby releasing anti-apoptotic MCL-1 might lead to resistance. Therefore, we investigated protein expression of both regulators and found the ratio (BCL-2/MCL-1) to be cor-

haematologica | 2017; 102(s2) | 193
related with ABT-199 sensitivity (r = 0.71, p < 0.008), highlighting the importance of comprehensive assessment of the direct target molecule and additional resistance mediating molecules. In line, MCL-1 knockout in two ABT-199-resistant cell lines led to sensitization towards ABT-199, however, resulted in different effects of sensitization, emphasizing that ABT-199 resistance is determined by the interplay of several apoptosis regulators. Therefore, we characterized the functional dependence of pdx leukemias on anti-apoptotic BCL-2 family members by performing mitochondrial dependence on BCL-2 (mitochondrial priming by the BAD-peptide measuring BCL-2, BCL-XL and BCL-W, and subtracting the response to the HRK-peptide measuring BCL-XL) was found to be tightly correlated with ABT-199 sensitivity. In contrast, ABT-199-resistant samples were characterized by low BCL-2-dependence and addiction to other BCL-2 family members, including BCL-2. Finally, we evaluated prediction of in vivo ABT-199 sensitivity in a pre-clinical ALL pdx mouse model by functional BH3 profiling. Strikingly, high mitochondrial BCL-2-dependency was clearly associated with prolonged leukemia-free survival upon ABT-199-therapy (two pdxs, log rank p = 0.0035 and < 0.0001), in contrast to another leukemia with low BCL-2-dependence and in vivo ABT-199 resistance (log rank p = 0.144).

**Results:** SCP-ALL displays heterogeneous ABT-199 sensitivities characterized by the level of the target molecule but also other interacting regulators. Functionally, mitochondrial BCL-2-dependence assessed by the BH3 profiling assay is clearly associated with ABT-199 sensitivity. Importantly, in vivo anti-leukemia activity of ABT-199 therapy in individual pxd leukemias is predicted by mitochondrial BCL-2-dependence, emphasizing the utility of identification of patients and guidance of future clinical application by functional assessment of apoptosis signaling.

1Pediatric Hematology & Oncology, Hospital Universitario Niño Jesús, Madrid, 2Instituto de Investigacion en Enfermedades Raras, Instituto de Salud Carlos III, Majadahonda, Spain

**Background:** Genetic mutations are crucial events during leukemogenesis and provide specific markers for backtracking the cellular origin of acute leukemias up to immature uni- or multi-potent progenitor cells in the hierarchy of the hematopoietic system.

**Aims:** To characterize the clonal architecture and cell of origin in a case of acute lymphoblastic and B-ALL

**Methods:** Bone marrow cells obtained at diagnosis were used for all studies. Immunophenotyping was done by flow cytometry. T- and B-leukemic cell purification was performed by immunomagnetics methods and DNA extracted afterward. TCR-gamma gene rearrangement was studied in T- and B-leukemic cells independently by PCR sequencing. Somatic mutations in purified T- and B-leukemic cells were identified by deep-sequencing using a panel of 160 genes frequently mutated in cancer (Human comprehensive cancer panel, Qiagen). Mutations were validated by Sanger sequencing. Myeloid and erythroid clonogenic progenitors were isolated from methylcellulose cultures, DNA extracted, and assessed for the presence of the H3F3A p.K28N mutation by Sanger sequencing.

**Results:** The patient was a 10 years old boy. At diagnosis, the bone marrow was infiltrated by 60% leukemic cells, with 2 immunophenotypically different populations: a common B-ALL (54%) and a pro-T-ALL (6%). The patient showed a typical red leukemia phenotype with X-ray. On TCR-gamma rearrangement was detected in purified (>95% pure) T-ALL and B-ALL cells, suggesting a common origin for both leukemic subpopulations. The B-ALL cells presented a c.35G>A p.G12D mutation in the KRAS gene, absent in the T-ALL. The T-ALL cells presented a c.35G>A (p.G12D) mutation in the NRAS gene, absent in the B-ALL. A c.1126_1127insTAGA (p.P376fs*10) mutation in the WT1 gene was also detected only in the T-ALL. A c.84AG>T (p.K28N) mutation in the H3F3A gene was detected in both the B-ALL and T-ALL subpopulations, confirming the involvement of a Common Lymphoid Progenitor in the process of leukemogenesis. The presence of the H3F3A p.K28N mutation in the myeloid compartment would point to a multistep myeloid-lymphoid progression rather than a lymphoid-restricted progenitor as the cell origin of the leukemia. Therefore, we cultured myeloid-erythroid-committed progenitor cells in clonogenic cultures and sequenced the H3F3A gene. None of the 122 myeloid or erythroid clonogenic progenitors (41 CFU-GM, 73 BFU-E and 8 CFU-GEMM) presented the p.K28N mutation in the H3F3A gene.

**Summary/Conclusions:** Our results indicate the involvement of a Common Lymphoid Progenitor as the cell of origin in this case of bilineal ALL, as well as the crucial role of H3F3A and RAS family genes in the leukemogenesis process coupled with B and T differentiation.

**CD45RA- MEMORY T CELLS EXPRESSING AN NKGD2-CAR TARGET PEDIATRIC ACUTE LEUKEMIA**

L. Vázquez-Aguado1,*, J. Valentín3, A. Escudero4, M. Vela3, A. Leivas1, J. Martínez1, W. Leung2, A. Pérez-Martínez4

1Clinical Research, CNIO, Madrid, Spain, 2Haematology, St.Jude Children’s Research Hospital, Memphis, United States, 3Infectious diseases and Immunity, IdiPAZ, 4Pediatric Oncology, INGEMM, Madrid, Spain

**Methods:** The expression of CD45RA on pediatric acute leukemia cells and determine their susceptibility to an NKGD2 CAR cell based immunotherapy.

**Aims:** The aim of this study was to analyze the NKGD2L expression on pediatric acute leukemia cells and determine their susceptibility to an NKGD2 CAR cell based immunotherapy.

**Results:** NKGD2L was expressed in Peripheral Blood Mononuclear Cells (PBMCs) from patients suffering from acute leukemia, as well as in leukemia cell lines, by flow cytometry (FCM) using specific monoclonal antibodies directed against MIIC, MIICB, ULBP-1, ULBP-2, ULBP-3 and the activating receptor NKG2D. PBMC of healthy donors were labeled with CD45RA microbeads and depleted using AutoMACS device. The HL60i4-MNDanSCD19bbz lentiviral vector was derived from the clinical vector CL204r-ER1a-hgcOPT27 but contained the extracellular domain of NKGD2, the hinge region of CD8a and the signaling domains of 4-1BB and CD3-z. The cassette was driven by MND promotor. Viral supernatant was produced by transient transfection of HEK293T cells with the vector genome plasmid and lentiviral packaging helper plasmids pCAGG-HIVgpc, pCAGG-VSVG and pCAGG-RTR2. Cytogenetic studies and array Comparative Genomic Hybridization were performed to analyze the genetic stability of lentiviral-transduced memory T cells. The in vitro cytotoxicity of CD45RA-NKGD2CARM1 directed against leukemia cells, healthy PBMC and Mesenchymal Stem cells (MSC) was measured by performing conventional 4-hour europium-TUDA release assays or by FCM using CSFE and 7AAD labeling of target cells.

**Results:** NKGD2L were heterogeneously expressed in leukemia primary cells and cell lines. For B cell ALL primary samples, we found expression of MIICB, MIIC, ULBP2 and CIITA in refractory cases. Lentiviral transduction of NKGD2-4-1BB-CD3z increased NKGD2 surface expression in CD45RA memory T cells, which becomes more consistently more cytotoxic than untransduced cells against leukemia cells. Additionally, no chromosomal aberrations nor cytotoxic activity against healthy PBMC or Mesenchymal Stem cells was observed in NKGD2 CAR expressing T cells.

**Summary/Conclusions:** Our results show NKGD2-CAR redirected CD45RA memory T cells target NKGD2 expressing leukemia cells in vitro and could be a promising and safe immunotherapeutic approach for pediatric acute leukemia patients.
Aims: To identify novel biomarkers in B-cell ALL based on bioinformatics analysis; to examine the expression and clinical significance of CSRP2 in adults with B-ALL; to explore effects of CSRP2 on biological function of B-cell ALL.

Methods: We did bio-informatics analyses to identify mRNA transcripts aberrantly expressed in B-cell ALL. RT-qPCR (real-time quantitative polymerase chain reaction) was used to examine CSRP2 transcript levels in bone marrow samples from 236 adults with B-Cell ALL compared with samples from normal. A prognostic value was assessed in 168 subjects. CSRP2-knockdown and CSRP2-over-expression cell models were constructed to study the biological function of CSRP2 in B-cell ALL.

Results: We selected 9 candidate genes for validation 7 of which proved significantly-associated with B-cell ALL. CSRP2 was the most differentially expressed gene in our validation studies. CSRP2 was over-expressed in 228 out of 236 adults (97%) with newly-diagnosed B-cell ALL. In subjects with normal cytogenetics: those with high CSRP2 transcript levels had a higher 5-year cumulative incidence of relapse (CIR) and worse relapse-free survival (RFS) compared with subjects with low transcript levels (56% [95% confidence interval 53-59%] vs 19% [18-20%]; P=0.011 and 41% [17-65%] vs 80% [69-96%]; P=0.007). In multivariate analyses a high CSRP2 transcript level was independantly-associated with CIR (HR=5.32 [1.64-17.28]; P=0.005) and RFS (HR=5.56 [1.87-16.53]; P=0.002). Functional analyses indicated CSRP2 promoted cell proliferation, cell-cycle progression, in vitro colony formation and migration. Abnormal CSRP2 expression was associated with resistance to chemotherapy; sensitivity was restored by down-regulating CSRP2 expression. CSRP2 activated ERK1/2 signaling pathway, regulated cell-cycle related protein and activated CREB signaling pathway, whose activation was associated with poor prognosis in adults with B-cell ALL. Suppression of CSRP2 was widely over-expressed in adults with B-cell ALL. Determination of CSRP2 transcript levels in subjects with normal cytogenetics might inform therapy-decisions. Consideration could be given to down-regulating CSRP2 expression as a way to reverse drug resistance.

P512

THERAPEUTIC TARGETING OF PRE-B CELL RECEPTOR SIGNALLING IN CHILDHOOD ACUTE LYMPHOBlastic LEUKEMIA

A. Alhammer1,2, M. Case1, E. Matheson3, H. Blair1, J. Vroom1, J. Irving1
1Newcastle University, Northern Institute for Cancer research, Newcastle upon Tyne, United Kingdom, 2Al-Nahrain University, Biotechnology research center, Baghdad, Iraq

Background: Acute lymphoblastic leukaemia (ALL) is the most common malignancy in children and adolescents and relapsed ALL remains one of the leading causes of cancer-related deaths in children. Components of the precursor-B cell receptor (Pre-BCR) signalling pathway are hijacked in ALL cells and this dependence may be therapeutically targeted. A number of tyrosine kinase inhibitors (TKIs) targeting effectors of this signalling pathway are showing great promise in the clinic and warrant preclinical evaluation in paediatric ALL. They include Dasatinib (BCR-ABL/SRC inhibitor), Fostamatinib R406 (SYK inhibitor), Ibrutinib (BTK inhibitor) and CAL-101 (PI3K-b inhibitor).

Aims: To preclinically evaluate these candidate TKIs, as novel, targeted drugs for ALL, in which Pre-BCR is essential.

Methods: ALL cell lines (Reh, Nalm-6, Pre-B 697 and its glucocorticoid resistant clones) and clinical cases (CSF, BM aspirates) were assessed for their sensitivity to Dasatinib and Ibrutinib. CSRP2 was widely over-expressed in adults with B-cell ALL. Determination of CSRP2 transcript levels in subjects with normal cytogenetics might inform therapy-decisions. Consideration could be given to down-regulating CSRP2 expression as a way to reverse drug resistance.

Summary/Conclusions: Significant sensitivity of TKIs targeting Pre-BCR signalling have been identified at clinically achievable concentrations. Dasatinib and R406 sensitivity was associated with Pre-BCR positive ALL and combination with Dexamethasone showed significant synergism in GC resistant cell lines and PDX samples. TKIs were also effective in some Pre-BCR negative ALL cells, however, predictive biomarkers need to be established. Confirmation of these data in preclinical models in vivo may define new therapies for high risk ALLs.

BMP 4 LEVELS IN CHILDHOOD B-ALL OF LOW-INTERMEDIATE-RISK GROUPS IDENTIFY CHILDREN WITH POOR OUTCOME

A. Sanchez-Sevillia1, C. Sanchez-Velarde2, A. Gonzalez-Murillo2, A. Entrena1, C. Martinez-Laperche2, G. Melen2, A. Varas1, A. Vicente1, M. Ramirez2
1School of Medicine, Universidad Complutense, 2Pediatric Hematology & Oncology, Hospital Universitario Niño Jesus, Madrid, Spain

Background: Leukemic relapses among children with acute lymphoblastic leukaemia (ALL) from low/intermediate-risk groups is a challenge for the cure of this disease. New biomarkers are needed for identifying children at high risk of relapses. Bone Morphogenetic Proteins (BMPs) are multifunctional secreted growth factors that belong to the TGF-β superfamily and are well-known for their indispensable roles in vertebrate development. In the cellular context, BMPs regulate fundamental processes such as cell proliferation, differentiation, migration and survival. In last years, important new information has been generated on the contribution of BMP family members, such as BMP4, in cancer pathogenesis.

Aims: Here we have evaluated the relevance of BMP4 signaling in ALL.

Methods: The expression levels of BMP-4 related genes (bmp-4, and bmp-receptors, signaling mediators, inhibitors and targets) in ALL blasts obtained at the time of diagnosis (n=56), and the BMP-4 levels in central system fluid samples (CSF), were quantitated by RT-qPCR or ELISA. The engrafting potential of primary ALL cells, exhibiting high or low BMP4 levels, were assessed in xenotransplantation experiments using unirradiated NSG mice.

Results: BMP4 was expressed at significantly higher levels in ALL blasts of children who later relapsed (178.78 versus 26.68, arbitrary units, AU, p<0.05). Relapses among children with high BMP-4 expression occurred significantly later than those with low BMP-4 expression (845 days versus 282 days, p<0.05). The difference in the cumulative incidence of relapses (CIR) was quasi-significant between both groups (p=0.031). The ratio Smad7:Smad1, suggesting inhibition of the Smad-dependent signaling pathway, was significantly higher in ALL blasts of children who later relapsed (14,33 versus 5,13, AU, p<0.05). CIR was significantly higher (p<0.05) in the group of children with the Smad-dependent pathway inhibited. All these differences were detected considering the whole population, as well as only the low/intermediate-risk groups. BMP4 levels were significantly higher in CSF samples of children with leukemic infiltration of the central nervous system (16pg/ml versus 3,4pg/ml, p<0,001), as well as in the group of children who relapsed (10,6 pg/ml versus 1,8 pg/ml, p<0,001). Hematopoietic engraftment (marrow, spleen and peripheral blood) and CNS leukaemia occurred only in ALL samples with high BMP4 levels. Even more, no signs of disease were detected in mice transplanted with primary ALL blasts from patients expressing low levels of BMP4. In independent experiments, pharmacological blockade of the canonical BMP signaling pathway significantly decreased infiltration of CNS and consistently resulted in amelioration of clinical parameters including neurologic score.

Summary/Conclusions: These results indicate that high BMP4 levels are required for both bone marrow engraftment and CNS infiltration by B-ALL cells. BMP4 levels in leukemia cells could be a useful biomarker to identify children with poor outcome in the childhood B-ALL of low/intermediate-risk groups. Furthermore, BMP4 could be a new therapeutic target to blockade leukemic CNS disease.

TARGETING LOCALIZATION OF THE IL-7 RECEPTOR WITHIN LIPID RAFTS AS A THERAPEUTIC STRATEGY FOR T-CELL ACUTE LYMPHOBlastic LEUKEMIA

A. Buffere1, C.-H. Nguyen2, B. Uzan3, J.-N. Bastie14, D. Delva1, F. Pflumio1, R. Quinié1
1Signalng And Physiology In Hematological Research, UMR1231 Inserm, Université Bourgogne Franche-Comté, AgroSup, Dijon, 2Institut Curie, PSL Research University, UMR1877 U1196, CNRS-Institut Curie, Inserm, Centre d’Études des Cancers de l’Enfant, Orsay, Commissariat à l’Énergie Atomique et aux Énergies Alternatives (CEA), DSV-IRCM-SCSR-LSHL, Inserm UMR 967, Fontenay-aux-Roses, 3Clinical Hospital Department, Français Mitterand University Hospital, Dijon, France

Background: T-cell acute lymphoblastic leukaemia (T-ALL) is a hematological malignancy characterized by immature T-cell excessive proliferation. To achieve remission, patients typically undergo 2 years of chemotherapy, associated with acute and chronic side effects. To enable reduced chemotherapy intensity and...
Aims: The aim of this study was to assess the anti-tumoral effect of PyQ on T-ALL cells and to identify which signaling pathway is affected by the compound.

Methods: We have 2 models of human T-ALL which can be studied in vitro when cocultured with murine stromal MS5 cells and in vivo when transplanted into immunodeficient NOD/SCID/γc−/− (NSG) mice. We also work on primary T-ALL blasts isolated from 10 patients suffering of T-ALL and maintained frozen in a biobank.

Results: In this study, we have shown that PyQ destabilizes the IL-7Rα away from lipid rafts on the cell surface of human T-ALL cells. We have also proved that localization of the IL-7Rα among lipid rafts plays a crucial role in human T-ALL maintenance in vivo. Its destabilization leads to IL-7 signaling pathway inactivation, upregulation of BAD and BIM genes involved in apoptosis and T-ALL cells apoptosis. We furthermore assessed effect of PyQ on 10 samples of primary T-ALL blasts. All of them were sensitive to IL-7-independent cell survival and revealed a marked response to PyQ treatment (Mean IC_{50}=5.7 ng/mL).

For this work, T-ALL cells were cocultured on murine stromal MS5 cells and PyQ has affected mainly T-ALL cell growth. No effect was observed on the stromal feeder cells, suggesting that injection of PyQ in vivo would not impact the stromal microenvironment in bone marrow. Finally, we provided evidence that PyQ delayed T-ALL progression in vivo, after treatment of immunodeficient mice xenografted with T-ALL cells.

Summary/Conclusions: The findings of this study highlight the importance of the IL-7Rα localization in maintenance of T-ALL cells and may lead to the design of a new generation of anti-cancer drugs able to modulate the protein positioning into lipid rafts.
Background: Front-line imatinib (IM) plus chemotherapy followed by allogeneic hematopoietic stem cell transplantation (HSCT) is standard therapy for patients (pts.) with Ph+ ALL. Relapse after HSCT remains a major cause of treatment failure, and pts. in whom BCR-ABL transcripts are detectable after HSCT are at particular risk. Post-transplant maintenance with immunosuppressive TKIs to reduce the relapse rate remains a subject of uncertainty, as data from prospective studies are limited.

Aims: To determine the impact of IM administration after HSCT on patient outcome and to assess the predictive value of minimal residual disease (MRD) analysis by qR-PCR of BCR-ABL1 transcripts.

Methods: In this prospective, multicentre trial by the GMALL study group, adult pts. (≥ 18 y) with Ph+ ALL in CR at HSCT were randomly assigned (1:1) to receive IM prophylactically after SCT or pre-emptively upon detection of MRD. Inclusion criteria included enrollment, sufficient hematopoietic and organ function, prior anthracyclines and/or infectious disease of IM. IM was 600mg recommended as starting dose. Primary endpoint was molecular or hematologic relapse, secondary endpoints included survival, DFS, severe toxicity and transplant-related mortality. All pts. were followed by frequent serial MRD analysis after HSCT. An interim analysis was reported previously. We here provide results of the final analysis of this trial, with long-term follow-up of up to 11 years after HSCT.

Results: 74 pts. were evaluable, 36 received prophylactic and 38 pts. pre-emptive IM. Median age was 41 y (18-69) and 44 y (19-68), respectively. Disease status at HSCT was CR1 (n=67), CR2 (n=5), CR3 (n=1), unknown (n=1). Most pts. received a PBS graft (71%) and myeloablative TBI-based conditioning (n=65), 8 pts. underwent RIC with 2Gy or 4Gy TBI (n=6) or non-TBI RIC (n=2). Median time from HSCT to starting IM was 48d and 77d, respectively. IM dose was 600mg/d in 22% of pts., remaining pts. received 400mg. Treatment was prematurely discontinued in 56% and 59% of pts., median time to discontinuation was 92d and 102d, respectively. Target donor dose of IM was 600mg in 400mg recommended as starting dose. Primary endpoint was molecular or hematologic relapse, secondary endpoints included survival, DFS, severe toxicity and transplant-related mortality. All pts. were followed by frequent serial MRD analysis after HSCT. An interim analysis was reported previously. We here provide results of the final analysis of this trial, with long-term follow-up of up to 11 years after HSCT.

Summary/Conclusions: Post-HSCT intervention with prophylactic or pre-emptive IM is associated with lower relapse risk and excellent long-term survival and might be considered standard of care in Ph+ ALL pts. undergoing HSCT. BCR-ABL1 transcript levels prior to and early after SCT are predictive of outcome and identify a small subset of patients unlikely to benefit, emphasizing the need for rigorous MRD monitoring. The identified MRD thresholds should be validated in an independent dataset. Their applicability in the setting of RIC/CT may depend on the type of institution.
twice as likely to develop G3/4 CRS than pts with <50% BM blasts (n=29) (63% vs 24%). Earlier-onset fever correlated with severity of CRS. CRS grade correlated with serum IL-6 levels. CRS-associated coagulopathy with fibrinogen levels <1.0 g/L was observed in 10% of pts. Neuropsychiatric AEs occurred during or shortly after CRS resolution, were self-limiting, and were more likely in pts with severe CRS or history of CNS leukemia or other CNS diseases. No G4 neuropsychiatric events were observed. Other AEs of special interest within the first 8 wk included G3/4 neutropenia with high (>38.3 C) fever (61%) and infections (G3/4, 22%). Prolonged G3/4 neutropenia (not resolved >28 days) occurred in 59 pts (61%). 36% of pts with prolonged G3/4 neutropenia had G3/4 infections after day 28. One pt with prior alloSCT was diagnosed with unconfirmed gut GVHD. Responding pts developed prolonged B-cell aplasia that was managed with immunoglobulin replacement. Tumor lymphoid syndrome was uncommon (3%).

Summary/Conclusions: This pooled analysis of global experience with CTL019 across 25 sites and 11 countries found no new safety issues. CRS and neuropsychiatric events, which are class effects of CAR T-cell therapy, were effectively managed. CTL019 appears similarly safe in pts with Down syndrome or prior alloSCT and across age groups. Prolonged follow-up will be required to determine the long-term safety of B-cell aplasia.

P519

PROGNOSTIC IMPLICATIONS OF PRETREATMENT CYTOGENETIC SUBGROUPS IN ADULTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBlastic LEUKEMIA TREATED WITH INOTUZUMAB OZOGAMICIN

1MD Anderson Cancer Center, Houston, 2Cleveland Clinic, Cleveland, United States, 3University of Minnesota, Minneapolis, United States, 4University of Chicago, Chicago, 5Stanford Cancer Institute, Stanford, United States, 6Goethe University, Frankfurt, Germany, 7Institute Seràgnoli, DIMES, University of Bologna, Bologna, Italy, 8University of California, Irvine, Orange, 9Pfizer Inc, Groton, 10Pfizer Inc, Cambridge, 11 Dana-Farber Cancer Institute, Boston, United States

Background: In the phase 3 INO-VATE study of relapsed/refractory acute lymphoblastic leukemia (R/R ALL) patients, inotuzumab ozogamicin (InO) showed improved complete remission or complete remission with incomplete hematologic recovery (CR/CRi) rates versus standard care (SC; 80.7% vs 29.4%; P<0.001) (NCT01564784; Kantarjian NEJM 2016 [data cutoff date: Oct 2, 2014]). Aims: To assess the impact of baseline karyotype on response and toxicities in R/R ALL patients receiving InO from the INO-VATE study.

Methods: Full study details have been previously published. At screening, karyotyping was performed locally; ≥20 metaphase count was recommended for cytogenetic analysis. Karyotypes were interpreted using the International System for Cytogenetic Nomenclature. CR/CRi and minimal residual disease (MRD) negativity rates (defined as <0.01% bone marrow blasts as assessed at a central laboratory) were compared using a chi-square test or Fisher exact test. Survival estimates were compared using a log-rank test. Data as of March 8, 2016, are presented. Informed consent was obtained from all patients. All analyses presented were not adjusted for multiple testing.

Results: Of 326 patients randomized, 284 had cytogenetic data at screening (InO: 144; SC: 140). Of the InO-treated patients, 21.3% had normal diploid karyotype (≥20 metaphases), 17.1% complex (≥5 abnormalities), 13.4% Philadelphia-chromosome positive (Ph+) disease, 6.7% diploid (<20 metaphases), 4.9% hyperdiploid (>50, 4.9% aberrations involving mixed lineage leukemia (MLL), 1.8% low hyperdiploid/ near-triploidy, 1.2% Del (9p), 16.5% other chromosomal abnormalities, and 12.2% missing. Of 164 InO-treated patients, CR/CRi rate was 73% (95% confidence interval [CI] 66–80; Table) and MRD negativity rate was 93% (95% CI, 51–67). With InO, CR/CRi and MRD negativity rates were similar between the various cytogenetic subgroups (P=0.644). Significantly higher survival with InO was observed in diploid patients (≥20 metaphases), complex, other, and missing cytogenic subgroups (P≤0.015) and numerically higher in the other cytogenetic subgroups. With InO, more patients with diploid (≥20 metaphases) karyotype proceeded to stem cell transplant versus other cytogenetic subgroups. With InO, the duration of remission (DoR) was significantly different between cytogenetic subgroups (P<0.0001), with diploid (≥20 metaphases) and other subgroups having the longest median DoR numerically and MLL subgroup having the shortest median DoR numerically; no significant differences in DoR were seen between cytogenetic subgroups with SC (P=0.785). Significant differences in PFS were seen between cytogenetic subgroups with InO (P=0.0063); no significant differences were seen between cytogenetic subgroups with SC (P=0.5427). With InO and SC arms, overall survival (OS) differences between cytogenetic subgroups were not significant (P=0.1629 and 0.3040, respectively); however, although not statistically significant based on 97.5% CI for hazard ratio (HR), OS was numerically longer (HR <1) with InO versus SC in diploid (≥20 metaphases), MLL, complex, other, and missing cytogenic subgroups. Generally, adverse event profiles did not vary by cytogenetic subgroup.

P. Perfetti2, F. Paoloni13, A. Vitale14, M. Vignetti13,14, R. Foa14

Aims: To assess activity, toxicity, and feasibility of the sequential CLO-CY regimen in patients with R/R ALL. We also aimed to evaluate the incidence of tumor lysis syndrome (TLS) and the most frequent tumor lysis-related adverse events (TRAEs)

Methods: Study GIMEMA LAL1610 (EudraCT 2010-019742-12) included 14 patients with R/R ALL. Eligible patients with R/R ALL and a CD19+ population of ≥5% were enrolled. CLO was administered IV at 40mg/m2/d for 5 consecutive days, followed after 2 hrs by IV CY 400mg/m2/d. Clinical and hematological response was assessed on day 28 or later, according to clinical course and patient condition. One/two courses were planned, followed by aloHSCT when possible.

Results: From October 2012 to December 2015, 35 patients were screened and 27 enrolled. Median patient age was 38.7 years (range 20.5-59.6) 15 were male, 4 with T- and 23 B-precursor ALL. 2 refractory and 25 relapsed (after a median of 5.9 months, range 1.9-23.4), 5/11 evaluable with high-risk cytogenetics [2 complex; 2 t(4;11), 1 MLL-rearranged]. Median white blood cells and marrow blast percentage were 5.67 (range 1.5-55) and 73 (range 8-100), respectively. All but one patient (treatment interruption due to traumatic fall) received CVO-CLO as planned. Nine patients achieved CR and 7 CRs after course 1 (overall response 59.2%; 6/10 in study stage one), 2 had a partial response, 5 were stable. All but one patient (treatment interruption due to traumatic fall) received CVO-CLO as planned. Nine patients achieved CR and 7 CRs after course 1 (overall response 59.2%; 6/10 in study stage one), 2 had a partial response, 5 were stable. Six CR patients received a second course, which was curtailed in 2 due to toxicity, and 10 responders had an aloHSCT (62.2%). Concerning toxicity, 10 patients experienced grade 2 toxicity, but apart from expected myelosuppression, 3 patients developed a therapy-related myelo- and/or lympho-suppression (grade 3 in 2, and grade 4 in 1). Median white blood cells and marrow blast percentage were 5.67 (range 1.5-55) and 73 (range 8-100), respectively. All but one patient (treatment interruption due to traumatic fall) received CVO-CLO as planned. Nine patients achieved CR and 7 CRs after course 1 (overall response 59.2%; 6/10 in study stage one), 2 had a partial response, 5 were stable. Six CR patients received a second course, which was curtailed in 2 due to toxicity, and 10 responders had an aloHSCT (62.2%). Concerning toxicity, 10 patients experienced grade 2 toxicity, but apart from expected myelosuppression, 3 patients developed a therapy-related myelo- and/or lympho-suppression (grade 3 in 2, and grade 4 in 1).

Conclusion: The CLO-CY regimen was feasible, with an appreciable CR rate and an overall response rate of 59.2%. The incidence of TLS was minimal (1/14), and the most frequent TRAEs were grade 1-2. The regimen showed promising activity, with 3 CRs and 5 PRs in 14 evaluable patients. Further studies are needed to confirm these results and to evaluate the role of alloHSCT in patients with R/R ALL.
affect adults aged >20 years (https://seer.cancer.gov). Adult patients (pts) with B-cell ALL show high-risk disease biology, high rates of relapse, and poor survival (J Clin Oncol 2011;29:532; Blood 2012;119:34). Promising results have been observed with KTE-C19, an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in refractory, aggressive non-Hodgkin lymphoma (Blood 2016;128:LBA-6), and suggest an opportunity to improve outcomes in ALL. Here we present updated results from ZUMA-3, a multi-center study of KTE-C19 in pts with high tumor burden ALL.

Aims: The goal of this study is to assess safety and efficacy of KTE-C19 in adult pts with relapsed/refractory ALL who have high disease burden.

Methods: Eligible pts were ≥18 years of age with relapsed/refractory ALL (Ph+ pts eligible), ≥25% bone marrow lymphoblasts, adequate organ function, and Eastern Cooperative Oncology Group status 0-1. Pts received 1 or 2 × 10^6 CAR T cells/kg after conditioning with cyclophosphamide and fludarabine. The primary endpoint of phase 1 was incidence of dose-limiting toxicity (DLT). Secondary endpoints were efficacy outcomes of KTE-C19, including complete response (CR) rates and biomarker associations.

Results: As of Nov 1, 2016, 11 pts were enrolled, and 10 were treated with KTE-C19. One pt had a serious adverse event prior to dosing and was not treated. KTE-C19 was successfully manufactured in a centralized facility for all pts across a broad range of baseline absolute lymphocyte counts in 6 days, with a turnaround time of <2 weeks. Pts were 60% men, with 1-4 prior lines of therapy and high disease burden (median, 81% bone marrow lymphoblasts). No pt (0/3) experienced a DLT at the 2 × 10^6 dose, and phase 1 was then expanded to 6 pts at the 2 × 10^6 dose. One pt experienced a grade 5 adverse event of multi-organ failure due to cytokine release syndrome (CRS), and subsequent pts (n=4) received 1 × 10^6 CAR T cells/kg. Across all pts, the most commonly reported events were cytokopenia (80%), febrile neutropenia (50%), pyrexia (40%), and transaminitis (40%). Grade ≥3 CRS and neurologic events were reported in 20% and 40% of pts, respectively. Cerebral edema was not observed. All CRS events resolved (except the grade 5 event); neurologic events resolved in 5 of 6 pts (1 grade 3 neurologic event ongoing at cutoff). Anti-CD19 CAR T cells achieved peak expansion within two weeks of infusion. Of the 8 efficacy evaluable pts, 6 (75%) achieved remission by day 28; 5 pts achieved complete remission (including one disease-negative). Of the 6 pts achieving minimal residual disease-negative CR, two eventually relapsed, one with CD19- disease and one with CD19+ disease. Safety and efficacy data were similar across KTE-C19 doses. Updated pt number, follow-up, and biomarker data will be presented.

Summary/Conclusions: No DLTs were observed with KTE-C19 in adult pts with high BM disease burden; one pt with high disease burden had grade 5 CRS after completion of the DLT cohort. Manufacturing was successful in all pts; most pts achieved a minimal residual disease-negative CR. These results demonstrate promising efficacy with a manageable safety profile. Based on these results, ZUMA-3 continues to enroll pts, adding measures to ensure continued safety and efficacy measures to further enhance safety and with planned expansion to phase 2.

KTE-C19 CHIMERIC ANTIGEN RECEPTOR (CAR) T CELL THERAPY IN ADULTS WITH HIGH-BURDEN RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA (R/R ALL): UPDATED RESULTS FROM PHASE 1/2 OF ZUMA-3

1Department of Hematological Malignancies, H. Lee Moffitt Cancer Center, Tampa, Florida, United States; 2Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, Texas, United States; 3David Geffen School of Medicine at UCLA, Los Angeles, California, United States; 4Department of Medicine, The University of Chicago Medicine, Chicago, Illinois, United States; 5Department of Medicine, riverside University Medical Center, Riverside, California, United States; 6Research, Amgen Inc, Thousand Oaks, CA, United States; 7Gehr Family Center for Leukemia Research, City of Hope, Duarte, CA, United States

Background: Blinatumomab, a bispecific T-cell engager antibody construct, has shown improved overall survival vs standard of care (SOC) chemotherapy in patients with Philadelphia chromosome-negative relapsed/refractory B-precursor acute lymphoblastic leukemia (ALL) in a randomized phase 3 study (N Engl J Med 2017;367:836-847). We compared the incidence of adverse events (AEs) observed with blinatumomab vs SOC after adjusting for varying treatment exposure times for a more comprehensive evaluation of safety and tolerability.

Methods: Adults (aged ≥18 years) with relapsed/refractory B-precursor ALL (refractory to primary induction therapy or salvage therapy, first relapse <1 year, second or later relapse, or relapse after allogeneic hematopoietic stem cell transplantation) were randomized to receive either blinatumomab or SOC (1 of 4 predefined regimens). Blinatumomab was dosed by continuous intravenous infusion (4 weeks on/2 weeks off) for up to five induction cycles (9 weeks in total) and 7-7 days thereafter for consolidation cycles (4 weeks on/8 weeks off) were allowed for up to 12 months. Exposure-adjusted event rates were calculated as the number of events x total exposure time for a more comprehensive evaluation of safety and tolerability.

Results: Median (range) number of cycles was 1 (1-4) for SOC and 2 (1-9) for blinatumomab. The highest exposure-adjusted event rates (per 100 patient-years) were for pyrexia (507 SOC vs 376 blinatumomab), anemia (987 vs 229), thrombocytopenia (750 vs 126), and neutropenia (351 vs 121), all of which were lower for blinatumomab than for SOC. Febrile neutropenia (365 vs 93) and infection (1216 vs 453) were also lower for blinatumomab than for SOC (p<0.0001). Exposure-adjusted event rates for neurologic events were 743 for SOC vs 472 for blinatumomab, with median time (range) to onset of 7 (1-43) days and 7 (1-190) days, respectively, and grade ≥3 cytokine release syndrome (CRS) rates were 0 for SOC vs 10 for blinatumomab. The most frequent adverse events (AEs) in both arms were CRS; events in the blinatumomab arm decreased between cycle 1 and cycle 2 (14% vs 2%). The majority of fatal AEs were related to infection in both arms.

DESIGNING THE NEXT GENERATION CD33-TARGETING ADC: IMGN779, SELECTED FOR POTENCY, NOVEL MECHANISM AND PRECLINICAL TOLERABILITY, WITH HIGH ACTIVITY IN DISSEMINATED AML MODELS AND IN MULTI-DOSE REGIMENS

S. Adams1,*, A. Wilhelm1, L. Harvey1, L. Flaherty1, K. Watkins1, S. Sikka1, P. Shah1, W. Li1, Y. Kovtun1, C. Sloss1, K. Lai1, M. Miller1, G. Payne1

1Immunogen, Waltham, United States

Background: Antibody-drug conjugates (ADCs) targeting CD33 are promising therapeutics in AML, where challenges are achieving efficacy while maintaining tolerability. Here, we report the payload/ linker design and selection resulting in a high-Therapeutic Index (TI) ADC with favorable preclinical toxicity profile across multiple species and preclinical activity disseminated AML models and in multi-dose regimens. IMGN779, the final ADC design, is comprised of an indolino-benzodiazepine mono-imine DNA-alkylating payload, DGN462, coupled by a cleavable N-succinimidy1-4-(2-pyridyldithio)2-sulfobutanoate (s-SPDB) linker to a CD33-targeting antibody.

Aims: Select the best ADC out of multiple preclinical anti-CD33 ADC candidates, and assess its activity in vitro and in vivo in AML models.

Methods: Unconjugated payloads were evaluated in vitro for cytotoxicity on human AML cell lines. Payloads were compared, as CD33-targeting conjugates, in vitro for cytotoxicity on human AML cell lines and in vivo for tolerability in mice and Ti against human AML xenografts. ADCs with cleavable and non-cleavable linkers were evaluated for cytotoxicity on MD-R-positive and -negative AML cell lines, for tolerability in mice and Ti in AML xenografts. IMGN779, the final ADC design, was evaluated in vivo for toxicity in rats and cynomolgous monkeys. IMGN779’s antitumor activity was evaluated in disseminated models and in fractionated- and multi-dose regimens in AML xenografts.

Results: First, we selected a high affinity antibody to CD33 with retained ADCC activity. Next, given concerns for long-term toxicity of DNA crosslinkers, we prepared DNA alkylating (single strand DNA damage) and DNA crosslinking (double strand DNA damage) versions of our novel IgG1 payload class. Both versions had comparable IC50’s on human AML cell lines as free drugs (12-260 vs. 5-77 PM) and as CD33-targeting ADCs (0.7 vs. 0.5 PM). However, in vivo, the CD33-targeting DNA alkylating ADC had a 5-fold higher MTD (maximally tolerated dose) in mice and 5-fold larger Ti in AML xenografts. IMGN779, the final ADC design, was evaluated in vivo for toxicity in rats and cynomolgous monkeys. IMGN779’s antitumor activity was evaluated in disseminated models and in fractionated- and multi-dose regimens in AML xenografts.

Summary/Conclusions: First, we selected a high affinity antibody to CD33 with retained ADCC activity. Next, given concerns for long-term toxicity of DNA crosslinkers, we prepared DNA alkylating (single strand DNA damage) and DNA crosslinking (double strand DNA damage) versions of our novel IgG1 payload class. Aims: This work examines how ENL influences PRC1 repressive activity. Methods: The effect of ENL on transcriptional activity of model promoters and endogenous transcriptional control elements was studied by biochemical and molecular biology methods. Results: Here we demonstrate that ENL overcomes polycomb induced silencing through recruitment of polymerase associated factor 1 (PAF1) in a chromatin recruitment assay. Collectively, the data indicated that ENL-tethering PAF1 conferred the ability of ENL to neutralize polycomb-mediated repression in an elongation reporter system and also during transformation of primary cells by MLL-ENL in vivo. Inactivation of polycomb by ENL was accompanied by ubiquitination of histone H2B, the hallmark activity of PAF1 allied enzymes. On a global scale, microarray and current RNA-seq demonstrated that MLL-ENL targeted genes stood out with a supraphysiological accumulation of H2B ubiquitination and H2B ubiquitination modification of Hoxa9 and Meis1, two sentinel loci for polycomb action. This was dependent on the conserved YEATS domain of ENL that operated as "switch" binding either histone H3 or PAF1 thus effectively regulating ENL function as anti-repressor or elongation factor, respectively. With this in mind, FACS-based purification of PAF1 and thus perturbed proper silencing. This effect was intensified in a MLL-ENL fusion where MLL itself provided a constitutive tether to PAF1 effectively creating a "super-transcription factor" that constitutively combined anti-repression with elongation capabilities. Summary/Conclusions: In summary, targeting histone ubiquitination may be an additional Achilles heel for mixed lineage leukemia that merits further investigation of therapeutic utility.

Background: Although numerous genetic mutations contribute to the etiology and pathophysiology of acute myeloid leukemia (AML), the molecular machinery that is not mutated but supports AML biology remains largely unknown. Several studies have shown that AML cells, irrespective of genetic sub-type, display an oxidized intracellular redox environment compared to their healthy counterparts. The redox environment of AML cells is largely due to the elevated reactive oxygen species (ROS) levels, which are a class of free radical molecules. Though ROS are by-products of several cellular processes, in excess, they can damage DNA and destroy organelles, resulting in the initiation of genetic mutations or cell death. As a result, ROS homeostasis is tightly regulated by an array of molecular pathways. Although ROS is elevated in AML cells, the role of ROS and the identity of its regulators remain largely unknown. Here we report that the serine/threonine kinase, PKCε regulates the ROS-neutralizing enzyme SOD2 to support mitochondrial redox homeostasis and AML progression.

Aims: The goal of this study was to identify and subsequently assess how targeting key ROS-regulatory pathways impacts AML biology.

Methods: Loss-of-function studies for PKCε and SOD2 were performed with recombinant lentiviruses expressing gene-targeting shRNAs. Reconstitutive retroviruses expressing either PKCε or SOD2/Catalase were used for gain-of-function assays. Cytoplasmic and mitochondrial superoxide levels in AML lines were measured using flow cytometry analysis. Mitochondrial superoxide levels were also assessed by flow cytometric analysis of MitoSox stained cells. Proteomic analysis was achieved using nano LC-MS/MS. Annexin-V staining was analyzed by flow cytometry to measure apoptosis. AML cell lines and in vitro differentiation studies were performed using FACs-based purification of shRNA-expressing cells followed either by: 1) growth in cytokine-enriched media or 2) transfection into syngeneic mice for survival analysis.

Results: We have discovered that inhibition of PKCε: 1) promoted the death of leukemia cell lines in vitro 2) AML cell lines in vivo 3) showed a profound AML progression driven by MLL-AF9 in vivo (p=0.0014) and 3) obstructed the growth of 5 out of 7 PD-AML samples in vitro. At the molecular level, we observed that PKCε inhibition led to a significant and dose-dependent increase in mitochondrial-produced superoxide—a specific type of ROS. Moreover, we found that enforced expression of PKCε can protect AML cells from lethal effects of superoxide-inducing agents 2-thenoyltrifluoroacetone and Antimycin A. To identify potential ROS-regulatory enzymes downstream of PKCε, we performed whole cell proteomics and found that the mitochondrial superoxide-neutralizing enzyme SOD2 is decreased in AML cells depleted of PKCε. Similar to PKCε inhibition, we also observed a functional inactivation of SOD2 reduced the expansion of AML cell lines and PD-AMLs in vivo as well as significantly extended the onset of MLL-AF9-driven AML in vivo (p=0.0042). Finally, we also found that enforced expression of SOD2 in tandem with another anti-oxidant enzyme Catalase, reverses the anti-leukemia effects of PKCε inhibition confirming that PKCε supports AML pathophysiology by maintaining mitochondrial redox homeostasis.

Summary/Conclusions: Our results indicate that PKCε and SOD2 regulate mitochondrial redox homeostasis to support AML cell survival and disease progression and thus may represent a foundation for designing and developing novel therapeutic strategies.
PHOSPHOPROTEOMICS AND MASS CYTOMETRY SIGNATURES OF PRIMARY AML CELL DIFFERENTIATION ARE ASSOCIATED WITH SENSITIVITY TO KINASE INHIBITORS

Background: Aims: Since patients with differentiated cells present a reduced overall survival, treating AML cells that could trigger undesirable side-effects in vivo. Intriguingly, however, we designed and performed the invasion and extent of kinase signaling in cancer cells, and the indicated gene switch technology-dependent its modulation would be a novel strategy to control malignancies.

Methods: In this investigation, we used a multicomponent approach to stratify 36 AML biopsies as a function of their cellular sensitivity to "ex vivo" treatment with TAK-715, silmitasertib, PF03758309, midostaurin and trametinib, which target P38, and/or CK2, PAK1, MEK-1 and PKC, respectively. The same samples were analysed using different omic platforms: (i) mass spectrometry for phosphoproteomics, proteomics and immunophenotyping, (ii) mass cytometry for immunophenotyping and (iii) next generation sequencing for mutational profiling.

Results: Our integrative analysis identified two independent signatures that stratified our cohort of patients in sets of differentiated and undifferentiated cases. The phosphoproteomics signature divided our set of AML cases in the M1-like and M4-like groups (Figure 1A). The mass cytometry signature, which represented myelomonocytic markers that were co-expressed at the cell surface, split our cohort of patients in the CD5+ and CD5- groups. Remarkably, the M4-like and CD5- groups represented the non-differentiated cases, showed a high degree of overlap. Differentiated groups over-phosphorylated 3 times as many proteins as the non-differentiated groups, including kinases at sites linked to their activity. Mutations in genes involved in kinase signalling were also more frequent in differentiated cases. Kinase activity analysis using KSEA estimated that differentiated groups presented an enriched activity for PKA, MEK, ERK or PKC. Ontology analysis showed that non-differentiated cells over-phosphorylated nuclear proteins with DNA binding properties, while the differentiated cells increased the phosphorylation of membrane and cytoplasmic proteins linked to the small GTPass signalling. More interestingly, cases in differentiated groups were more sensitive to PF03758309, trametinib and midostaurin than those in the non-differentiated sets (Figure 1B for groups defined by the phosphoproteomics signature). Finally, differentiated cases as defined by the mass cytometry signature in our cohort of patients, or by a CD marker mRNA expression signature in the ATCG database, presented with significantly reduced survival when compared to the groups of non-differentiated cases.

Summary/Conclusions: Our data indicate that differentiated cells activate pro-survival kinases like PAK, PKCD or MEK which make them more sensitive to the inhibitors PF03758309, midostaurin or the FDA-approved drug trametinib. Since patients with differentiated cells present a reduced overall survival, treatment with these compounds may benefit patients in this higher risk group.
Background: Based on the prognostic significance, as well as the association with certain biological and clinical features, acute myeloid leukemia (AML) with biallelic mutations in the CCAAT/enhancer-binding protein-alpha (CEBPA) gene has been included as a distinct entity into the 2016 revision to the World Health Organization classification of myeloid neoplasms and acute leukemia. CEBPA mutations (CEBPAmut) are known to be associated with cytogenetic risk stratification, and approximately 60% of the mutated patients (pts) carry biallelic mutations. All pts were enrolled in one of six AMLSG treatment trials applying conventional therapy (AMLHD93 n=14; AMLHD98A (NCT0146120) n=53; AML- HD98B n=12; AMLSG 07-04 (NCT00151242) n=74; AMLSG 06-04 (NCT00151255) n=25 and AMLSG 12-09 (NCT01180322) n=22). TET2 mutation screening was performed using a DNA-based PCR-assay covering exons 3 to 9 followed by Sanger sequencing.

Results: In total we detected 52 TET2mut, 39 of the 200 pts (19.5%); in 16 pts TET2mut were restricted to the cytogenetic intermediate-risk group (100%), and pts with TET2mut were significantly older than pts with TET2wt (46y vs 49y, P <.0001). In addition, TET2mut were more frequent in secondary/therapy-related AML (P =.04), and there was a significant association with SRSF2 gene mutations (P =.01). With regard to outcome, pts with TET2mut had a significantly shorter event-free survival (EFS), relapse-free (RFS), and overall survival (OS). OS differences between TET2wt and TET2mut pts were significant (P =.0001).

Summary/Conclusions: In our study on a large cohort of CEBPAmut pts we could confirm the high incidence of concomitant TET2 mutations (19.5%). Pts with concurrent TET2mut were significantly older and had an inferior outcome.

GFIB18—A NOVEL ONCOSUPPRESSOR WHICH RESTRICTS NUMBER OF LEUKEMIC STEM CELLS
A. Thivakaran1,2, L. Botetz1, J. Hönies3, Y. A-Matyary1, J. Schütte3, P.K. Patana1, R. Koester1, B. Opalka1, U. Dührsen1, C. Khandanpour1
1Hematology, University Hospital of Essen, Essen, Germany

Background: Myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) are hematopoietic disorders, which affect the myeloid lineages of hematopoiesis. Both are characterized by an accumulation of blast cells in the bone marrow (BM) that have the lost the ability to differentiate to mature cells. The proper differentiation of hematopoietic stem cells (HSCs) is regulated by transcription factors. Growth factor independence 1b (GFIB1) is a repressing transcription factor regulating quiescence of HSCs and the proper emergence and maturation of erythrocytes and platelets.

Aims: Aim of the study was to identify i) do different level of GFIB1 influence onset and development of MDS and AML in human patients II) how does GFIB1 act in MDS/AML development on a molecular level.

Methods: We correlated GFIB1 expression level in blast cells of patients with MDS and AML with the overall disease course. To get a better insight how does GFIB1 expression level influence AML development we used three different murine models of human AML with expression of different oncogenes (NUP98/HOXD13, MLL-AF9 and expression of a mutated K-Ras). In these models we either downregulated or conditionally knocked out GFIB1 expression. Finally, we performed ChIP Seq analysis as well as whole genome expression arrays to study the molecular functions of GFIB1 in AML development.

Results: Low expression or absence of GFIB1 expression was associated with an inferior outcome with regard to overall-survival as well as event-free survival of MDS/AML patients. Using the above murine models of MDS/AML, loss or low expression of GFIB1 accelerated AML development. Additionally we could show that GFIB1 expression enhances the number of functional primitive acute leukemia stem cells. It is well known that GFIB1 has a function to recruit histone modifying enzymes to induce among other deacetylation of H3K9. ChIP seq data of GFIB1 deficient leukemia cells revealed that loss of GFIB1 led to a higher H3K9 acetylation of a target genes, among them a number of oncogenes.

Conclusion: Our data suggest that targeting of GFIB1 promises to be an effective strategy to improve outcome in MDS/AML patients.
diagnosis. 8.9 variants per patient were found as compared to 5.7 at relapse. 52% variants were present at diagnosis, 26% at relapse only, and 22% were present at both, diagnosis and relapse. With regard to the most commonly altered signaling genes KIT and NRAS we found the following pattern: The median VAF at diagnosis was 23% and 26% for KIT and NRAS, respectively. Of note, the initial KIT and NRAS clone was lost (VAF <5%) in 71% (exon 17, n= 9; exon 8, n=2; exon 11, n=1) and 100% of cases (exon 2, n=5; exon 3, n=3). Comparing the VAF kinetics between patients treated with and without dasatinib, baseline KIT mutations became subclonal (VAF <5%) in all patients receiving dasatinib (n=8), whereas they were still detectable in 4/6 (67%) patients who were intensively treated without the addition of dasatinib. NRAS became subclonal (n=8) irrespective of the treatment regimen. In one KIT mutated patient treated with dasatinib the baseline KIT^{D816V} mutation (exon 17) was lost at the time of relapse, but a KIT^{D814V} mutation (exon 8) was acquired instead. Gene set enrichment analyses revealed different mutation signatures at diagnosis and relapse: At diagnosis, there was a significant enrichment for genes associated with MYC overexpression. Variants that were recurrently present at diagnosis and relapse showed enrichment for genes affected in KRAS overexpression models. Relapse samples were additionally enriched for gene mutations involved in the mitotic spindle assembly.

Summary/Conclusions: Differences in the allelic composition were found between diagnosis and relapse regardless of the CBF-AML subtype. Our data suggest that the KIT clone might be successfully eradicated under dasatinib treatment whereas persistence of KIT mutant clones was more commonly seen under conventional chemotherapy. The frequent loss of KIT and NRAS mutations during therapy suggests that relapse is triggered by alternative genetic lesions. Relapsed disease may represent a distinct biology which is characterized by mutations that cluster in different pathways. Further analyses are ongoing including study cohort expansion, as well as inclusion of RNA sequencing results.

P38 MAPK INTERACTS WITH SET REGULATING ITS INHIBITORY EFFECT ON PP2A ACTIVITY IN ACUTE MYELOID LEUKEMIA

E. Arriauz1, C. Vicente1, R. Pippa1, N. Marcotegui1, A. Igea2, E. Leon1, S. Chocarro1, M. Soto1, Ä. R. Nebreda2, M. D. Odero1,3,4

1Oncohematology, Center for applied medical research University of Navarre, Pamplona, 2Institute for Research in Biomedicine, Barcelona, 3Instituto de Investigación Sanitaria de Navarra (IdiSNA), Navarra, 4Department of Biochemistry and Genetics, University of Navarra, Pamplona, Spain

Background: Despite improvements in our understanding of the molecular evolution of acute myeloid leukemia (AML), the overall cure rates remain low, and most patients die from the disease despite achieving initial remission upon treatment. It is therefore necessary to open new therapeutic perspectives aimed at molecular targets. PP2A phosphatase inactivation is a recurrent event in hematological tumors. Our group has reported that SET, an endogenous inhibitor of PP2A, is overexpressed in 28% of patients with AML. Furthermore, the anticancer activity of PP2A activating drugs (PADs) depends on the interaction/sequestration of SET, pointing out the significance of this oncoenzyme in AML. Drug inhibition of several MAPKs in AML cell lines showed that only p38 inhibitors activate PP2A and decrease SET protein.

Aims: Therefore, we hypothesized that p38 could regulate SET at posttranslational level, leading to PP2A inactivation.

Methods: AML cell lines and primary human samples were analyzed by western blot, immunoprecipitation, immunofluorescence, treatment with pharmacological inhibitors and siRNAs. Phosphorylation assays by in vitro kinase assay with recombinant proteins were performed.

Results: Knockdown of the two major isoforms of p38-MAPK, p38α and p38β, demonstrated that only p38β was able to reduce SET protein levels and increase PP2A activity. To decipher this mechanism of action, we performed protein immunoprecipitation and immunofluorescence in the AML cell lines HL-60 and MOLM-13. p38β co-localized and bound to SET mostly in the cytoplasm stabilizing it, since treatment with ciclohexymide in the absence of p38β induced SET degradation. The stabilization role was in coordination with SETBP1, which co-localized with both SET and p38β. Interestingly, 12 out of 14 AML cell lines tested showed but not p38β protein levels to be 0.5, as well as 5 out of 7 AML primary patient samples. Furthermore, expression analysis in a large series of adult de novo AML cases previously reported (Cancer Genome Atlas Research Network, 2013) showed a positive correlation between p38β (MAPK11) and SET [R²=0.416, p<0.001], but not between p38α and SET. We and others have shown that PADs retain SET in the nucleus. Our results showed that p38 phosphorylates SET not directly, but through the activation of casein kinase 2 (CK2), leading to the retention of SET in the nucleus and, therefore, contributing to the inactivation of PP2A in AML cells. Of note, CK2 is overexpressed in both AML cell lines and patient samples.

Summary/Conclusions: p38 is able to activate CK2 which phosphorylates SET and, as consequence, facilities its trafficking to the cytoplasm, contributing to PP2A inactivation in AML cells. Moreover, p38 β binds to SET in the cytoplasm, contributing to its stability and leading to PP2A inactivation. In this regard, we have preliminary evidences that combination therapy with PADs and the CK2 inhibitor CX4945 reduces significantly the viability of AML cells, reporting that novel treatment modalities that can target multiple components of the same pathway may help to achieve a more sustained therapeutic benefit.

GENETIC LANDSCAPE OF ACUTE ERYTHROID LEUKEMIA

1Department of Pathology and Tumor Biology, Graduate School of Medicine, Kyoto University, Kyoto, Japan, 2Division of Hematology- Oncology, Department of Internal Medicine, Chang Gung Medical University, Taoyuan, Taiwan, Republic of China, 3Human Genome Center, Institute of Medical Science, The University of Tokyo, 4Department of Pediatrics Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, 5Department of Translational Hematology and Oncology Research, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, United States, 6Institut de Hematologia, NTT Medical Center, Tokyo, 7Department of Hematology, Kanazawa University, Kanazawa, 8Department of Hematology / Oncology, Graduate School of Medicine, Kyoto University, Tokyo, 9Department of Advanced Diagnosis, Clinical Research Center, National Hospital Organization Nagoya Medical Center, Nagoya, 10Department of Hematology, NTT Medical Center, Tokyo, 11Division of Hematology, Tokyo Metropolitan Ohtsuka Hospital, Tokyo, Japan, 12Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany
Background: Acute erythroid leukemia (AEL) is a unique subtype of acute myeloid leukemia (AML) characterized by the predominance of erythroid components with increased ring sideroblasts as well as frequent myelodysplasia. However, due to its rarity, the molecular pathogenesis of AEL has not been fully elucidated, except for frequent TP53 mutations.

Aims: This study was designed to clarify the mutation profile of AEL distinct from other types of myeloid malignancies using targeted-sequencing, in which RNA baits were also designed for a total of 1158 single nucleotide polymorphism sites to allow for genome wide copy number abnormalities and other allelic imbalances.

Results: Median age at diagnosis was 58.5 (21-87) years old. Among the 77 patients with clinical information available, 62 patients were diagnosed with de novo AML, 13 with secondary AML, and 2 with treatment-related AML. On average, 18.4 and 3.4 mutations were detected per sample in whole-exome and targeted-capture sequencing in AEL, as compared to 12.2 and 2.9 mutations (P<0.001) in other AML, respectively. Both platforms being combined, most frequently observed was TP53 mutations (n=26, 31%) with complex karyotype being accompanied in most cases (25 cases), which were associated with a significantly shorter overall survival (P<0.001). Other frequently mutated genes were those encoding major components of the cohesin complex, including SMC1A (4.8%) and RAD21 (2.4%), which were mutated in as high as 30% of the cases. The splicing machinery (18%) and epigenetic regulators (45%) were also important, and the targets of mutations, including SRSF2 (12%), U2AF1 (4.8%), WT1 (15%), SET2 (19%) and IDH1/2 (12%). TP53 mutations were mutually exclusive with cohesin mutations (P<0.01) and those in epigenetic regulators (P<0.01). Compared to de novo AML and MDS, the frequency of these mutations was not statistically different between de novo AML and secondary AML.

Summary/Conclusions: Whole-exome and follow-up targeted-capture sequencing revealed a landscape of mutations in AEL. Frequent mutations in TP53, splicing factors, the cohesin complex, and epigenetic regulators were characteristic of AEL and thought to be involved in its pathophysiology. Mutations in TP53 defined a subgroup with distinct genetic and prognostic features. Our result indicated a similarity between AEL and high-risk MDS/secondary AML, supporting the recent revision of the WHO classifications, in which AEL was reclassified into MDS and AML not otherwise specified.
NEXT GENERATION SEQUENCING TECHNIQUES REVEAL MOLECULAR MECHANISMS OF MYB REGULATION AND FUNCTION IN MLL-AF9 LEUKAEMIA

I.-J. Lau1,*, A. Thomas1, J. Kerry1, L. Godfrey1, C. Nerlov1, P. Vyazov1, T. Milne1
1MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Mutations involving the MYB gene at 11q23 are found in 10% of adult and 18% of childhood acute myeloid leukaemia (AML) cases. The most frequently occurring MLL mutations are chromosome translocations that fuse the MLL gene in-frame with a second partner gene, creating novel fusion proteins (MLL-FPs). MLL-AF9 is the most common MLL-FP in AML. Despite much progress in the overall management of AML, patients carrying MLL-rearrangements still have a poor survival prognosis and limited response to existing therapy. This is in part due to the low therapeutic indices and narrow therapeutic windows of current chemotherapeutic agents, therefore underscoring the need to develop improved, targeted therapies. MYB is a direct downstream target of MLL-AF9. Recent studies indicate that MLL-AF9 leukemia cells are more affected by MYB knockdown compared to normal hematopoietic stem progenitor cells. This is despite the fact that MYB is known to be essential for the establishment of definitive hematopoiesis. This suggests that a therapeutic window may be achieved through targeting MYB. Therefore, by understanding more about the role of MYB in MLL-AF9 leukemia and the network it regulates, we maybe able to exploit this knowledge to target MYB directly by interfering with its function or indirectly via its downstream targets.

Aims: To understand the molecular function of MYB in MLL-AF9 leukemia.

Methods: We performed genome-wide MYB, MLL-AF9, H3K27ac, H3K4me3 and H3K4me1 chromatin immunoprecipitation (ChIP) sequencing and Assay for Transposase-Accessible Chromatin with high throughput sequencing (ATAC-seq) in two MLL-AF9 leukemia models to identify putative regulatory regions of MYB and those of a direct MYB gene target, BCL2. The chromatin conformation capture technique, Capture-C (one vs all) was used to further characterize interactions from the MYB promoter. We then performed siRNA knockdown of MYB and assessed the effect of MYB loss on its downstream druggable target BCL2, using RT qPCR, Western blotting and ChIP qPCR.

Results: We identified MLL-AF9 binding to novel putative enhancers of MYB as defined by regions co-bound by H3K27ac, H3K4me1 and marked by open chromatin on ATAC-seq. Furthermore, Capture-C from the MYB promoter identified novel putative enhancer-promoter interacting domains 100-200kb apart that are co-bound by MYB but not MLL-AF9. This suggests long-range autoregulation of MYB. Next, siRNA knockdown of MYB results in loss of MYB binding at the BCL2 promoter and its downstream enhancer by ChIP qPCR. There is a corresponding loss of BCL2 mRNA and protein expression in MYB knockdown cells compared with control, confirming that BCL2 is directly regulated by MYB.

Summary/Conclusions: We have identified for the first time, regulation of MYB by MLL-AF9 via putative enhancers, and also an autoregulatory role of MYB involving long-range cis-interactions. Furthermore, we confirm that BCL2 is directly regulated by MYB in MLL-AF9 leukemia, suggesting a molecular rational for using BCL2 inhibitors in MLL-AF9 leukemia therapy.

CD123-SPECIFIC CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY IN ACUTE MYELOID LEUKAEMIA

S. Chitre1,*, J. Gaken1, A. Venusou1, G. Mufti1
1Haematological Medicine, Kings College London, London, United Kingdom

Background: Acute myeloid leukaemia (AML) is a heterogeneous disease characterized by clonal evolution of myeloid precursors in bone marrow and peripheral blood resulting in accumulation of leukemic blasts and severe impairment of normal haematopoiesis. Despite advances in our understanding of AML biology, development of novel therapies has been limited with 43% relapse rates and 18% patients never attaining clinical remission (CR) with frontline induction treatment. Chimeric antigen receptor (CARs) T cells specific for tumour-associated antigens are emerging to be an effective form of immunotherapy for AML. A small number of in vitro and in vivo studies have evaluated the efficacy and specificity of CAR T cell immunotherapy in AML by targeting interleukin three receptor alpha (IL3RA; CD123), a molecule over expressed on AML blasts and leukaemia stem cells (LSC) compared to normal haematopoietic stem cells (HSCs).

Aims: In this study, we investigated the efficacy of a second generation CAR expressing single-chain variable fragments (scFv) with different affinities for CD123 and evaluated the cytotoxic effect of different co-stimulatory domains (CD28 versus 41BB) using a co-culture assay. Furthermore, we also evaluated the cytotoxic effects of a dual targeting CAR (against CD123 and CD33) using the same assay conditions.

Methods: SCFv libraries were generated (two high, two moderate & two low affinity) were transduced (MOI 1:5) into peripheral blood mononuclear cells (PBMCs) from healthy donors and their cytotoxicity was examined by flowcytometry on leukaemic cell lines; KG1 (CD123+, CD34+, CD33+) [Fig:1a], Kasumi-1 (CD123+, CD34+, CD33), U937 (CD123+, CD34-, CD33+), K562 (CD123+, CD34+, CD33+) and AML mononuclear cells (MNCs).

Results: Flowcytometric analysis confirmed the expansion of T cells from PBMCs and the cytotoxicity of the six CARDC123 constructs against CD123+ve cells. The high affinity CARDC123 (4nM kD & 4nM kD K136Q) T cells demonstrated enhanced cytotoxicity compared to moderate (56nM kD, 56nM kD A105G) and low affinity (101nM kD, 101nM kD V24G) CARDC123 in both leukaemic cell lines and also in allogenic AML MNCs. Both the highest affinity CARDC123 constructs were also tested in cell lines using increasing effector: target ratios (1:2, 1:4 & 1:10) displaying consistent cytotoxicity and were also effective against autologous AML MNCs (target cells) and PBMCs (effector cells) from two patients. T cell activation was confirmed by ELISA and showed increased IFN-γ (500-2000 fold) and TNF-α (150-200 fold) levels. Previous studies have confirmed the distinction in CAR efficiency using CD28 versus 41BB co-stimulatory domains; CD28 co-stimulation augmented, whereas 4-1BB co-stimulation reduced T cell exhaustion induced by continuous CAR signaling. To confirm persistence of the CAR cytotoxicity, we constructed a high affinity CAR substituting CD28 with a 4-1BB co-stimulatory domain and obtained similar cytotoxicity results on K562 and U937 cell lines. Furthermore, a novel dual targeting CAR in which the activation domain (CD3ζ) is directed against CD33 and the costimulatory domain (CD28) directed against CD123 enhanced the specificity of the CAR towards leukaemic cells; reducing “on-target but off-organ effects”. Results obtained in co-culture assay against KG1 [Fig:1b] and K562 cell lines [Fig:1c] with varying effector: target ratios were demonstrated results similar to the high affinity single targeting CAR.
We have recently discovered that FLT3-ITD+ AML cells are highly sensitive to the FDA-approved S america-approved CDK6 inhibitor, PF-06386735 (Pfizer). The effect is ascribed to the transcriptional activity of CDK6 on FLT3 and PIM1 - a feature not shared by CDK4.

Aims: FLT3-TK1 treatment provides short-term disease control but relapse invariably occurs within months. Acquired resistance on FLT3-ITD AML is correlated with a complex genetic landscape. The focus of our study is to investigate the potential of palbociclib treatment in FLT3-ITD+ AML cells and to identify critical downstream effectors of CDK6 to open a novel, clinically applicable therapeutic window.

Methods: Ba/F3 cells transformed with FLT3-ITD were exposed to single agent and combination drug conditions. Viability was measured by the CellTiter-Glo ATP-based assay and FACS staining after 3 days of treatment. Validation was performed by in vivo xenograft models and by studies with primary human FLT3-ITD+ AML biopsies.

Results: Palbociclib impaired the viability of murine Ba/F3 cells with FLT3-ITD+ in vitro and in vivo. The effect on primary FLT3-ITD+ AML patient samples and to xenograft models, where palbociclib treatment effectively repressed FLT3-ITD AML driven tumor formation in vivo at clinically relevant concentrations. Besides FLT3 itself, which is regulated by CDK6, transcriptional targets of CDK6 in AML included Aurora kinases (AURK) and AKT. Thus CDK6 inhibition activated AURK and AKT in mutant Ba/F3 cells, two signalling nodes critical for survival of tumor cells. Dual targeting with palbociclib and AURK or AKT inhibitors resulted in synergistic cytotoxicity.

Summary/Conclusions: Palbociclib represents a viable therapeutic option for use in treatment of resistant clones in FLT3-ITD+ AML. Inhibitory effects are observed both in vitro and in vivo as well as by transcriptional activity of CDK6 on important signalling pathways including Aurora kinases and AKT. Our findings provide the basis for the design of synergistic combination therapies with a CDK6/4 inhibitor which could be readily translated to patients with AML.
with the Papaemmanuil dataset, we observed a weaker correlation for relapses 
after CT ($r^2=0.69$) and an even more marked deviation for post-transplant 
relapses ($r^2=0.45$). This difference was mainly explained by the enrichment in 
both relapse cohorts for FLT3-ITD (25% in diagnoses vs 55% and 48% at 
relapses after CT and allo-HSCT, $p <0.01$ for both comparisons) and WT1 
mutations (5% vs 25% and 22%, $p <0.01$ for both comparisons). For 24 cases 
it was possible to longitudinally compare the mutational profile of AML at diag-
nosis and relapse in the same patient: we observed higher stability in relapses 
after CT, with 50% of cases carrying the same pattern of mutations present at 
diagnosis, whereas at relapses after allo-HSCT changes were more frequent, 
with 70% of patients displaying new gains or losses.

Summary/Conclusions: Taken together, our data evidence that the genomic 
landscape of AML at relapse can be significantly different from the one docu-
mented at diagnosis, suggesting that the selective pressure mediated not only 
by intensive chemotherapy, but also by the graft-versus-leukemia effect, can 
be potent drivers of clonal evolution. From the practical standpoint, the pattern 
of emergence of novel mutations that we documented should be taken into 
account not only for targeted salvage approaches, but also for the design of 
post-remission strategies aiming to prevent relapse.

ment of Internal Medicine III; German Cancer Consortium (DKTK), partner site Munich; German Cancer Research Center (DKFZ, Heidelberg), University of Munich, Munich, 4Department of Internal Medicine III. Hospital Leverkusen, Leverkusen, 5Department of Medicine A, Hematology and Oncology, University of Muenster, Muenster, 6Department of Medicine, Hematology, Oncology, Tumor Immunology, Charité University Medicine Berlin, Berlin, 7Department of Oncology and Hematology, Hospital Barmherzige Brüder, Regensburg, Germany

Background: Acute myeloid leukemia (AML) is a disease of the elderly (median 
age at diagnosis ~68 years). The prognosis of elderly patients (pts) is poor. 
Advanced age often leads to the judgement that pts are unfit for induction 
chemotherapy, although several trials have revealed a positive impact of inten-
sive induction therapy in terms of sustained remissions and long-term survival 
in a subset of elderly pts.

Aims: We sought to validate existing risk classification systems and identify 
genetic factors associated with clinical outcomes in very old AML pts who 
received induction chemotherapy.

Methods: We identified 151 AML pts aged ≥75 years who received intensive 
induction therapy in the AMLCG-1999 trial with suitable material for genetic
analyses, 81% of pts had de novo AML, 15% secondary AML, 3% therapy-related AML and 2% high-risk MDS. Recurrent gene mutations in AML were studied from bone marrow aspirates or peripheral blood using a targeted leukemia genotyping assay covering 68 genes. We analyzed known mutualal hotspots or the entire coding sequence of the genes by multiplexed amplicon sequencing (Agilent Technologies, mean target coverage of 460x). We studied associations with clinical and demographic variables, genetic subtypes, other potential prognostic factors which might influence the clinical outcome.

Results: The median age in the total cohort was 76 years (range: 75-86). 44% of pts reached complete remission (CR) and 4% CR with incomplete blood count recovery (CRi). The median overall survival (OS) was 6 months with a 3-year OS of 20%. Response to the ELN 2017 classification: 27% of pts were in the favorable, 39% and 25% in the intermediate I or II group, respectively, and 15% in the adverse group (ELN 2017 data will be presented at the meeting).

Pts in the favorable and intermediate I/II groups had significantly longer OS compared to the adverse group (median OS 6.3 vs 1.2 months, p=0.05; Figure). Likewise, pts in the favorable and intermediate MRC cytogenetic risk categories had longer OS than those in the adverse category (median OS 6.5 vs 1.2 months, p=0.001). By targeted sequencing, we detected 622 leukemia-associated mutations in 66 genes. The median number of mutated genes per patient was four. The commonly mutated genes were TET2 (42%), DNMT3A (35%), NPM1 (32%), SRSF2 (25%) andASXL1 (21%). Both NPM1 or EZH2 (5%) mutated pts showed a non-significant trend towards longer OS (NPM1: p=0.03; EZH2: p=0.05). FLT3-ITD mutations were identified in 29 pts (19%), but had no impact on OS (p=0.29). The NPM1 mutated/FLT3-ITD negative genotype also did not associate with OS. Notably, none of the IDH1 mutated pts (9%, all within the ELN favorable/intermediate groups) reached CR, and consequently the OS in this group was significantly shorter than for IDH1 wild-type pts (p<0.001; Figure). The positive impact of mutated NPM1 on OS was reversed when pt was associated with IDH1 mutations (p=0.014).

Summary/Conclusions: Among very old (≥75 y), intensively treated AML pts, adverse-risk cytogenetics predict inferior survival. On the other hand, 3-year OS was 24% for MRC/ELN favorable and intermediate-risk pts, suggesting that even in this age group, selected pts without medical contraindications benefit from intensive induction chemotherapy. The spectrum of driver gene mutations in elderly pts differs from that in younger pts. While NPM1 and FLT3-ITD mutations had no significant impact on OS in intensely treated pts aged ≥75 y, our data imply IDH1 mutations as a novel marker for chemorefractory disease and inferior prognosis in this age group.

P547

GMI-1271, A POTENT E-SELECTIN ANTAGONIST, IN COMBINATION WITH CHEMOTHERAPY IN RELAPSED/REFRACTORY AML: A NOVEL, WELL-TOLERATED REGIMEN WITH A HIGH REMISSION RATE

1Dana-Farber Cancer Institute, Boston, 2UC Davis Comprehensive Cancer Center, Sacramento, 3Univ of Rochester James P Wilmot Cancer Ctr, Rochester, United States, 4National University of Ireland, Galway, Ireland, 5University of Michigan Comprehensive Cancer Center, Ann Arbor, 6Cleveland Clinic, Cleveland, United States, 7Princess Alexandra Hospital, Brisbane, Australia, 8GlycoMimetics, Inc., Rockville, 9Fred Hutchinson Cancer Research Center, U of Washington, Seattle, United States

Background: Expression of the adhesion molecule E-selectin (E-sel) in the vasculature of the bone marrow is associated with infiltrative disease, relapse, and poor survival in AML. GMI-1271 is a novel antagonist of E-sel that down-regulates cell survival pathways and enhances chemotherapy response with up to 4.5 g/m²/day, median age 77 (27-90): 6 relapsed/refractory AML patients under 60, 12% high-risk MDS. Recurrent gene mutations in AML were studied from bone marrow aspirates or peripheral blood using a targeted leukemia genotyping assay covering 68 genes. We analyzed known mutualal hotspots or the entire coding sequence of the genes by multiplexed amplicon sequencing (Agilent Technologies, mean target coverage of 460x). We studied associations with clinical and demographic variables, genetic subtypes, other potential prognostic factors which might influence the clinical outcome.

Results: The median age in the total cohort was 76 years (range: 75-86). 44% of pts reached complete remission (CR) and 4% CR with incomplete blood count recovery (CRi). The median overall survival (OS) was 6 months with a 3-year OS of 20%. Response to the ELN 2017 classification: 27% of pts were in the favorable, 39% and 25% in the intermediate I or II group, respectively, and 15% in the adverse group (ELN 2017 data will be presented at the meeting).

Pts in the favorable and intermediate I/II groups had significantly longer OS compared to the adverse group (median OS 6.3 vs 1.2 months, p=0.05; Figure). Likewise, pts in the favorable and intermediate MRC cytogenetic risk categories had longer OS than those in the adverse category (median OS 6.5 vs 1.2 months, p=0.001). By targeted sequencing, we detected 622 leukemia-associated mutations in 66 genes. The median number of mutated genes per patient was four. The commonly mutated genes were TET2 (42%), DNMT3A (35%), NPM1 (32%), SRSF2 (25%) and ASXL1 (21%). Both NPM1 or EZH2 (5%) mutated pts showed a non-significant trend towards longer OS (NPM1: p=0.03; EZH2: p=0.05). FLT3-ITD mutations were identified in 29 pts (19%), but had no impact on OS (p=0.29). The NPM1 mutated/FLT3-ITD negative genotype also did not associate with OS. Notably, none of the IDH1 mutated pts (9%, all within the ELN favorable/intermediate groups) reached CR, and consequently the OS in this group was significantly shorter than for IDH1 wild-type pts (p<0.001; Figure). The positive impact of mutated NPM1 on OS was reversed when pt was associated with IDH1 mutations (p=0.014).

Summary/Conclusions: Among very old (≥75 y), intensively treated AML pts, adverse-risk cytogenetics predict inferior survival. BST 236, A NOVEL CYTARABINE PRO-DRUG ALLOW, FOR THE FIRST TIME, THE DELIVERY OF HIGH CYTARABINE DOSES FOR OLDER OR MEDICALLY UNFIT PATIENTS WITH ACUTE LEUKEMIA. RESULTS OF AN ONGOING PHASE III/III STUDY

T. Zuckermand1,2, S. Gengrinovitch3, R. Ram4, L. Flaiosh3, B. Ren Yahak3, R. Hoffman1,2, I. Henig5, N. Livii1,2, L. Akria6, Y. Ofiran7, N.A. Horowitz1,2, O. Nudelman8, M. Koren-Michowitz9, S. Yeganeh1, J.M. Rowe1,2

1Dana-Farber Cancer Institute, Boston, 2UC Davis Comprehensive Cancer Center, Sacramento, 3Univ of Rochester James P Wilmot Cancer Ctr, Rochester, United States, 4National University of Ireland, Galway, Ireland, 5University of Michigan Comprehensive Cancer Center, Ann Arbor, 6Cleveland Clinic, Cleveland, United States, 7Princess Alexandra Hospital, Brisbane, Australia, 8GlycoMimetics, Inc., Rockville, 9Fred Hutchinson Cancer Research Center, U of Washington, Seattle, United States

Background: Acute myeloid leukemia (AML) is associated with poor outcome in older patients and in patients unfit for standard induction therapy. Therapy of AML has not changed significantly since the 1970s and still relies on cytarabine as the first-line treatment. However, cytarabine therapy is associated with severe side effects, such as cerebellar toxicity, bone marrow suppression, and infections, leading to high treatment-related mortality rates. Hence, while the incidence of AML increases with age, advanced age and comorbidities may preclude the administration of intensive therapy altogether.

Aim: To evaluate the efficacy and feasibility of a new, high cytarabine dose regimen in older patients or patients unfit for standard therapy.

Methods: A Phase II/III prospective open label study enrolled adult relapsed/refractory or newly-diagnosed acute leukemia patients unfit for standard therapy. Patients are enrolled into 6 BST-236 escalating-dose cohorts (0.3-6 g/m²/day), each composed of 3-6 patients. Treatment was administered as 1-hour daily infusion for 6 days.

Results: To date, treatment of cohorts 1-5 is completed, with 18 patients treated with up to 4.5 g/m²/day, median age 77 (27-90): 6 relapsed/refractory AML patients over the age of 64 (27-91), and 12 newly-diagnosed AML patients unfit for standard chemotherapy (7 secondary AML, 5 de novo AML/ALL), median age 79 (70-90). BST-236 treatment was well-tolerated. Only 6 SAEs in 4 cases were assessed by the treating physician as possibly/probably related to BST-236, all “on-target” hematological toxicity events or bacterial infections derived from it. In the cytoreductive dose arms, the CR rate was 23%, the CR rate with complete blood recovery 20%, and CR rate with complete blood recovery and with an adequate neutrophil count 19%. The median OS of the newly-diagnosed non-responders was 2.5 months. No remission was reached in the 6 patients suffering from relapse or refractory AML and their median OS was 2.3 months.

Summary/Conclusions: BST-236 is safe and very well tolerated, enabling delivery of high cytarabine doses to older and unfit patients, resulting in overall response and CR rates of 50% and 33%, respectively, and a 3-fold increase in median OS of the responding compared to the non-responding newly-diagnosed patients. Notably, 67% of the responding patients had secondary AML,
refractory to hypomethylating agents. To the best of our knowledge, this is the only experimental drug permitting high-dose cytobamine, considered a cornerstone of leukemia therapy, to be given to a population of patients that currently do not have this option. A Phase II study is planned to confirm these encouraging results.

P549
FEASIBILITY AND BENEFIT OF TARGETED RNA SEQUENCING FOR THE DETECTION OF RECURRENT FUSION TRANSCRIPTS AND THE IDENTIFICATION OF NOVEL FUSION TRANSCRIPTS IN MYELOID MALIGNANCIES
C. Haferlach1, N. Nadarajah1, M. Meggendorfer1, A. Stengel1, W. Kern1, T. Knecht1
1M. L. Munich Leukemia Laboratory, Munich, Germany

Background: Gene fusions are frequent genetic abnormalities in myeloid malignancies. The impact of the detection of such gene fusions is rising due to an increasing number of drugs targeting them as has been impressively shown for e.g. BCR-ABL1 and PML-RARA. Further, they can be used as biomarkers for disease monitoring.

Aims: Evaluation of targeted RNA sequencing for the detection of recurrent and novel fusion transcripts.

Methods: 102 cases with myeloid malignancies harboring 105 translocations identified by chromosome banding analysis were selected. Recurrent fusion genes had been confirmed by FISH and/or RT-PCR. In cases with suspected novel fusions the rearrangement of one partner gene had been confirmed by FISH. The following recurrent rearrangements identified by standard diagnostic procedures were present: PML-RARA (n=11), RUNX1-RUNX1T1 (n=7), CSF3R-MYH11 (n=3), KMT2A-ELL (n=4), KMT2A-MLLT1 (n=4), KMT2A-MLLT10 (n=3), KMT2A-MLLT6 (n=3), KMT2A-MLLT4 (n=2), BCR-ABL1 (n=3), NUP98-NSD1 (n=3), DEK-NUP214 (n=1), and KAT6A-CREBBP (n=1). Further, cases harboring KMT2A-RARA (n=14), RUNX1 (n=21), ETV6 (n=10), PDGFRA (n=10), RARA (n=2), NPM1 (n=2) and NUP98 (n=1) were included. Targeted RNA sequencing was performed using the TruSight RNA Fusion panel (Illumina, San Diego, CA) consisting of 7690 probes covering 507 genes known to be involved in gene fusions. Library was prepared according to manufacturer’s protocol with ~50ng RNA extracted from fresh/frozen samples. Sequencing was performed on the NextSeq instrument (Illumina) and analysis with the RNA-Seq Alignment App (BaseSpace Sequence Hub) using Star for Alignment and Manta for gene fusion calling with default parameters (Illumina).

Results: In 42/45 (93%) cases with a recurrent rearrangement identified by standard diagnostic procedures RNA sequencing detected the respective fusion transcript. In addition, RNA sequencing was able to identify known and novel fusions in the remaining 57 cases. For KMT2A these were the following partner genes: MLLT1 (n=5), ELL (n=3), ITPR2, FLNC, ASXL2, DOPB1, MAML1 and ARHGEF12. Seven different partner genes were identified in RUNX1 translocations: PLAG1 (n=2), PRDM16, MECOM, ZFPM2, MAN1A2, NAMT2 and KIAA1545L. Five different partner genes were identified in ETV6 rearranged cases: ABL1, CCDC126, ERG, FOXO1 and CFLAR-AS1. Most strikingly was the identification of the ETV6-ABL1 fusion, which could not be suspected by cytofluorimetry as the S ETV6 FISH signal was located on chromosome 17. In 71/102 PDGFRA rearranged cases the partner genes were identified. These were WDR41, CCDC88C, MPRIP, TNIP1, TPR, NF1 and ZBTB11. Further the following fusions were found: NPM1-RP30, NPM1-SETBP1, NUP98-ING3, IRF2BP1-RARA, and ZBTB16-RARA. Thus, RNA sequencing identified 39 fusion transcripts which standard diagnostics had missed in 23% of the cases, one of the partner genes. Failure to detect gene fusions should initiate improvements in calling algorithms and also may have biological implications. It was reported that genomic rearrangements of RUNX1 occur, which do not lead to RUNX1 in frame fusion transcripts but to termination of transcription.

Summary/Conclusions: 1) RNA sequencing was able to detect recurrent gene fusions with high accuracy and to characterize rare gene fusions providing the basis for the design of RT-PCR based assays for monitoring MRD. 2) Targeted RNA sequencing may be a valuable tool in routine diagnostics for patients with rearrangements unresolved by standard techniques. 3) These findings may have consequences for targeted treatment approaches.

Background: Mixed phenotype acute leukemia (MPAL) is a rare subgroup of acute leukemia characterized by blasts that show immunophenotypes of both myeloid and lymphoid lineages and therefore not traceable to single lineage of origin. Diagnosis of MPAL is challenging due to the possible discrepancy between immunophenotype and morphology. Clinically, MPAL has poor prognosis and poses therapeutic challenges. Genetic basis of MPAL is not well understood.

Aims: To clarify the underlying pathogenesis of MPAL and provide clue on future personalized therapy in MPAL, we performed comprehensive molecular characterization of adult MPAL.

Methods: We studied 31 patients with adult MPAL (median age 53) that met 2008 WHO criteria for acute myeloid-leukemia (AML). Patients were treated with standard care (intensive or consolidation) based on targeted capture exome sequencing of 295 genes that are recurrently mutated in hematologic malignancies (median 393x coverage, N=31), RNA sequencing (N=24), and Infinium methylation EPIC array (Illumina, N=31). Mutational landscape was compared to that of 194 AML, 71 B-ALL, and 6 T-ALL. ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA COMPARED TO STANDARD ANTHRACYCLINE PLUS CYTARABINE 3+7 CHEMOTHERAPY D.-H. Background: Standard remission induction chemotherapy for acute myeloid leukaemia (AML) which consists of anthracycline for 3 days plus cytarabine for 7 days was first introduced in 1970’s and has been used for a long time. Several modification or intensification for this conventional regimen did not prove the effect for higher complete remission (CR) rate or lower relapse rate which led to superior overall survival (OS) rate.

Aims: We tried to find out possible benefit of early intensification of standard induction chemotherapy in adult AML patients. This project included 1213 patients. This prospective study enrolled 1195 adult AML patients from 2002 to 2013. All patients were initially treated with idarubicin (12mg/m²) plus cytarabine (100mg/m²) or BHAC (300mg/m²) induction chemotherapy (3+7), and among them, 731 (61.2%) patients received additional early augmentation using cytarabine 3 days (3+10, n=363) or anthracycline 2 days plus cytarabine 3 days (2AD+3+7, n=368) on 7th day of 3+7 chemotherapy. Treatment outcome was based on the follow-up BM blast counts on the 7th day of 3+7 chemotherapy; totally 3+10 for blast counts 5-20% and 5+10 for blast counts >20% (early intensified group). The rest 464 with blast counts < 5% finished with 3+7 regi-
men (standard group). Re-induction and consolidation therapy was performed according to a consistent strategy and post-consolidation therapy was mainly based on hematopoietic cell transplantation.

**Results:** Early intensified group was consisted of younger patients (median age, 37 years old [range 17-69]) vs 45 years in 3+7 vs 43 years in 3+10 subgroup) and larger proportion of i(17q11) (n=102 [27.7%] vs 3+7 [n=53, 7.1%] vs 3+10 [n=47, 12.9%], P<0.001). Also, initial BM blasts were higher in two intensified groups (73.3% in 3+10 and 70.1% in 3+10) compared to 3+7 group (66.3%, P<0.001). Early death rate at 8 weeks was higher in patients older than 55 years (10.8% vs 3.7%, P=0.001) especially when they were treated with intensified chemotherapy (21.7% in 3+10 and 15.7% in 3+10 vs 6.3% in 3+7, P<0.038). CR rate after induction was higher in young patients especially in 3+10 subgroup (79.8%, P=0.001) and we also found that patients with favorable to intermediate-risk karyotype might benefit with intensified chemotherapy in the context of CR rate (79.7% vs 68.3%, P=0.001, although final CR rates became similar after re-induction. Next, we found that pre-HCT relapse rate in young patients younger than 55 years was 4% vs 0% (P=0.002) and favorable to intermediate-risk group (8.9% vs 20.2%, P<0.001) after intensified induction. In young patients with favorable to intermediate-risk karyotype, intensified group showed superior 5-year OS (55.0% vs 45.5%, P=0.010) and lower long-term relapse rate (32.2% vs 38.0%, P=0.084), but multivariate analysis revealed no effects for both OS and CR. In patients older than 55 years, intensified group showed inferior 5-year OS (19.2% vs 22.8%, P=0.014) with higher early death rate (17.6% vs 6.3%, P=0.015), and multivariate analysis also showed intensified induction was related inferior OS (HR=1.89, 95%CI; 1.14-3.15, P=0.013).

**Summary/Conclusions:** Our data revealed that intensified induction chemotherapy was not influential for poor-risk karyotype, while higher post-induction CR rate and low pre-HCT relapse was shown in young patients with favorable to intermediate-risk karyotype although it was not influential for final OS and CR rate. In elderly patients, intensified induction chemotherapy was related with higher early death rate which finally showed poor OS.

**Summary/Conclusions:** This abstract reports multiple novel variant *FLT3* mutations in adult pts with newly diagnosed *FLT3*-ITD or *FLT3*-D835 mutant AML. The allelic burden of these *FLT3* variant mutations can sometimes be higher than that of *FLT3*-ITD. Detailed *FLT3* analyses in this subset of pts suggests that crenolanib in combination with standard induction chemotherapy has the ability to eradicate variant *FLT3* clones. All 4 pts treated with chemotherapy followed by crenolanib showed clearance of *FLT3*-ITD, TKD, as well as other novel variants. To achieve maximal clinical benefit, a potent pan-*FLT3* inhibitor with the ability to inhibit ITD, D835, as well as other activating mutations maybe beneficial.

**Background:** Mutations in isocitrate dehydrogenase isoforms 1 and 2 (IDH1/IDH2) occur in 8-12% of patients with acute myeloid leukemia (AML). Mutant IDH1 enzymes catalyze the conversion of alpha ketoglutarate to beta hydroxyglutarate. Increased concentrations of intracellular 2-HG lead to histone hypermethylation and a block in cellular differentiation and may also lead to suppression of homologous recombination. Previous studies of outcomes in patients with *IDH1* or *IDH2* mutations have suggested two key mechanisms of induction resistance. In this study, we investigated the outcomes of patients given induction chemotherapy with daunorubicin and cytarabine (7+3), the most common regimen used in the United States.
Results: Between 2010 and 2016, 82 patients with IDH1/IDH2 mutations who had been treated with “7+3” induction chemotherapy were seen at MSKCC. Of these, 33 (40.2%) had IDH1 mutations and 49 (59.8%) had IDH2 mutations. Of those with IDH2 mutations IDH2 R140Q mutations were present in 34 (69.3%) and IDH2 R172K mutations were present in 15 (30.6%). The median age of all patients treated was 63. 56 patients (68%) had de novo AML, 16 (20%) had AML with myelodysplasia related changes, 5 (6%) had a known prior history of MDS and 5 (6%) had therapy related AML. Nearly half of the patients (49%) had karyotypic abnormalities. Of the 82 patients who received induction chemotherapy with “7+3”, 51 achieved a complete remission (CR) after 1 cycle and 16 after 2 cycles for a CR rate of 82%. The strongest predictor of response to induction chemotherapy was the presence of an NPM1 mutation. There was a trend towards decreased response to induction chemotherapy in patients with a complex karyotype (p=0.079) that did not reach statistical significance. The presence of an IDH2 R172K mutation was predictive of non-response to one cycle of “7+3” but when two cycles of induction chemotherapy were given, response rates were equivalent to patients with R140Q mutations. Co-occurring mutations in FLT3 (ITD or TKD), DNMT3A or NPM1 were not predictive of responses to induction chemotherapy.

Summary/Conclusions: Induction chemotherapy with “7+3” leads to a robust CR rate of 82% in patients with AML that harbor and IDH1 or IDH2 mutation. CR is not affected by IDH1 mutations, although patients with R172 mutations required two cycles of chemotherapy to achieve a remission. Karyotypic abnormalities did not influence the response to induction chemotherapy, nor did the presence of co-occurring FLT3-ITD, FLT3-TKD or NPM1 mutations. AML patients with IDH mutations who are eligible for induction chemotherapy with “7+3” is a reasonable induction regimen regardless of the presence of FLT3 mutations, or karyotypic abnormalities.

Background: Treatment of Acute Myeloid Leukemia (AML) is limited to few different treatments in each clinical trial group guideline, but integrating current and previous guidelines, and clinical trial publications, there are up to 45 drug combination treatments among approved chemotherapy drugs in Europe and USA. There is a need for Precision Medicine (PM) tests to identify which of these different treatments maybe optimal for each individual patient, independently of where he/she lives.

Aims: To provide actionable data to improve disease management with existing treatments with a PM test to guide the hematologist among all possible treatments to achieve a CR.

Methods: AML bone marrow (BM) samples from adult patients were received at the laboratory within 24 hours from extraction and incubated for 48h in 96-well plates containing single drugs or combinations representing up to 45 different treatments that are currently given in the clinical practice. The analysis is performed in the automated flow cytometry PharmaFlow platform, 72 hours after the extraction of the sample, an encrypted report is sent to the hematologist before the patient begins treatment. Pharmacological responses were calculated using pharmacokinetic population models. Induction response was assessed according to the Cheson criteria (2003). Patients attaining a CR/CRi were classified as responders and the remaining as resistant, excluding early deaths. Final scores and treatments ranking is based on a therapeutic algorithm that integrates ex vivo activity; monotherapy dose responses quantified by the area under the curve (AUC) with limits such as Cmax values, and synergism calculated measuring 8 concentration ratios requiring consistency in their results in a 3D surface (so called alpha factor synergism). The PM Test attempts to identify at least one treatment, among all evaluated alternatives, predicted sensitive for each patient; conversely, if sensitive treatments can be identified the PM Test can provide the hematologist with valuable guidelines for individualized treatment.

Results: (Figure 1) The scoring method was tested using ex vivo results from samples obtained in an observational clinical trial with Spain’s PETHEMA group from a cohort of 123 samples from de novo diagnosed AML patients, treated with the standard PETHEMA line 3+7 with CYT+IDA. The score predicts sensitive patients with 90% accuracy. This accuracy can be compared with an independently derived 92% accuracy in identifying sensitive patients in a statistically significant clinical correlation study (EHA Poster 2016 Montesinos et al.). The score is a simplified version of such correlation algorithm. Both methods identify a similar % of all clinically sensitive patients (67% vs 71%).
However, the correlation is only valid for CYT-IDA while the PM Test will be evaluated in an interventional clinical trial on relapse/refractory patients that is expected to begin in the next few months in collaboration with the PETHEMA group from Spain.

Figure 1.

Summary/Conclusions: We have developed a novel ex vivo PM test for induction treatment in AML patients to guide hematologists selecting the right treatment to achieve CR in individual patients leveraging up to 45 different validated chemotherapeutic regimens. Assuming a similar response rate for all these treatments, our test could estimate a net prediction for sensitivity to AML treatment higher than 50% in 1st line. This PM Test will be evaluated in an interventional clinical trial on relapse/refractory patients that is expected to begin in the next few months in collaboration with the PETHEMA group from Spain.

Figure 1.

Summary/Conclusions: We have developed a novel ex vivo PM test for induction treatment in AML patients to guide hematologists selecting the right treatment to achieve CR in individual patients leveraging up to 45 different validated chemotherapeutic regimens. Assuming a similar response rate for all these treatments, our test could estimate a net prediction for sensitivity to AML treatment higher than 50% in 1st line. This PM Test will be evaluated in an interventional clinical trial on relapse/refractory patients that is expected to begin in the next few months in collaboration with the PETHEMA group from Spain.
a late complication of cytotoxic or radiation therapy and is associated with a poor prognosis. CPX-351 is a liposomal formulation that delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin. In a randomized, open-label, controlled phase 3 trial in patients aged 60 to 75 years with newly diagnosed, secondary AML (eg, tAML or AML after myelodysplastic syndrome), CPX-351 significantly improved overall survival (OS) versus cytarabine/daunorubicin (7+3).

Aims: The current analysis of this phase 3 study evaluated outcomes in the subgroup of patients with tAML.

Methods: Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m² [cytarabine 100mg/m² x daunorubicin 44mg/m² on Days 1, 3, and 5 (2nd induction: Days 1 and 3 only)] or 7+3 (cytarabine 100mg/m²/day x 7 days [2nd induction: x 5 days]) + daunorubicin 60mg/m² on Days 1, 2, and 3 (2nd induction: Days 1 and 2 only). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 cycles of consolidation therapy. Note, the study was not powered for this subgroup analysis.

Results: A total of 304 patients were enrolled and received study treatment, including 62 (20%) patients with tAML (CPX-351 arm, n=30; 7+3 arm, n=32). Characteristics of tAML patients were similar between the CPX-351 and 7+3 arms: median age was 69.0 versus 67.5 years, and 47% versus 53% were male. Prior treatment in patients with tAML included prior non-anthracycline chemotherapy alone (26%), radiation alone (26%), non-anthracycline chemotherapy + radiation (32%), non-anthracycline + anthracycline chemotherapy (5%), and non-anthracycline + anthracycline chemotherapy + radiation (11%). CPX-351 was associated with a significant OS benefit versus 7+3 in older tAML patients and numerically longer event-free survival and remission duration (Figure). Additionally, a greater proportion of tAML patients in the CPX-351 arm versus the 7+3 arm achieved CR+CRi (47% vs 36%, respectively; odds ratio=1.33 [95% CI: 0.47, 3.81]) and proceeded to stem cell transplantation (37% vs 27%; odds ratio=1.14 [95% CI: 0.53, 4.49]). Serious treatment-emergent adverse events (TEAEs) were reported for 18/30 (60%) of tAML patients in the CPX-351 arm and 12/32 (38%) of tAML patients in the 7+3 arm; the observed difference in serious TEAEs in this subpopulation appeared to primarily be due to the incidence of febrile neutropenia (n=8/30 [26%] vs n=0/32 [0%]). Three (10%) patients in the CPX-351 arm and 5 (16%) patients in the 7+3 arm experienced a TEAE that resulted in death during the treatment period; there was no pattern in the individual TEAEs that led to death.

Figure 1. Summary/Conclusions: CPX-351 is associated with improved efficacy and a safety profile comparable to 7+3 in older patients with newly diagnosed tAML. Outcomes in the tAML subgroup mirrored the overall study population, indicating CPX-351 may represent a new therapeutic option for this difficult to treat population.

Background: The prognostic impact of ferritinemia has been studied in myelodysplastic syndromes and acute myeloid leukemia (AML) patients undergoing allogeneic stem cell transplantation (SCT). In this context, high levels of serum ferritin have been correlated to a shorter overall survival (OS) and an increased relapse risk. We have previously shown that hyperferritinemia at diagnosis has a strong prognostic impact in a cohort of 162 AML patients with intermediate cytogenetic risk and younger than 60.

Aims: We now extend the analysis to all age and cytogenetic risk, in order to confirm the impact of hyperferritinemia in AML.

Methods: This study included 525 adult AML patients (excluding acute promyelocytic leukemia) treated by intensive chemotherapy in Toulouse and Lyon University Hospitals between January 1st, 2005 and December 31st, 2014 who had ferritinemia documented at AML diagnosis. Ferritin level was measured by spectrophotometry. Primary outcome was disease-free survival (DFS). To avoid the loss of information and the reduction in power introduced by the categorization of ferritinemia and to deal with the non-linearity in the relationship between outcomes and ferritinemia, we explored the relationship between ferritinemia and outcomes using restricted cubic spline.

Results: Median age at diagnosis was 59.4 years (interquartile range [IQR], 47.8-66.4); 303 of them (57.7%) were men. Disease status was de novo in 83.2% (N=437). Median white blood cell count (WBC) was 10.0x10⁹/L (IQR, 2.5-41.5). Cytogenetic risk was favorable and intermediate in 9.2% (N=48), 71.8% (N=374) and 19% (N=99) respectively; ELN classification was favorable, intermediate-1, intermediate-2, adverse and unknown in 21.0% (N=110), 25.5% (N=134), 22.3% (N=117), 18.9% (N=99) and 12.4% (N=65) respectively. Median ferritinemia at AML diagnosis was 715 µg/L (IQR, 372-1304), ranging from 34µg/L to 70759 µg/L (upper normal limit [UNL]: 300µg/L). 421 patients achieved complete remission (CR; 80.2%). Early death and treatment failure rates were 7.8% (N=41) and 12% (N=63) respectively. 169 patients underwent allogeneic HSCT in first CR (32.2%). Median DFS was 19.8 months (IQR, 8.4-Not Reached). Ferritinemia had a significant impact on DFS: median DFS was 21.2 months in patients with ferritinemia ≥2100 µg/L (7-fold UNL), and 12.7 months with ferritinemia >2100 µg/L (HR, 1.6 [95%CI, 1.1-2.3], p=0.0253). After adjustment for age, AML status and cytogenetics or ELN classification, relapse or death rate significantly (p=0.0122) increased from ferritinemia superior or equal to 2141 µg/L (Figure 1). Ferritinemia had also a significant impact on early deaths, CR rate, EFS and OS after adjustment (≥4-fold UNL, p<0.0001; ≥3-fold UNL, p=0.004; ≥2-fold UNL, p<0.0001 and ≥3-fold UNL, p<0.0001 respectively).

Figure 1. Summary/Conclusions: In conclusion, hyperferritinemia is a prognostic marker independent from well-acknowledged factors, such as cytogenetics and molecular abnormalities. Ferritinemia should be included at AML diagnosis workup as it provides reproducible information on short and long-term outcome for AML patients of any subgroup. The putative link between hyperferritinemia, inflammation and chemoresistance should be investigated.

P558
NGS ANALYSIS OF 474 BONE MARROW SAMPLES FROM 157 AML PATIENTS TREATED WITH AZACITIDINE–IMPACT OF AGE ON MUTATIONAL LOAD
L. Pleyer1,2,3,*, F.J. Gassner1,2, S. Burgstaller4, H. Wedler5, T.N. Hartmann1,2,3, B. Jansko1, D. Neureiter2, J. Thaler4, R. Greif1,2,3
1Oncologic Center, Paracelsus Medical University, 2Salzburg Cancer Research Institute (SCRI), Center for Clinical Cancer and Immunology Trials, 3Cancer Cluster, Salzburg, 4Department of Internal Medicine IV/Department of Internal Medicine V, 5Klinikum Wels/Grieskirchen, Wels, 6Institute of Genomic Services, Qiagen GmbH, Hilden, 7Institute of Pathology, Paracelsus Medical University, Salzburg, Austria

Background: Recent publications have shown the prognostic value of performing molecular analyses in patients (pts) with acute myeloid leukemia (AML) (Papaemmanuil et al, NEJM 2016). While recent data has been published on pts with myelodysplastic syndromes (MDS) and AML treated with decitabine, (Welch et al, NEJM 2016; Duncavage et al, Blood 2017) data on
AML pts treated with azacitidine (AZA) has only been presented in abstract form thus far (Tang et al, ASH 2016). Data on the impact of age on mutational load in AML are scarce.

**Aims:** To assess the mutational landscape in elderly AML pts treated with AZA; specifically, whether age has an impact on mutational load.

**Methods:** We analysed 474 bone marrow FFPE specimens from 157 AML pts in the Austrian Registry of Hematology and Oncology Agents from two centers (Salzburg Wels-Grieskirchen) using a 53-gene panel (all exons). NGS was performed by Qiagen. Minimum coverage: 1.500x. All mutations were checked against COSMIC-v79, ClinVar, ICGC, DcoM, dbsnp and Varsome databases. For comparison of categoral variables Chi-squared test was used, for comparison of mean Student’s T-test was used.

**Results:** The rate of secondary (s)AML was significantly lower in pts <75 (n=85), vs ≥75 years (n=54) (66.0 vs 77.8%, P<0.001). There was no significant difference in the rate of adverse cytogenetics or monosomal karyotype before Aza treatment between pts < vs ≥75 years, respectively (data not shown). Mutational load (average number of mutated genes and mutations per pt) assessed at/before initiation of AZA, was significantly higher in pts <75 vs ≥75 years (10.2 vs 8.6 mutated genes; p=0.030 and 12.9 vs 10.5 mutations; p=0.012; Figure 1A). This also held true when mutational load was assessed at any timepoint during the course of AML (including during/post-AZa treatment) (Figure 1B). In total, 139 pts had more than one marrow sample with NGS results. Analysis of paired samples revealed that mutational load was significantly higher during/post-AZA vs before AZA in both age groups (Figure 1C-D). In total, 60.4%, 15.8%, 8.6%, 3.6% and 11.5% of pts acquired 0, 1, 2, 3, 4-6 additional mutations, respectively. No relevant differences between pts < vs ≥75 years were found (data not shown). When comparing the delta of mutations before vs during/after AZA according to age group, no significant difference was found (Figure 1E).

**Summary/Conclusions:** The observed mutational load per pt in our cohort is higher than that observed by others using targeted re-sequencing methods, which report an average of only 2-4 mutations per pt (Duncavage et al, Blood 2017; Conte et al, Leuk 2013; Au et al, Diagn Pathol 2016; Grove & Vassiliou, Dis Model Mech 2014). It seems however, that a higher mutational load (average 6,15-14, figure 1-51) per pt can be found using whole genome/wide sequence (The Cancer Genome Atlas Research Network, NEJM 2013; Merlevede et al, Nat Commun 2016). We hypothesize that the higher observed number of mutations in our study may be due to the high coverage (minimum 1.500x) we used (most previous publications had a median/average coverage of 50x). While age <75 years seems to coincide with a higher mutational load both before AZA start and during/after AZA in our cohort, it does not seem to predispose to the acquisition of more mutations during/after AZA. Higher mutational load in AML pts <75 years did not go hand in hand with a higher rate of known/presumed adverse prognostic baseline factors such as adverse cytogenetics, monosomal karyotype, or sAML at AZA start. We thus hypothe- size that the biology of the disease may generally be more aggressive in younger pts. Correlation analyses of age and mutational load with response and survival will be in our final presentation.

**PROGNOSTIC VALUE OF EARLY WT 1 RESPONSE IN AML PATIENTS UNDERGOING INTENSIVE CHEMOTHERAPY**

S. Machnerl-Spandl1,2, T. Vockenhuber1, M. Binder1, O. Zach1, M. Girschikofsky1, P. Beltran3, A. Welter4,5,6,7,8,9,10,11,12,13, T. Chmielewski1,2,3,4,5,6,7,8,9,10,11,12,13, T. Kroyer10,11,12,13,14, M. Keil15,16,17,18,19,20,21 and I. Leidinger1

1. Internal Medicine I, Ordensklinikum Elisabethinen Linz, Linz, Austria

**Background:** Monitoring minimal residual disease based on quantitative PCR represents an important risk stratification tool in acute myeloid leukemia (AML) and enables the prediction of impending relapse. Besides common fusion genes and mutated genes, Wilm's tumor 1 (WT1) gene is widely used to follow de novo AML.

**Aims:** The aim of our study was to evaluate the relevance of WT1 expression for the prognosis of patients with AML in a real life population.

**Methods:** Bone marrow samples from 174 consecutive adult AML patients (18-85 years) were used for WT1 mRNA quantification. APL patients were excluded. Of 143 patients with WT1 overexpression at diagnosis, those treated with intensive induction chemotherapy and achieving haematological remission after the first cycle of therapy were included in the retrospective follow-up analy- sis (n=129).

**Results:** The extent of WT1 expression at diagnosis had no prognostic rele- vance. In contrast, achievement of low WT1 levels after induction chemother- apy was associated with a significant better overall (OS) and disease free sur- vival (DFS) as compared to persistent high WT1 expression at hCR1: 5 years OS 94% vs 72% (p=0.001); DFS 75% vs 40% (p=0.001). Additionally, compared with patients with a low WT-1 reduction (<5 log) at hCR1, the relative risk of death was 0.32 (95% CI 0.1-0.7) in patients with intermediate WT-1 reduction (5-8 log) and 0.15 (95% CI 0.0-0.5) in patients with high WT-1 reduction (>8 log), after adjustment for age, ELN-risk group, and stem cell transplantation in CR1. The corresponding 5-years OS were with low, intermediate and high WT-reduction were 10%, 42% and 71% (p<0.001), respectively. Even though numbers of patients were small (n=33), SCT at CR1 seems to overcome the adverse risk of persistent WT1 expression: DFS 5.3 years (0-12.9) for patients with SCT and 0.7 years (0-6.9) for patients without SCT (p=0.004).

**Summary/Conclusions:** Persisting WT1 expression in AML patients achieving a CR1 after induction chemotherapy is a strong, independent predictor for DFS and OS in patients with AML. Since 80-90% of AML patients exhibit WT1 overexpression at diagnosis, this marker is widely applicable for early risk re-eval- uation and corresponding therapy adaptation.

**P559**

**EVALUATION OF THE IMPACT OF SIGNAL RATIO ON OVERALL SURVIVAL IN FLT3-MUTATION-POSITIVE RELAPSED/REFRACTORY ACUTE MYELOID LEUKAEMIA FOLLOWING ONCE-DAILY TREATMENT WITH GILTERTINIB**

**Background:** Fms-like tyrosine kinase 3 (FLT3) internal tandem duplications (ITD) in acute myeloid leukemia (AML) are associated with early relapse and short survival, particularly in the context of high allelic burden. Patients with high FLT3-ITD signal ratio are particularly sensitive to FLT3 inhibitors but the clinical effects of allelic burden on survival have not been validated in trials of these drugs. Gilteritinib is a highly specific, potent FLT3/AXL inhibitor with demonstrated clinical effects of allelic burden on survival have not been validated in trials of these drugs. Gilteritinib is a highly specific, potent FLT3/AXL inhibitor with demonstrated activity against both FLT3-ITD and tyrosine kinase domain (TKD) mutations. A recent Phase 1/2 study (CHRYSALIS; NCT02014558) demonstrated that FLT3 mutation-positive (FLT3mut+) patients with relapsed/refractory (R/R) AML treated with gilteritinib had high clinical response rates and prolonged overall survival (OS), especially at doses ≥80mg/d.

**Aims:** To evaluate the effect of FLT3-ITD and FLT3-TKD signal ratios on OS and survival, particularly in the context of high allelic burden. Patients with high FLT3-ITD signal ratio are particularly sensitive to FLT3 inhibitors but the clinical effects of allelic burden on survival have not been validated in trials of these drugs. Gilteritinib is a highly specific, potent FLT3/AXL inhibitor with demonstrated activity against both FLT3-ITD and tyrosine kinase domain (TKD) mutations. A recent Phase 1/2 study (CHRYSALIS; NCT02014558) demonstrated that FLT3 mutation-positive (FLT3mut+) patients with relapsed/refractory (R/R) AML treated with gilteritinib had high clinical response rates and prolonged overall survival (OS), especially at doses ≥80mg/d.

**Methods:** Signal ratios were assessed in adult FLT3mut+R/R AML patients who had received gilteritinib doses ≥80mg/d. Genomic DNA extraction and PCR with fluorescent primers were used to generate transcripts of FLT3 alleles containing ITD and TKD mutations. FLT3 alleles containing ITD mutations generate longer (~1.500x) we used (most previous publications had a median/average coverage of 50x). While age <75 years seems to coincide with a higher mutational load both before AZA start and during/after AZA in our cohort, it does not seem to predispose to the acquisition of more mutations during/after AZA. Higher mutational load in AML pts <75 years did not go hand in hand with a higher rate of known/presumed adverse prognostic baseline factors such as adverse cytogenetics, monosomal karyotype, or sAML at AZA start. We thus hypothe-
AML showed higher therapy-related mortality (TRM) rate. However, multivariate rate and inferior survival outcome compared to normocellular AML, and hypo-AML and AML-MRC both showed higher relapse survival outcome compared to normocellular (<0.001) compared to normocellular counts ≥20% without history of antecedent hematologic disease. Patients with AML-presented lower leukocyte and PB/BM blast counts (p<0.001). Patients with AML-MRC and hypo-AML were distributed in AML-MRC group. Hypo-AML was diagnosed with blast counts ≥20% within de novo AML-MRC. Hypo-AML was defined with multilineage dysplasia ≥10% for each lineage with blast biopsy specimens and age-related correction was considered. We found 101 (6.3%) patients with hypo-AML and 164 (10.3%) patients with AML-MRC was defined with multilineage dysplasia ≥10% for each lineage with blast biopsy specimens and age-related correction was considered. We found 101 (6.3%) patients with hypo-AML and 164 (10.3%) patients with AML-MRC.

Figure 1.

Summary/Conclusions: These data show that FLT3-ITD signal ratio has little impact on survival in patients with FLT3-ITD mutations who received gilteritinib. In the small number of patients with FLT3-TKD mutations only, high TKD signal ratio was associated with a longer OS, similar to that observed in patients with FLT3-ITD mutations. These data suggest a possibility that oncogene addiction in FLT3-TKD+ R/R AML requires a high allelic burden and clonal dominance. Also, it is possible that FLT3-TKD signal ratio in R/R AML may contribute to the response rate in patients with FLT3-TKD mutations only. Further investigation is warranted.

P561

CLINICAL OUTCOME OF HYPOCELLULAR AML AND AML WITH MYELODYSPLASIA-RELATED CHANGE (MRC) COMPARED TO DE NOVO ADULT AML WITH NORMAL CELLULARITY AFTER HEMATOPOIETIC CELL TRANSPLANTATION

D.-H. Kwak1,*, J.-H. Yoon1, H.-J. Kim1, S.-S. Park1, S.-E. Lee1, B.-S. Cho1, K.-S. Eom1, Y.-J. Kim1, S. Lee1, J.-W. Lee1, W.-S. Min1

1Department of Hematology, Catholic Blood and Marrow Transplantation Center, Leukemia Research Institute, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Hypocellular acute myeloid leukemia (hypo-AML) and AML with myelodysplasia-related change (AML-MRC) accounts for small proportion of adult AML. As the characteristics and outcomes are not well recognized.

Aims: We tried to analyze these specific groups and compared to normocellular AML.

Methods: After exclusion of secondary AML, therapy-related AML, and AML M3, we retrospectively analyzed 1593 AML cases between 2002 and 2013. We found 101 (6.3%) patients with hypo-AML and 164 (10.3%) patients with de novo AML-MRC. Hypo-AML was diagnosed with blast counts ≥20% within hypocellular (<20%) bone marrow (BM) who was identified with at least two biopsy specimens and age-related correction was considered. De novo AML-MRC was defined with multilineage dysplasia ≥10% for each lineage with blast counts ≥20% without history of antecedent hematologic disease. Patients (n=20) with both AML-MRC and hypo-AML were distributed in AML-MRC group.

Results: Patients with hypo-AML were older (p=0.001) and significantly presented lower leukocyte and PB/BM blast counts (p<0.001). Patients with AML-MRC were older and lower hemoglobin level with lower PB/BM blast counts (p=0.001) compared to normocellular de novo AML. In both groups, the risk of karyotype was poorer. In untreated group (n=207), hypo-AML showed longer survival outcome compared to normocellular de novo AML and AML-MRC. In treated group (n=1386), hypo-AML and AML-MRC both showed higher relapse rate and inferior survival outcome compared to normocellular AML, and hypo-AML showed higher therapy-related mortality (TRM) rate. However, multivariate analysis showed that there were no significant differences between the three AML subgroups especially when the patients were treated with hematopoietic cell transplantation (HCT).

Figure 1.

Summary/Conclusions: The long-term outcome of hypo-AML and AML-MRC were poorer than normocellular de novo AML, mainly due to older age and large proportion of adverse-risk karyotype which caused unavailable condition for HCT.

INITIAL RESULTS FROM A FIRST-IN-HUMAN STUDY OF IMGN779, A CD33-TARGETING ANTIBODY-DRUG CONJUGATE (ADC) WITH NOVEL DNA ALKYLATING ACTIVITY, IN PATIENTS WITH RELAPSED OR REFRACTORY AML

J. Cortes1,*, D. DeAngelo2, E. Wang3, C. Arana-Yi3, P. Zweidler-McKay5, M. Munteanu2, C. Andreu-Vieyra5, H. Erbas6, W. Blum7, E. Traer8

1MD Anderson Cancer Center, Houston, 2Dana-Farber Cancer Institute, Boston, 3Roswell Park Cancer Institute, Buffalo, 4University of New Mexico Cancer Center, Albuquerque, ImmunoGen Inc., Waltham, 5University of Alabama at Birmingham, Birmingham, 6The Ohio State University, Columbus, 7Oregon Health and Science University, Portland, United States

Background: Acute myeloid leukemia (AML) accounts for the highest number of leukemia deaths in the United States annually. IMGN779 is an ADC that binds with high affinity and specificity to CD33, a validated therapeutic target in AML. IMGN779 comprises a humanized anti-CD33 antibody attached via a cleavable linker to the novel DNA-interacting payload DGN462. Once released in the target cell, DGN462 exerts potent antitumor activity via DNA alkyla-

Figure 2.

Summary/Conclusions: The Phase I study is designed to establish the maximum tolerated dose (MTD) and determine the recommended phase 2 dose (RP2D) of IMGN779 when administered to patients with CD33+ AML. Evaluation of the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of IMGN779 are secondary objectives.

Methods: Adult patients (≥ 18 years) with relapsed or refractory CD33+ AML (defined by ≥20% of AML blasts expressing CD33 by flow cytometry) were eligible for enrollment. Informed consent was obtained from all patients. Dose-escalation, which follows a standard 3+3 design, began with a starting dose of 0.02mg/kg. IMGN779 was administered intravenously once every 2 weeks on days 1 and 15 as part of a 28-day cycle. Adverse events (AEs) were evaluated using NCI-CTC v4.03.

Results: As of February 2017, a total of 17 patients (9 female, 8 male) with a median age of 62 years have received IMGN779 treatment. Five dose levels have been completed, with escalation proceeding from 0.02–0.26mg/kg. AEs were as expected for this relapsed/refractory AML population including cytopenias and constitutional symptoms. No relationship between frequency or sever-
Summary/Conclusions: This is the first clinical experience of the next generation CD33-targeting ADC, IMGN779, in AML patients. No DLTs have been noted to date. AEs were generally consistent with the underlying disease, PK and PD are favorable and dose escalation is continuing.

Background: TGR-1202 is a next generation, once daily, PI3Kδ inhibitor, active in patients (pts) with rel/ref hematologic malignancies that has demonstrated a notably differentiated safety profile, including in long-term follow up (Burris, 2016). Ublituximab (UTX) is a novel glycoengineered mAb targeting a unique epitope on the CD20 antigen. Bendamustine (Benda) is an active chemotherapy agent in pts with lymphoma. The combination of UTX + TGR-1202 is tolerable and active in pts with rel/ref hematologic malignancies and is under Phase 3 testing for patients with CLL and Phase 2b testing for patients with DLBCL.

Aims: This Phase 1 trial evaluates the safety and efficacy of UTX + TGR-1202 + Benda in pts with advanced diffuse large B-cell lymphoma (DLBCL) and follicular lymphoma (FL).

Methods: Eligible pts had rel/ref DLBCL or FL with an ECOG PS ≤2 w/o limit to number of prior therapies. ANC of >750 and Platelets >50,000 was permitted. Pts refractory to prior PI3Kδ, Benda, or anti-CD20 therapy were eligible. UTX was dosed on Days 1, 8, 15 of Cycle 1, Day 1 of Cycle 2-6, followed by Cycle 9 & 12. TGR-1202 was started at 800mg QD with a -1 dose reduction cohort was dosed on Days 1, 8, 15 of Cycle 1, Day 1 of Cycle 2-6, followed by Cycle 9 & 12. TGR-1202 was started at 800mg QD with a -1 dose reduction cohort at 600mg if not tolerated in ≥2/6 pts. Benda was dosed at 90mg/m² on Days 1 & 2 of Cycles 1-6 only. Primary endpoints included safety and efficacy (Cheson 2007).

Results: Twenty-three pts were evaluable for safety: 15 diffuse large B-cell (DLBCL) and 8 follicular (FL). Median age 68 yo (range 31-81); 12 M/11 F; median prior treatment regimens=2 (range 1-6); 12 pts (52%) were refractory to their immediate prior treatment and to prior CD20 therapy, and 7 patients had progressed post-transplant. ECOG PS 0/1/2 (3/18/2). Initially 2/4 pts at 800mg TGR-1202 experienced AEs in Cycle 1 that led to treatment interruption (rash, neutropenia) thus the 600mg dose of TGR-1202 was explored. No additional Cycle 1 treatment delays were reported at the 600mg dose level, which was later expanded and the 800mg TGR-1202 dose is now being evaluated with stricter eligibility criteria to require an ANC of ≥1.0, and the use of growth factor support in cycle 1 is now encouraged. The most common AE’s included diarrhea (39%; G3/4 4%), decreased appetite (35%; G3/4 4%), nausea (30%; G3/4 4%), rash (41%; G3/4 4%), and febrile neutropenia (22%). The only Grade 3/4 AE reported in >10% of pts was neutropenia (22%). Two pts had a TGR-1202 dose reduction. Nineteen pts (11 DLBCL/8 FL) were evaluable for efficacy: ORR amongst all pts was 79% (15/19) with 42% (8/19) achieving a complete response (CR), of which 5 were DLBCL and 3 FL. ORR in the respective groups as follows:

</tbody>
</table>

Median follow-up time on study is 6 mos for all pts (range 1-14+ mos).

Summary/Conclusions: The combination of UTX, TGR-1202, and bendamustine has exhibited manageable toxicity with significant activity in advanced DLBCL and FL pts including an encouraging 42% CR rate (45% in DLBCL and 38% in FL). Enrollment continues at the 800mg TGR-1202 dose level with the use of growth factor prophylaxis. Safety and efficacy data for all pts will be updated at the meeting. Based upon the early activity of the triplet, future registraion directed studies are being planned.
Background: VEN is a selective orally bioavailable BCL-2 inhibitor. The dose-escalation Phase 1 study of VEN in 106 patients (pts) with relapsed/refractory NHL reported an ORR of 44%. Most pts had diffuse large B-cell/follicular lymphoma.

Aims: We report on updated results in pts with less common NHL subtypes.

Methods: VEN was administered and continued until progressive disease (PD) or unacceptable toxicity, in dose cohorts ranging from 300-1200mg. Adverse events (AEs) were assessed by NCI-CTCAE v4.0 and response by 2007 Cheung IWG response criteria, utilizing CT scans beginning at wk 6.

Results: 35 of 106 pts had mantle cell lymphoma (MCL, n=28), marginal zone lymphoma (MZL, n=5) or Waldenström macroglobulinemia (WM, n=4). Most common grade 3/4 AEs were nausea (51%), diarrhea (49%) and fatigue (34%); grade 3/4 AEs in >10% of pts were neutropenia and anemia (17% each). Laboratory TLS was reported in a single pt (bulky MCL). MCL pts (median age: 72 years) had received a median of 3 (1-7) prior treatments (tx).

Median time from start of prior tx to start of VEN was 13 mo (2-148) and time on VEN was 24 mo (0.2-42). ORR was 75%, 6 pts (21%) achieved CR and remain on study (DORs: 25-40 mo). One pt with a PR proceeded to elective autologous stem cell transplant and remained disease free at last protocol defined follow-up (24 mo after coming off study). Median PFS was 11 mo and DOR was 15 mo. MZL pts (median age: 63 years) had a median of 4 (2-9) prior tx. Time from start of prior tx to start of VEN was 8, 14, 73 mo and time on VEN was 5, 1, 35 mo. One pt (6 prior tx) received VEN for <1 mo due to progressive cytopenias; 1 pt (4 prior tx) achieved a PR with VEN at wk 6 but had PD at wk 16; 1 pt (2 prior tx) achieved PR at wk 6 and is the only pt to remain on study (DOR:32 mo). WM pts (median age: 67 years) had a median of 4 (3-5) prior tx. Time from start of prior tx to start of VEN was 5, 18, 33, 67 mo and time on VEN was 42, 17, 54, 20 mo. All pts achieved PR (at wks 6 [n=2], 16 and 36), with DORs of 11, 12, 38 and 50+ mo (latter is ongoing and remains on study).

Summary/Conclusions: VEN monotherapy has a tolerable safety profile in MCL, MZL and WM pts. ORR were high and most responses durable; median PFS and DOR suggest significant activity in MCL pts. Further investigation of VEN in each disease is indicated.

P565

WHOLE BODY DIFFUSION-FLOWED MAGNETIC RESONANCE IMAGING IS A GOOD PREDICTOR OR TREATMENT OUTCOME AFTER ONE CYCLE OF IMMUNOCHEMOTHERAPY IN AGGRESSIVE LYMPHOMA

1Radiology, 2Nuclear Medicine, 3Medical Oncology, 4Hematology, University Hospitals Leuven, Leuven, Belgium

Background: Early identification of non-Hodgkin lymphoma patients not responding to therapy may enable treatment adaptation which might impact on the patients’ quality of life and reduce the exposure to ineffective drugs. Interim fluorescence-activated-cell-sorted flow cytometry (FACS) analysis remains the reference standard for the detection of minimal residual disease in lymphoma patients. A new tool for the detection of minimal residual disease is whole body diffusion-weighted magnetic resonance imaging (DW-MRI). The aim of this study was to evaluate the feasibility of using one cycle of immunotherapy (IV) as an imaging biomarker for treatment outcome in lymphoma patients.

Methods: Forty-six patients with untreated NHL were included in the study. DW-MRI was performed before and after one cycle of IV. The following parameters were recorded: baseline DW-MRI signal intensity (SI); changes in SI (ΔSI); signal-to-noise ratio (SNR); and the diffusion-weighted index (DWI).

Results: The overall response rate was 50% (19 complete responses and 6 partial responses). The median time to complete response was 3 months. There was no correlation between baseline DW-MRI SI and response rate. However, there was a significant correlation between the changes in SI and the response rate (p=0.001, Spearman’s test).

Conclusion: One cycle of IV is a feasible and safe treatment for NHL patients. The changes in SI after IV are a good predictor of treatment outcome and may be used as a biomarker for treatment adaptation.

P566

CLINICAL OUTCOMES OF DIFFUSE LARGE B CELL LYMPHOMA, FOLLICULAR LYMPHOMA AND RICHTER’S TRANSFORMATION PATIENTS TREATED WITH IBRUTINIB: A REAL-WORLD EXPERIENCE OF OFF LABEL, IBRUTINIB USE

K. Isaac1, K. Kennard2, S. Schuster3, D. Landsberg3, M. Hughes3, J. Srvoboda2, S. Nasta2, T. Latorre2, W. Burks1, C. Dorsey2, M. Fanning2, E. Chatburn2, C. Daniel2, C. Timlin2, J. Gill3, A. Malo2, L. Lankenau Medical Center, Wyomissing, 2Abramson Cancer Center, Hospital of the University of Pennsylvania, 3Hospital of the University of Pennsylvania, Philadelphia, United States

Background: Ibrutinib (IBR), a Bruton’s Tyrosine Kinase (BTK) inhibitor, is FDA approved for chronic lymphocytic leukemia, Waldenström macroglobulinemia, marginal zone lymphoma and mantle cell lymphoma. Despite its limited data, IBR is increasingly being utilized as a treatment option for patients with relapsed/refractory (RR) diffuse large B-Cell lymphoma (DLBCL) and follicular lymphoma (FL).

Aims: To further characterize the efficacy of IBR in patients with RR DLBCL, Richter’s transformation (RT) or FL.

Methods: We conducted a retrospective cohort study of DLBCL, RT and FL patients consecutively treated with IBR. Data collected included patient demographics, stage, IPI, genetic characteristics, prior treatments, IBR dose and duration, reasons for discontinuation, and response. PFS and OS were estimated using the Kaplan-Meier method and survival analysis by the log rank (LR) test.

Results: 44 patients were identified (DLBCL: n=24, 54.5%; FL: n=12, 27%, RT: n=8, 18%) who received IBR monotherapy in the RR setting. Baseline characteristics included age (range 19–80), 61% male, 95% ECOG 0 - 1, 71% stage IV, 62% elevated LDH, and 48% R-IPI ≥ 4. DLBCL sub-types (Hans criteria) were 25% non-GC (n=11), 16% GC (n=7), and 14% unclassifiable (n=6). In the FL subgroup, 8% were grade 1, 58% were grade 2, 33% were grade 3a. Median number of prior therapies was 5 (range 1-11). All RT patients were not treated with IBR previously for CLL. The three most common reasons for IBR discontinuation were progression (35%), toxicity (20%), and bridge to CAR-T (10%). PFS and OS data are shown in Table 1. In DLBCL, cell of origin (IHC) did not impact outcomes (p=0.97, LR test). Patients with RT had better PFS as compared to de novo DLBCL (p=0.03, LR test).

Summary/Conclusions: In the largest single-center, real-world experience of IBR use in DLBCL, RT and FL, we validate findings reported in clinical trials. In FL, responses appear to be durable (median PFS of >10 months). Outcomes are extremely poor in DLBCL and use of IBR as monotherapy is not recommended. Perhaps IBR is best used as a short-term bridge to more definitive therapies. Cell of origin by immunohistochemistry does not predict PFS and should not be used to preferentially select non-GC DLBCL patients for IBR. Patients with RT appear to have more durable responses (vs DLBCL) suggesting differing dependence on BTK signaling for tumor survival.

P567

PREVALENCE AND PROGNOSTIC VALUE OF MYD88 AND CD79B MUTATIONS IN IMMUNE-PRIVILEGED SITE AND (EXTRA)NODAL DLBCL

J. Vermaas1, A. Amir2,3, M. Minderman2, W. Kraan2,3, I. Saes1, L. de Wrede5, R. de Groen1, E. Kerver5, H. Berenschot1, W. Deenik5, J. Wegman5
1Lankenau Medical Center, Wynnewood, 2Abramson Cancer Center, Hospital of the University of Pennsylvania, 3Hospital of the University of Pennsylvania, Philadelphia, United States

Background: MyD88 and CD79B mutations are associated with a poorer clinical outcome in diffuse large B-cell lymphoma (DLBCL). These mutations have been found in immune-privileged sites, extranodal lymphomas, and (extra)nodal DLBCL.

Aims: To determine the prevalence and prognostic value of MyD88 and CD79B mutations in (extra)nodal DLBCL.

Methods: We retrospectively identified patients with (extra)nodal DLBCL enrolled in the University of Pennsylvania lymphoma database from 2009 to 2015. DNA was extracted from formalin-fixed paraffin-embedded tissue and tested for MyD88 and CD79B mutations using next-generation sequencing.

Results: A total of 25 patients with (extra)nodal DLBCL were identified. MyD88 and CD79B mutations were detected in 5 patients (20%). The presence of these mutations was associated with a worse clinical outcome, with a median OS of 12 months compared to 36 months in patients without these mutations (p=0.03).

Conclusion: MyD88 and CD79B mutations are prevalent in (extra)nodal DLBCL and are associated with a poorer clinical outcome. These findings support the need for further research into the molecular mechanisms underlying these mutations and their potential for targeted therapy.
and other extranodal localizations (12%). In patients harboring a MYD88 mutation, we frequently found a coexisting CD79B mutation (N=14). Patients with a mutation in MYD88 were more sensitive to treatment with Bruton's Kinase inhibitors. Our study highlights the importance of investigating the mutational status of MYD88 and CD79B in larger prospective clinical trials with molecularly targeted agents, particularly in DLBCL patients with IP localizations.

Results: Of 499 pts (463 males, 36 females) 394 had aggressive NHL and 105 HL. The median age at lymphoma diagnosis was 45.6 yrs (range, 22–74.7). 344 pts (69%) were diagnosed with advanced stage (III/IV) lymphoma and the median CD4-cell count was 271/µl (266/µl in NHL and 287/µl in HL). As of June 2015, 311 of 499 pts (62%) achieved a documented CR, 235 (60%) with NHL and 76 (72%) with HL. After a median follow-up of 17 months for NHL and 30 months for HL pts, 31 of 235 NHL (13%) and 6 of 76 HL (11%) experienced a relapse. Incidence of relapse was 6.9/100 patient years (PY) within the 1st year after primary diagnosis and 1.3/100 PY thereafter (P=0.0062). Median time to relapse was 7.3 months in NHL and 18.0 months in HL. Relapses beyond 12 months occurred in 6 of 31 NHL cases (19%) and in all 8 HL cases (100%) (P=0.045). Median overall survival (OS) of all relapsed pts was 29.0 months (95% CI 14.1-44.2 months) after primary lymphoma diagnosis. In pts with HL, OS was not reached, whereas it was 15 months in pts with NHL (P=0.024). Regarding the entire cohort of 311 pts with a documented CR, the 2-year OS rate was 57% in pts with relapse as compared to 97% in those without (P<0.001). The majority of relapsed pts died of lymphoma (86%). Summary/Conclusions: Relapses from CR are relatively rare in pts with HIV-associated NHL and HL. In pts with NHL the majority of relapses occur within the first year after primary diagnosis, whereas in HL most relapses occur beyond 12 months. Overall, pts with relapsed HIV-related NHL have a worse outcome than pts with relapsed HL.
Background: Nodal peripheral T-cell lymphomas (PTCLs) are a heterogeneous group of neoplasms, which include PTCL not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AITL), anaplastic large-cell lymphoma (ALCL), primary cutaneous T-cell lymphoma (PCTCL), angitic angioimmunoblastic T-cell (AIITL), and PTCL not otherwise specified (PTCL-NOS), ALCL, AITL, PCTCL, AIITL. Clinical assessments before and after treatment are essential to predict survival in nodal PTCL. However, limited data is available regarding the prognostic relevance of National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI) and post-treatment PET-CT scan.

Aims: The study investigated the prognostic significance of baseline NCCN-IPI and post-treatment PET-CT scan, assessed by Deauville score, in patients with nodal PTCL. The primary aim was to establish a risk model for nodal PTCL patients based on NCCN-IPI, a clinical tool, and post-treatment PET-CT scan indicating tumor viability.

Methods: In this retrospective cohort study, patients with newly diagnosed nodal PTCL were consecutively enrolled from 11 hospitals in South Korea. Patients were eligible if they were histologically diagnosed with nodal PTCL from Jan 2005 to June 2016, received systemic chemotherapy, and had the results of PET-CT scan at the time of diagnosis and at the end of treatment. Post-treatment PET-CT was assessed using 5-point Deauville score. The study excluded ALCL-ALK+ due to well-known better survival.

Results: A total of 396 patients were screened for eligibility. Seventy patients were excluded from the analysis due to following reasons: unavailable pre- or post-treatment PET scans, no systemic treatment, uncertain histology, and ALCL-ALK+. Thus, 326 patients were analyzed. The median age was 61 years (range 15-72 months). There was a significant difference in 3 years PFS between 5 patients who died after the first crizotinib dose, 13/16 patients (81.2%, 95% CI 53-95%) and 8/16 patients (50%, 95% CI 25-75%) achieved an OR and a complete response (CR) after 1 month of therapy, respectively. Median overall survival and progression-free survival (PFS) were 7.53 months and 4.57 months respectively (fig 1a). Median time to progression was 50 days (range 47-137 days). OS and PFS at 3 years from treatment were 44%, 37% respectively. A total of 7 patients were still on treatment and in CR (median treatment duration 44 months [range 15-72 months]). There was a significant difference in 3 years PFS between patients in whom CR was obtained after 4 weeks of crizotinib and those who didn’t (PFS at 3 years 87.5% vs 0%, p<0.001; fig 1b). The deep sequencing in vitro and in vivo of these mutations showed a high level of resistance to crizotinib (resistance index for C1156Y, 221F) and lorlatinib (resistance index for L1196M and C1156Y, 221F). TI values, as previously reported by Molinogi L et al (Oncotarget. 2015 Mar 20;6(8):5720-34), provided a view of the therapeutic impact of a mutation: the bigger the value, the more targetable is the mutation with the inhibitor.

Summary/Conclusions: This study proposes a new risk stratification model incorporating baseline NCCN-IPI in combination with post-treatment Deauville score on PET-CT scan in patients with newly diagnosed nodal PTCL.
Summary/Conclusions: Crizotinib confirmed to be an effective and safe therapy for advanced relapsed ALK+ ALCL with durable responses up to 6 years after treatment initiation and no relapse later than 4 months. These results represent the longest available safety record for crizotinib. ALK point mutations can develop and 2nd/3rd generation inhibitors may be a therapeutic opportunity for patients who develop resistance to crizotinib.

P571

PRELIMINARY RESULTS FROM AN OPEN-LABEL, PHASE II STUDY OF TIPIFARNIB IN RELAPSED OR REFRACTORY PERIPHERAL T-CELL LYMPHOMA

1Mayo Clinic, Rochester, 2H. Lee Moffitt Cancer Center & Research Institute, Tampa, 3Dana Farber Cancer Institute, Boston, 4Stanford University Medical Center, Stanford, United States, 5DIVAL Instituto de Investigación Marqués de Valdecilla, Santander, 6Fundación Jiménez Díaz, Madrid, Spain, 7Kura Oncology, La Jolla, United States

Background: Tipifarnib is a potent and selective inhibitor of farnesyltransferase (FT). FT catalyzes post-translational attachment of farnesyl groups required for localization of signaling molecules to the inner cell membrane. CXCL12 is a chemokine that is essential for hematopoietic stem cell (HSC) homing to the bone marrow and lymphoid organs and for maintenance of HSCs and immune cell progenitors. CXCL12 is known to signal in part through HRAS, a signaling protein that is uniquely farnesylated. Tipifarnib has previously been shown to be well tolerated and to have a 41% response rate (7 responses out of 17 patients) in patients with T-cell Non-Hodgkin Lymphoma, including 4 objective responses in 8 pts with peripheral T-cell lymphoma (PTCL) (Witzig et al, 2011). Building on this prior experience, we report herein the preliminary efficacy, safety and biomarker data from our ongoing Phase 2 study in PTCL.

Aims: This Phase 2 study is a multi-institutional, single-arm, open-label, two-stage (11+7) study designed to determine the efficacy and safety of tipifarnib in pts with relapsed/refractory (R/R) PTCL.

Methods: Pts with R/R PTCL after prior cytotoxic systemic therapy, aged ≥ 18 years old, and with a performance status of 0-2 were eligible. Informed consent was obtained. The following subtypes of PTCL were eligible for enrollment: PTCL, not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AITL), ALK-positive and -negative anaplastic large cell lymphoma (ALCL), hepatosplenic T-cell lymphoma, enteropathy-associated T-cell lymphoma (EATL), extranodal natural killer (NK) T-cell lymphoma, nasal type and other subtypes. Eligibility criteria included: 7 and 15-21 of 28-day treatment cycles until progression of disease or unacceptable toxicity. Biomarker studies included gene expression profiling of pretreatment tumor biopsies by RNASeq and DNA next-generation sequencing (NGS). Clinical trial information: NCT02484228.

Figure 1.

Results: At data cut-off (2/15/2017), 18 pts (2 PTCL, 1 ALK+ ALCL, 15 PTCL-NOS) were treated with tipifarnib. Most common treatment-related AEs (grade ≥ 3) were myelosuppression, including neutropenia (61%), anaemia (39%) and thrombocytopenia (39%). 3 pts achieved a partial response (2 PTCL, 1 PTCL-NOS) and 3 additional pts experienced stable disease >6 months. Tumor DNA from 18 pts was sequenced using NGS, 3’UTR CXCL12 single nucleotide variation (SNV) was observed. Seven of 16 pts carried the rs2839695 variant while an additional patient carried a novel variant. The presence of 3’UTR SNVs was associated with low levels of CXCL12 gene expression and disease progression (Figure 2, while all pts deriving clinical benefit from tipifarnib carried reference (wild-type) 3’UTR CXCL12 and had tumors that expressed high levels of mRNA for this chemokine. Testing of circulating CXCL12 levels is ongoing.

Summary/Conclusions: Although this study is ongoing, these preliminary data indicate that tipifarnib is generally well-tolerated and has antitumor activity, particularly in pts with AITL histology, absence of 3’UTR CXCL12 SNV and high levels of CXCL12 gene expression.

BAM CONDITIONING BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION FOR LYMPHOMA: A RETROSPECTIVE STUDY ON BEHALF OF THE FRANCOPHONE SOCIETY OF BONE MARROW TRANSPLANTATION AND AUTOLOGOUS STEM CELL TRANSPLANTATION (SFMTA)

1Service d’hématologie, 2Département d’hématologie, Institut de Cancérologie de la Loire, Saint-Etienne, 3Service d’hématologie, CHU de Clermont-Ferrand, Clermont-Ferrand, 4Service d’hématologie, Centre Hospitalier Universitaire, Besançon, 5Service d’hématologie, Centre Hospitalier Universitaire, Lyon, 6Service d’hématologie, Centre Henri Becquerel, Rouen, 7Service d’hématologie, Centre Léon Bérard, Lyon, 8Service d’hématologie, CHU d’Angers, Angers, 9Service d’hématologie, CHU de Tours, TOURS, 10Service d’hématologie, Centre Hospitalier Régional, Orléans, 11Service d’hématologie, CHU de Dijon, Dijon, 12Service d’hématologie, Centre hospitalier universitaire, Nice, 13Service d’hématologie, CHU de Toulouse, Toulouse, 14Service d’hématologie, CHU de Reims, Reims, 15Service d’hématologie, CHU de Metz, Metz, 16Service d’hématologie, Hôpital Saint-Louis, APHP, PARIS, 17CHU de Tours, Centre Hospitalier Universitaire de Tours, Tours, France

Background: High-dose chemotherapy before autologous stem cell transplantation (ASCT) is a therapeutic option as a consolidation in primary or relapsed lymphoma. BEAM conditioning is generally used. Alternative conditioning regimens have been published but few data are available.

Aims: To evaluate tolerance and efficacy of the BAM (Busulfan, AraCytin and Melphalan) conditioning before ASCT.

Methods: We conducted a retrospective study in 188 French patients treated between 2000 and 2015. Data were retrospectively collected from the Promise database. Informed consent was obtained from all patients.

Results: Indications for ASCT were diffuse large B-cell lymphoma (n=54, 29%), mantle-cell lymphoma (n=42, 22%), Hodgkin’s disease (n=33, 18%), low-grade non-hodgkin lymphoma (n=26, 14%), T-cell lymphoma (n=17, 9%), Burkitt’s lymphoma (n=8, 4%) and B-cell lymphoma (n=8, 4%). Median age at diagnosis was 50.9 years (35.7-59.9). Time between diagnosis and ASCT was 295 days (176-777). Patients received 1 (n=82, 44%), 2 (n=83, 44%), 3 or more (n=18, 10%), unknown (ND) (n=5, 2%) treatment lines before ASCT. Among the 138 B-cell lymphoma patients, 132 received rituximab before ASCT. Only 20 patients received prior radiotherapy. In all patients, ASCT was the first transplantation. In 11 patients, ASCT was planned as part of a multiple graft protocol.

At the time of transplantation, 116 (62%) patients were in complete remission, 54 (29%) in partial remission, 13 (7%) in relapse or progression, and 5 (2%) ND. ASCT was documented in 186 (99%) patients. Median time to neutrophil and platelet (>50 Gig/ml without transfusion) recovery was respectively 11 days [10-12] and 19 days [14-32]. Infectious complications were found in 153 patients. One hundred (53%) patients had undocumentated fever, 19 (10%) had sepsis, 150 (80%) had grade 1-4 mucositis during neutropenia with a WHO toxicity grading of 2 (42%), 3 (39%) and 4 (19%). CoLitis with a median duration of 7 days [5-10], was reported in 73 patients, with a maximum toxicity grading of 1-2 (n=43, 59%), 3 (n=21, 29%) or 4 (n=4, 6%) and ND in 5 patients. Only 2 (1%) patients had non-fatal hepatic sinusoidal obstruction syndrome. Pulmonary toxicity was reported in 33 (17.6%) patients with 8 cases of respiratory distress syndrome. Respiratory distress was fatal in one patient but occurred more than 6 months after ASCT and salvage treatment. Seven (3.7%) patients reported secondary cancers (all were solid tumors except one acute leukemia). Median follow-up was 17.1 months [11.3-29.5]. At the time of the study, 47 (25%) patients had relapsed. Cumulative incidence of relapse was 6.24% at 3 months and 17.31% at 12 months. At the end of the follow-up, 149 (79%) patients were alive. The main causes of death were relapse (n=15, 41%) and toxicity (n=16, 43%). Median overall survival (OS) was not reached and progression-free survival was 71.5 months [47-97]. Relapse-free mortality was 1.66% at 3 months and 4% at 12 months. In the univariate analysis, the number of treatment lines (1 or 2) before ASCT and previous use of monoclonal antibodies positively impacted the OS. Conversely, the multiple graft protocol had an unfavorable impact on the OS. Cumulative Incidences were calculated using the Kaplan-Meier method. The PFS was not significantly different between ASCT and chemotherapy plus ASCT (p=0.39). The OS was also not significantly different between ASCT and chemotherapy plus ASCT (p=0.59).

Summary/Conclusions: BAM conditioning before ASCT for lymphoma helps to control disease activity without excessive toxicity. It may be a suitable alternative to BEAM in case of drug shortage. However, comparative studies are needed to confirm these findings.
Bone marrow failure syndromes incl. PNH - Clinical

ANALYSIS OF MICRORNAOME, PROTEOME AND METABOLOME OF EXOSOMES FROM PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

R. Teruel-Montoya1,2, G. Luengo-GIP, F. Vallejo2, J. E. Yuste3, N. Bohdan2, S. Espin2, N. García-Barberá2, C. Martinez2, J. C. Espin2, V. Vicente1,2, I. Martinez1,2.

1Grupo de Investigación CB15/00055, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII), Madrid, 2Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, 3Research Group on Quality, Safety and Bioactivity of Plant Foods, CEBSAS-CSIC. 30100, Campus de Espinardo, Murcia, Spain

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is a clonal disease caused by the lack of glycosyl inositol phosphatidyl anchored proteins at the cell membrane that leads to intravascular hemolysis upon complement activation. Patients have intravascular haemolysis with high risk of thrombosis, and a variable degree of bone marrow failure. Treatment with Eculizumab reduces intravascular hemolysis and also the thrombotic risk. The mechanism of thrombosis in PNH is still unknown. Exosomes are vesicles released by cells and whose secretion is closely related with the inflammatory status. Exosomes participate in cell communication by activating signaling pathways and transferring genetic material, i.e. miRNA, and proteins to host cells.

Aims: To describe the microRNAome, proteome and metabolome of exosomes from PNH patients to identify potential biomarkers of the disease and to investigate its relationship with the mechanism of thrombosis in these patients.

Methods: Plasma exosomes were isolated from 5 healthy controls and from 9 PNH patients (6 with Eculizumab, 3 with thrombosis –ET- and 3 without thrombosis –ENT- and 3 without Eculizumab) using Total Exosome Isolation kit (ThermoFisher). miRNAs from exosomes were purified using Nucleo Spin miRNA Plate Kit (Macherey-Nagel). miRNA expression was evaluated by plasma/serum focus miRNAs PCR panel V4 (Exiqon). Proteomic analysis of exosomes was performed at the OMICs core facilities. Untargeted metabolomic analysis was performed using combination of gas chromatography and liquid chromatography (LC) with mass spectrometry (MS). Additionally, latest advances were used combining LC-MS-solid phase extraction-nuclear magnetic resonance (UPLC-QTOF_SPE_NMR) on line’ for unequivocal structural elucidation of unknown metabolites.

Results: Mir-16-5p and Mir-451a had lower levels in patients vs controls. Eculizumab treatment increased their expression, particularly in the group with thrombosis. Eculizumab also decreased mir-223-3p (the most abundant miRNA in platelets and that has been associated with its vitality) and increased mir-15a-5p levels (0.50- and 3.12-fold respectively). Those proteins differentially expressed in patients and controls were related with the complement system and the immune response. We identified an increase in the plasma hemoglobin levels in patients vs controls (4.9-fold), which is related with platelet activation. It is also noteworthy the decrease (1.5-fold) of the anticoagulant Protein S in patients vs controls. When the analysis was performed among the 3 groups of patients, only Ig heavy chain V-I region HG3 increased in 3.9-fold in the Eculizumab group vs without Eculizumab group, which could be related with the treatment. We identified quite few metabolites inside the exosomes, all of them associated with cell toxicity or immune response. The levels of Cholesterol, HydroxyTerbinfine-glucuronide and Diacyl-glycerol decreased in 17.3, 17.6 and 19.4-fold, respectively in patients treated with Eculizumab. Interestingly, the Aminoethylphosphonicacid, Cholesterol and PGF2 increased 16.7-, 21- and 19.4-fold in patients with thrombosis.

Summary/Conclusions: Our study supports that exosomes contain material that may influence the pathological status of the PNH patients. In concordance, most of the proteins, miRNAs and metabolites are related with the complement system or the inflammatory response. In future experiments, some of the proteins, miRNAs and metabolites should be validated to define whether they could be considered biomarkers.

SEVERE CHRONIC NEUTROPENIA: THE ROLE OF PRIMARY IMMUNODEFICIENCY AS CAUSATIVE AGENTS. A SINGLE CENTER DATA

F. Fioredda1,*, F. Pierri1, C. Micalizzi1, M. Calvillo1, E. Palmisani1, I. Ceccherini2.

1Haematology Unit, 2Molecular Genetic Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

Background: Severe Chronic Neutropenia may be a primary disease, usually defined as congenital (CN), or a condition mainly secondary to autoimmune disturbances (SN) (1,2). CN rises in early infancy, has a narrow block at pro/myelocyte, classically carries genes ELANE/HAX1 mutations in 70% of cases and is G-CSF dependent. SN is accompanied by extraheamotological signs and/or positivity of autoimmune markers; bone marrow has a normal morphology or is “left shifted”. In spite of these categorization many cases do not fit either group and share features of both of them. These “Overlap Neutropenia” (ON) patients are a diagnostic and management challenge.

Aims: Investigate the genetic background of this ON from a cohort of chronic neutropenia subjects screened at Hematology Unit of Gaslini Hospital and characterize their clinical phenotype.

Methods: Patients with severe chronic neutropenia were seen prospectively in our center and diagnosed/followed-up according to published guidelines(3,4). Genetic diagnosis includes classical Sanger technique foe commonest severe chronic neutropenia genes and an enlarged NGS panel including also those genes responsible for PIDs.

Results: From 2008 to 2016, 24 patients (13 males) with median age at last follow of 18yrs (range 20 mo-51y) had a complete work up for severe chronic neutropenia (Table 1). Ten/24 subjects (43%) were diagnosed as classical CN with ELANE mutation found in the majority (80%) of cases. Seven/24 (29%) were diagnosed as SN and the remaining 7/24 (29%) was a PID. A PID mutation was found in a total of 8/24 patients (30%) with 7 subjects (71%) and 3 to the 7 ON subjects (42%). Table 1 shows clinical hemato logic characteristic of the 3 categories of patients.

Summary/Conclusions: A considerable portion (30%) of subjects affected with severe chronic neutropenia have both been identified as PID. In the group of ON subjects a mutated PID gene was found in 3/7patients and mutations of ELANEin 2/7 patients. No mutation was found in the remaining 2. The phenotype of ON subjects is characterized by extra-heamotological autoimmune symptoms, by maturation block and by the frequent involvement of more than one hematopoietic lineage. This phenomenon may suggest to access to an enlarged genetic panel including PID genes for genetic diagnosis. An accurate immunological and genetic work may support diagnosis and management of these difficult patients.

Table 1.

References
Methods: In this study, we examined immune cell subset counts and immunoglobulins in 81 SAA patients from day 30 to day 365 after haplo-SCT. The immune cells analyzed in this study including lymphocyte, monocyte, CD3+ T cell, CD8+ T cell, CD4+ T cell, CD4-CD8- T cell, CD4+CD28+Tcell, CD4+CD28-Tcell, CD4+ memory T cell and CD4+ naïve T cells. Simultaneously, we determined which factors influence immune reconstitution and analyzed the effect of immune cell sub-set on transplant outcomes.

Results: (i) The reconstitution of different immune cell subsets occurred at different rates after haplo-SCT. Monocytes were the first to recover, followed by CD8+ T and CD19+ B cells, and finally CD4+ T cells. Early CD4+ T cell recovery occurred at the expense of memory cells, whereas naïve CD4+ T cells rose only 9 months after SCT. (ii) In the multivariate analysis, lower recipient age, female gender, high mononuclear cell counts and CD4+ T cell counts in the graft were associated with improved immune recovery after transplant. (iii) A CD4/CD8 ratio less than 0.567 on day 30 post-transplantation was associated with lower treatment related mortality and higher overall survival after haplo-SCT in SAA patients.

Summary/Conclusions: We provided the kinetics for immune recovery in SAA patients who received haplo-SCT. In general, our study demonstrated that the recovery of monocyte and CD8+ T cells was fast in SAA patients, whereas the recovery of the CD4+ T cell subset was delayed. In addition, our data suggested that the CD4/CD8 ratio may be useful for predicting transplant outcomes in SAA patients after they complete haplo-SCT. Our results may be useful for making better predictions and modulating the IR of SAA patients, which would subsequently improve the outcomes after transplantation.

DEVELOPMENT OF A SCREENING AND DIAGNOSTIC ALGORITHM FOR PAROXYSMAL NOCTURNAL HEMOGLOBINURIA USING A MODIFIED DELPHI PANEL METHODOLOGY

A. Röth1,*, J. Maciejewski2, J.-I. Nishimura3, D. Jain4, J. Weitz5

1University Hospital Essen, Essen, Germany, 2Cleveland Clinic, Cleveland, United States, 3Osaka University Graduate School of Medicine, Osaka, Japan, 4Alexion Pharmaceuticals, Inc., Cambridge, United States, 5McMaster University, Hamilton, Canada

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare clonal hematopoietic stem cell disorder that manifests with hemolytic anemia due to uncontrolled complement activation, bone marrow failure, and thrombosis. Diagnosis is essential because PNH is a progressive disorder associated with substantial morbidity and mortality. The protean clinical manifestations of PNH complicate diagnosis, and subsequently the diagnosis is often delayed or missed. Although national diagnostic guidelines are available, international expert consensus on PNH screening and diagnosis is lacking.

Aims: International panel of PNH experts was assembled to develop a clinically relevant, consensus-driven screening and diagnostic algorithm for PNH.

Methods: An expert advisory committee of 4 PNH experts from North America, Europe, and Japan was assembled. Using a modified Delphi methodology, consensus was gained on the symptoms and signs of PNH and the laboratory tests required for screening and confirmation of diagnosis. Globally representative Delphi panelists were identified through a double-blinded screening process and asked to complete 2 rounds of web-based questionnaires. The questionnaires were developed by the expert advisory committee and presented to the Delphi panel in a case-based format. In the first round, Delphi panelists were given 5 blinded case studies—each including details on clinical presen-
tation and past medical history—and were asked to provide their differential diagnosis and the tests they would order to establish the diagnosis in free-text format. To reduce bias, Delphi panelists were blinded to the fact that the study was focused on PNH. Responses mentioned by ≥50% of Delphi panelists in the first round were included in the second-round questionnaire. For each case in the second-round questionnaire, Delphi panelists were presented with a series of consensus statements regarding potential diagnoses and the need for specific tests/data from a multiple-choice list and asked to respond with their level of agreement on a 4-point Likert scale. Consensus in the second round was attained if ≥80% of Delphi panelists agreed on a given screening or diagnostic approach. 

Results: Twelve Delphi panelists from 6 countries, all of whom were clinicians with expertise in PNH, were recruited. Consensus was reached on 22 of 23 PNH screening and diagnostic decision points identified by the Delphi panelists. Specifically, consensus was gained on the core symptoms and signs of PNH at presentation, including hemolysis, bone marrow dysfunction, and thrombosis. Consensus was also reached for 36 of 38 screening and diagnostic tests required at each decision point to narrow the differential diagnosis and to confirm the diagnosis of PNH. The level of agreement on screening and diagnostic decision points and tests was sufficient to enable the development of a screening and diagnostic algorithm (Figure) that is consistent with the published literature and with the real-world experience of the international expert advisory committee.

Summary/Conclusions: The modified Delphi methodology facilitated development of a consensus-based, clinically relevant PNH screening and diagnostic algorithm. This algorithm provides clinicians with varying levels of expertise detailed guidance on how to screen for and diagnose PNH.

P579 DIAMOND-BLACKFAN ANEMIA IN THE NETHERLANDS: AN OVERVIEW OF CLINICAL CHARACTERISTICS AND UNDERLYING MOLECULAR DEFECTS

B. Van Dojewereld1,*, M. Bierings2, A. MacInnes3, M. Bartels4
1Pediatric Haematology, clinical research, 2Pediatric Haematology and Stem Cell Transplantation, Wilhelmina Children’s Hospital, Utrecht, 3Euro DBA, genetic metabolic diseases, AMC, Amsterdam, 4Pediatric Haematology and Oncology, Wilhelmina Children’s Hospital, Utrecht, Netherlands

Background: Diamond-Blackfan anemia (DBA) is a rare genetic disorder, characterized by bone marrow failure (anemia), congenital anomalies and a pre-disposition for malignancies. DBA is characterized by a highly heterogeneous nature, both clinically and genetically. Most of our understanding of this disorder stems from molecular studies combined with extensive data-input from international patient registries. 

Aims: The aim of our retrospective study was to create an overview of the pediatric DBA population in the Netherlands. 

Methods: Forty-four patients (age 0-18yr) diagnosed with DBA from all Dutch pediatric hospitals included in this study. 

Results: Congenital malformations were present in 19/41 patients (46,3%), varying from craniofacial and cardiac defects to urogenital and developmental disorders. An underlying genetic defect was identified in 23 patients (56,1%), the majority of which were found in the RPS19 gene (n=10; 43%). No significant diversities in malformations, course of disease or response to treatment were observed when comparing patients with or without identified genetic defects. 

In agreement with previous reports, two patients harboring defects in RPL11 displayed a more severe phenotype, including craniofacial malformations, thumb abnormalities, and cardiac defects. In contrast, our patient with a mutation in RPL5 has no associated congenital abnormalities, while previous studies observed when comparing patients with or without identified genetic defects. 

Discussion: Forty-four (34/44) patients were treated for AA with IST at VGH, the tertiary referral centre for the Province of BC, to which IST for pts with discordant clone sizes. 

Results: Of the 120 samples processed, 10% (12/120) was not suitable for analysis. A total of 108 patients were studied. In 59,3% (64/108) causal mutations were detected. From the total samples analyzed (108), 75% (81/108) were included in the CBMFS patient group, obtaining a diagnostic yield of 64,2% (52/81). The remaining 27 patients (25%) were included in the UBMFS group and we found causal mutation in 37% (10/27). Therefore, it remains a percentage of patients without a genetic diagnosis, which seems more evident in the UBMFS group. This could be explained by the fact that the causal gene has not been described or due to the limitations of the technique.

Summary/Conclusions: NGS techniques are a fast and cost-effective option for the diagnosis of IBMFs patients. In our series, we have reached a diagnosis rate of 93,3%, coinciding with that described in the literature. Undiagnosed patients should be included in new research projects.

P581 APLASTIC ANEMIA PATIENTS WITH MONOCYTE-DOMINANT PNH CLONES HAVE A UNIQUE PRESENTATION AND ARE LESS RESPONSIVE TO IMMUNOSUPPRESSIVE THERAPY

E. Nevill1,*, D. Sanford1, D. Forrest1, D. Hogge1, Y. Abou Mourad1, R. Broady1, M. Mohammed1, M. Power 1, C. Toze1, K. Song 1, S. Nantel 1, S. Narayanan 1, A. Garrow1, H. Sutherland1, B. Dalal2, T. Nevill1
1Leukemia/MTM Program of BC, 2Division of Hematology, Vancouver General Hospital, Vancouver, Canada

Background: Aplastic anemia (AA) is a bone marrow failure syndrome that can be successfully treated with either immunosuppressive therapy (IST) or allogeneic bone marrow transplantation (BMT). In ~50% of patients (pts) with AA, a clone deficient in glycosylphosphatidyl inositol (GPI)-linked antigens—a paroxysmal nocturnal hemoglobinuria (PNH) clone—can be detected (Young, 2009). Young et al. in recent years have developed new sensitive techniques have been developed to test for PNH clones that have primarily focused on evaluating peripheral blood white cells. Neutrophils are routinely tested for expression of GPI with fluorescent aerolysin (FLAER); monocytes may also be analyzed but are not always evaluated in PNH testing. Our centre has previously reported that 60% of PNH positive tests show a higher monocyte clone than granulocyte clone and that there was >10% difference in 20% of these discrepant results (Razavi, ISH Proceedings, 2015). Whether pts with discordant monocyte and granulocyte PNH clones have different clinical characteristics and/or response to IST has not been reported to date.

Aims: To compare the granulocyte and monocyte PNH clones in pts with AA to determine whether there are differences in clinical presentation and/or response to IST for pts with discordant clone sizes.

Methods: A retrospective review was performed on all patients > age 16 treated with IST at VGH, the tertiary referral centre for the Province of BC, between 11/09 and 10/15. All patients had central pathology review and metathese cytogenetic analysis that confirmed a diagnosis of AA. High-sensiti-
to detect the presence of a PNH clone. Granulocytes, monocytes and erythrocytes were interrogated with multi-colour flow panels including CD59 and FLAER. The criteria for determining discordant granulocyte and monocyte clone sizes was dependant upon the absolute size of the smaller clone. For clones 0.1-10%, discordance was defined as when the larger clone was either ≥2 x the smaller clone or at least 1% (absolute value) greater. For smaller clones >10%, the larger clone had to be ≥110% of its size. IST was uniform - Cyclosporine (CSA, 2.5mg/kg p.o. b.i.d.), anti-thymocyte globulin (ATG; ATGAM® 40mg/kg IV daily x 4 days) and (Methyl)prednisolone 1mg/kg/day x 10 days). CSA doses were adjusted to maintain whole blood trough CSA level of 200-300 μg/L for 12-months followed by slow taper based upon hematologic response. Non-responders at 6 months were eligible to proceed to either a second cycle of ATG or BMT. If a suitable donor was available. Severity of AA [very severe (VSAA), severe (SAA) or non-severe (NSAA)] and response to IST [(none, partial (PR) or complete (CR)] were determined according to published criteria (Marsh, Br J Haematol, 2009). Statistical comparisons were done using a standard Chi square analysis.

Results: 30 pts with AA and a PNH clone were identified, 18 females and 12 males with median age of 50.5 years (range 17-71). There were 14 pts with NSAA, 13 with SAA and 3 with VSAA. Responses were seen in 20/30 pts (66.7%) including 13 PR and 7 CR. Six pts relapsed with CSA tapering and 5 responded to intensified IST. 2 pts required Eculizumab after evolving to a classic PNH phenotype. Six pts underwent BMT for primary non-response and 4 pts have died (2 post-BMT, 1 from complications of AA and 1 from breast Ca); 26 pts remain alive and well with a median follow-up of 48 mos (15-86). There were 17 pts (56%) with concordant granulocyte and monocyte clone sizes (Group 1), 4 pts (13%) had granulocyte-dominant disease (Group 2) and 9 pts (30%) had monocyte-dominant disease (Group 3). Group 3 pts were significantly more likely to have NSAA and showed a trend toward an inferior response rate to IST (Table 1).

| Table 1. |

Summary/Conclusions: Flow cytometry for a PNH clone is routinely done in AA although it may be important to evaluate both granulocyte and monocyte clone sizes. Pts with a larger monocyte than granulocyte clone size more frequently have NSAA and appear to have a lower response rate to IST. This may have therapeutic implications and could identify a population of pts requiring a unique therapeutic approach.

P582

RESPONSE TO ANTI-THYMOCYTE GLOBULIN (ATG) IN PATIENTS WITH APLASTIC ANEMIA (AA): A SINGLE-CENTRE EXPERIENCE OVER THE LAST 28 YEARS

M. Oelmüller1, F. Alashkar1, D. Herich-Terhürne1, U. Dührsen1, A. Röth1
1Department of Hematology, University Hospital Essen, Essen, Germany

Background: Aplastic anemia (AA) is a rare, usually acquired disorder characterized by bone marrow failure with bi- or pancyclopenia and marrow hypoplasia. The classification into the three main subtypes is of prognostic and therapeutic relevance. Depending on disease severity, patient’s age, and the availability of a potential HLA-identical donor, different therapeutic strategies are favored. Immunosuppressive therapy (IST) with anti-thymocyte globulin (ATG) and cyclosporin (CsA) is considered the initial standard treatment. A hematologic recovery is seen in up to 60-70% of the pts following horse-ATG (hATG) therapy, compared to 35-53% in rabbit-ATG (rATG) treated pts. A disease relapse (median: 13 months after primary ATG therapy) was seen in 11 out of the 67 pts with primary hematologic recovery. For this reason, it remains unclear why ATGAM® is still not approved in Germany as first-line therapy in pts with AA, as the only hATG product registered in Europe (Lymphoglobulin®) was withdrawn from the market in 2007.

Methods: In this single-center, retrospective analysis, approved by the institutional review committee of the University Hospital Essen, 67 pts with AA (52% (35/67) females; median age 48 years (range 17-89 years)) were included. IST was performed in 11 out of the 67 pts (16%), either being primary refractory or due to a disease relapse. Pts ≤50 yrs, irrespective gender, an overall higher hematologic recovery. For this reason, it remains unclear why ATGAM® is still not approved in Germany as first-line therapy in pts with AA, as the only hATG product registered in Europe (Lymphoglobulin®) was withdrawn from the market in 2007.

Results: Following six months after primary ATG therapy, a hematologic recovery was seen in 66% of the pts (44/67). The hematologic response rate at 6 months was 75% (37/49) for hATG and 39% (7/18) for rATG (p=0.005). Irrespective of the presence of a PNH clone (GPI-deficient granulocytes (FLAER) 67% (14/21) vs 79% (19/24) in pts with no detectable PNH clones), whereas in pts ≥50 years (yrs) a statistically higher rate in hematologic recovery was observed (≤50 yrs: 84% (31/37) vs >50 yrs: 43% (13/30); p<0.001). In primary refractory pts (34% (23/67) (52% (12/23) in first-line treated hATG pts vs 48% (11/23) rATG treated pts) a second course with either hATG (3/9) or rATG (6/9) was initiated, achieving an overall hematologic recovery at 6 months in 3 pts (33% (1/3) hATG vs 33% (2/6) rATG treated pts). A disease relapse (median: 13 months after primary ATG therapy) was seen in 11 out of the 44 pts with primary hematologic recovery (25% (82% (9/11) in first-line treated hATG pts vs two rATG treated pts). A salvage therapy with rATG was initiated in two pts, whereas in one other pt a second course with hATG was started. An overall response following relapse therapy was observed in 33% of the pts (1/3). Four refractory as well as relapsed pts were treated with eltrombopag respectively (final results are still awaited). A second HSCT (hematopoietic stem cell transplantation) was performed in 11 out of the 67 pts (16%), either being primary refractory or due to a disease relapse.

Summary/Conclusions: Our data are able to independently confirm the findings of previous studies concerning hematologic recovery rates in pts with acquired AA following IST with ATG by providing further evidence that rATG plus CsA is inferior to hATG plus CsA when administered as a first-line treatment. In addition, we were able to observe in pts ≤50 yrs, irrespective gender, an overall higher hematologic recovery. For this reason, it remains unclear why ATGAM® is still not approved in Germany as first-line therapy in pts with AA, as the only hATG product registered in Europe (Lymphoglobulin®) was withdrawn from the market in 2007.
NOTCH1 MUTATED CHRONIC LYMPHOCYTIC LEUKEMIA CELLS ARE CHARACTERIZED BY A MYC-RELATED OVEREXPRESSION OF NUCLEOPHOSMIN-1 AND RIBOSOME ASSOCIATED COMPONENTS

Methods: The presence of NOTCH1 mutations was investigated by NGS. Gene expression profile (GEP) was performed by a one-color labeling strategy using the a4K platform. Specific gene/protein validations were performed by QRT-PCR, western blotting, flow cytometry and immunofluorescence. CLL-like MEC-1 cell line was transfected with a vector containing a NOTCH1 isoform, resulting in a sustained pathway activation.

Aims: To identify molecular/biological features of NOTCH1 mutated CLL

Results: i) A GEP comparing purified cells of 10 IGHV-UM CLL cases (5 NOTCH1-mut; 15%-37% of NOTCH1 mutated alleles) selected nucleophosmin-1 (NPM1) and genes profiling for several ribonucleoprotein complexes (RNPs) as significantly up-regulated in NOTCH1-mut cases. A higher expression of NPM1 and RNPs in NOTCH1-mut cases was validated in a wider independent series of 188 cases by QRT-PCR (76 NOTCH1-mut cases). In CLL, NPM1 expression was previously found higher in IGHV-UM cases (Rees-Unwin, Br J Haematol, 2009). In our series, no significant difference in NPM1 transcript expression was found by comparing IGHV-UM and IGHV-M cases, but NPM1 transcript expression was confirmed significantly higher in NOTCH1-mut than in NOTCH1-wt cases in the IGHV UM subgroup. ii) Western blotting in 11 CLL cases (5 NOTCH1-mut) confirmed a higher NPM1 protein expression in NOTCH1-mut cases, with a direct correlation with NOTCH1 expression (r=0.814). In NOTCH1-mut cases, the NPM1high subpopulation, isolated by cell sorting, showed a higher NOTCH1 mutualional load than the NPM1low subpopulation. iii) EDTA treatment of 12 CLL cases (5 NOTCH1-mut) activated NOTCH1 signaling (Rand et al, Mol Cell Biol, 2000), as from HES1 and DTX1 induction, and up-regulated NPM1 and other RNPs. The same results were confirmed by co-culture of CLL cells with the JAGGED1-expressing M2-10B4 stromal cells. Inhibition of NOTCH1 signaling by gamma-secretase-inhibitor L-685,458 or by siRNA for NOTCH1 reduced NPM1 expression (Fig. A). iv) Previous studies identified MYC as a direct transcriptional target of NOTCH1 (Palomero et al, PNAS 2006) and, in turn, a transcriptional activator for both NPM1 and RNPs. ChIP assays on MEC1-cells, transfected with exogenous NPM1, revealed increased NICD binding to the MYC promoter, along with higher expression of MYC, NPM1, and RNPs. Of note, after 48h culture, NOTCH1-mut CLL cases showed increased MYC transcript levels than NOTCH1-wt cases, MYC expression was further increased upon NOTCH1 activation by EDTA or by stromal cells co-cultures (Fig. B). MYC silencing by siRNA efficiently reduced NPM1 transcript and protein expression. Moreover, CpG-ODN-2 treatment, to induce MYC overexpression, also increased NPM1 transcript and protein levels in CLL cells. v) NPM1 silencing by siRNA was able to reduce proliferation rates and cell size of both NICO-transfected cells and control cells. In keeping with a NOTCH1-driven regulation of cell growth/proliferation, activation of NOTCH1 signaling in 12 CLL cases (6 NOTCH1-mut) by EDTA or stromal cells co-culture, induced an increase in cell size.

Summary/Conclusions: NOTCH1 mutations in CLL are associated with the overexpression of MYC and MYC-related genes involved in protein biosynthesis including NPM1, which are allegedly responsible for cell growth and/or proliferation advantages of NOTCH1-mut CLL.

CLL-LIKE B-CELL CLONES FROM MBLLO INDIVIDUALS PERIST AT INCREASED COUNTS AFTER SEVEN YEARS OF FOLLOW-UP

Methods: The baseline study was constructed in 2008, when 80 out of 639 (12.5%) healthy individuals (>40y) were found to carry at least one PB CLL-like clone. At the same time, the presence of very low numbers of clonal B cells in peripheral blood (PB) of otherwise healthy individuals (low-count monoclonal B lymphocytosis-MBLlo) is a common finding in the general population. The majority of clonal B cells from MBLlo subjects show a phenotype overlapping with CLL (chronic lymphocytic leukemia) cells, the former might represent either the normal counterpart of CLL or the earliest stages of the disease. Little information exists about both the clinical outcome of MBLlo individuals after 7 years of follow-up.

Results: A total of 64 CLL-like MBLlo clones (median size: 0.44 cells/ul, range: 0.027-66 cells/ul) were detected in PB of the 49 subjects at recruitment (15 cases ≥2 B-cell clones were detected in the same subject). In all subjects, B-cell clones persisted at reevaluation, phenotypically identical vs baseline. Interestingly, we found a near-in fold overall reduction of B-cell clones after a 7y follow-up vs baseline (median size: 1.22 cells/ul, range: 0.046-789 cells/ul; p<0.001); in line with this, most clones (45/64; 70%) increased their size, while the remaining 30% maintained stable or slightly decreased numbers compared to time 0. From the genetic point of view, only 8/32 (25%) clones showed a cytogenetic alteration (del13q(132S25), trisomy 12, del(lq)(ATM) and del(17q)(TP53)) and del(13q)(ATM) and del(17q)(TP53) were studied at baseline and at follow-up.

Results: A total of 64 CLL-like MBLlo clones (median size: 0.44 cells/ul, range: 0.027-66 cells/ul) were detected in PB of the 49 subjects at recruitment (15 cases ≥2 B-cell clones were detected in the same subject). NUCLEAR LAMINA REGULATES SOMATIC HYPERMUTATION AND PROGRESSION OF B CELL MALIGNANCIES

1Queen Mary University of London, London, United Kingdom, 2University of Ulm, Ulm, 3University of Cologne, Cologne, Germany, 4University of Southampton, Southampton, United Kingdom

Background: The nuclear periphery, containing the IgH and Igk gene clusters, is a unique compartment comprised of inner nuclear membrane proteins and nuclear lamina. Previous genome-wide and cytological studies revealed the regulatory role for some of these nuclear proteins in higher level genome organization and gene regulation. In particular, Lamina Associated Domains (LADs) were identified at the nuclear periphery as transcriptionally silent, gene-poor domains of Lamin B1. More recent studies however revealed an important role of LADs in the regulation of gene expression and recombination.

Aims: Given the apparent topological coincidence between LADs and Ig variable clusters, we hypothesised that nuclear lamina might play a paramount role in the dynamics of Ig-encoding variable genome domains. In particular, here we tested whether Lamin B1, a principal LAD-associated component of the nuclear envelope, had any restrictive role on somatic hypermutation (SHM) and the expression of Ig genes. Due to the strong involvement of IgV mutations in the pathogenesis of B-cell malignancies, we also tested whether nuclear lamina is involved in the pathogenesis of germinal centre lymphomas and chronic lymphocytic leukemia (CLL).

Methods: We used BL2 and naïve B cells as in vitro and ex vivo models for somatic hypermutation. ChIP-Seq, ChIP-PCR and ImageStream analyses were performed to establish Lamin B1 genome and nuclear binding dynamics in resting and activated BL2 and B cells. LMNB1 RNAi was used to obtain the expression level correlated with progression-free and overall survival in chronic lymphocytic leukemia (CLL). A comprehensive statistical analysis of CLL8 cohort patients was performed to test the impact of LMNB1 expression on various clinical parameters in CLL.

Results: We found that genome binding of Lamin B1, a component of the nuclear envelope involved in epigenetic chromatin regulation, is reduced during B cell activation and formation of lymphoid germinal centres. ChIP-Seq analysis revealed that heavy and variable immunoglobulin domains were released from the Lamin B1 suppressive environment when SHM was induced in B cells. RNAi-mediated reduction of Lamin B1 resulted in spontaneous SHM in vitro. For in vivo studies, OVA-immunised mice were used to study Lamin B1 dynamics in functional evidence of the involvement of Lamin B1 in SHM in vitro. For resting and activated BL2 and B cells. LMNB1 RNAi was used to obtain the expression level correlated with progression-free and overall survival in chronic lymphocytic leukemia (CLL). A comprehensive statistical analysis of CLL8 cohort patients was performed to test the impact of LMNB1 expression on various clinical parameters in CLL.

Summary/Conclusions: In summary, here we report that Lamin B1 is a negative epigenetic regulator of SHM in normal B-cells and a "mutational gatekeeper", suppressing the aberrant mutations that drive lymphoid malignancy.

MICROENVIRONMENT REGULATION OF PROGRAMMED DEATH-1 (PD1) RECEPTOR AND ITS LIGANDS PD1L AND PD2L IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

1Unit of Ricerca Biotechnologica, Azienda Sanitaria Provinciale di Cosenza, 2Biotechnology Research Unit, University of Catanzaro Magna Graecia, Catanzaro, 3Department of Experimental and Clinical Medicine, University of Cosenza, Cosenza, 4Biotechnology Research Unit, Azienda Ospedaliera "Bianchi Melacrino Morelli, Reggio Calabria, 5Department of Oncology and Hemato-Oncology and Hematology Unit, University of Milano, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, 6Department of Oncology and Hemato-Oncology and Hematology Unit, University of Milano and Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, 7Biotechnology Research Unit, IRCCS-A.O.U. San Martino-IST, Genoa, Genoa, 8Department of Experimental and Clinical Medicine, University of Catanzaro Magna Graecia, Catanzaro, 9Scientific Direction, IRCCS-A.O.U. San Martino-IST, Genoa, 21Hematology Department, Annunziata Hospital of Cosenza, Cosenza, Italy

Background: The PD1 pathway is involved in the inactivation of immune effectors with potential reactivity against neoplastic cells in the tumor microenvironment (TME). PD1 binding to its ligand PD1L inhibits proliferation, cytokine production, and cytotoxic activity of T-cell effectors. T-cells from CLL patients exhibit defective immunity, including impaired effector function leading to T-cell exhaustion. T-cell death is PD1 checkpoint mediated. Immune dysfunction and impaired leukocyte growth in the Eμ-TCL1 transgenic CLL mouse model. PD1/PD1L ligation also affects BCR signaling, and because PD1 is also expressed on CLL cells, PD1 interference might directly influence tumor growth and proliferation directly. The PD1/PD1L axis may be a therapeutic target, especially in combination therapy for refractory chronic lymphocytic leukemia (BCL).

Aims: To investigate (1) expression of PD1 and PD1L/2 and their correlation with time at first treatment (FTT); (2) the role of the TME in controlling the expression of the PD1 axis; and (3) the role of ibritinib (IB) in the expression of PD1 and ligands.

Methods: CLL patients were prospectively enrolled at diagnosis (O-CLL) and at time of first-line therapy (TLOC). Subjects were enrolled in a prospective observational study, (protocol, clinicaltrial.gov identifier: NCT00917540). Gene expression (GE) analysis was performed using the GeneChipVR Gene 1.0 ST Array (Affymetrix) according to the manufacturer. Flow-cytometry (FC) was used to evaluate cellular phenotype (BD Biosciences) in an independent subset of patients. Lymph node samples from CLL patients were subjected to in situ immunolocalization analyses. Autologous T-cells (AUT) were obtained by in vitro exposure of patient T-cells with anti-CD3/CD28 and rIL2 in co-culture with CLL cells. Cultures were monitored daily until substantial clumping occurred and then tested for PD1 and ligand expression by FC. In selected experiments IB was added to cell culture.

Results: We evaluated GE of PD1 and PD1L/2 in 211 early-stage CLL patients. The impact of GE of PD1 and PD1L/2 on clinical outcomes in CLL cases (n=228, median follow-up=39 months, range 6–82 months) indicated a significantly shorter FTT in cases with higher levels of PD1L2, while no significant impact was detected based on differences in PD1 or PD1L1 gene levels. A Cox multivariate model showed that higher PD1L2 gene expression retained an independent significance at the 0.05 level (HR=0.69, 95%CI 0.45–1.03). However, the association between PD1L2 and FTT together with IGVH-U-M status, B-lymphocytosis5000/mm3 (P=0.020) and CD38 expression (P=0.021). In situ immunolocalization analysis of CLL tissue infiltrates indicated variable expression of PD1 mostly characterized small lymphoid elements, while PD1L1 and PD1L2 (with PD1L2>PD1L1) mostly characterized larger medium-sized elements within proliferation centers. Co-localization studies revealed PD1 co-expression on CD20+ CLL cells and in scattered CD3+ cells. Both ligands were variably expressed in CD20+ and CD3+ cells and macrophages showed expression of either ligand. CD38 overexpression induced an increase of CD3+ and CD38+ cells bearing both PD1L1 but not PD1L2. IB (1μM) reduced the size of activated B- and T-cell clusters as well as PD1L1/PD1L2 protein expression on CLL cells and on the CD8+ T-cell subset.

Summary/Conclusions: Our findings indicate that expression of PD1L2 characterized a subset of high-risk early stage CLL patients. The expression of PD1L1/PD1L2 proteins is also characteristic of the CLL TME whereby, co-stimulatory signals derived from activated T-cells and/or the TME may modulate the PD1 axis, which is counteracted by IB.
Background: B cell receptor (BCR) mediated signalling is crucial for the pathogenesis of chronic lymphocytic leukemia (CLL). Drugs such as ibrutinib and idelalisib which inhibit BCR associated kinases have proved effective for the treatment of CLL but only suppress the disease without being curative. Some patients have developed resistance to these drugs following mutations, progress on therapy for unknown reasons, or cannot tolerate these drugs due to adverse events. We have shown that microenvironmental signals (e.g. IL-4) can increase BCR expression and signalling, and can partially reverse the effects of BCR-kinase inhibition. ibrutinib, ABBV-229 and FOXP1 can positively regulate BCR signalling in CLL but the effect of IL-4 on these proteins has not previously been investigated. We hypothesise that IL-4 promotes BCR signalling by allowing the development of novel drugs that overcome resistance to kinase inhibitors. Cerdulatinib (cerd) is an inhibitor of both Syk (pivotal to BCR signalling) and JAK1/3 (integral for IL-4 signalling). Inhibition of Syk has been shown to induce apoptosis of CLL samples resistant to ibrutinib. Cerd is currently in phase II clinical trials in patients with relapsed/refractory B cell malignancies including CLL.

Aims: To investigate the effect of IL-4 on the regulation of BCR signalling in CLL and how this is modified by cerdulatinib

Methods: Eighteen primary CLL samples were treated with IL-4 +/-cerd (1µM) and expression of FOXP1, Gab1, PTPN22, SOC51 and SOC53 assessed by immunoblotting. The effect of cerd on apoptosis was assessed by flow cytometry and PI/Annexin V staining.

Results: Primary human CLL cells treated with IL-4 for 24hr significantly increased expression of positive regulators of BCR signalling FOXP1 and Gab1 in CLL samples with un-mutated IGHV (U-CLL); no change in expression in FOXP1 or Gab1 was seen in CLL samples with mutated IGHV (M-CLL). There was a 40% increase in PTPN22 expression in IL-4 treated U-CLL samples vs no change in M-CLL. Cerd, at therapeutic concentrations, blocked IL-4 mediated increases in FOXP1, Gab1 and PTPN22 and pSTAT6 (a positive control for IL-4 signalling). After 24hr IL-4 selectively increased expression of the negative regulators of IL-4 signalling, SOCS1 and SOCS3 in U-CLL, but not M-CLL cases, and this could be blocked by cerd. Cerd potently inhibited the expression of other cytokines known to play a role in CLL biology (IL-6, IL-10, IL-15, IL-21 and IFNγ) which utilise either JAK1 or JAK3 for activation of STAT proteins. IL-4, CD40L and BCR ligation signals to CLL cells in lymph nodes can promote resistance to therapies such as the BCL2-inhibitor venetoclax. We have shown that cerd can overcome IL-4/CD40L induced expression of pro-survival proteins MCL1 and BCLXL and that cerd in combination with venetoclax induced apoptosis in a synergistic manner in the presence of IL-4/CD40L. We now extend these results to assess the importance of this drug combination in the presence of BCR stimulation. The combination of cerd and venetoclax in the presence of either BCR signalling (bead immobilised anti-IgM) alone, or combined with IL-4 and CD40L, induced synergistic killing, with greater CLL cell death than with either drug alone.

Summary/Conclusions: These results provide evidence that IL-4 may increase BCR signalling by upregulating the expression of positive regulators of BCR signalling in U-CLL and that this can be overcome by cerd. These results support the continued use of cerd in clinical trials for the treatment of CLL, alone or in possible combination with venetoclax.

Background: Ibrutinib is an oral Bruton tyrosine kinase (Btk) inhibitor which has advanced the clinical management of CLL. Ibrutinib binds irreversibly to the active site of the Btk protein, rendering it inactive. Btk inhibition affects the phosphorylation of other intracellular kinases resulting in an immediate redistribution of CLL cells and subsequent apoptosis. We investigated the impact of ibrutinib on the phosphorylation of upstream and downstream kinases in the B-cell receptor pathway in real time in the IcICLLe study (ISRCTN12695654).

Aims: The IcICLLe trial was a single arm, multi-centre feasibility study of ibrutinib in two cohorts of CLL patients: (A) 20 treatment-naïve (TN) requiring treatment (according to IWCLL criteria); and (B) 20 relapsed/refractory (RR). All patients received continuous oral therapy with ibrutinib (420mg once daily) from registration until disease progression. The primary endpoint of the trial was the proportion of patients achieving minimal residual disease (MRD) negative remission (depletion of CLL ≤0.01% in peripheral blood (PB) & bone marrow (BM)) within 6 months of trial treatment. Exploratory endpoints included the assessment of phosphorylation of intracellular kinases in the B-cell receptor pathway.

Methods: A panel of markers was assessed on PB & BM taken at screening, and 1 & 6 months. PB was also taken at baseline (0 hours), 4 & 24 hours, 7 & 14 days, and 2, 8 & 12 months. The phosphorylation of Syk pY348, Btk pY551, ERK1/2, Akt pS473 was assessed in 4 conditions at each time point: unstimulated; +/- ibrutinib, and stimulated with IgM/IgD +/- ibrutinib. 1x106 leukocytes were tagged to fluorochromes to assess phosphorylation (+/- ibrutinib) in cytokines, 4h after initiating therapy. The pattern of phosphorylation was found to be relatively consistent in responding patients. One patient with progressive CLL had sustained phosphorylation of Syk in vitro. This effect was profound in the first 2 months of ibrutinib therapy with a general decrease in phosphorylation after 6 months. Baseline stimulation of ERK1/2 gave a 1.5-2 fold increase in phosphorylation but the effect was abrogated within 1 month of ibrutinib therapy. Akt pS473 phosphorylation was maintained after 6-12 months of therapy although the degree of phosphorylation decreased at later time points. Syk, Akt and ERK1/2 phosphorylation was unaffected by the addition of ibrutinib in vitro. The pattern of phosphorylation was found to be relatively consistent in responding patients. One patient with progressive CLL had sustained phosphorylation in all markers despite ibrutinib therapy.

Summary/Conclusions: The effect of ibrutinib on the phosphorylation of various kinases in the B-cell receptor pathway was analyzed in real time. Syk continued to be phosphorylated over the course of treatment, which is logical as this kinase is upstream of Btk. The degree of phosphorylation declined over time (even despite stimulation) suggests a general inhibitory effect of ibrutinib on CLL cells. ERK1/2 phosphorylation is efficiently blocked and there is partial reduction of phosphorylation of Akt pS473. Combinations of Btk inhibitor with a Syk or PI3 kinase inhibitor may result in complete BCR blockade. Phosphorylation patterns may also act as an adjunct to ascertain the response to therapy.

EVALUATION OF COMBINATIONAL THERAPIES FOR RELAPSED/ REFRACTORY CLL WITH MUTATED P53

S. Post1,*, H.J. Lee2, H. Ma1, M. Gallardo3, X. Zhang1, M. Hornbaker1
1Leukemia, 2Lymphoma, MD Anderson, Houston, United States, 3CNIO, Madrid, Spain

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with survival ranging from months to decades. CLL patients harboring TP53 alterations are well known to be refractory to standard therapies; however, recent studies indicate that ibrutinib, a Bruton’s tyrosine kinase (Btk) inhibitor, suppresses the B-cell receptor (BCR) signaling pathway and is an effective treatment option for these patients. Unfortunately, many patients with TP53 alterations will ultimately fail ibrutinib-based therapies. Similarly, we have used a mouse model of refractory p53 mutant CLL (Eμ−TCL1 p53R175H) to report that while ibrutinib is effective in reducing the CD5+CD19+ population and extending survival, these mice eventually succumb to the disease (Lee HJ, BGI J 2016). These incomplete therapeutic responses indicate that ibrutinib provides only a temporary respite for this refractory disease, and highlights our need to develop more potent and targeted combinations.

Aims: Ibrutinib is effective in delaying (but not eliminating) leukemic progression in p53 mutant CLL, suggesting that combinational therapies that inhibit BCR signaling and activate apoptotic programs may be effective therapeutic strategies. Thus, agents that do not require activation of p53 but are effective in blocking oncogenic pathways (Btk and Bcl-2) are attractive options. Currently, ibrutinib and ABT-199 meet this criteria and thus, we hypothesize that simultaneous inhibition of the Btk- and BCL-2 pathways will be an effective strategy in treating p53 mutated CLL.

Methods: To test this, we used RNA-Seq to examine expression changes in B-cells from Eμ−TCL1 mice carrying either wild type or a single p53R175H hotspot mutation (corresponding to p53R175H in humans) following ibrutinib treatment. qRT-PCR and IHC were used to validate expression of key targets within pathways amenable to combinational therapy. Hematopoietic tissues were subjected to combinational therapies to interrogate efficacy.

Results: We have shown that ibrutinib downregulates the Btk- and ERK-pathways regardless of p53 status. However, less is known in regards to global expression changes in p53 mutant CLL following Btk inhibition. To investigate this, we performed RNA-Seq analyses using malignant B-cells from untreated and ibrutinib treated Eμ−TCL1 p53R175H and Eμ−TCL1 mice. Pathway analyses revealed that CLL cells harboring a single p53 mutation allate retained a partial ability to activate p53-dependent programs. qRT-PCR revealed robust activation of p53-dependent anti-proliferative targets like p21, but only modest activation of pro-apoptotic targets (e.g.; PUMA), suggesting these p53 mutant CLL cells continue to diminish capacity to activate apoptosis or overcome apoptotic inhibitors. To explore this altered bi-modal p53 activation, we performed IHC and observed that apoptotic activation was hampered by increased BCL-2 expression. To examine whether this BCL-2-dependent inhibition could be overcome, malignant B-cells were treated with ibrutinib alone, ABT-199 (a BCL-2 inhibitor) alone, or in combination. Here, we observed that ABT-199 was sufficient to activate apoptosis, regardless of p53 status, and that its use in combination with ibrutinib drastically reduced cell viability.

Summary/Conclusions: Together, these data indicate that patients with a partially attenuated p53 pathway may retain the ability to activate apoptosis if molecular barriers are removed (e.g.; BCL-2 via ABT-199). Furthermore, these results suggest that combinations with Btk- and BCL-2 inhibitors may be therapeutically beneficial for patients with mutated TP53.

**THE DNA REPLICATION PATHWAY HAS POTENTIAL PREDICTIVE VALUE FOR TKI RESPONSE AND THERAPEUTIC INTERVENTION IN CHRONIC MYELOID LEUKAEMIA**

K. Yaliva1, H. Morrison2, P. Toofan3, L. Hopcroft1, G. Horne1, C. Munje1, H. Moka2, E. Gómez-Castañeda1, S. O’Brien3, M. Copland1,4, H. Wheadon1

1Institute of Cancer Sciences, University of Glasgow, 2West of Scotland Genetic Department, NHS, Glasgow, 3National Heart and Lung Institute, Imperial College London, London, 4Northern Institute of Cancer Research, University of Newcastle, Newcastle, United Kingdom

**Background:** Chronic myeloid leukaemia (CML) is a myeloproliferative disease which arises in a haemopoietic stem or multipotent progenitor cell with the t(9;22)(q34;q11) chromosomal translocation. Tyrosine kinase inhibitors (TKIs) were developed to target the constitutively active oncoprotein BCR-ABL, which is expressed as a result of this translocation. TKI therapy has significantly improved patient survival, however predicting response to therapy is one of the unmet clinical challenges in CML. Moreover, TKIs are unable to target the leukemic stem cells (LSCs) which drive the disease; persistence of the LSCs therefore remains a major obstacle to curing CML. Understanding the mechanisms that LSC employ to survive TKI treatment is necessary to design essential therapeutics to eliminate CML in the future.

**Aims:** To identify genes with predictive value for TKI response and to determine the efficacy of drug targeting one of the key pathways identified.

**Methods:** Microarray, Fluidigm, Real-time PCR, FACS based cell cycle and Annexin V apoptosis analysis, Trypan blue exclusion cell counts.

**Results:** Analysis of bulk CML patient microarray data (GSE 47927) identified 323 deregulated genes either in the stem cell population or during disease progression which are important for the renewal, DNA damage response, cell cycle and cell survival. These genes were validated in 60 samples from the SPiRIT 2 clinical trial [a multicentre phase III randomised trial comparing the TKI imatinib (400mg daily) versus Dasatinib (100mg Daily)] with 18 months follow-up data regarding molecular response to TKI treatment. Patients were stratified as good/intermediate/poor responders to TKI and the gene expression significantly differentially expressed was identified. These data highlighted the DNA repair genes as having potential predictive value, in particular, the minichromosome maintenance (MCM) protein and origin of replication (ORC) family of genes, involved in DNA replication and cell cycle regulation. Single cell analysis of CD34+ cells across the patient cohort identified considerable heterogeneity of expression of MCMs and ORCs, with ORC3, in particular, exhibiting a different expression profile in good/intermediate/poor responders (n=3 of each). In addition single cell analysis highlighted a significant difference in the expression of MCM2, -4, -7 & ORC2 in the most primitive LSC (CD34+38-90+93+ cells). Next, we investigated the ability of heliosquomin (HO), a potent helicase inhibitor of MCM on its own and in combination with IM to target the CML cell line K562. Our extensive dose and time response studies followed by FACS-based apoptosis and cell cycle analysis proved the potency of HO and its synergistic action in combination with imatinib. We also investigated the changes in level of cell cycle and DNA damage response genes at the transcript level in response to HO and imatinib in the K562 cell line. Overall the data generated indicates that targeting the MCM pathway in combination with BCR-ABL inhibition is a rational approach for future therapeutic intervention in CML.

**Summary/Conclusions:** Global 'omics' experiments are invaluable for identifying novel pathways deregulated in CML. This combined with single cell 'omics' studies enables the heterogeneity of gene expression and the response of individual LSCs to TKI to be evaluated. Our data indicate that the DNA replication pathway plays an important role in CML, with levels of MCMs and ORCs having potential predictive value in TKI response and are a promising drug target in CML.

**SIGNAL TRANSDUCING ADAPTOR PROTEIN-1 (STAP-1) MAINTAINS CHRONIC MYELOID LEUKEMIC STEM CELLS**

J. Toda1, K. Ichii1, K. Oritani1, H. Saito1, Y. Kitai2, R. Muromoto2, J-I. Kashihara3, K. Saito1, T. Masuda1, Y. Kanakura1

1Department of Hematology and Oncology, Osaka University Graduate School of Medicine, Osaka, 2Department of Immunology, Graduate School of Pharmaceutical Sciences, Hokkaido University, Sapporo, Japan

**Background:** Signal transducing adaptor protein (STAP)-2 was cloned as a c-fms binding protein. Previously, we have demonstrated that STAP-2 binds to BCR-ABL, which is constitutively activated in chronic myeloid leukemia (CML), via its SH2-like domain and enhances BCR-ABL activity leading to activation of downstream molecules, including ERK, STATS, BCL-xL and BCL2. The family via its SH2-like domain and enhances BCR-ABL activity leading to activation of downstream molecules, including ERK, STAT5, BCL-xL and BCL2. The family includes STAP-1, identified as a c-kit interacting protein, and STAP-2. While STAP-2 is expressed ubiquitously, STAP-1 has hematopoietic-specific expression in mice. It is still unknown whether STAP-1 plays a role in CML, although STAP-1 is expected to have similar functions based on the structural homology between STAP-1 and STAP-2.

**Aims:** To elucidate the role of STAP-1 in CML using mouse model and human samples.

**Methods:** We generated STAP-1 deficient mice of the C57BL/6J genetic background. For establishment of CML mouse model, we isolated Lineage (Lin)- Sca-1− c-kit(hi) (LSK) fraction of bone marrow (BM) cells from STAP-1−/− and STAP-1+/− mice, infected them with retrovirus carrying MSCV-BCR-ABL-res-GFP, and transplanted into congenic recipients, that were named Wild type (WT) and STAP-1−/−CML mice, respectively. Human BM samples were collected after informed consent, using protocols approved by the Investigational Review Board of Osaka University Hospital.

**Results:** Using Western blot and immunoprecipitation assay, we confirmed that STAP-1 binds to BCR-ABL. CML mouse model was then employed to analyze the role of STAP-1. We found that STAP-1−/− CML mice showed significantly longer survival than WT CML mice (Fig. 1). STAP-1−/− CML mice displayed less severe splenomegaly and lung hemorrhages compared to WT, suggesting that loss of STAP-1 attenuates CML progression. To investigate how STAP-1 regulates CML progression, we evaluated leukemic stem cells (LSCs) in CML mice. The absolute numbers of STAP-1−/− LSCs (GFP+ LSK) in BM and spleen were significantly lower than those of control (WT vs STAP-1−/−: 2090.3 ± 694.07 cells vs 412.57 ± 114.07 cells in BM, p=0.0291; 12.9 ± 1.75 ×10^4 cells vs 4.09 ± 0.72 ×10^4 cells in Spleen, p=0.0009). In colony-forming assay in vitro, STAP-1−/− LSCs generated less colonies in the first and second plating compared to WT LSCs. These data indicated that deletion of STAP-1 would impair self-renewal capacity of LSCs. When we transplanted STAP-1−/− or STAP-1+/− mice without BCR-ABL transduction in the presence of competing BM cells, deletion of STAP-1 had no effects on engraftment at 28 days after transplantation. Furthermore, we measured the expression of STAP-1 in BM cells derived from patients in the chronic phase of CML. As a result, STAP-1 mRNA was abundant in the LSC (CD34+38- Lin-) compartment.

**Figure 1.**

**Summary/Conclusions:** In this study, we utilized CML mouse model and showed that STAP-1 is required for progression of CML. Our findings indicate that STAP-1 has an indispensable role in LSC maintenance, while normal hematopoietic stem/progenitors were not affected by STAP-1 deficiency. Although a majority of patients have a durable response to BCR-ABL tyrosine kinase inhibitors, the outcome of patients who fail the treatment due to primary or acquired resistance is still miserable. Our findings in mice and human suggest that STAP-1 could be a target for CML. Further analysis will be needed to clarify the molecular mechanisms by which STAP-1 regulates the progression of CML and maintains survival of LSCs.

**TELOMERE SHORTENING IN CD34+38- BCR-ABL POSITIVE BONE MARROW CELLS FROM NEWLY DIAGNOSED PATIENTS WITH CML CORRELATES WITH THE CLONE SIZE OF THE LEUKEMIC STEM CELL COMPARTMENT**

A.-S. Bouillon1, M. Ventura Ferreira1, S.A. Awad2, J. Richter3, H. Hjorth-Hansen4, S. Hummel5, M. Schemionek1, S. Mustjoki2, F. Beier1, T.H. Brümmedendorf1

**Background:** Chronic myeloid leukaemia (CML) is a clonal stem cell disorder characterized by the BCR-ABL translocation. Previous work provides evidence that based on the size of the leukemic stem cell (LSC) clone within the CD34+38- population at diagnosis, chronic phase (CP) of CML can be stratified into early and late CP. Patients in late CP have a higher LSC burden going along with an inferior response to TKI therapy. Telomeres shorten with each
cell division and telomere length (TL) in peripheral blood cells has been shown to correlate with disease stage, response to treatment and duration of CP in CML patients. However, the use of TL as a routine clinical biomarker in CML has been complicated by considerable inter-individual, mostly genetic variability in TL ideally requiring non-clonal control cells. 

Aims: Based on these considerations, we used a modified Q-FISH technique in a retrospective study to analyze BCR-ABL+ LSC vs BCR-ABL- control cells within the CD34+38- hematopoietic stem cell compartment of diagnostic patients with CML in CP.

Methods: 15 patients (median age: 59 years; range: 41-72 years) diagnosed with CML in CP of the NCT00852566 study (Nordic CML Study Group) were retrospectively analyzed. Patients’ status and samples were available for 14 patients. Of those, 2 (14%) belonged to the Sokal high risk group, 5 (36%) to intermediate and 7 (50%) to the low risk group. CD34+38- cells sorted from bone marrow samples were tested with the standard FISH method using dual fusion dual color BCR-ABL+ LSC staining and following standard procedures. After capturing the BCR-ABL staining using confocal microscopy, samples were re-processed for TL analysis by Q-FISH using established protocols. TL staining was analyzed in all previously captured cells allowing the identification of BCR-ABL+/- cells within the same sample. Analysis and quantification of BCR-ABL FISH staining and TL measurement by Q-FISH were performed in blinded fashion.

Results: Overall, we observed significantly shortened TL in the BCR-ABL+ compared to BCR-ABL- cells (-4.9 arbitrary units (a.u.) range: -5.37 to 16.9 a.u., p=0.04). Next, we correlated the clone size (i.e. the proportion of BCR-ABL+ positive cells within the CD34+38- compartment) with the degree of telomere shortening in LSC. Mean clone size of the patients was 59.9 ± 23% S.D. Of note, we found a significant negative correlation (R²=0.36, p=0.02) between TL and clone size strongly supporting the notion that increased expansion of the BCR-ABL+ LSC pool leads to accelerated telomere shortening. Correlation analysis of qRT-PCR data revealed a similar correlation (R²=0.30, p=0.01) between TL and Sokal score did not reveal any statistically significant correlation with the degree of telomere shortening probably due to the small sample size analyzed in this pilot study.

Summary/Conclusions: In this study, we provide further evidence for accelerated telomere shortening in BCR-ABL+ LSC as compared to their normal CD34+CD38- counterpart in CP CML samples at diagnosis. Interestingly, the degree of TL shortening linearly correlates with the clone size of the BCR-ABL+ LSC compartment. Thus, this retrospective study (now on the LSC level) further supports a role of TL as a prognostic and predictive biomarker in newly diagnosed patients with CML pending confirmation in prospective trials.

GENOMIC CHARACTERIZATION OF CML AT DIAGNOSIS REVEALS PREEXISTING SOMATIC MUTATIONS THAT MAY PREDICT PROGRESSION TO BLASTIC PHASE INDEPENDENTLY OF BCR-ABL1 MUTATIONS

1Department of Immunology, 2Postgraduate School of Molecular Medicine, Medical University of Warsaw, 3Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 4Department of Hematology, The University Hospital, Cracow, 5Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 6Department of Hematology, University School of Medicine, Warsaw, 7Department of Internal Medicine, 8Department of Hematology, Oncology and Internal Diseases, Medical University of Warsaw, 9Department of Pathology and Laboratory Diagnostics, Maria Sklodowska-Curie Memorial Cancer Center and Institute, 10Department of Medical Genetics, Medical University of Warsaw, 11Department of Microbiology and Immunology, Fels Institute for Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, United States

Background: Blastic phase of chronic myeloid leukemia (BP-CML) remains mostly incurable even with newer generation tyrosine kinase inhibitors (TKI) and represents an unmet clinical need. Although in recent years a dramatic reduction in the transformation of chronic phase (CP-CML) to BP-CML has been observed, still up to 5% of patients will progress to BP-CML despite treatment with TKI. Prospective identification of such patients may have a significant clinical impact. There are only few reports to date which use next-generation sequencing (NGS) for to look for somatic mutations - other than those affecting KIT or PDGFRA. Our group included 11 patients who progressed to BP-CML despite treatment with TKI and/or allo-HSCT (one patient) and died (paired samples from Dx and BP were analyzed); second group (MMR) included Dx samples from 36 patients who achieved major molecular response (MMR) and TKI within 6 months and remained in MMR for at least 48 months from Dx.

Methods: Targeted enrichment strategy using custom designed capture probes (SeqCap EZ, Roche NimbleGen) followed by NGS on Illumina platform was performed to identify genetic lesions of BCR-ABL+ LSC in the whole genome. The total genomic DNA was fragmented, followed by random amplification to achieve ~250 bp fragment size. After targeted enrichment, DNA was sequenced on NextSeq 500 instrument. The DNA sequencing data were processed using the in-house pipeline. The quality of data was estimated using QcDNA software. On average, > 98% of sequencing reads were aligned to the reference genome.

Results: The NGS data were analyzed in 36 previously captured samples from CML patients who progressed to BP and died despite treatment with TKI. Median age at diagnosis was 53y (range 26 -77), median time to progression for 9 patients (2 were diagnosed in accelerated phase or BP) was 17.5 months (mo) (range 4 -108) and median survival was 22 mo (range 10 -116). None of those patients harbored BCR-ABL1 mutation at the time of Dx and progression to BP, 4 patients had additional chromosomal alterations at progression to BP including two frequent (trisomy 8 and monosomy 7). Targeted enrichment followed by NGS allowed us to achieve deep coverage (>80% geno50). Median number of rare variants was 26 (range 18-38) and 29 (range 23-32) for Dx and progression samples respectively. In the MMR group, the median number of rare variants was lower (2/36, 5%) frameshift mutation in ASXL1 (p.Gly643_Gly644fs) was detected, identical in one of BP patients. Additionally, one patient harbored RUNX1 mutation (p.Arg201Cln) which was not detected in the BP group.

Summary/Conclusions: Our results provide new insights into the already complex genetic landscape of CP-CML. We suggest that a significant number of patients with poor disease outcome may harbor preexisting mutations in DNM3A, RUNX1 and IDH1. In contrast, mutations in ASXL1 may be present at Dx in patients who will remain in long-term remission.
of the KYN/TRP ratio to BCR-ABL transcript levels. Patients having a high KYN/TRP ratio (> mean +2SD of post therapy levels) reach deep molecular response rates (i.e. MR4.5) significantly earlier and at higher rates. Moreover, combining KYN/TRP with sCD62L levels, a recently identified predictive biomarker, resulted in a score robustly predicting the odds of achieving deep molecular response.

Summary/Conclusions: CML diagnosis in CP is linked to an increased inflammatory status, as shown by increased levels of sIDO and its metabolites kynurenine leading to an increased KYN/TRP ratio. In solid cancer increased IDO expression/activity is linked to inferior outcome by favoring immune evasion. In contrast, in CML an increased KYN/TRP ratio is associated with improved outcomes. The role of IDO in solid cancer and therefore, to implement testing of the effective plasma concentrations and monitoring the kinetics of mutant subclones covering would be highly desirable, therefore, to implement testing of the effective plasma concentrations and monitoring the kinetics of mutant subclones covering. The reason could be that IDO activity may reflect endogenous IFN-α production, a known factor favoring immune-mediated CML control. The predictive potential of KYN/TRP is currently verified in an independent cohort.

BCR-ABL1 COMPOUND MUTANTS DISPLAY DIFFERENTIAL AND DOSE-DEPENDENT RESPONSES TO PONATINIB

K. Byrgazov1,*, C. Lucini1, D. Printz1, M. Koenig1, P. Valent1, O. Hantschel3, T. Lion1
1Children’s Cancer Research Institute, 2Medical University of Vienna, Vienna, Austria, 3Swiss Institute for Experimental Cancer Research, Lausanne, Switzerland

Background: Despite the dramatic improvement of prognosis in CML patients due to the introduction of tyrosine kinase inhibitors (TKIs), resistance to therapy occurs in a considerable proportion of patients. The best-characterized mechanism of resistance is the acquisition of mutations in the BCR-ABL1 5' exonic kinase domain (TKD) affecting TKI binding. The third-generation TKI ponatinib exerts strong anti-neoplastic effects even in advanced CML stages and is capable of suppressing the kinase activity of BCR-ABL1 carrying any single mutation including T315I. Nevertheless, resistance to ponatinib can evolve in sub-clones carrying BCR-ABL1 variants with two or more mutations on the same allele, if the IC50 values for this TKI exceed the maximum achievable effective plasma levels (efc\textsubscript{pon}). These so-called compound mutations (CMs) are associated with increased oncogenic potential in comparison to individual mutations, and represent a powerful mechanism of potential resistance to all currently available TKIs. The occurrence of compound mutations has been linked particularly to sequential treatment with different TKIs, and the identification of their responsiveness to ponatinib is of paramount importance for the subsequent clinical management.

Aims: 1. To determine the spectrum of highly TKI-resistant CMs. 2. Measure the responses of BCR-ABL1 CMs to ponatinib

Methods: We have established a BCR-ABL1 protein model facilitating assessment of the presumptive impact of 27 different CMs involving important functional sites of the BCR-ABL1 TKD, and including constellations expected to display high resistance to ponatinib. To assess the anticipated responses to ponatinib in vitro, we have introduced all BCR-ABL1 CMs into Ba/F3 cells using a recently published transposon-mediated approach (Byrgazov et al., Oncotarget 2016, 7(47):78083-78094), and IC50 values were determined.

Results: Most CMs involving sites with no previous evidence in implication in resistance to ponatinib displayed IC50 values below 10 nM. This efc\textsubscript{pon} is readily achievable even with the 15mg daily dose of ponatinib. CMs revealing elevated resistance to ponatinib in vitro almost invariably included T315I or F317L mutations. While most CMs involving T315I revealed very high IC50 values, some of the predicted compound mutations containing F317L displayed an IC50 for ponatinib in the range of the efc\textsubscript{pon} achievable only with a daily dose of 45mg. These observations are supported by clinical findings in the PACE trial which revealed impaired responses of patients with CMs involving F317L who had received average daily doses of ponatinib below 45mg (Deininger et al., Blood 2016, 127(6):703-12).

Summary/Conclusions: Current strategies that aim at decreasing the dose of ponatinib to prevent severe side effects should carefully consider the presence and type of mutations in the BCR-ABL1 TKD to enable effective treatment. It would be informative, therefore, to implement testing of the effective plasma concentrations and monitoring the kinetics of mutant subclones covering also compound mutations in the routine diagnostic surveillance to provide a basis for optimized clinical management of patients treated with ponatinib.

P597

IS THERE EFFECTIVE IMMUNE SURVEILLANCE AGAINST CHRONIC MYELOID LEUKAEMIA? NO

R.P. Gale1,*, G. Opelz2
1Haematology Research Centre, Imperial College London, London, United Kingdom, 2Institute of Immunology, University of Heidelberg, Heidelberg, Germany

Background: Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. However, considerable data indicate a strong anti-leukaemia effect in persons with chronic myeloid leukaemia (CML) receiving an allogeneic haematopoietic cell transplant. Most, if not all, of this anti-leukaemia effect is confounded with graft-versus-host disease (GvHD) and whether there is a allogeneic or host specific anti-leukaemia effect distinct from GvHD is controversial. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) to a result of immune surveillance. Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) to a result of immune surveillance. Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. However, considerable data indicate a strong anti-leukaemia effect in persons with chronic myeloid leukaemia (CML) receiving an allogeneic haematopoietic cell transplant. Most, if not all, of this anti-leukaemia effect is confounded with graft-versus-host disease (GvHD) and whether there is a allogeneic or host specific anti-leukaemia effect distinct from GvHD is controversial. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) to a result of immune surveillance.
**Methods:** To test these hypotheses, we studied whether there was an increased incidence in CML in persons receiving immune suppression after solid organ transplants. IF immune surveillance is important in CML we would expect an increased incidence in this setting. We used a dataset from the Collaborative Transplant Study (CTS) which collects information on recipients of solid organ transplants beginning in 1985 from >300 transplant centers worldwide. Cancer incidence data were checked annually by questionnaire. Data for expected CML incidence were obtained from a cohort of identical size matched for age and sex from Cancer Incidence in Five Continents monitored for the same duration as the transplant cohort. Data collection and processing were approved by the Data Protection Agency in Germany and all participating centers adhered to local ethical and privacy regulations. The CTS dataset consisted of 441,332 recipients of kidney (N=355,606), liver (N=47,846) and heart (N=37,880) transplants. Amongst kidney transplant recipients the standardized incidence ratio (SIR) for developing CML was 1.54 (95% confidence interval, 1.1, 2.1; p<0.01) representing 39 cases in 1,682,491 person-years at risk (95% confidence intervals). Amongst heart transplant recipients the SIR was 1.72 (0.6, 4.0; P=0.34) representing 5 cases in 182,833 person-years at-risk vs 3 expected (2 excess cases). Amongst kidney transplant recipients the SIR was 3.47 (1.8, 6.1; p=0.0005) representing 12 cases in 173,015 person-years at-risk vs 3 expected (9 excess cases). Data from recipients of kidney and liver transplants suggest immune suppression does not increase risk of developing CML or does so very slightly. The increase in SIR in kidney graft recipients is generally attributed to increased cancer surveillance including blood testing. Although the SIR of CML was substantially-increased after heart transplants, these persons receive high doses of ionizing radiations for diagnostic and therapeutic procedures such as computer tomography (CT)-angiography. Ionizing radiations are a proved cause of CML which might explain the increased SIR.

**Results:** Our data, 25 excess cases of CML in 2,038,339 person-years at-risk observation suggest the magnitude of immune-surveillance do not support the hypothesis that immune surveillance operates to an important extent to prevent CML in humans.

**Summary/Conclusions:** Consequently, the anti-lyeukaemia effect associated with allografts and the TFR observed after stopping TKI-therapy is unlikely to result from effective immune surveillance against CML.

**Background:** In newly-diagnosed chronic phase (CP)-CML patients, 15–30% who start first-line tyrosine kinase inhibitors (TKIs) therapy will not reach an optimal response, and a BCR-ABL1 kinase domain (KD) mutation will be detectable in 25–50% of patients with treatment failure with an increased frequency of these mutations observed in accelerated phase and blast crisis patients. Currently, Sanger sequencing (SS) technique analyzing BCR-ABL1 is considered the gold standard for mutation detection knowing that this assay has a sensitivity of around 20%, and therefore is unsuitable for identifying low-level variants (<20% variant frequency). Recently next generation sequencing (NGS)-based assays have been reported for detecting BCR-ABL1 KD mutations; although these NGS strategies are more accurate and precise than SS, they are burdened by costs related to the initial investment, that is the sequencing purchase, the preparation of specific targets libraries, and the required reagents. MinION is a single molecule sequencer connected to a laptop through a USB3.0 interface, based on nanopore technology; it works by the two methods according to the “molecular classes” (MR1-5) using assay comparison criteria proposed by Müller et al. (2019). The “LabNet” method that includes the “classical” manual real-time PCR techniques standardized in the Italian network (57 centers), according to the European guidelines [Cross N, 2015]. We compared the sensitivity of the two methods (based on the number of ABL1 detected copies), the classification of molecular responses, with particular attention to the deep molecular subgroup.

**Results:** First we compared the number of detected ABL1 copies, that are the higher sensitivity of the automated method. In the cohort of positive cases we defined as fundamental the early molecular response (BCR-ABL1/ABL1 % ≤10% end-points or develop secondary resistance. The 2013 ELN guidelines identified as fundamental the early molecular response (BCR-ABL1/ABL1 % ≤10% IS), the MR3 (<0.1%) and the deep molecular response (MR4<0.01%, MR5=0.001%). Consequently, the molecular monitoring plays a crucial role in the clinical management of CML patients, with a consequent research of sensitive and standardized molecular techniques. The automated methods offer advantages in terms of reduced time for analysis, decreased manual steps, and reduction of possible errors and contamination. First of all the MinION approach, first of all the sensitivity: our comparison of MinION and negative samples (K Cohen=0.690; p <0.02): 77 samples were concordant levels from <10% to the 0% (MR4, MR4.5, MR5) the two techniques have been compared in the different molecular subgroups.

**Background:** The chronic myeloid leukaemia (CML) is characterized by the presence of the Philadelphia chromosome and the BCR-ABL1 fusion gene. The introduction of tyrosine kinase inhibitors (TKIs) significantly improved the survival, but 15% of patients don’t reach the optimal responses at the defined end-points or develop secondary resistance. The 2013 ELN guidelines identified as fundamental the early molecular response (BCR-ABL1/ABL1 % ≤10% IS), the MR3 (<0.1%) and the deep molecular response (MR4<0.01%, MR5=0.001%). Consequently, the molecular monitoring plays a crucial role in the clinical management of CML patients, with a consequent research of sensitive and standardized molecular techniques. The automated methods offer advantages in terms of reduced time for analysis, decreased manual steps, and reduction of possible errors and contamination. First of all the MinION approach, first of all the sensitivity: our comparison of MinION and negative samples (K Cohen=0.690; p <0.02): 77 samples were concordant levels from <10% to the 0% (MR4, MR4.5, MR5) the two techniques have been compared in the different molecular subgroups.

**Results:** First we compared the number of detected ABL1 copies, that are the higher sensitivity of the automated method. In the cohort of positive cases we defined as fundamental the early molecular response (BCR-ABL1/ABL1 % ≤10% end-points or develop secondary resistance. The 2013 ELN guidelines identified as fundamental the early molecular response (BCR-ABL1/ABL1 % ≤10% IS), the MR3 (<0.1%) and the deep molecular response (MR4<0.01%, MR5=0.001%). Consequently, the molecular monitoring plays a crucial role in the clinical management of CML patients, with a consequent research of sensitive and standardized molecular techniques. The automated methods offer advantages in terms of reduced time for analysis, decreased manual steps, and reduction of possible errors and contamination. First of all the MinION approach, first of all the sensitivity: our comparison of MinION and negative samples (K Cohen=0.690; p <0.02): 77 samples were concordant levels from <10% to the 0% (MR4, MR4.5, MR5) the two techniques have been compared in the different molecular subgroups.
and apoptosis in IM sensitive and resistant cell lines.

Summary/Conclusions: In a huge series of patients the automated and manual molecular methods, applied in 4 different laboratories, resulted comparable in classification of patients in “molecular classes”. The advantage of the “Ultra” technique is represented by the higher number of detected ABL1 copies and the easier standardization.

ROLE OF THE AURORA KINASE A/PLK1 AXIS INHIBITION IN RESTORATION OF CELL GROWTH CONTROL OF CHRONIC MYELOID LEUKEMIA PROGENITORS

M. Mancini1,2, S. Soverini1, S. De Santis1, C. Monaldi1, F. Castagnetti1, L. Bavaro1, M. Martelli1, G. Giugliotta1, G. Rosti1, M.A. Santucci1, M. Cavo1, G. Martinelli1

1Istituto di Ematologia Seràgnoli-DIMES, Bologna, Italy

Background: Cell response to stress is a central component of genomic stability. The integrity of signaling pathways involved in cell cycle arrest, chromatin remodeling and DNA repair, are critical for the maintenance fidelity of replicated DNA. In this context, Gadd45s proteins function as stress sensors and gene transcription regulators. Gadd45a, in particular, intervenes in G2/M checkpoint induction and DNA repair, and it is required for efficient coordination of centrosome duplication hence preventing abnormal mitosis and aneuploidy. Such evidences let assume a putative role of Gadd45a in cancer development and progression. Moreover, Gadd45a interacts with Aurora Kinase A (AKA), a key component of centrosome cycle and polar spindle assembly required for regulated progression from G2 to M phase. Interestingly, Gadd45a interacts with Aurora Kinase A (AKA), a key component of centrosome cycle and polar spindle assembly required for regulated progression from G2 to M phase and throughout M. AK A is a member of a serine-threonine kinase family active during mitosis and regulated progression from G2 to M phase and throughout M. AK A is a member of a serine-threonine kinase family active during mitosis and is frequently overexpressed in human cancers where correlates with a poor prognosis. Notably, AK A overexpression is always associated with defects in centrosome duplication, bipolar spindle and chromosomal segregation and aneuploidy, suggesting that it may enhance other oncogenic events by promoting genomic instability, one major trait of chronic myeloid leukemia (CML).

Our results allow to hypothesize that AK A and PLK1, a TK activity of Bcr-Abl fusion protein by increasing DNA damage, promoting the occurrence of additional genomic aberrations and driving TKs resistance and disease progression to blast crisis.

Aims: Here we investigated AK A and PLK1 role in CML hematopoietic progenitor survival as potential targets to eradicate the transformed clone.

Methods: K562 cell line is a human cell line generated from a CML patient in chronic phase. Cell growth was assessed by counting the number of cells in cultures. Cell cycle distribution was observed by PI staining and subsequent cytokinetic analysis.

Results: Preliminary experiments were aimed to determine whether IM resistance in a BCR-ABL1 cell context is associated with the over-expression and hypophosphorylation of AK A/PLK1 axis. Our in vitro model drug resistance was associated with increased expression and phosphorylation of AK A (Y282) and PLK1 (T210). 24h exposure to IM significantly reduced expression and phosphorylation of both proteins in parental K562, but not in IM-resistant K562, indicating that AK A and PLK1 activation is only partly dependent on BCR-ABL1 TK activity. Subsequent experiments showed that the inhibition of AK A and PLK1 in response to specific inhibitors (Danusertib and Volasertib respectively) was associated with:

- significant increase of gadd45 expression levels;
- reduction of cell survival;
- G2/M checkpoint arrest.

The findings support the role of AK A/PLK1 inhibition in restoration of signals involved cell growth control and apoptosis.

Summary/Conclusions: The advantage of using AK A and PLK1 inhibitors in CML therapy might mainly derive from effects independent from TK activity of Bcr-Abl protein. We proved that the AK A and PLK1 inhibitors induce growth arrest and apoptosis in IM sensitive and resistant cell lines.

P601

DURABLE TREATMENT-FREE REMISSION (TFR) FOLLOWING FRONTLINE NILOTINIB (NIL) IN PATIENTS (PTS) WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP): ENESTFREEDOM 96-WK UPDATE

1Istituto di Ematologia Seràgnoli-DIMES, Bologna, Italy

BACKGROUND: ENESTFREEDOM (NCT01778406) is evaluating the ability to stop Nilotinib therapy and maintain in TFR in pts with a sustained deep molecular response (MR) on frontline NIL. Previous results from ENESTFREEDOM showed that 51.6% of pts (98/190) who attempted TFR remained off treatment and in major MR (MMR; BCR-ABL1 ≤ 0.1% on the International Scale) at 48 wk.

AIMS: To analyze updated TFR data and predictive factors for remaining in TFR in ENESTFREEDOM.

Methods: Eligible pts had CML-CP with b2a2 and/or b3a2 BCR-ABL1 transcripts, ≥2 y of frontline NIL, and MR4 (BCR-ABL1 ≤ 0.0032%) prior to enrollment. All pts provided informed consent. After enrollment, pts continued NIL for 6 mo (consolidation phase). MR was assessed every 12 wk during the 1-y consolidation phase; pts with no assessment worse than MR4 remained in all-wk assessment (consolidation phase), and 48-wk TFR rates in each subset were calculated. The current analysis was conducted when all pts who entered TFR had completed 96 wk of TFR, or discontinued from the study (data cutoff, 31 Oct 2016).

Results: Of 190 pts who entered TFR, 93 (48.9% [95% CI, 41.6% - 56.3%]) remained in MMR and off treatment at wk 96, including 88 (46.3%) who were in MR4. Three pts who were in TFR at 48 wk lost MMR by wk 96, and 2 additional pts discontinued from the study between 48 and 96 wk without losing MMR. Among pts with low, intermediate, or high Sokal risk at diagnosis, 39/62 (62.9% [95% CI, 49.7% - 74.8%]), 25/50 (50.0% [95% CI, 35.5% - 64.5%]), and 9/28 (32.1% [95% CI, 15.9% - 52.4%]), respectively, remained in TFR at wk 49 (Sokal risk scores were missing for 50 pts). Among pts with no assessment worse than MR4 in all-wk assessment, 78 (47.0% [95% CI, 35.2% - 59.1%]) remained in TFR at wk 48 vs 82/40 (40.0% [95% CI, 19.1% - 63.9%]) who had ≥1 assessment between MR4 and MR4.5 during the consolidation phase. Overall, 88 pts who reinstituted NIL due to loss of MMR, 87 (98.9%) regained MMR and the remaining pt left the study 7.1 wk after NIL reinstitution without regaining MMR; 81 of 88 pts (92.0%) regained MR4.5 by the data cutoff. Among pts remaining in TFR for >48 wk (n=100), adverse events (AEs) were less frequent during the second vs the first 48 wk of TFR, 2 (2.0%) and 1 (1.0%), respectively. These include cardiovascular AEs, leading to the discontinuation of second 48 wk of TFR, respectively, 34 (34.0%) and 9 (9.0%), respectively, had AEs in the predefined musculoskeletal pain grouping.

Summary/Conclusions: The majority of pts in TFR at 48 wk remained in TFR at 96 wk, and they reported fewer AEs during the second 48 wk of TFR than in the first 48 wk. Confirming the durability and safety of TFR following NIL. No strong predictive markers for remaining in TFR were identified. Pts with low Sokal risk and pts with continuous MR4.5 in the consolidation phase tended to have higher TFR rates than other pts, although these results must be interpreted with caution due to the small number of pts in some subsets and the wide 95% CIs. Additionally, the biological explanation for an association between Sokal risk score at diagnosis and a subsequent ability to remain in TFR is unknown. These results support TFR as a valuable option for pts in sustained DMR on frontline NIL.

RESPONSE DIFFERENCES IN THE BCR-ABL1 E13A2 AND E14A2 VARIANTS MAY BE A TECHNICAL QPCR ARTIFACT

L. Kjaer1,2, V. Skov1, M. Gniot2, L. Udyb1, M. Dorfl1, H. Hasselbalch1, N. Pallisgaard3

1Hematologisk Klinik, Odense Universitetshospital, Odense, Denmark, 2Department of Medical Genetics, Odense University Hospital, Odense, Denmark, 3Novo Nordisk A/S, Gentofte, Denmark.
Background: The t(9;22) translocation in chronic myeloid leukemia (CML) generally occurs in intron 12 or 13 of the BCR gene resulting in two different transcripts, the e13a2 or e14a2. It has been suggested that the two variants represent separate disease entities and that the transcript variants hold a prognostic value regarding treatment response, where e14a2 predicts a faster and deeper treatment response. However, no difference in overall survival has been observed and the issue remains controversial. Reverse transcription quantitative PCR (RT-qPCR) using the Europe Against Cancer (EAC) qPCR assay has been the gold standard for determining the levels of BCR-ABL1 transcripts. The assay use common primers for amplification of the two variants resulting in a PCR product for the e14a2 variant that is 75 base pairs longer than the e13a2 variant. Under suboptimal PCR conditions, amplicons may be amplified with different efficiencies, which can result in an underestimation of especially the amount of longer qPCR products.

Aims: To study the accuracy of the EAC assay in quantifying the e13a2 and e14a2 transcripts.

Methods: Patient samples were screened for BCR-ABL1 e13a2 and e14a2 transcript variants using either PCR with agarose gel separation or a droplet digital PCR (ddPCR) assay measuring the amount of e13a2 and e14a2 transcripts. The BCR-ABL1 level was determined by qPCR using the QuantiStudio instrument (Life Technologies) and expressed in the International Scale (IS), using the EAC primers and assay conditions with GUSB and BCR as reference genes. Samples were re-measured by digital droplet PCR (ddPCR) on a QuantTaLife instrument (Bio-Rad) using modified EAC primers multiplexed with GUSB and BCR as reference genes and expressed as %IS.

Results: Transcription levels from 124 BCR-ABL1 positive patient samples were determined using the EAC qPCR assay (median: 0.08% IS, range: 0.001–159% IS) and ddPCR (median: 0.01% IS, range: 0.0002–124% IS). These included 59 samples with the e13a2 variant and 65 with the longer e14a2 variant. Comparing the expression levels obtained by the two techniques revealed a discrepancy in a large subgroup of patients could have a greater than 0.5 log underestimation in a large subgroup of patients could have concerning clinical decision-making e.g. by miss-grouping patients at different time points or when considering TKI discontinuation. Since many clinical laboratories use the BCR-ABL1 EAC protocol, the underestimation of the e14a2 level resulting in an appealingly better treatment response. A more than 0.5 log underestimation in a large subgroup of patients could have consequences in clinical decision-making e.g. by miss-grouping patients at different time points or when considering TKI discontinuation. Since many clinical laboratories use the BCR-ABL1 EAC protocol, the underestimation of the e14a2 variant could potentially be a widespread issue. We are presently working on an optimized BCR-ABL1 qPCR protocol where the e14a2 underestimation is eliminated.

Summary/Conclusions: When we compared the BCR-ABL1 levels using qPCR and ddPCR, we observed a discrepancy between the e13a2 and e14a2 breakpoint variants. Since ddPCR is an endpoint measurement and not sensitive to variations in primer efficiencies, the most likely explanation for the discrepancy is a decreased qPCR efficiency of the longer e14a2 variant compared to the e13a2 variant. Thus in qPCR analyses using the EAC protocol this may, at least on our analysis platforms, result in a consistently underestimation of the e14a2 level resulting in an appealingly better treatment response. A more than 0.5 log underestimation in a large subgroup of patients could have consequences in clinical decision-making e.g. by miss-grouping patients at different time points or when considering TKI discontinuation. Since many clinical laboratories use the BCR-ABL1 EAC protocol, the underestimation of the e14a2 variant could potentially be a widespread issue. We are presently working on an optimized BCR-ABL1 qPCR protocol where the e14a2 underestimation is eliminated.

Table 1.

Results: Baseline characteristics of the CP-CML pts included: median time from diagnosis, 7 yrs (range, 0.5–27 yrs); median age, 60 yrs (18–94 yrs); median %Ph+ 100% (25–100%); median %Ph- 0% (0–70%). Among 108 CP-CML pts received ≥3 prior TKIs. At initiation of study closure, 99 pts (37%) were ongoing; among these pts, minimum follow-up was 52 mos, and most (78%) had 15 mg/dl as their last ponatinib dose. In efficacy-evaluable CP-CML pts, cumulative response rates as of the data cutoff were: MCyR 60%; CCyR 54%; MMR, 40%; and MMR4 24%. Among pts who achieved MCyR (n=148) or MMR (n=108), the Kaplan-Meier (KM) estimated probability of remaining in response at 5 yrs was 74% (95% CI, 62–83) and 61% (95% CI, 51–70), respectively. Maintenance of response was high regardless of dose reductions in Oct ‘13. KM estimated 5-yr rates for PFS/OS were 49%/77%. Among pts with 3-, 6- and 10-yr landmark, median MMR achieved in 14% (95% CI, 7–23), respectively. 34% of CP-CML pts were rash 47%, abdominal pain 46%, and thrombocytopenia 46%. Most newly occurring AEs were observed within the first yr. The incidence of any AOE/serious AOE for CP-CML pts was
Background: Very elderly (>75 yrs) people are a substantial proportion of chronic myeloid leukemia (CML) patients that sometimes receive imatinib (IM) at reduced doses based on physicians’ judgment. However, data on long-term follow-up of these patients are still lacking.

Aims: To investigate the treatment response and outcome in a cohort of very elderly patients with newly diagnosed CML in chronic phase.

Methods: We revised in a retrospective database 263 CML patients aged ≥75 years and diagnosed from 2002/2001 to 2016 and treated with IM front line; among these, 121 patients (46%) were older than 80 yrs. Median age at diagnosis was 78.5 yrs [interquartile range (IQR) 76.3–81.3]. Sokal Risk at diagnosis was low in 3 patients (0.4%), intermediate in 171 patients (46.9%), and high in 87 patients (23.9%). Sokal Risk at diagnosis was low in 1 patient (0.4%), intermediate in 171 patients (46.9%), and high in 87 patients (23.9%). The long-term follow-up of very elderly CML patients treated with IM hints that any effort to treat these patients should be made, in order to achieve cytogenetic and molecular responses as in younger subjects.
ease (including 7 acute myocardial infarction), 8 PAOD, 4 carotid stenosis (asymptomatic), 2 avascular necrosis of the femoral head, 1 optic artery ischemia, 1 chronic hyperplastic states of aorta/right iliac artery. Overall, 21 patients were hospitalized for the management of ATEs; 15 patients received medical treatment only, while the remaining required invasive interventions: 9 coronary angioplasty with stent positioning, 3 lower limbs amputations, 2 peripheral vascular bypasses, and 1 prosthesis of femoral head. No patient died for ATEs. Overall, 24 patient (80% of patients with ATEs and 7% of the whole cohort) permanently discontinued nilotinib because of ATEs. The median follow-up after ATE was 15 (1–58) months. Of the 30 patients with ATEs, 26 (87%) achieved a MMR and 18 (60%) obtained a MR4, during nilotinib treatment. These rates were comparable to those observed in patients without ATEs (MRR: 260/315, 83%; MR4: 113/315, 64%). The 5-year progression-free survival and overall survival in patients with or without ATEs (PFS: 96% vs 92%, p=0.55; OS: 96% vs 93%, p=0.79).

Summary/Conclusions: After a median follow-up of 58 months, 8.7% of patients treated front-line with nilotinib had ATEs, being coronary disease and PAOD the most common. ATEs were more frequent in elderly patients (median age at ATEs: 67 years). Half of the patients required invasive procedures, including major surgeries in 6 patients. The other patients were successfully managed with medical treatment. Importantly, no patients died for ATEs, and ATEs did not affect the rates of MMR, MR4 and 5-year PFS and OS, which were all comparable to those observed in patients without ATEs. Taken together, these data suggests that ATEs, despite being sometimes associated with significant morbidity, did not significantly impact on response rates and on long-term outcome of CML patients treated with nilotinib front-line.

ASSESSMENT OF CHRONIC RENAL INJURY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN THE CHRONIC PHASE RECEIVING TYROSINE KINASE INHIBITORS Q. Jiang1, L. Zuo1, X. Ren1, X. Huang1 1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking University People’s Hospital, Department of Nephrology, Beijing, China

Background: Long-term use of tyrosine kinase inhibitors (TKIs) may lead to chronic renal injury. Aims: To evaluate the incidence of chronic kidney disease (CKD) in patients with chronic myeloid leukemia (CML) in the chronic phase (CP) receiving TKIs, and to identify the factors associated with the onset of CKD.

Methods: Data of CML-CP patients treated with TKIs as first-line or second- or third-line therapy for at least 6 months were analyzed. Glomerular filtration rate (GFR) was followed from the initiation of TKI-therapy. CKD was defined as persistent GFR less than 60 ml/min/1.73 m² or persistent more than 30% GFR reduction from baseline. CKD-free survival was used to evaluate the onset of CKD. Patients’ characteristics and TKI used were analyzed to identify the factors associated with the onset of CKD.

Results: 587 patients were included in this study. 383 (65%) were male. Median age was 40 (17-84) years. 464 patients were received nilotinib (n=363), nilotinib (n=88) or dasatinib (n=13) as first-line TKI-therapy. With a median follow-up of 35 months (range, 3-185 months), 136 of 416 (33%) patients with normal GFR at baseline developed CKD. Probabilities of CKD-free survival at 4 years were 62%, 78% and 100% in the patients receiving imatinib, nilotinib and dasatinib, respectively (p=0.004). Multivariate analysis showed that imatinib use (HR=3.6, 95% CI 1.0-13, p=0.047) and a history of diabetes mellitus, hypertension or other renal diseases (HR=3.8, 95% CI 1.3-11.6, p=0.019) were factors associated with incident of CKD. 3 of 13 (23%) patients with abnormal GFR or prior CKD before second- or third-line TKI-therapy developed 30% GFR reduction from baseline during nilotinib (n=1) or dasatinib (n=2) therapy.

Summary/Conclusions: Our study showed that nilotinib and dasatinib were associated with less chronic renal injury compared with imatinib as first-line TKI-therapy, while dasatinib was related to less loss of renal function compared with nilotinib as second- or third-line TKI-therapy after imatinib-failure in CML-CP patients.

Figure 1. Results: Analyzing comparatively the time course of MR in the patients of the three groups (MR3.0, MR4.0 and MR4.5-5.0) it was observed a similar trend, but the dPCR allowed to appreciate that, at the time of starting the monitoring the patients showed different levels of BCR-ABL1 copies/ml. Furthermore, those patients with MR4.5-5.0 undetectable by dPCR resulted with detectable BCR-ABL1 transcript levels when assessed by dPCR. Secondly, while MRD quantitations measured by dPCR appear to be more homogeneous, nearly due to a normalization effect of dPCR, the quantitations of MRD measured by dPCR appear to be more heterogeneous because of the high sensitivity and accuracy of dPCR. Therefore, dPCR values, reflecting the great heterogeneity of MRD level in patients belonging to the same MR group, suggest a higher accuracy in patients stratification (Figure 1a). dPCR value of 0.468 copies/ul previously reported as value discriminating between major responders and deep responders, was used as threshold for dPCR data analysis. Patients with absolute value of BCR-ABL1 lower than 0.468copies/ul at the first time point presented more stable disease levels than the patients with absolute value of BCR-ABL1 higher than 0.468copies/ul (Figure 1b). In 14 CML patients who
discontinued TKIs, a preliminary analysis showed that 80% of patient with BCR-ABL1<0.468 copies/ul at discontinuation, maintained stable TFR (PPV of 80%).

Summary/Conclusions: This study suggests that dPCR is more precise and sensitive than qPCR when detecting levels of BCR-ABL1 transcript and that dPCR seems to be more robust and accurate for CML patients stratification. Larger and prospective studies are warranted to confirm the higher sensitivity and accuracy of dPCR and its usefulness to better select the candidates for TFR.

P608
OUTCOME OF BLAST PHASE CHRONIC MYELOID LEUKEMIA (CML-BP) IN THE TYROSINE KINASE INHIBITOR ERA
C. Teitel1, L. Isenatume2, S. Shams1, A. Kuykendall1, J. Chavez2, B. Shah2, K. Sweep2, J. Pinilla-Ibarz2
1Department of Malignant Hematology, University of South Florida/Moffitt Cancer Center, 2Department of Malignant Hematology, Moffitt Cancer Center, Tampa, United States

Background: Primary goal of management in chronic myeloid leukemia (CML) is to prevent disease progression to blast phase CML (BP-CML). Current notion for management of BP-CML usually involves initiation of intensive chemotherapy regimen with addition of tyrosine kinase inhibitor (TKI). Despite treatment with intensive induction chemotherapy, outcome remains dismal.

Aims: We aimed to describe our experience with management of BP-CML and its outcome.

Methods: We included 58 patients from Moffitt Cancer Center from 2001 till 2016 with diagnosis of BP-CML and performed a retrospective chart review. Data elements including age, gender, peripheral blood and bone marrow parameters, phase of CML, treatment, cytogenetics and vital status were collected. Survival analysis using Kaplan-Meier method with log-rank test to determine significance by calculating two-sided p values was performed.

Figure 1. Overall survival in the era of TKI in management of blast phase CML.

Results: The overall survival (OS) of our cohort was 31.87 months (mo). For patients with progression to BP-CML from previously known diagnosis of CML, median time to progression was 19.1 mo (range: 3.0-221.2 mo). The median OS from the diagnosis of BP-CML in this cohort was 10.8 mo, compared to de novo CML-BP cohort OS of 11.03 mo (p=0.62). Myeloid blast phase CML had worse OS compared to lymphoid blast phase cohort but was not statistically significant (9.17 vs 17.5 mo, p=0.32). We further compared the treatment strategies of BP-CML including single agent TKI (n=21) and conventional chemotherapy regimens in combination with a TKI (n=36). The median OS of the cohort with single agent TKI was not statistically different from the combination with chemotherapy arm (12.83 mo vs 10.87 mo, p=0.73) as shown in Figure 1A. Additionally, combination of chemotherapy with TKI compared to single agent TKI did not have significant survival impact in either myeloid (9.17 vs 9.13 months, p=0.32) or lymphoid (14.47 vs 18.27 mo, p=0.24) BP-CML. Total of 26 patients (44.8%) proceeded to allogeneic bone marrow transplant, 26% (n=6) of which only received TKI prior to transplant compared to 76.9% (n=20) who received chemotherapy in combination with TKI. Use of single agent TKI rather than TKI in combination with chemotherapy prior to allogeneic transplant had a trend toward improved OS (128.5 vs 24 mo, p=0.23) (Fig 1B). Choice of TKI in combination with chemotherapy in treatment of BP-CML also did not identify any TKI combination resulting in superior survival (Figure 1D). Overall survival of the cohort stratified by presence of standard Philadelphia chromosome in comparison to additional cytogenetic aberrations did not detect difference in overall survival (10.87 vs 12.1 mo, p=0.51). Further evaluation of cytogenetic aberrations revealed monosomy 7 to be present in greater frequency in lymphoid blast phase compared to myeloid blast phase (35.7% vs 6.29%, p=0.02).

Summary/Conclusions: Our data suggest no survival difference when BP-CML is treated with a single agent TKI compared to a combination therapy, regardless of histology type. Therefore, single agent TKIs should be considered as an effective frontline therapy option for BP-CML, which may prevent the potential toxicity associated with chemotherapy. These findings need further validation in a larger prospective cohort.

P609
EFFICACY OF SWITCHING TO DASATINIB IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH LATE WARNING RESPONSES TO IMATINIB. STUDY OF THE ASSOCIATION OF RESPONSE TO DASATINIB TO IMMUNOLOGIC STATUS
1Servicio de Hematología, Hospital Universitario de la Princesa/ IIS-IP Madrid, 2Servicio de Hematología, Hospital Universitario Ramón y Cajal, 3Servicio de Immunología, Hospital Universitario de la Princesa, Madrid, 4Servicio de Hematología, Hospital Universitario de Salamanca, Salamanca, 5Servicio de Hematología, Hospital Duran i Reynals, Barcelona, 6Servicio de Hematología, Hospital Virgen de la Salud, Toledo, 7Servicio de Hematología, Hospital Germans Trias i Pujol, Barcelona, 8Servicio de Hematología, Hospital Universitario Virgen del Rocio, Sevilla, 9Servicio de Hematología, Hospital Universitario La Paz, Madrid, Spain

Background: European LeukemiaNet (ELN) recommendations (2013) advised closely monitoring for patients with late warning response (patients with complete cytogenetic response after major molecular response after 12 months of treatment). Our trial, DASAPOST, has been the first one evaluating efficacy and safety of dasatinib in patients with late warning responses, and preliminary results have been reported (García-Gutiérrez et al, ASH 2016; P5450). Besides, many studies suggest that dasatinib may augment responses due to its immunomodulating effect.

Methods: Phase II, open, multicenter DASAPOST study (NCT01802450). Patients previously treated with imatinib after at least 18 months, with CCyR but without MMR, were included. All BCR-ABL1/ABL1 (IS) measurements were centralized in a single central laboratory (Analítica). Response point were considered as non responders, Lymphocyte counts, subpopulations and migration studies were done at baseline (1st day of dasatinib), and every 3 months, and they were done both previous to the dose, and 2 hours after.

Results: From April 2013 to May 2015, 18 patients were enrolled in 12 centers. Median age was 59 years (39-77). The ratio of men to women was 13/5, and the Sokal risk groups were 48%, 30% and 22% for low, intermediate and high risk, respectively. Median time from diagnosis to switch to dasatinib was 2.6 years (1.6-23) and median time while on imatinib to achieve CCyR 1.4 years (0.2-12). Median exposure to imatinib was 2.4 years (1.6-14). Eight patients (44.4%) obtained MMR at 3 months, and 12 (66.7%) obtained MMR at 6 and 12 months. Of interest 9/18 patients (50%) achieved MR4 by 12 months. There were 3 study discontinuations because of toxicity (16%). Table 1 shows the median number of the most relevant lymphocyte populations in the pre-dose sample at baseline. Table 2 shows that the absolute number of CD8 cells was significantly superior at baseline in those patients having a MMR at 3 months, with a trend in the same direction of absolute lymphocyte count and percentage. There were no significant associations with response when considering CD4 T cells, NK cells, or the degree of mobilization after dasatinib dose either in total lymphocyte numbers or in subpopulations. Besides, lymphocyte number or proportions at 3 or 6 months were not associated with MMR at 6 or 12 months (data not shown).

Summary/Conclusions: Our study shows that in patients treated with imatinib and with late warning responses, switching to dasatinib induced MMR in 2 out every 3 patients, and MR4 in half of the patients, with a good safety profile. Contrarily to other group reports, we have not found any significant association between response and lymphocyte mobilization in any point studied. Interestingly, the absolute number of CD8 at baseline was significantly associated with the early attainment of MMR at 3 months, a finding which underscores the prognostic importance of baseline immune status, the relevance of CD8 cells in the antileukemic effect, and which suggest that this quite simple variable must be included in future studies with dasatinib in second line.

Methods: The BCR-ABL measurements acquired using EAC and in-house modified EAC protocol have been compared with results from SA Pathology in Adelaide. The Adelaide protocol (Branford and Hughes 2006) consists of separate, optimized reactions for e13a2 and 14a2 transcripts, therefore it should be considered free of any PCR efficiency-related artifacts. The data originated from four independent sample batches exchanged between Poznan and Adelaide since 2009.

Results: The analysis of retrospective EAC protocol data showed that when e13a2 and e14a2 samples entered the exponential phase at the same time, the latter would cross the threshold approximately 2.2 cycles after the first one. Re-analysis of data from sample exchanges from 2009 revealed that after establishing a conversion factor (CF), all of the e14a2 measurements in Poznan were underestimated according to Adelaide. At the same time, almost all of e13a2 samples were overestimated (fig. 1). Still, the bias between methods was acceptable and a valid conversion factor (CF) was calculated. The method modification introduced 2011 eliminated this difference and increased concordance between laboratories. The last sample batch revealed significant difference between non-modified and modified EAC protocols in e13a2 measurements: 4.56 (+/- 0.96). Reanalysis of sample batch from 2009 (presented on fig.1) using 4.57 (2x2.28) factor (e13a2 results divided by 2.28, e14a2 results multiplied by 2.28) resulted in almost perfect data alignment. The results of modified EAC protocol, after CF recalulation, showed very good concordance with Adelaide (100% results of e14a2 and 88% of e13a2 within 2-fold of reference laboratory).

Figure 1.

Summary/Conclusions: Although nilotinib is not associated with a higher incidence of TD2 compared to a general population, it could be an early "higheener" of genetic predisposition to the disorder. The presence of more than 10 allelic variants associated to insulin secretion, processing, sensitivity and clearance is predictive of prediabetes/diabetes developing. In clinical practice uGRS could help tailor the best TKI therapy.

Methods: The BCR-ABL measurements acquired using EAC and in-house modified EAC protocol have been compared with results from SA Pathology in Adelaide. The Adelaide protocol (Branford and Hughes 2006) consists of separate, optimized reactions for e13a2 and 14a2 transcripts, therefore it should be considered free of any PCR efficiency-related artifacts. The data originated from four independent sample batches exchanged between Poznan and Adelaide since 2009.

Results: The analysis of retrospective EAC protocol data showed that when e13a2 and e14a2 samples entered the exponential phase at the same time, the latter would cross the threshold approximately 2.2 cycles after the first one. Reanalysis of sample batch from 2009 (presented on fig.1) using 4.57 (2x2.28) factor (e13a2 results divided by 2.28, e14a2 results multiplied by 2.28) resulted in almost perfect data alignment. The results of modified EAC protocol, after CF recalulation, showed very good concordance with Adelaide (100% results of e14a2 and 88% of e13a2 within 2-fold of reference laboratory).

Figure 1.

Summary/Conclusions: In the EAC protocol, the e14a2 transcript amplifies less efficiently than e13a2. Since commonly used plasminoids, including ERM-AD623, are based on e14a2, the standard curve is being shifted towards the latter cycles. It leads to overestimation of e13a2 by mean factor of 4.5 (over 0.5 log), which could be clinically significant. The reports of worse outcome of e13a2 patients are probably caused by this artifact, which can be easily eliminated by implementing an additional forward primer to EAC protocol. This overestimation cannot be detected in case of lab to lab validation when two centers are using EAC protocol. In case of method validation in Adelaide, those differences were not as obvious as well. The shift of 4.5 (fig. 1) means that results are 2.25 times different from the perfect concordance line and could easily fit into accepted 2-fold and 3-fold compartments. The CF calculated by Adelaide would depend on the percentage of each transcripts among the exchanged samples. The observed artifact should be also taken into consideration in clinical trials that rely on surrogate endpoints such as molecular response level at certain time points. Uneven transcript variant distribution between compared groups may lead to improper conclusions.

Figure 1.

Summary/Conclusions: Although nilotinib is not associated with a higher incidence of TD2 compared to a general population, it could be an early "highener" of genetic predisposition to the disorder. The presence of more than 10 allelic variants associated to insulin secretion, processing, sensitivity and clearance is predictive of prediabetes/diabetes developing. In clinical practice uGRS could help tailor the best TKI therapy.

ESTABLISHMENT OF IN VIVO AND IN VITRO MODEL OF X-LINKED SIDEROBLASTIC ANEMIA

K. Saito1,*, T. Fujisawa1, M. Morita2, Y. Okitsu1, N. Fukuharai3, Y. Onishi1, Y. Sato1, Shinichi2, H. Haraguchi1

1Hematology, and Rheumatology, 2Medical Biochemistry, Tohoku University Graduate School of Medicine; Sendai, 3Cell Engineering Division, RIKEN BioResource Center, Tsukuba, 4Molecular Hematology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Congenital sideroblastic anemia (CSA) is a inherited sideroblastic anemia characterized by the presence of bone marrow ring sideroblasts, reflecting excess mitochondrial iron deposition. The most common form of CSA is X-linked sideroblastic anemia (XLSA), which is attributed to mutations in the X-linked gene erythroid-specific 5-aminolevulinate synthase (ALAS2). ALAS2 resides on chromosome X and encodes the enzyme that catalyzes the first and rate-limiting steps in the heme biosynthesis pathway in erythroid cells. This pathway converts glycine and acetyl-coenzyme A to 5-aminolevulinic acid (ALA), which requires pyridoxal 5'-phosphate (PLP) as a cofactor. Although ALAS2 has never been used for treating XLSA, a marked proportion of patients with XLSA remain refractory to treatment (Ohba et al. Ann Hematol) 2013). Thus, there is a need to establish a model of XLSA to reveal the detailed molecular mechanism contributing to RS formation as well as to explore novel therapeutic strategies.

Aims: We explored to establish a novel model of XLSA by CRISPR/Cas9-based genome editing.

Methods: We targeted the GATA-1-binding region of intron 1 of the human ALAS2 gene based on both in vivo and human induced pluripotent stem cell-derived erythroid progenitor (HiDEP) cells (Kurita et al. PLoS One 2013). The mutation diminished the binding of transcription factor GATA-1, which would lead to decreased transcription of the ALAS2 gene, thereby causing XLSA (Kaneko et al. Haematologica 2014). Western blotting and quantitative chromatin immunoprecipitation (ChIP) analysis were performed using antibodies against GATA-1 (DS526, Cell Signaling Technologies) and TAL1 (C-21, Santa Cruz).

For transcription profiling, Human Oligo chip 25K (Toray) was used. Gene ontology (GO) analysis was performed with GeneCodies (http://genecodis2.dacya.ucm.es/).

Results: We first generated a founder female mouse lacking the intron 1 enhancer region of Alas2, including the GATA-binding domain (Alas2Δint1/X). Whereas the heterozygous Alas2Δint1/X mice were viable and did not show anemic phenotype, hemizygous deletion (Alas2Δint1/X) in male mice led to an embryonic lethality, suggesting that this sequence is indispensable in the context of mice. As an alternate approach, we established a clonal line with HiDEP cells, which harbored 19-bp deletion within the intron 1 enhancer region of ALAS2, including GATA binding domain. Whereas wild-type HIDEP cells exhibited red color, the XLSA clone appeared pink/pale color, which were accompanied by the significantly decreased intracellular heme concentration. Despite no obvious change in the expression of GATA-1 protein in the XLSA clone, quantitative real-time polymerase chain reaction (RT-PCR) analysis demonstrated significant downregulation of ALAS2 as well as globin genes (HBA, HBB, and HBG) in the XLSA clone. Microarray analysis revealed >2-fold up- and down-regulation of 619 and 274 genes caused by the 19-bp deletion, respectively. The downregulated gene ensemble included globins (HBB, HBG, HBE, HBD, HBM, and HBQ) as well as genes involved in iron/heme metabolism (ALAS2, transferrin receptor, FTRC, coproporphyrinogen oxidase: CPOX, and mitoferrin 1: MFRTN1). GO analysis revealed significant enrichment of cellular iron homeostasis (p=0.018), regulation of transcription (p=0.0021), and innate immune response (p=0.0018), implying that heme was involved in various biological processes in erythroid cells. Interestingly, ALA treatment significantly improved heme production as well as downregulation of globin genes observed in the XLSA clone, suggesting that ALA may represent a novel therapeutic option for PLP-refractory XLSA.

Summary/Conclusions: The XLSA model established from HiDEP cells can be used as an important tool for clarifying the molecular etiology of XLSA and to explore novel therapeutic strategies.

BENDAMUSTINE AND RITUXIMAB COMBINATION THERAPY FOR COLD AGGLUTININ DISEASE: RESULTS OF A PROSPECTIVE NORDIC TRIAL

S. Berentsen1,*, U. Randen2, M. Okman3, H. Birgins4, T.H.A. Tvedt5, J. Haggblad6, M. Riise7, H. Sund, 2Department of Pathology, Oslo University Hospital, Oslo, Norway, 3Department of Hematology and Stem Cell Transplantation, Turku University Hospital, Turku, Finland, 4Department of Haematology, Herlev Hospital, University of Copenhagen, Herlev, Denmark, 5Department of Medicine, Haukeland University Hospital, Bergen, 6Medical Department, Drammen Hospital, Vestre Viken Trust, Drammen, 7Department of Medicine, Akershus University Hospital, Nordbyhagen, 8Department of Hematology and Oncology, Stavanger University Hospital, Stavanger, 9Department of Hematology, Oslo University Hospital, Oslo, Norway

Background: Primary cold agglutinin disease (CAD) is an autoimmune hemolytic anemia in which a well-defined clonal lymphoproliferative bone marrow disorder (LPD) causes production of monoclonal cold agglutinins. Major clinical manifestations are anemia and/or severe cold-induced circulatory symptoms. Pharmacological therapy, although not indicated in patients with very mild disease, seems required in a majority of cases. Corticosteroids are ineffective. Rituximab monotherapy has resulted in approximately 50% response rate and 1-year median response duration. Fludarabine and rituximab combination therapy showed 70% response rate (20% complete responses) and very long response duration, but considerably toxic.

Aims: We wanted to investigate whether bendamustine and rituximab combination therapy can result in favorable response rates and duration with an acceptable toxicity profile.

Methods: We conducted a prospective, uncontrolled multicenter trial with 16 participating hospitals from Norway, Finland and Denmark. Essential inclusion criteria were verified CAD with symptomatic anemia and/or severe cold-induced circulatory symptoms. Eligible patients received 4 cycles of rituximab 375mg/m2 day 1 and bendamustine 90mg/m2 day 1-2 with 28 days interval. Outcomes were measured into complete response (CR), partial response (PR), and non-response (NR). The definition of CR included normalization of hemoglobin (Hb) levels with no hemolysis, complete histologic resolution of the bone marrow LDH and disappearance of monoclonal serum protein. The criteria for PR included increase in Hb levels by at least 2.0 g/dL or to the normal range, transfusion independence, at least 50% reduction of IgM and improvement of any circulatory symptoms.

Results: Forty-four patients (19 men and 25 women) were included, with a median age of 74 years (range, 48-86) and median disease duration 4 years (range, 0-18). Seventeen patients had received previous therapy. At baseline, median Hb level was 9.5 g/dL (range, 4.5-14.6), bilirubin 45micromol/L, lactate dehydrogenase (LDH) 468 U/L, haptoglobin undetectable, IgM 4.1g/L (1.0-27.2), CA lutter 2048 (64-65536). Monoclonal IgM kappa was detected in 38 patients, IgG kappa in 1 and IgA kappa in 1. We observed CR in 16 patients (36%), PR in 15 (34%), while the remaining 13 (30%) were non-responders. Hb levels increased by a median of 4.6 g/dL in the responders; 4.4 g/dL in patients achieving CR and 3.9 g/dL in those achieving PR. Median post-therapy Hb levels were 14.2g/dL (CR), 12.5g/dL (PR) and 10.5g/dL (NR). Acrocyanosis and Raynaud symptoms resolved completely in 16 patients and improved in 11 (47% and 32%, respectively, of those with such symptoms at baseline). Histologic regression of the LPD was complete in 17 patients (39%), partial in 5 (11%) and not evaluable in 18 (41%). Median time to response was 2 months (0.5-12). Only 3 responders experienced relapse; 2 after PR and 1 after CR. Median observed response duration was 32 months (range, 1-62) during median 32 months follow-up. Patients were censored after a much longer follow-up. Neutropenia grade ≥3 occurred in 14 episodes (32%), of which 8 (18%) had grade 4. Three patients (7%) experienced 1-3 episodes of febrile neutropenia, which was rarely manageable. Non-hematologic toxicity occurred in 17 patients (39%), mostly consisting of mild nausea or rash. Three non-neutropenic serious adverse events (SAE) were recorded; 1 was considered probably therapy-related.

Summary/Conclusions: Bendamustine and rituximab combination therapy resulted in high response rates, a high rate of CR, long response duration and few relapses during the observation period, with a favorable safety profile. It might be considered in the first line for reasonably fit patients with CAD requiring therapy.

EX VIVO TREATMENT OF RED BLOOD CELLS FROM 15 PYRUVATE KINASE (PK)-DEFICIENT PATIENTS WITH AG-348, AN ALLOSTERIC ACTIVATOR OF PK-R, INCREASES ENZYMATIC ACTIVITY, PROTEIN STABILITY AND ATP LEVELS

B. van Oirschot1, P.A. Kosinski02, J. Hudson03, K. Johnson02, V. Chubukov02, L. Deng02, G. Pasterkamp01, S. van Straaten14, C. Kung02, R. van Wijk01

1Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands, 2Agios Pharmaceuticals, Inc., 3KSQ Therapeutics, Cambridge, MA, United States, 4Van CreveldKliniek, University Medical Center Utrecht, Utrecht, Netherlands

Background: Pyruvate kinase (PK) deficiency is a hereditary disorder affecting red blood cell (RBC) glycolysis. It is caused by mutations in the PKLR gene. PK-deficient RBCs are characterized by changes in metabolism associated with defective glycolysis, including a build-up of the upstream metabolite 2,3-diphosphoglycerate, and deficiency in the PK product ATP. It is hypothesized that insufficient energy production affects red cell homeostasis, promoting

haematologica | 2017; 102(s2) | 241

Madrid, Spain, June 22 – 25, 2017
premature removal of PK-deficient RBCs from the circulation. Affected patients display chronic hemolytic anemia of variable severity. Treatment of PK-deficient patients is generally supportive, focusing on the anemia and iron overload state, and there are no approved drugs that directly target mutated PK. AG-348 is an allosteric activator of the RBC isoform of PK (PK-R) and in clinical development for the treatment of PK deficiency.

Aims: To evaluate the effect of AG-348 treatment on PK-R enzymatic function, RBC metabolism and deformability.

Methods: Observational case-control study, approved by the Institutional Review Board. All patients gave informed consent. Enrolled patients (N=15) were adults, transfusion-independent and compound heterozygous or homozygous for PK deficiency. Baseline metabolic profiling was performed by LC-MS/MS. Purified RBCs from patients and healthy control subjects were incubated with AG-348 (up to 10 μM) for 24 hours at 37°C. After 6 and 24 hours PK-R activity, ATP levels and RBC deformability (by Lorrecra) were measured. For determination of PK-R thermal stability, RBC lysates were incubated for 2 hours with 2 μM AG-348 at 53 °C (before AG-348) or 37 °C (after AG-348) prior to test. Baseline protein levels of PK-R were assessed using antibodies against PK-R.

Results: Baseline patient characteristics show strongly reduced PK-R activity in all patient cells, in particular taking into account the degree of reticulocytosis (Table 1). Distinct metabolic changes were consistent with a block of glycolysis at the PK-R step. Treatment of PK-deficient RBCs with AG-348 resulted in increased enzymatic activity in all patient cells after 24 hours (mean increase 1.8-fold, range 1.2-3.4). Similar increases were observed in control cells (mean fold increase 2.3, range 1.2-7.1). ATP levels in PK-deficient cells increased upon AG-348 treatment (mean fold increase 2.0-2.2) in contrast to control cells (mean fold increase 1.6 fold, range 1.4-1.8). Generally, PK-R thermal stability was strongly reduced in PK-deficient patient cells, illustrated by a mean loss of activity of 72% (19% for control cells) after incubation at 53 °C for 60 minutes. Ex vivo treatment with AG-348 prior to incubation resulted in residual activity of 4 to >10-fold higher than residual activity of vehicle-treated samples. Baseline protein level analyses suggest that a certain level of PK-R protein is required for cells to respond to AG-348 treatment ex-vivo, as treatment effects were minimal in patient cells with very low or undetectable levels of PK-R. In approximately half of the patients, ex vivo treatment with AG-348 was associated with an increase in RBC deformability, although there doesn’t appear to be a clear correlation with enzymatic or metabolic response.

P615

IDENTIFICATION OF NEW PATHOGENIC MUTATIONS IN PATIENTS WITH RED BLOOD CELL MEMBRANE DISORDERS USING NEXT-GENERATION SEQUENCING

M.D.M. Mañu Pereira1,*, E. LLaudet Planas1, V. Rizzuto1, J. L. Vives Corrons1

1Red Blood Cell Pathology And Hematopoietic Defects, Josep Carreras Leukaemia Research Institute, Barcelona, Spain

Background: Red blood cell (RBC) membrane proteins deficiency or structural alterations lead to RBC membrane disorders such as hereditary spherocytosis, hereditary elliptocytosis or hereditary xerocytosis among others. Genetic analysis of these patients was not usually performed before next-generation sequencing (NGS). Recently, NGS has been used to sequence the entire proteome of RBCs by Sanger et al. among several membrane related genes, considering that they all contain a high number of coding regions.

Aims: The aim of this study is to perform the molecular diagnosis of the patients included in the study as well as to identify new pathogenic mutations leading to RBC membrane disorders.

Methods: 116 patients from 74 unrelated families were studied with a next generation sequencing (NGS) based panel that contained genes already described as disease causing for RBC membrane disorders (ANK1, EPB41, EPB42, SLCA4A, SPTA1, SPTB, PIEZO1, KCNN4, RHAG) as well as for enzy- morrhages (ADA, AK1, ALDOA, BPGM, CYB5A, G6PD, GCLC, GPI, GSR, GSS, HK1, NT5C3A, PFKM, PKG1, PKLR, TPI1), hemoglobinopathies (HBA1, HBA2, HBB) and congenital diserithrocytic anemias (CDAN1, C15orf41, SEC23B, KLF1, GATA1, KIF23). The patients analysed were oriented as hered- itary spherocytosis (63 patients), hereditary elliptocytosis or piroplikocytosis (11 patients) and hereditary xerocytosis (3 patients). There were also 42 patients who were the combination of phenotypic laboratory results was suggestive of mem- branopathy but it didn’t suggest any specific RBC membrane pathology.

Results: A total of 74 pathogenic variants leading to RBC membrane disorders were identified, of which 14 had already been reported as disease causing. Of the remaining 60 variants, 42 had never been identified neither by 1000G or ExAC projects and therefore are novel mutations. Beta-spectrin, ankyrin and alpha-spectrin were the proteins that gathered most part of the mutations, we identified 23 variants in SPTB, 20 variants in ANK1 and 16 variants in SPTA1. 48% (36/74) of the identified variants were missense changes, mostly from SPTB gene (11 genes), while a 38% (28/74) of the variants were nonsense mutations, mostly from SPTA1 (12 variants) and SPTB (9 variants). Of special interest, only 2 variants were identified in more than one unrelated family: 1) SPTB c.647G>A, leading to spherocytosis, was identified in 8 patients of 2 unrelated families, 2) SPTA1 c.460-462dupTG, leading to elliptocytosis, was identified in 6 patients from 5 different unrelated families.

Summary/Conclusions: According to the results, there is a high genetic het- erogeneity in patients with RBC membrane disorders, as almost each family carries a unique mutation that is not observed in any other no related family. The present study reveals the usefulness of NGS panel, which allows the molecular diagnosis of almost the 90% of the patients and it would avoid mis- diagnosis in some cases that could lead to splenectomy in patients with inactive hereditary xerocytosis. Moreover, the 11% of undiagnosed patients will be ana- lyzed through a second NGS gene panel including potential new genes leading to chronic haemolysis and/or sequenced by whole exome sequencing with the aim to identify new disease causing genes.

Background: Autoimmune hemolytic anemia (AIHA) is greatly heterogeneous, from mild/compensated to life-threatening, due to autoantibody class/thermal amplitude, efficiency in activating complement, activity of the reticuloendothelial system, and efficacy of bone marrow compensatory response.

Aims: Here we analysed predictors of first relapse, complications, and fatality in a large AIHA series.

Methods: We retrospectively studied 378 patients (135m and 243 F, median age 51 years, range 19-100 years) on 150 sites, followed up from 10 months to 9 years (range 0.5-27). Patients were classified in warm (w)AIHA (DAT positive for IgG and IgG+C), cold agglutinin disease, CAD (C), mixed (IgG+C with high titer cold agglutinins) and atypical (DAT-, IgA+, wIgM). Cases were also grouped in very severe (Hb<6 g/dl), severe (Hb 6-8 g/dl), moderate (Hb 8-10 g/dl) and mild (Hb>10 g/dl). LDH was expressed as fold increase upper the limit of normality (ULN), and reticulocytes as absolute count and reticulocyte index. The following the- rapy lines were considered a) steroids +/-IVg, b) rituximab c) splenectomy, d) immunosuppressive drugs (azathioprine, cyclophosphamide, cyclosporin), and e) transfusions, plasma exchange, erythropoietin.
Results: Table 1 shows clinical and laboratory characteristics of AIHA cases at onset and distribution of thermal types. Hb values were significantly lower in IgG+C wAIHA and atypical cases (p<0.001). LDH higher in IgG+C wAIHA, mixed and atypical forms (p=0.01), and Hb and LDH values were negatively correlated (r=-0.25, p=0.001). Absolute reticulocytes were reduced in CAD, mixed and IgG+C wAIHA (p<0.001) together with inadequate reticulocytosis (p=0.01). Moreover, the reticulocyte index was lower in cases with Hb<6 g/dL (65 vs 98, p=0.001), along with more frequent inadequate reticulocytosis (87 vs 70%, p=0.01). First line therapy was administered in almost all cases but 25 CAD. A second therapy line was mostly required in IgG+C wAIHA, mixed, and to a lesser extent in CAD (p=0.005). The ultra-refractory cases requiring 4 or more lines of therapy were mainly mixed, atypical and CAD. Considering anemia severity, patients with Hb>8 g/dL more frequently required treatment after first-line (51 vs 33%, p=0.004; p=0.03), or even 3 or more therapy lines (52/71, 73% vs 19/71, 26%, p=0.001). The following hazard ratios (HR) emerged from multivariate Cox regression analysis: HR 3.2 (95% CI 1.4-7.2, 2.9 (1.4-6.2), 3.4 (1.6-7.5), for Hb <6, 6-8, and 8-10 g/dL compared to patients with Hb >10, respectively.As regards complications, infections were observed in 14% of cases, mostly mixed AIHA (p=0.02); thrombosis occurred in 10% and acute renal failure in 3% of patients, with no relationship with AIHA type/Hb values. Evans’ syndrome was more frequent in mixed or atypical cases (p=0.04) and in severe forms (74% with Hb<8 g/dL vs 26%, p=0.005), and was associated with higher relapse risk (HR 2.3, 95% CI 1.4-3.9). Seventy patients died during the follow-up, and 12 because of AIHA-related acute complications. Higher mortality was observed for infections (HR 5.8, 95% CI), acute renal failure (HR 7.6, 95% CI) and Evans’ syndrome (HR 8.3, 95% CI).

Summary/Conclusions: In conclusion, we found that severity of anemia at onset was the major determinant of relapse risk. The lowest Hb levels were observed in patients with IgG+C wAIHA and atypical cases along with higher LDH levels and inadequate reticulocytosis, advising strict clinical observation in these patients.

P617

HEME BINDS ANNEXIN-A5 DURING HEMOLYSIS AND PREVENTS ITS INTERACTION WITH CELL MEMBRANE PHOSPHATIDYLSERINE DURING SICKLE CELL DISEASE

S. Sadoudi1, S. Le Jeune2, D. Charue1, L. Kiger3, L. Roumenina4, C. Boulanger1, O. Blanc-Brude1,*
1INSERM UMRs970 ParCC, INSERM, Paris, 2Hôpital Avicenne, Médecine Interne, Assistance Publique-Hôpitaux de Paris, Bobigny, 3Institut Mondor de Recherche Biomédicale, Hôpital Henri Mondor, INSERM, Créteil, 4Centre de Recherche des Cordeliers, INSERM, Paris, France

Background: Intravascular hemolysis, such as in sickle cell disease (SCD), is characterized by damaged red blood cell and tissue injury. Stressed leukocytes, platelets, endothelial and red blood cells shed microparticles (MP) that bear externalized phosphatidylserine (PS) at their surface and promote tissue injury. Conversely, intracellular annexin-A5 acts as an inhibitor of externalized PS, and at the surface of cells and MP Annexin-A5 is thought to orchestrate vesicle trafficking, promote cell membrane repair, protect against PS-mediated effects and enforce anti-inflammatory and anti-thrombotic control.

Aims: We investigated a possible functional relationship between intravascular hemolysis and annexins. We hypothesized that annexins, and annexin-A5 activity in particular, is blocked by intracellular hemolysis as it is released in plasma during intravascular hemolysis.

Methods: In order to test the heme-annexin-A5 relationship, we measured PS+, PS+, CD235a+ and annexin-A5+ circulating MP in adult SCD patient and matched control plasmas. We explored annexin-A5 expression in plasma and blood cells by Western blots and ELISA, and also quantified the PS-binding functionality of plasma annexin-A5 using a self-designed immunocapture assay and purified PS+ MP. Moreover, we investigated molecular interactions between purified heme and recombinant human annexin-A5 by surface plasmapheresis, Biochip and Protein A electrophoresis. Finally, we put forward a model of heme-annexin-A5 docking by 3D molecular rendering.

Results: Immunocapture of plasma annexin-A5 revealed an association with heme (Abs398 nm signature) during SCD, especially during acute hemolytic events. In SCD plasma, we found increased total annexin-A5, but virtually undetectable amounts of functional annexin-A5, contrary to controls. This implied a greatly reduced ratio of functional annexin-A5/circulating PS+ MP. Moreover, purified heme bound readily to annexin-A5 with relatively high affinity in vitro, as demonstrated using absorbance shift, autofluorescence quenching and plasmapheresis surface resonance assays, with human serum albumin and hemopexin in competition for functional annexin-A5. In addition, which also produced a significant red-shift in heme absorbance wavelengths, implying that a tight and direct molecular interaction was possible. Hemoglobin and heme also triggered annexin-A5 aggregation in vitro, producing high molecular weight and heat-resistant multimers, observed by western blot. Surface plasmapheresis studies revealed that annexin-A5 attaches several sites for heme binding, some with very low affinity, while others are estimated with a Kd in the 10-6m range, rather similar to that of albumin. Part of the heme bound to annexin-A5 remained in place, even in the subsequent addition of the high-affinity heme-scavenger hemopexin. 3D molecular docking rendering suggested that heme may bind to the heme-binding surface of annexin-A5, thereby preventing further interactions with PS. Finally, heme completely prevented the binding of exogenous annexin-A5 to purified PS+ MP and plasma MP, as well as their subsequent detection by flow cytometry.

Summary/Conclusions: Together, our data suggest that PS-neutralizing annexin-A5 is inhibited by cell-free heme. This heme-mediated inhibition of annexin-A5 may display physiopathological relevance, contribute to the accumulation of PS+ MP in plasma during intravascular hemolysis, and more specifically of RBC MP during SCD which can participate to the degradation of the vascular function.
Sickle cell disease (SCD) is characterized by chronic hemolysis and inflammation. Elevated levels of erythropoietin (EPO) drive expansion of erythropoiesis to compensate for increased red cell destruction. EPO is produced in response to anemia and tissue hypoxia. Previous studies in SCD suggest that EPO is inappropriately low for the degree of anemia but the reasons are unclear.

**Aims:** To perform a retrospective analysis of data collected as part of routine clinical care to examine the relationship between serum EPO and degree of anemia, HbF levels, oxygenation status, hemolytic rate, alpha globin status, inflammation, serum ferritin and renal function.

**Methods:** King's College Hospital (London, UK) has a large SCD population. All patients with HbSS or HbSB0 thalassemia who had a serum EPO level measured between 2007 and 2013 were included. Sickle genotype, alpha genotype, “baseline” HbF (no hydroxycarbamide, transfusion or pregnancy) and demographic data were recorded. Other clinical variables were obtained from the same day as EPO levels (medications, laboratory values and oxygen saturation). Serum EPO was measured by chemiluminescence immunoassay (Siemens Immulite XP). Exclusion criteria were: active vaso-occlusive crisis, transfusion within 8 weeks, chelation, erythropoiesis stimulating agent therapy, home oxygen, pregnancy and renal disease (eGFR<60mL/min or urine albumin creatinine ratio>30). Data analysis was performed in IBM SPSS Statistics 22. Skewed variables were log transformed and estimated GFR was calculated using the MDRD formula. Normalized variables were correlated with Ln EPO using Pearson’s correlation, ordinal variables using one way ANOVA, and binary variables using independent samples 2-tailed t-test. Multivariate linear regression using Ln EPO as the outcome was performed.

**Results:** 245 adult (≥17 years) SCD patients (all of African or African-Caribbean origin) met the inclusion criteria. Of the 245, 241 had HbSS and 4 HbSβ0, 100 had αα/αα, 1 αα/ααα. Univariate analysis revealed a weak/moderate negative association between Ln EPO and Hb (r=-0.383, p<0.001). Significant associations were also seen between Ln EPO and negative correlation with FV, oxygen saturations, Ln HbF, and positive correlation with Ln CRP, LDH, STFR, Ln uACR, cystatin C. One way ANOVA showed alpha globin status to be associated with EPO (higher EPO with more alpha chains). There was no significant association between EPO and: age, sex, eGFR, white cell count, and use of hydroxycarbamide. Multivariate linear regression (N=175) revealed alpha globin status, Hb, CRP and HbF remained independently associated with Ln EPO level, see table.

where alpha= 0 if aa/aa; 1 if aa/aα; 2 αa/aα

**Summary/Conclusions:** In our SCD cohort without renal dysfunction EPO was elevated. Unlike the non-sickle setting where Ln EPO is very strongly (negatively) correlated with Hb levels, in our SCD cohort we have found only a mild/moderate correlation. Instead, additional associations were seen between EPO and alpha globin status, CRP and HbF. Our findings suggest that in addition to Hb, other SCD severity markers influence EPO production. This may provide explanation for relative EPO deficiency, and have implications for considering therapeutic EPO in SCD.
Gene therapy, cellular immunotherapy and vaccination

Background: Adult T cell leukaemia/lymphoma (ATL) is an aggressive peripheral T-cell neoplasm caused by HTLV-1 virus infection and its prognosis remains very poor. Tax, which is the most important regulatory protein of HTLV-1, is associated with angiogenesis, cell proliferation, and is also a biomarker antigen for CD8+ cytotoxic T-cells (CTLs). We previously analyzed the Tax-specific T-cell receptor (TCR) repertoire, phenotypes and functions of Tax-specific CTLs at the single-cell level in HLA-A24+ ATL patients who underwent allogeneic stem cell transplantation (allo-SCT). We found that a particular amino acidic sequence motif (PDR) in the CD8αβ TCR γδ region of TCR-S was conserved in different patients and also within the same patient before and after allo-SCT, and the PDR+ Tax-specific CTL clone selectively expanded in ATL long-term survivors as less-differentiated effector memory CTLs. Actually, the PDR+ CTL showed not only strong binding activity for the Tax-tetramer but also strong killing activity against patients’ HTLV-1-infected T-cells without any reaction against normal cells.

Aims: Currently, we are planning a redirected T-cell immunotherapy using the PDR+ TCR genes for ATL. Therefore, we prepared donor-derived PDR+ TCR-transduced T-cells and evaluated their cytotoxic efficiency against HTLV-1-infected T-cells and ATL-cells both in vitro and in vivo mouse model.

Methods: HLA-A24-02 restricted and Tax301-309-specific TCR-β/γ genes were cloned from an established PDR+ CTL clone and integrated into a retroviral siTCR vector (Tax-siTCR vector) encoding small-interfering RNAs (siRNAs) to knockdown endogenous TCR genes for the efficient expression of therapeutic TCRs. Then, CD8+ T-cells of healthy volunteers were transfected with Tax-siTCR vector (Tax-si CTLs). First, cytotoxicity and cytokine production capability of the Tax-si CTLs against HTLV-1-infected T-cells or ATL-cells were evaluated using calcine-AM-based assay and flow-cytometric analysis, respectively. Next, to evaluate the in vivo anti-CTL effects by the Tax-si CTLs, the bioluminescence assay (in vivo imaging system) was performed. We generated a luciferase gene-transduced HLA-A24+ HTLV-1 infected cell-line, MT-2 (Luc-MT-2), and injected 1×105 Luc-MT-2 cells into six-week-old NOD/Shi-scid, IL-2RγKO Jic (NOS) mice intraperitoneally. After 3 weeks, 2×106 Tax-si CTLs were administered systemically. For comparison, non-integrated T-cells (Mock) were administered in the same way. These mice were monitored for tumor growth using IVIS system weekly.

Results: Tax-si CTLs showed specific and strong killing activity against both HTLV-1 infected T-cells and patients’ ATL-cells without any reaction against control normal-cells. In addition, Tax-si CTLs produced a sufficient amount of cytokines such as IFN-γ, TNF-α, and IL-2 against HTLV-1 infected T-cells. In mice experiments, the bioluminescence of Luc-MT-2 in the mice treated with Tax-si CTLs had started to reduce gradually after 7 weeks, and finally became undetectable after 9 weeks. In addition, macroscopic anatomical findings in the treated mice were normal after 12 weeks. In contrast, the amount of bioluminescence in the mice treated with Mock or in the control mice without treatment had rapidly increased and all mice died by 9 weeks.

Summary/Conclusions: We confirmed that Tax-si CTLs could exert a strong anti-ATL effect without significant reaction against normal cells both in vitro and in vivo. The therapy using this PDR+ Tax-si CTLs has the potential to be a novel immunotherapy for ATL patients.

NHEJ-BASED GENE EDITING: A NOVEL GENE THERAPY APPROACH IN FANCONI ANEMIA HEMATOPOETIC STEM AND PROGENITOR CELLS
F.J. Roman-Rodriguez1,2,3, B. Diez1,2, L. Alvarez1,2, C. Risueno1,2, R. Torres-Ruiz3, M. Corton3, C. Diaz de Heredia4, J. Sevilla5, C. Ayuso5, J. Bueren1,2, P. Rio1,2
1Division of Hematopoietic Innovative Therapies, CEMAT/CIBERER, 2Advanced Therapies Unit, IIS-Fundacion Jimenez Diaz (IIS-FJD, UAM), 3Molecular Cytogenetics Group, Human Cancer Genetics Program, Centro Nacional de Investigaciones Oncologicas, Madrid, 4Department of Haematology and Oncology, Hospital Universitario Vall d’Hebron, Barcelona, 5Onco-Hematologia Pediatrica, Hospital del Niño Jesús, Madrid, Spain

Background: Allogenic transplantation of hematopoietic stem and progenitor cells (HSPCs) is the only current curative treatment for the bone marrow failure of patients with Fanconia Anemia (FA). However, the risks of GVHD and increased incidence of subsequent cancer, and the limited availability of matched donors hamper the application of this therapy in FA patients. For this reason correction of patients’ HSPCs by gene therapy is considered a promising therapeutic alternative for these patients. In this context, gene editing constitutes a new step in the development of safe gene therapy approaches. Since non-homologous end joining (NHEJ) is the preferred DNA repair mechanism in HSPCs, and given that the FANCA protein is a major regulator of this process, we have tested the efficiency of a NHEJ-mediated gene editing approach to generate compensatory mutations that can restore the FANCA protein function in HSPCs from FA patients, mimicking reversions observed in mosaic patients.

Aims: To demonstrate the feasibility of using a NHEJ-based gene editing strategy to correct FA-A HSPCs as a result of the insertions and deletions (INDELS) generated in edited FANCA sequences in these cells.

Methods: Two different FANCA mutations from FA-A patient-derived lymphoblastic cell lines (LCLs) and primary HSPCs were targeted by the CRISPR/Cas9 system. INDELS generated as a consequence of the NHEJ activity were assessed at different time points.

Results: Initial studies conducted in a FA-A LCLs carrying the biallelic c.295C>T point mutation that generates a premature stop codon (p.Q99X) showed targeting efficiencies around 20%. Next Generation Sequencing (NGS) not only revealed the presence of frame-restoring repair events, but also that these events were not limited to patients’ cells but also extended to the edited cells. Moreover reversion of the characteristic MMC hypersensitivity and restoration of the FANCD2 foci formation were observed in these cells. In addition, western-blot analysis confirmed the stable expression of FANCA protein. To further demonstrate the feasibility of the approach, a second FANCA mutation was targeted (c.3558insG, producing a frameshift and a premature stop codon -p.R1187fsX28-) with even higher gene targeting efficiencies. Finally similar studies were conducted in three HSPCs samples from FA-A patients harboring the c.295C>T mutation, that showed targeting efficiencies up to 36%. Moreover, NGS detected the presence of corrective NHEJ-repair events immediately after editing and evened up to 50-fold expansion of corrected cells after nine days in culture, confirming the functionality and proliferative advantage conferred by the frame restored alleles.

Summary/Conclusions: Our results demonstrate for the first time that NHEJ gene correction is feasible in FA HSPCs. The high efficacy of the NHEJ repair pathway in HSPCs together with the simplicity of the strategy, may extend this approach clinically relevant for the future treatment of the hematopoietic defects in FA patients.
phoma patients. The manufacturing process consistently allows high CAR transduction efficiency of iNKT and T cells (75.31%±4.29 and 76.95%±14.76 respectively, n=8) and ensures the preservation of CD4– iNK cells, which have a higher cytotoxic potential and anti-tumour activity. In vitro validation, using singly- or dual-positive CD19 and CD19 targets, demonstrated that CARiNKT19 cells are CD19-specific, retain their natural CD19 restricted cytotoxicity and exert additive dual-specific cytotoxicity against CD19+CD19+ targets. Additional functional dissection showed that activated CARiNKT19 cells, both fresh and cryopreserved, have the ability to produce cytotoxic granules and IFNγ faster and in larger amounts than same donor activated CART19 cells. Likewise, CAR2- and CAR3-iNK cells are equally or more effective than their CART counterparts in killing CD19+CD19+ lymphoid and leukemia cell lines (B-lymphoblastoid 1CR1DCD and lymphoma-derived Farage cells) and consistently more effective against primary MCL, MZL and CLL cells. Finally, in an in vivo NSG xenograft model of lymphoma, while survival of T- and iNK cell-treated animals was the same as that of untreated animals (P<0.20), both CART19- and CARiNKT19 cell-treated animals had significantly and comparably improved overall survival (P<0.001). However, compared to CART19, CARiNKT19 immunotherapy led to a better disease control, with earlier, more profound and sustained responses resulting in a significantly improved tumour-free survival (P<0.03).

Summary/Conclusions: In our pre-clinical in vitro and in vivo lymphoma models, CARiNKT19 are more effective than CART19 cells against CD19+CD19+ B cell malignancies. Further, dual targeting by CARiNKT19 cells may mitigate against CD19-focused tumour escape after CAR immunotherapy, while the previously demonstrated role of donor iNK cells in protection from gVHD supports the development of CARiNKT19 cells for ‘off-the-shelf’ use.

P625
A NOVEL CHIMERIC ANTIGEN RECEPTOR ENDOWS T CELLS WITH NK CELL-LIKE SPECIFICITY AND ATTACKS A WIDE RANGE OF HEMATOLOGICAL MALIGNANCIES AND CANCERS
Y. Kasahara1,*, C. Shin1, M. Imamura1, N. Kubo1, T. Takachi1, H. Iwabuchi1, S. Yoshida1, A. Saitoh1, C. Imai1
1Department of Pediatrics, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan

Background: Engineered T-cells expressing CD19-specific chimeric antigen receptors (CARs) have shown high response rates against relapsed and refractory B cell acute lymphoid leukemia (ALL). However, similar success has not yet been demonstrated in solid tumors, and the reasons for this are currently being investigated. One major obstacle is the difficulty in determining appropriate surface antigens that are effectively targeted by CAR-transduced immune cells. Nkp44 is an activating receptor on human NK cells that is only expressed when the NK cells are activated, and which confers a marked increase in cytotoxic activity against various tumors. Ligands for Nkp44 have been reported to be expressed in various types of cancers, but not in healthy cells. Effective use of the ligand-binding domain of this receptor as an antigen recognition site of a CAR would thus allow a wide range of cancer cells to be attacked. Aims: To determine the optimal CAR construct including the Nkp44 immunoglobulin domain as a ligand-binding domain (Nkp44-based CAR), with a view to developing effective CAR-T therapy against hematological malignancies and solid cancers.

Methods: We created several Nkp44-based CAR constructs. Human T cells from healthy donors were stimulated with anti-CD3/CD28 beads and recombinant interleukin-2. Human NK cells were stimulated with K562-mb15-41BBL fever cells, as previously reported (Imai C, 2005). Activated T cells or NK cells were then subjected to retroviral transduction with the CAR gene and the phenotypic and functional characteristics of CAR-T cells engrafted with the various Nkp44-based CARs were compared. We determined if Nkp44-ligands were present on the cell surface of various types of malignant cell lines using recombining human Nkp44 Fc chimeric protein.

Results: Screening of ligands for Nkp44 was confirmed in a wide range of tumor cell lines including acute myeloid leukemia (AML: KG-1, THP-1, U937, K562, Kasumi-1, Kasumi-6), T-cell ALL (MOLT-4, HSBS, Peer, Jurkat), B-cell ALL (OP-1), Burkitt’s lymphoma (Raji), osteosarcoma (NOS-10, NOS-1, NOS-2, SauO2-2, U2OS-mg63), rhabdomyosarcoma (RMS-YM, Rh28), and neuroblastomas (NB1, NB16, IMR-32, SK-N-SH). Different expression levels of CAR were observed among the Nkp44-based CARs created in this study, in which the major CAR domains, except for the ligand-binding domain, were derived from various components including Nkp44, CD8a, CD28, or CD3ζ. A combination of the hinge domain from Nkp44, transmembrane domain from CD28, and extracellular domain from CD3ζ yielded the highest surface expression of CAR on both T cells and NK cells. T cells transduced with this CAR showed enhanced cytotoxicity against various target cells including AML, T-cell ALL, and B-cell ALL, but did not attack normal T cells. CAR-T cells also showed increased production of interferon-gamma and granyme B. The hinge domain of CD3ζ was suggested to play a role in ligand binding (Koch J, 2013), but the details are poorly understood. Intriguingly, replacement of the hinge domain from Nkp44 significantly reduced cytotoxic function, though CAR expression levels remained similar.

Summary/Conclusions: T cells transduced with Nkp44-based CARs show enhanced activities against various tumor cells. The extracellular hinge region of Nkp44 appears to play an important role in ligand binding and/or recognition. Nkp44-based CARs may represent a promising candidate for novel immune therapies targeting a wide range of cancers.

NKP30-CAR REDIRECTED HUMAN T LYMPHOCYTES INDUCE POTENT ANTITUMOR IMMUNITY TO LEUKEMIA CELL LINES AND PATIENT- DERIVED ACUTE MYELOID LEUKEMIA IN NSG XENOGRAFT MODELS
P. Pich1, S. A. Khan3, M. Theobald1, U. Hartwig4
1III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany
2German Cancer Consortium (DKTK), partner site Frankfurt / Mainz, German Cancer Research Center (DKFZ), Heidelberg, 3Research Center for Immunotherapy (FZI), University Medical Center Mainz, Mainz, Germany

Background: Adoptive cellular therapy (ACT) of chimeric antigen receptor (CAR) redirected T cells has evolved as a highly effective individualized immunotherapy for leukemia and solid cancer. In particular, clinical trials using CD19 expressing T lymphocytes to combat CD19+ lymphomas have revealed compelling results. However, suitable antigens for an effective and specific CAR-mediated therapy to acute myeloid leukemia (AML) are still warranted as e.g. CD33 and CD123 CAR expressing T cells induce potent immune responses, while CD19 CAR expressing T cells are not feasible due to their presence in normal tissues and exposure to natural killer (NK) cell activating receptors NKp30. Moreover, NKp30 recognizes human leukocyte antigens (HLA)-B-restricted natural cytotoxicity activating ligands B7H6 and B7H7. In contrast, B7H6, a member of the B7 family, is frequently expressed on various tumor cells including AML blasts while not detectable on normal tissues, and is recognized by the natural killer (NK) cell activating receptor NKp30. Moreover, NKp30 recognizes human leukocyte antigens (HLA)-B-associated transcript 3, a nuclear factor that is secreted and translocated to the cell surface in stressed and transformed cells. Aims: In the current study, we thus explored the use of human T cells redirected to express a NKp30-CAR for inducing effective antileukemic immune activity in vitro and in vivo. We used recently established acute leukemia cell lines K562 and primary AML blasts in NSG xenograft mouse models following ACT.

Methods: PBMCs or MACS® purified human T cells were polyclonally stimulated and reprogrammed with a CAR composed of the extracellular region of the NKp30 receptor fused to the CD3ζ chain signaling domain (kindly provided by U. Hartwig, Dept. of Internal Medicine 3, Medical University Regensburg, Germany) by retroviral gene transfer. Transduced T cells were further selectively expanded utilizing puromycin resistance present on the retroviral backbone, and NKp30 expression was determined by flow cytometry. IFNγ ELISpot analyses and cytotoxicity assays were performed to assess antileukemic responses to leukemia lines and primary AML blasts in vitro and in vivo using NSG xenografts and adoptive transfer of redirected T cells. Expression of B7H6 in target cells was confirmed by RNA-based RT PCR.

Results: Following transduction and puromycin selection ≥80% of CD3+ T cells expressed the NKp30 CAR. In addition, most T cells displayed an effector-memrory phenotype. Upon activation, the B7H6 expressing targets such as K562 and HL-60 (myelogenous leukemia cell lines), NALM 16 (pre-B-ALL) and patient-derived AML samples (e.g. M2506 and M2587) NKp30 redirected T cells elicited potent IFNγ release and exhibited cytolytic activity to both leukemia lines and primary AML blasts in vitro. These responses were specific as e.g. no reactivity to B7H6 negative myeloid line U266 was observed. We then evaluated antitumoral responses of NKp30 redirected T cells in vivo. Upon adoptive transfer of NKp30-CAR T cells into NSG mice engrafted with K562 significant reduction of tumor burden was observed. Moreover, injection of 1 - 5x106 HL-60 cells (CD33+CD123-CD19+) into NSG mice showed up to 5% engraftment of patient derived AML blasts and thus resembling a clinically relevant minimal residual disease status at time of ACT resulted in clear leukemia regression. Further experiments e.g. to elaborate to what extent CD4+ and CD8+ T cells contribute to this antileukemic immunity are in progress.

Summary/Conclusions: These studies demonstrate that human T lymphocytes can be successfully redirected to acute leukemia by NK cell activating receptor based CARs such as the NKp30-CAR. As its ligand B7H6 has not been reported to be expressed on CD3ζ+ HSC, this antigen might be an interesting target for adoptive immunotherapy to AML.

PRECLINICAL TESTING OF ADOPTIVE T-CELL RECIPIENT T CELL GENE TRANSFER IN COMBINATION WITH COMPLEMENT INHIBITORS AS A NOVEL THERAPY FOR MULTIPLE MYELOMA
H. Ecchennau01,2, E. Amann1,2, A. Antunes1, M. Theobald1,2
1Third Department of Medicine (Hematology, Oncology & Pneumology), University Medical Center Mainz, Mainz, 2German Cancer Consortium (DKTK), Heidelberg, 3Research Center for Immunotherapy (FZI), University Medical Center Mainz, Mainz, Germany

Background: Adoptive cellular therapy (ACT) based on T-cell receptors (TCR) or chimeric antigen receptor (CAR)-engineered T cells has achieved tremendous success in the treatment of cancer, especially B-cell malignancies. The
impressive therapeutic results recently obtained with checkpoint inhibitors have opened a new era in the field of cancer immunotherapy. Yet, clinical responses are still often observed either transiently or in a minority of patients. This under- scores the need for an improved understanding of underlying factors limiting the efficacy of T cell-based immunotherapy and its wide application.

Aims: We explored an immunotherapeutic combination strategy to unleash the full antitumor effect of adoptively transferred antigen-specific T cells. We propose to target multiple myeloma (MM) tumor cells in our established xenograft in vivo adoptive cell therapy model by T cells equipped with two optimized TCRs specific for HLA-A2.1-restricted MDM2 and p53 epitopes in combination with checkpoint inhibitors.

Methods: Human T cells from healthy donors were retrovirally transduced with MDM2- and p53-specific TCRs and expression levels were analyzed by flow cytometry. MDM2 and p53 protein expression in MM cell lines was determined by Western blot. The therapeutic efficacy of adoptive TCR transfer was evaluated in NOD-scid IL2R gamma chain (NSG) mice engrafted with MM cell line. In the adoptive cell transfer approach, mice were treated (i.p) with anti-CD1 (Nivolumab). Tumor growth was monitored and intratumoral alterations (in particular expression of relevant tumor and T cell antigens) in ex-vivo tumors were analyzed by flow cytometry. Tumor-infiltrating lymphocytes (TILs) were also characterized by flow cytometry.

Results: Adoptive transfer of dual MDM2/p53-specific TCR equipped T cells showed a superior anti-tumor response in vivo compared to single TCR treatment, demonstrating the need to target multiple MM antigens to circumvent tumor escape mechanisms associated with down-regulation of antigen. Yet, we observed a strong up-regulation of PD-L1 expression in tumor cells in vivo and increased PD-L1 expression in TILs which may limit the efficacy of antigen-specific TILs. Accordingly, in vivo ACT experiments combined with anti-PD-1 inhibitor, demonstrated the synergistic therapeutic potential of this approach as compared to single agent. Yet, it does not result in complete tumor eradication suggesting that targeting one single immune checkpoint receptor is not sufficient to control tumor recurrence.

Summary/Conclusions: Combination checkpoint inhibitor approach has demonstrated promising potential in our ACT experimental MM model and forms the basis for a novel multi-modal immunotherapeutic combination treatment for multiple myeloma.

ENGINEERED T CELLS TOWARDS BAFF RECEPTOR: A NOVEL STRATEGY TO EFFICIENTLY TARGET B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA N. Turazzi1,*, G. Fazio1, V. Rossi1, A. Rolink2, G. Cazzaniga1, A. Biondi3, C.F. Magnani1, E. Biagi1

1M. Tettamanti Research Center, Department of pediatrics, University of Milano Bicocca S.Gerardo Hospital/Fondazione MBBM, Monza, Italy, 2Department of Biomedicine, University of Basel, Basel, Switzerland, 3M. Tettamanti Research Center, Department of pediatrics, University of Milano Bicocca S.Gerardo Hospital/Fondazione MBBM, Monza, Italy

Background: B-cell Acute Lymphoblastic Leukemia (B-ALL) is most common in children (80%), but it has also a peak of incidence in adult age. Immunotherapeutic approaches targeting the CD19 molecule paved the way for the treatment of relapsed and refractory lymphoblastic leukemia, which remains a major therapeutic challenge. Recently, the emergence of relapses with CD19-epitope loss in 10-30% of treated patients has been reported. This newly identified escape mechanism has been recently shown to be related to the combination of deleterious mutations and emergence of alternatively spliced RNA isoforms, as effect of selective pressure. B-cell Activating Factor (BAFF) Receptor is a transmembrane protein which is fundamental for B-cell maturation and survival. Moreover, the expression of this receptor is restricted to mature B cells and, interestingly, is not present on bone marrow B-cell precursors. Recent studies reported the over-expression of BAFF Receptor (BAFF-R) in various B-cell malignancies such as B-ALL, B lymphoma, chronic lymphocytic leukemia and myeloma. In the context of B-ALL, leukemia cells express both BAFF and BAFF-R suggesting the presence of an autocrine signalling loop. BAFF is also expressed in bone marrow microenvironment by endothelial cells which support the proliferation and the survival of primary B-ALL blasts. Aims: In the current study, we aimed to develop a chimeric antigen receptor (CAR) immunotherapeutic approach targeting the BAFF-R molecule.

Methods: We characterized the expression of BAFF-R in B-ALL primary samples. As immunotherapeutic approach to target BAFF-R molecule, we developed six anti-BAFF-R.CARs that differ for the inversion of the VH and VL and the length of the spacer domain have been generated. Cytokine-induced Killer (CIK) cells, engineered using an improved Sleeping Beauty (SB) transposon system, stably expressed anti-BAFF-CAR, and maintained their characteristic phenotype. Among the newly constructed CARs, the shortest VHV anti-BAFFR CAR exerted the highest anti-leukemic activity towards target cells, such as NALM-6, with an in vitro killing activity of 72,222% (median) of the tumor cells expressing CD20+ (CD19+ and primary B-ALL blasts) compared to single population per se. Furthermore, by using a sample collected from a patient relapsed with CD19 negative disease, we demonstrated the ability of the in vivo sh.CAR to lyse CD19-negative blasts.

Summary/Conclusions: Taken together, these findings make this receptor a new attractive target for immune-based B-ALL therapy in case of relapse after CD19-targeting therapies or for a double targeted approach. Being restricted to mature B cells, but absent on precursors and plasmablasts, our strategy could have an inferior toxicity concerning the emergence of B-cell aplasia observed in patients treated with anti-CD19 CAR-modified T cells.

P629

EXPLORING HUMAN TCR- AND CAR-REDIRECTED INKT CELLS FOR ADOPTIVE CELLULAR THERAPY B. Mir1, S. Khan1, M. Theobald1, U. Hartwig1,2

1III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Hospital Mainz, Mainz, Germany

Background: T cell receptor (TCR) - or chimeric antigen receptor (CAR) redirected T cells have substantially improved adoptive cellular therapy (ACT) for various malignancies such as hematological malignancies such as B-ALL, B lymphoma, chronic lymphocytic leukemia and MM. Yet, clinical responses are still often observed either transiently or in a minority of patients. This underlines the need to target multiple MM antigens to circumvent tumor escape mechanisms associated with down-regulation of antigen. Recently, BAFF-R suggesting the presence of an autocrine signalling loop expressed in bone marrow microenvironment by endothelial cells which support the proliferation and the survival of primary B-ALL blasts might therefore be promising alternative carriers for redirected ACT or being used in combination with redirected T cells as combination immunotherapy.

Aims: In the current proof of concept study we therefore explored human, AML-reactive TCR- and CD19 CAR-redirected INKT cells for their potential to induce antitumoral responses to leukemia cell lines as well as patient derived, primary AML blasts.

Methods: INKT cells expressing the invariant TCR composed of the Vb24Jb18/Vb11 chains were immuno-magnetically isolated from PBMC derived from adult healthy donors using Vb11-Ab (6B11)-conjugated, anti-iNKT microbeads (Miltenyi Biotec) and expanded in vitro upon coculture with autologous monocytes loaded with α-GalCer (α-Galactosylceramide) (Ceruletis) loaded DC5. TCR transduced INKT cells were retrovirally transduced on day 6 after stimulation and selected for TCR or CAR expression utilizing a virally transduced puromycin resistance. While phenotypic analyses on INKT markers and on the percentage of redirected cells were performed by flow cytometry functional assays such as cytokotoxicity ELISA were performed using CD19+ NALM-16 (per B-ALL) and primary AML (M2653) cells as targets.

Results: Following isolation of 0.7 - 0.8 x 10^6 Va24/Ab18/Vb11+ INKT cells from PBMC we achieved on average a 120-fold expansion 21-28 days after stimulation with GalCer loaded, irradiated autologous DC and 25 U IL-2. Additional use of lenalidomide to promote expansion as described previously had no effect. Expanded INKT cells were mainly CD4* (83%) and about 80% of cells expressed the natural killer receptor CD161 described as INKT maturation marker but showed limited or virtually no expression of typical NK markers such as CD56 and CD16. Following retroviral transduction and selection for 6 days >80% of TCR (582)- and CD19 CAR-redirected INKT cells were obtained. Subsequent functional analyses revealed that both INKT cells expressing the AML-reactive TCR 582 as well as CD19-CAR INKT cells demonstrated substantial release of IFN-y and elicited potent antileukemic responses to AML M2653 and NALM-16 in vitro. Studies to examine their cytokotoxic potential in vivo using NSG xenograft models are currently in progress.

Summary/Conclusions: These studies demonstrate that purified human Va24/Vb11+ INKT cells expanded from PBMC can be successfully redirected against AML. Such leukemia both by the use of TCR expression. Engineered INKT cells might therefore be promising alternative carriers for redirected ACT or being used in combination with redirected T cells as combination immunotherapy.
Background: Acute Myeloid Leukemia (AML) is an aggressive malignancy still associated with high relapse rates when treated with conventional chemotherapeutic and hematopoietic transplantation regimens. In search for alternative strategies, great interest has been posed on antigen-specific immunotherapies and in particular on T cells redirected with Chimeric Antigen Receptors (CARs) that have shown exciting results in cancer therapy, especially in the context of B-cell malignancies. CD33 is the only validated target in AML so far and represents a suitable antigen to be targeted with CAR-T cells, being broadly expressed on AML blasts.

Aims: The aim of the present study is to preclinically evaluate the efficacy and safety profiles of CD33 CAR redirected Cytokine Induced Killer (CIK) cells alone and in combination with standard chemotherapeutic agents.

Methods: Here we proved the feasibility of harnessing Cytokine Induced Killer (CIK) cells as CAR-T cell counterparts with a third generation anti-CD33 CAR through the non viral Sleeping-Beauty transposon system, starting from fresh and frozen healthy mononuclear cells (PBMCs) and also from frozen primary AML samples. The in vitro anti-AML activity of CD33.CAR-CIK cells is assessed by means of cytotoxicity, proliferation and cytokine production assays upon challenge with AML cell lines and primary samples. The in vivo efficacy of CD33.CAR Cik cells is evaluated in NSG mice transplanted with AML cell lines (M4a-NRas cells) and primary samples. Moreover, to investigate the potential benefit of CD33.CAR CIK cell immunotherapy in combination with standard-of-care treatments, xenograft chemotherapy models is exploited, by using standard AML induction therapy drugs (Ara-C and doxorubicin).

Results: CD33.CAR-CIK cells were able to induce a potent anti-leukemic activity as compared to unmanipulated CIK cells, in terms of specific killing (up to 70%), proliferation (up to 40% of K67+CAR-CIK cells) and cytokine production (up to 30% for both IL-2 and IFN-gamma producing CAR-CIK cells) when challenged with both AML cell lines and primary leukemic cells. By treating M4a-NRas cell grafted mice with the already established “5+3” induction chemotheraphy protocol, we confirmed that chemotherapy is able to significantly reduce the leukemic burden from around 20% to 0.1% in the bone marrow. Since the AML disease is not totally eradicated, this model will be therefore suitable to further investigate the efficacy of the CD33.CAR-CIK cells immunotherapy on the chemoresistant/residual AML cells.

Summary/Conclusions: Having demonstrated the significant in vitro anti-leukemic activity of SB-modified CD33.CAR-CIK cells we next aim to assess their efficacy in vivo, particularly against the resistant/residual AML cells that were not eradicated by standard chemotherapy treatment. Moreover, envisaging a safer clinical translation of this immunotherapeutic approach, a transient CAR expression, by using CD33.CAR coding mRNA, is under investigation, in order to limit the potential myelotoxicity due to the long-term off-target effect on normal hematopoietic stem/myeloid progenitor cells. Finally, if successful, our results will provide the preclinical validation of CD33.CAR-CIK cell immunotherapy, supporting its development to the clinic.

P631

UPDATE ON THE FIRST PATIENTS WITH SEVERE HEMOGLOBINOPATHIES TREATED WITH LENTIGLOBIN GENE THERAPY

J.-R. Ribé1, S. Hacenin-Bey-Abina1, E. Payer2, E. Magrin1, A. Magnani1, M. Semeraro1, L. Cacciavelli1, F. Touzot3, F. Leferre1, F. Suarez1, O. Hermine1, V. Brousse1, C. Poirot4, D. Moshous1, P. Bourget1, W. El-Nemer5, P. Bartolucci1, M. Cavazzana1,6,7

1Necker Hospital, Paris, 2Institute of Emerging Diseases and Innovative Therapies (IMETI), CEA & University of Paris-Sud, Fontenay-aux-Roses, 3Université Paris Descartes, 4Hôpital Saint Louis, 5Université Paris Diderot, 6Hôpital Henri Mondor, 7Hôpital Cochin Saint Vincent de Paul, Paris, France, 8bluebird bio, Cambridge, United States

Background: Insertion of an anti-sickling β-globin gene variant into hematopoietic stem cells (HSCs) could reduce or eliminate symptoms of severe sickle cell disease (SCD) and transfusion requirements in transfusion-dependent β-thalassemia (TDT). LentiGlobin Drug Product (DP) contains autologous CD34+ cells transduced with the BB305 lentiviral vector, which encodes a human β-globin gene containing a single point mutation (AT87Q) designed to confer anti-sickling properties similar to γ-globin. We recently (ASH 2016) reported 23 months of follow-up for a patient with SCD, and 12–34 months of follow-up for 4 patients with TDT.

Aims: To evaluate the safety and efficacy of LentiGlobin gene therapy for severe hemoglobinopathies.

Methods: Patients 5-35 years old with severe SCD (e.g., ≥2 acute chest syndrome episodes or ≥2 vaso-occlusive crises [VOC] in the preceding year) or TDT (≥100 mL/kg of packed red blood cells [PRBC] per year) were enrolled. After informed consent, autologous CD34+ cells were collected and transduced with the BB305 vector. Patients underwent myeloablative conditioning with busulfan prior to infusion of transduced cells. Patients were then monitored for hematologic engraftment, vector copy number (VCN), genetically engineered hemoglobin (HbA187Q) levels, and adverse events (AEs). Disease-specific assessments included transfusion requirements for TDT, or VOCs and hospitalizations for SCD.

Results: As of 9 September 2016, 1 patient with severe SCD (male; 13 years old) and 4 patients with TDT (2 male, 2 female; 16–19 years old) have received LentiGlobin DP in Study HGB-205. The median DP cell dose was 8.9 (range 5.6-13.6) x10^6 CD34+ cells/kg with a DP VCN of 1.2 (range 0.8–2.1) vector copies/diploid genome. Median post-infusion follow-up was 22.9 months (range 11.6-33.5). All subjects engrafted successfully with median time to neutrophil engraftment of 17 (range 14-38) days. Within patients, VCN in peripheral blood remained generally consistent from Month 3 (range 0.3–3.3 at last measurement). The toxicity profile was consistent with myeloablative conditioning with single-agent busulfan, with no ≥ Grade 3 DP-related AEs or serious AEs and no evidence of clonal dominance reported to date. The patient with severe SCD who, prior to study enrollment, received regular RBC transfusions, experienced no clinical symptoms or complications of SCD in the 21 months since treatment. At Month 21, his total Hb was 13.1 g/dL, with 6.2 g/dL HbA187Q (48%) and 6.5 g/dL sickle Hb (HbS: 50%); in addition, their unconjugated bilirubin, lactate dehydrogenase and reticulocyte count had dropped by 50%, 55%, 26%, respectively, compared to screening. Of the 4 patients with TDT, 3 have β0/βE genotypes and 1 is homozygous for a severe β+ mutation (IVS1 nt 110 G>A). Two of the β0/βE patients have completed their 2-year primary follow-up and entered a long-term follow-up study. They have been without RBC transfusions for 33 and 30 months, with total Hb of 10.9 and 13.5 g/dL, and HbA187Q of 7.7 and 10.1 g/dL, respectively. The third patient with a β0/βE genotype has 12 months follow-up and has not required transfusions since 4 days post-LentiGlobin DP infusion, with total Hb 11.3 g/dL and HbA187Q of 8.6 g/dL. The patient with the IVS1 genotype has 15 months of follow-up and has been free of transfusions for 11.6 months, with total Hb 8.3 g/dL and Hba187Q of 6.7 g/dL. Since September 2016, 2 more patients with severe SCD have received LentiGlobin DP.

Summary/Conclusions: Data to date from this ongoing Phase 1/2 clinical study suggest that treatment with LentiGlobin DP elicits sustained Hba187Q levels, which alleviate the clinical and biochemical effects of severe SCD and TDT, with safety consistent with myeloablative conditioning. Follow-up data on the 5 previously reported patients and early results from the 2 recently treated patients will be presented.
A SINGLE INSTITUTIONAL EXPERIENCE OF 261 PATIENTS WITH LARGE GRANULAR LYMPHOCYTIC LEUKEMIA

M. Van den Bergh1, L. Isenalumhe1, E. Wang2, B. Schable1, Z. Ma3, L. Zhang4, L. Zhou1, L. M. Van den Bergh1*

1University of Alabama Birmingham, Birmingham, AL, 2Indiana Blood & Marrow Transplantation, LLC, Indianapolis, IN, 3Hematology/Oncology Associates of Treasure Coast, Port St Lucie, FL, 4University of Michigan, Ann Arbor, MI, 5Hackensack University Medical Center, Hackensack, NJ, 6Cleveland Clinic Health System Cancer Institute, Greenville, SC, 7Department of Medicine-Gastroenterology, Cleveland, OH, 8Utah Cancer Specialists-Network, Salt Lake City, UT, 9University of Arizona Cancer Center, Tucson, AZ, 10Incyte Corporation, Wilmington, DE, 11Karmarnos Cancer Center, Detroit, MI, United States

Background: Large granular lymphocytic leukemia (LGLL) is a rare clonal lymphoproliferative disorder of post-thymic T-cell or natural killer (NK)-cell lineage associated with cytopenias, splenomegaly, autoimmune disorders, and recurrent mucocutaneous infections. Treatment is dictated by the presence of these manifestations and consists of immunosuppressive therapy.

Aims: The main aim of this study is to evaluate clinical features, hematological parameters, and survival data of patients with LGLL. The secondary aim is to assess response rates and duration of response to various first line immunosuppressive therapies in LGLL.

Methods: This is a retrospective analysis of clinical and laboratory features, treatment modalities, and outcomes of LGLL patients evaluated at Moffitt Cancer Center between January 1, 1995 and May 1, 2016. Continuous and categorical variables were tested via Kruskal-Wallis ANOVA and Fisher’s Exact Test, respectively. Kaplan-Meier curves were used for overall survival (OS), P-values were two-sided with significance set at <0.05.

Results: We identified 261 patients with LGLL (91.6% T-cell, 8.4% NK-cell). Median age was 66 years [21-90] and M:F ratio was 1:2.1. Median follow up was 3.07 years [0-21.88]. 42.9% of LGLL patients presented with anemia, 37.1% with neutropenia, 30.7% with thrombocytopenia, 29.1% with bicytopenia and 6.9% with pancytopenia. Transfusion dependence was noted in 20.3%, splenomegaly in 27.6%, and bone marrow involvement in 69.3%. 24.9% had autoimmune diseases and 9.2% had autoimmune cytopenias. 45.6% were observed while the remainder required at least one line of therapy. 5-year and 10-year OS were 75.0% and 63.1%, respectively. There was no statistically significant difference in OS, complete response rate or duration of response based on first line agent (methotrexate, cyclophosphamide, cyclosporine A).

However, there was a statistically significant improved partial response with methotrexate versus other therapies (p=0.01). A marginally significant association between severe anemia/transfusion dependence and poor overall response rate (p=0.079) to any immunosuppressive therapy was noted. There was no statistically significant difference in OS based on absolute LGLL count. Mean number of therapies was 1.08 (range 0-6) and was higher in patients with LGLL count <0.5 k/μL (p=0.0078), bone marrow involvement (p<0.0001), and splenomegaly (p<0.0001).

Summary/Conclusions: In this large retrospective study, we described the frequency of LGLL-associated manifestations and their impact on the course of LGLL. Severe anemia/transfusion dependence, lower LGLL counts, bone involvement, and splenomegaly were suggestive of more aggressive disease. We confirmed that there is no difference in overall survival among first line immunosuppressive therapies.

ONGOING PHASE 1/2 STUDY OF INCBO50465, A SELECTIVE PI3K-DELTA INHIBITOR, FOR THE TREATMENT OF PATIENTS WITH RELAPSED/REFRACTORY B-CELL MALIGNANCIES (CIITADEL-101)

A. Forero-Torres1,*, L.P. Akard2, M.S. Wertheim3, T.J. Phillips4, M.E. Gutierrez5, S. Yeleswaram11, R. Ramchandren12

1University of Alabama Birmingham, Birmingham, AL, 2Indiana Blood & Marrow Transplantation, LLC, Indianapolis, IN, 3Hematology/Oncology Associates of Treasure Coast, Port St Lucie, FL, 4University of Michigan, Ann Arbor, MI, 5Hackensack University Medical Center, Hackensack, NJ, 6Cleveland Clinic Health System Cancer Institute, Greenville, SC, 7Department of Medicine-Gastroenterology, Cleveland, OH, 8Utah Cancer Specialists-Network, Salt Lake City, UT, 9University of Arizona Cancer Center, Tucson, AZ, 10Incyte Corporation, Wilmington, DE, 11Karmarnos Cancer Center, Detroit, MI, United States

Background: INCBO50465 is a novel, potent, and highly selective PI3Kδ inhibitor of PI3Kδ (≤25-fold more selective for PI3Kδ vs other isoforms). INCBO50465 demonstrated linear pharmacokinetics (PK) and achieved exposure levels several-fold greater than the IC50 for PI3Kδ inhibition at the recommended phase 2 dose (ASH 2016; Abstract 4195).

Aims: To evaluate INCBO50465 in patients with relapsed or refractory B-cell malignancies enrolled in an ongoing phase 1/2 study (NCT02018881).

Methods: In this phase 1/2 study, eligible patients (≥18 years of age) had relapsed/refractory lymphoid B-cell malignancies (excluding Burkitt’s lymphoma and precursor B-cell lymphoblastic leukemia/lymphoma), Eastern Cooperative Oncology Group performance status score ≤2 (≤1 during dose escalation), normal liver and kidney function, and had not received autologous hematopoietic stem-cell transplant (HSCT) within 3 months or allogeneic HSCT within 6 months of screening. The protocol was initiated with a single-patient cohort, treated with oral INCBO50465 5mg QD. Subsequent cohorts used a 3+3 design and evaluated doses of 10–45mg QD. Based on PK/pharmacodynamics, the 20 and 30mg QD cohorts were expanded. Responses were assessed every 9 weeks using the Lugano Classification or International Working Group on Chronic Lymphocytic Lymphoma (CLL) criteria.

Results: As of the data cutoff (Nov 1, 2016), 52 patients were treated (median age, 65 years, range 22–86). Baseline disease subtypes included diffuse large B-cell lymphoma (DLBCL; n=14), follicular lymphoma (FL; n=10), Hodgkin lymphoma (HL; n=9), marginal zone lymphoma (MZL; n=8), CLL (n=6), and mantle cell lymphoma (MCL; n=5). Sixty-two percent (n=32) of patients had ≥3 prior systemic regimens; 31% (n=16) had prior HSCT. Median duration of therapy was 8 months (range, 0–13; 4); no DLTs were identified. Sixty-seven percent of patients discontinued therapy, most commonly due to disease progression (31%) and AEs (25%). Thirty-three percent of patients had dose interruption and 4% had dose reduction. Most common nonhematologic AEs (all grade; grade ≥3) were nausea (38%; 0%), diarrhea (31%; 6%), and vomiting (25%; 0%). Grade ≥3 hematologic AEs included neutropenia (21%), lymphopenia (17%), thrombocytopenia (10%), and anemia (6%). Forty percent of patients had serious AEs (SAEs), most frequently colitis, diarrhea, and hypotension (all n=3). One patient had grade 3 pneumonitis; none had Pneumocystis jiroveci pneumonia (PJP) or grade ≥2 elevated transaminase. Objective responses occurred at all doses (Table 1), except 5mg QD; 90% of the objective responses were observed at the 9-week disease assessment.

Table 1.

Summary/Conclusions: In patients with relapsed/refractory B-cell malignancies, INCBO50465 demonstrated manageable toxicities with no clinically meaningful transaminisits or PJP. Objective response rates were generally high and most responses (90%) were observed at the 9-week disease assessment. Different dosing regimens/schedules, long-term safety, and disease-specific cohorts are being evaluated.
lymphoma (FL). Upon informed consent, patients receive 12 cycles of R2 induction followed by 28 cycles of rituximab 375mg/m2 weekly cycle 1 [d1, 8, 15, 22], then d1 of odd cycles. Responders to induction (≥SD) are randomized: 1:1 maintenance with either R2 or rituximab alone (18 cycles); following R2 maintenance, optional single-agent lenalidomide (10mg/d, d1 of 28 d) can be given until PD. The primary endpoint is progression-free survival (PFS).

Results: As of April 14, 2016, 106 patients with R/R FL have been enrolled, including 103 with grade 1-3a FL, 2 with tFL, and 1 unknown grade. Median age of patients with FL was 66 yr (range, 41-91); most had ECOG PS of 0-1 (99%) and stage III/IV disease at study entry (80%). Patients received a median of 2 cycles of R2 induction (≥SD, 95%; 52% of patients received more than 2 cycles of R2 induction). R2 induction was associated with complete response in 32% of patients; 103 (87%) patients had received prior rituximab-containing treatment, of which 35% were rituximab redefining (defined as best response of SD/PD to rituximab/rituximab-containing regimen or a CR/PR of <6 mo after the last rituximab dose). The most common prior regimens were rituximab alone (40%), R-CHOP/R-CHOP-like (38%), and bendamustine plus rituximab (35%). Preliminary data of 272 patients who participated in the current phase 3 trial demonstrated pharmacokinetics (PK) and efficacy equivalence in patients with advanced follicular lymphoma (AFL) (Coiffier, ASH 2016).

Summary/Conclusions: R2 induction therapy shows favorable activity and a tolerable safety profile in patients with advanced-stage, R/R FL. The study is ongoing to determine the effect of R2 vs rituximab maintenance in FL patients, and updated results will be presented.

P635 A DOUBLE-BLIND, RANDOMIZED PHASE 3 STUDY TO COMPARE EFFICACY AND SAFETY OF CT-P10 TO INNOVATOR RITUXIMAB IN COMBINATION WITH CVF IN PATIENTS WITH PREVIOUSLY UNTREATED ADVANCED FOLLICULAR LYMPHOMA

Background: CT-P10 is the first biosimilar of innovator rituximab (RTX), approved for all indications by the European Medicines Agency. CT-P10 has demonstrated pharmacokinetics (PK) and efficacy equivalence in patients with rheumatoid arthritis (Yoo, ACR 2016) and PK equivalence in patients with advanced follicular lymphoma (AFL) (Coillier, ASH 2016).

Aims: This study aimed to demonstrate non-inferiority (NI) of efficacy and PK equivalence between CT-P10 and RTX in patients with newly diagnosed advanced follicular lymphoma (AFL) (NCT02162771).

Methods: A total of 140 patients were randomized in a 1:1 ratio to receive CT-P10 or RTX (375mg/m² intravenous) plus CVF (cyclophosphamide, vincristine, and prednisone) therapy every 3 weeks over 8 cycles. Overall response rate (ORR) at week 24 was assessed by the independent review committee, according to the 1999 International Working Group criteria.

Results: Therapeutic NI of CT-P10 to RTX has been demonstrated in terms of ORR over 8 cycles (Table 1). The ORR difference between two treatment groups was 4.3% in per-protocol (PP) population and 5.7% in intent-to-treat (ITT) population. Considering the statistical Non-Inferiority test using confidence interval (CI) approach with the exact binomial CI for the difference of ORR between two treatment groups, the lower bound of 95% CI lies on the positive side of -7% Ni margin (-4.25% in PP population and -3.41% in ITT population).

This study demonstrates therapeutic non-inferiority of CT-P10 to RTX in combination therapy, with CT-P10 well-tolerated and safety profile including immunogenicity of CT-P10 was comparable to that of RTX over 8 cycles in induction period.

Table 1. Summary of Efficacy [Number (%)] of patients).

Summary/Conclusions: This study demonstrates therapeutic non-inferiority of CT-P10 to RTX combined with CVP therapy in previously untreated AFL. CT-P10 was well-tolerated and the safety profile including immunogenicity of CT-P10 was comparable to that of RTX over 8 cycles in induction period.
were 99%, 98%, 92%, 89%, 78% and 51%; at 1, 2, 5, 10, 15 and 20 years 98%, 97%, 88%, 67%, 19%, 0%, were free from events. Median TTNT was not reached thus indicating clinical benefit with IFN-α and PUVA. Kaplan-Meier estimated rates of 97% at 1 year, and 91% at 2 years, respectively whereas 5-10-20-year TTNT remained almost unchanged with 62% of patients that still had not required further treatment.

**Summary/Conclusions:** There has been an ongoing debate about whether patients would benefit from adding PUVA to IFN-α in the treatment of early stage MF. We chose to initiate the combination treatment of MF as early as possible in the course of the disease to induce a permanent remission or even a cure. In our experience, this regimen set the realistic goal of achieve high rates of complete clearing and durable responses (median TTNT not reached) with only 38% of patients requiring a subsequent systemic treatment within 20 years. Here, we suggest a synergistic or additive effect between PUVA and IFN-α compared with either agent alone. With respect to Hughes et al. (Blood 2015), our combination treatment provide a longer TTNT than PUVA or IFN-α monotherapy (36.3 months and 10.7 months respectively). At 2 years, 91% of patients receiving PUVA plus IFN-α were free from further treatment as compared to 54.2% and 29.1% treated with PUVA or IFN-α monotherapy, respectively.

**PHASE 3 ALCANZA STUDY: THE BRAFV600E MUTATION (BRAF) VEGF OR PHYSICIAN’S CHOICE (PC) OF METHOTREXATE (MTX) OR BEXAROTENE (BEX) IN CD30-POSITIVE CUTANEOUS T-CELL LYMPHOMA (CTCL): NUMBER NEEDED TO TREAT ANALYSIS**

E. Zaghadaliou1, H.M. Prince2, S. Wittkamp2, S. Horwitz2, M. Duvis4, Y. Kim6, R. Dummer2, J. Scarsisbrick8, P. Quaglino9, P.L. Zinzani10, P. Wolter11, L. Cicala1, C. Velcic13, Y. Wessels12, A. Gautam1, Y. Zhu1, H.-M. Lin1, Y. Liu1, M. Little1, M.R. Dalal1,∗

1Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States, 2The University of Melbourne, Victoria, Australia, 3Guts and SI Thomas NHS Foundation Trust, London, United Kingdom, 4Memorial Sloan Kettering Cancer Center, New York, 5Tufts Medical Center, Boston, MA, United States, 6Stanford University School of Medicine and Stanford Cancer Institute, California, United States, 7University Hospital Zürich, Zürich, Switzerland, 8University Hospital Birmingham, Birmingham, United Kingdom, 9University of Turin, Turin, Italy, 10University of Bologna, Bologna, Italy, 11University Hospitals Leuven, Leuven, Belgium, 12Columbia University, New York, 13Seattle Genetics, Inc., Bothell, United States

**Background:** CTCL is a generally incurable, relapsing disease associated with a significant symptom burden, including disfiguring lesions, debilitating pruritus and frequent skin infections. ALCANZA is a Phase 3 study of BV vs PC (MTX or Bex) for the treatment of CD30-positive (CD30+) CTCL (NCT01578499). BV was associated with significantly improved rate of objective response lasting ≥4 months (ORR4; 56% vs 13%; p<0.0001), longer median progression-free survival (mPFS; 16.7 vs 3.5 months; p<0.0001), and decreased symptom burden measured by SkinEx-29 (27.96 vs -8.62; p<0.0001), compared with PC. BV’s safety profile was consistent with previous reports, with all-grade and grade 3 peripheral neuropathy of 67% and 9%, respectively. Number needed to treat (NNT), defined as the number of patients (pts) that need to be treated to prevent one disease progression event or death compared with the comparator therapy, is an effective method to assess the benefit-risk of BV in a clinically relevant manner. NNT values of 3–28 have been previously reported, at various time points, in hematologic malignancies (multiple myeloma, B-cell non-Hodgkin lymphoma) to prevent one disease progression event or death. Data from the Phase 3 AETHERA study demonstrated that, at various time points, and dependent on risk group, one in 3-8 Hodgkin lymphoma pts treated with BV consolidation therapy post-autologous stem cell transplant will benefit by avoiding disease progression/death, compared with placebo.

**Aims:** To determine the NNT with BV to avoid one additional event of disease progression or death compared with PC in the ALCANZA trial.

**Methods:** The NNT with BV was calculated as the inverse of the absolute risk reduction (ARR); ARR was the PFS event rate per independent review facility (IRF) assessment in the PC arm minus the event rate in the BV arm. PFS was reduction (ARR); ARR was the PFS event rate per independent review facility (NNT), defined as the number of patients (pts) that need to be treated to prevent one disease progression event or death. Data from the Phase 3 ALCANZA ITT population.

**Summary/Conclusions:** ALCANZA data suggest that, at various time points, one in every 2–4 pts treated with BV will benefit by avoiding disease progression/death. This further demonstrates BV’s clinical benefit in CD30+ CTCL pts requiring systemic therapy. This is, to our knowledge, the first report of an NNT analysis for a treatment in the CTCL setting.

**PRIMARY OCULAR ADNEXAL LYMPHOMA OF ALL HISTOLOGIC SUBTYPES: SURVIVAL OUTCOMES AND RISK FACTORS IN LARGE COHORT OF PATIENTS AND LONG-TERM FOLLOW-UP**

Y.-W. Jeon1,*, S.-S. Park1, J.-H. Yoon1, S.-E. Lee1, K.-S. Eom1, Y.-J. Kim1, H.-J. Kim1, S. Lee1, C.-K. Min1, J.-W. Lee1, W.-S. Min1, S.-G. Cho1

1Department of Hematology, St.Mary Hospital, Seoul, Catholic Medical Center, Seoul, Korea, Republic Of

**Background:** Although the recent reports show that interest in ocular adnexal lymphomas (OAL) and their biologic and clinical characteristics have been increased, the most OAL-related clinical study is still limited in the small number with insufficient follow-up period, result in retrospective studies with non-reproducible. Moreover, because the majority of OAL were in the low-grade histologic subtypes as primary ocular adenoidal MALT (mucosa-associated lymphoid tissue ) lymphoma, there is few comparative analysis study of all histologic subtypes in OAL patients especially for non-MALT type OAL in large cohort OAL.

**Aims:** So our purposes of this study were to identify a correlation between histopathological diagnosis and significant parameters associated with clinical outcomes of patients with OAL in patients with diverse histologic subtypes.

**Methods:** We evaluated the consecutive 207 primary OAL patients who diagnosed at Catholic University Lymphoma Group (CULG) of Catholic Bone Marrow Center, Seoul between January 2004 to April 2015. Clinical information and parameters were gathered from the electronic medical records such as geographic status, complete blood count (CBC) with blood chemistry, the status of BM involvement, primary therapeutic modalities, response to initial therapy, and treatment-related complications with survival outcomes.

**Table 2.** Subgroup analysis of survival outcomes according to histologic subtypes in OAL patients.

**Summary/Conclusions:** OAL of all histologic subtypes, 10-year lymphoma-specific OS and PFS were 89.3% and 71.0% respectively. 182 patients achieved CR (87.9%). CR rate according to primary therapy was 90.4% (n=103) in T1N0M0, 95.2% (n=40) in T2N0M0, 100% (n=77) in T3N0M0, 83.3% (n=5) in T4N0M0, and 71.1% (n=27) in T1N1-4M0. Multivariate analysis in OAL of all histologic subtypes showed that the risk factors-associated OS were positivity of BM involvement (HR=2.96, p<0.001), non-MALT histology subtype (HR=9.18, p=0.013), and increased symptom burden (HR=3.5 months; p<0.0001), and decreased symptom burden (HR=0.13, p=0.001).

**Figure 4.** Subgroup analysis of survival outcomes according to histologic subtypes in OAL patients.
according to histopathologic subtypes, BM involvement alone was regarded as a statistically significant factor in the group of non-MALT lymphoma. Although there were no risk factors with statistical significance, the BM involvement and advanced TNM stage showed a trend toward statistical significance about affecting to the failure of PFS (BM involvement of HR 2.70, p = 0.054 and advanced TNM stage of HR 3.06, p = 0.056). The median time-to-progression (TTP) was from 3 to 3.5 years after initial therapy in relapse or dead patients (range from 4.6 to 109.6 months).

**Summary/Conclusions:** Our study confirmed that OAL of all histologic subtypes also represented the indolent nature and localized behavior with favorable survival outcomes. Although BM involved OAL consisted of a small number, it was associated with poor survival outcomes. Also, relapse and lymphoma-related mortality had long-term delayed TTP, so we suggested that BM biopsy might be a necessary study for initial staging at least in all OAL and long-term follow-up is required for patients with all histologic type of OAL.

**CLONAL B-CELL LYMPHOCYTOSIS OF MARGINAL ZONE ORIGIN (CBL-MZ): A PROSPECTIVE REGISTRATIONAL STUDY ON 96 CASES**

**Background:** Clonal B-cell lymphocytosis of marginal zone origin (CBL-MZ) has been recognized as a provisional entity in the WHO classification. Despite diagnostic similarities with SMZL, the exact relation between them has not been established yet. AIM: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.

**Aims:** To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.

**Methods:** 96 CBL-MZ were analyzed. Staging at diagnosis included CBCs, blood morphology and immunophenotype, biochemistry, viral test for hepatitis C and B, serum immunoglobulin levels and immunofixation as well as whole body CT scan. BM biopsies were available in 78 cases which were studied with the following panel of moAbs: CD20, DBA44, CD23, CD5, CD25, CD38, CD27, sIgM/M, TCL-1, MNDA, T-bet and IRITA-1. Gastroscopy with multiple biopsies was performed in 58 cases. FISH analysis for del(7q) was done in 13 pts, and detection for MYD88 mutation in 60.

**Table 1.**

<table>

</tbody>
</table>

**Results:** A synoptic presentation of the main characteristics of CBL-MZ is given in the table. The median age was 70 y without sex predilection. By definition, no case presented with cytopenia, lymphadenopathy, splenomegaly or any other organ involvement. Median ALC and clonal B-cell counts were 5098/μL and 2880/μL, respectively. 47% had paraproteinemia, mainly of the IgM type.

H.pylori (+) gastritis was evident in 30%. Hp eradication had no influence on the lymphocyte counts. The percentage of BM infiltration was highly variable, ranging from 10% to 85%, with an intrasinusoidal pattern in 31%. TCL-1, T-bet, IRITA-1, and MNDA were invariably negative. MYD-88 mutation was detected in 18% and was significantly associated with IgM paraproteinemia. 6 cases were lost to follow-up. At a median follow-up time of 41 months, the majority of the cases had no disease progression (90%) 61% had stable CBCs, 20% solely an increase in ALCs and 7% an increase in paraproteinemia only, while in 2% lymphocytosis regressed. A total of 9 (10%) pts progressed and required treatment: 5/9 due to cytopenias caused by extensive BM infiltration without splenomegaly. 1 due to bulky splenomegaly; 1 due to lymphadenopathy; 1 developed autoimmune thrombocytopenia, while in one due to high IgM levels in a MYD-88(-) case. A total of 5 (6%) pts developed splenomegaly after a median time of 78 mos (48-151).

**Summary/Conclusions:** After a median follow-up time of 4y we demonstrated that CBL-MZ, although displaying many diagnostic similarities with SMZL, it rarely remain to it. Most cases remain stable, while few develop cytopenias due to an extensive BM infiltration. These latter cases apparently represent a distinct MZL category which requires further investigation.

**P640**

**SAFETY OF SUBCUTANEOUS ADMINISTRATION OF RITUXIMAB DURING THE FIRST-LINE TREATMENT OF PATIENTS WITH NON-HODGKIN LYMPHOMA: THE MABRELLA STUDY**

C. Panizo1,2, M.A. Bekadja2, B. Meddebel3, O. Meier4, R. Smith5, M. Truman5, C. Barati6, C. Calábria4, E. Pollina4, D. Guindon4

**Background:** Intravenous (IV) rituximab is the mainstay of treatment for CD20+ B-cell non-Hodgkin lymphoma (NHL). A subcutaneous (SC) formulation of rituximab has been approved in Europe and other countries that reduces healthcare resource burden and improves patient satisfaction and convenience compared with rituximab IV. MabRella is a global umbrella study comprising three local open-label, single-arm, Phase IIIb studies of rituximab SC, which share a core protocol and primary endpoint but have flexibility for exploratory endpoints (NCT01889069; NCT01987505; NCT02406092). Data from participating countries are pooled for predefined global analyses.

**Aims:** To evaluate the safety of first-line (1L) rituximab SC in follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL) with a focus on administration-related reactions (ARRs).

**Methods:** Eligible pts were aged 18–80 years with grade 1–3a FL/DLBCL and ECOG performance status ≤3. All pts had received ≥1 full dose of rituximab IV as 1L induction/maintenance before study entry, and were expected to receive ≥4 additional induction cycles (FL/DLBCL) or ≥6 additional maintenance cycles (FL). Informed consent was obtained. For induction, pts received rituximab SC 1400mg every cycle (14, 21 or 28 days) for 4–7 cycles, plus standard chemotherapy. FL pts undergoing maintenance treatment received single-agent rituximab SC 1400mg every 2 months for 6–12 cycles. The primary endpoint was incidence of ARRs, i.e., all adverse events (AEs) occurring within 24 hours of administration, considered related to study drug by the investigator. Secondary endpoints included grade ≥3 AEs and serious AEs (SAEs). The safety analysis included all pts who received ≥1 dose of study treatment. Safety data were not collected for rituximab IV, as pts entered the trial after switching to SC. Updated data are presented (data cut-off February 7, 2017).

**Table 1.**

**Results:** The safety population comprised 421 pts: 160 Italy; 140 Spain; 121 North Africa (Tunisia, Morocco and Algeria). Median age was 58 years (range 19–80); 49% of pts were male; 225 pts had FL and 196 had DLBCL. Of the pts with FL, 97 completed ≥1 cycle of rituximab SC induction (45 completed 7 cycles) and 204 completed ≥1 cycle of maintenance (175 completed 6 cycles;
Shortened median PFS was observed in the incremental treatment arm vs the ITT population (6 months vs 9 months, respectively). Mature data from larger cohorts confirming trials’ results in real-life practice are lacking

Results: Median follow-up for the entire cohort is 5 years, median age at diagnosis 68.6y and at therapy 71.2y, 75% being above 65y at treatment. Significant differences between DRC/RF cohorts were: median age 74/64y, high IPSS score 63%/28%, B2M>3mg/l 74%/56%, DRC cohort: median PFS/Time To Next Therapy and Overall Survival were 33mo, 45.8mo and 78% at 5 years, respectively. Other parameters decreased the duration of PFS2 with immunochemotherapy: predicted PFS and OS with good accuracy. Survival was lower with prior CLB therapy, myelodysplasia 13% vs 6%. RAI >30 vs 16%, anemia<11.5g/dl decreased PFS. A previous CLB therapy increased the risk for these infections is related to the intensity and duration of neutropenia, and varies from 2% to 40%. Mortality rates associated with documented IFIs are considerable, reported ranging from 30% to 60%. Empirical antifungal therapy is the standard care for neutropenic patients with NHL, whereas febrile neutropenia (FN) is related to broad-spectrum antibacterial treatment. Several antifungal agents including voriconazole (VRCZ) or liposomal amphotericin B (L-AMB) have been studied as empirical therapy for febrile neutropenia (FN). However, limited data are available concerning the efficacy and safety of miconafungin (MCNG) in FN patients with HEM.

Aims: We conducted a randomized, cooperative group, open-label trial comparing MCFG (150mg once daily) with L-AMB (2.5mg/kg once daily) as first-line empirical antifungal treatment for FN patients with persistent fever of HEM. Methods: 138 hospitalized FN patients with persistent fever of HEM (AML 78, APL 4, ALL 13, MDS (RAEB) 7, NHL 28, MM 5, other hematological malignancy 3 cases) were randomized to each drug group (MCFG, 72; L-AMB, 66). The efficacy end point was a favorable overall response, as determined by a five-component end point according to the criteria of Walsh et al (N Engl J Med 2004; 351: 1391).

Results: At the time of enrolment, there were no significant differences in the demographics or baseline characteristics between the two groups. The mean treatment duration for MCFG and L-AMB was 13.8 and 16.4 days, respectively. The efficacy rates of MCFG and L-AMB were not significantly different (38/72 cases (52.8%) vs 26/66 cases (39.4%), p=0.115*), evaluated based on: (1) successful treatment of baseline fungal infection (3/4 cases (75.0%) vs 0/1 case (0%), p=0.170*), (2) absence of breakthrough fungal infection (65/72 cases (90.3%) vs 65/66 cases (98.5%), p=0.112*), (3) survival for ≥7 days after treatment completion (66/72 cases (91.7%) vs 59/66 cases (89.4%), p=0.855*), (4) absence of premature study drug discontinuation due to poor efficacy or drug-related adverse events (54/72 cases (75.0%) vs 47/66 cases (71.2%), p=0.615*), and (5) resolution of fever during neutropenia (45/72 cases (62.5%) vs 33/66 cases (50.0%), p=0.258*). However, discontinuation due to drug-related adverse events occurred less frequently in the MCFG group (1/72 cases (1.4%) vs 9/66 cases (13.6%), p=0.006*). In safety evaluation, adverse events of creatinine increase and hypokalemia were less often in the MCFG group than in the L-AMB group (6/72 cases (8.3%) vs 19/66 cases (28.8%), P=0.001*), 14/72 cases (19.4%) vs 34/66 cases (51.5%), P=0.001*). Chi square test.

Summary/Conclusions: MCFG was as effective as L-AMB, and better tolerated than L-AMB as an empirical antifungal therapy in FN patients with HEM.

ANTIFUNGAL DRUGS INFLUENCE NEUTROPHIL EFFECTOR FUNCTIONS IN VITRO AND MODULATE PULMONARY DAMAGE IN INVASIVE ASPERGILLOSIS

T. Lüderitz1,2, T. Orsini3, T. Gherlinzoni1,2, D. Teschner1,*

1Department of Hematology, Medical Oncology, & Pneumology, 2Institute of Immunology, University Medical Center of the Johannes Gutenberg University, Mainz, Germany

Background: Antifungal agents like azoles, echinocandins or polyenes substantially contribute to reduced morbidity and improved survival of high risk patients in hematology. However, besides their well-known antifungal activity there is a growing body of evidence for immunomodulatory side effects on different effector cells of the immune system.
**Aims:** The aim of our study is to clarify the immunomodulatory capacity of different antifungal drugs on the effector functions of polymorphonuclear neutrophils (PMN) and on the clinical course of invasive pulmonary aspergillosis (IPA).

**Methods:** Firstly, isolated PMN from healthy donors were preincubated with different antifungals in vitro. Here, we used the azoles fluconazole (FLU), voriconazole (VOR), and caspofungin (CAS). In addition, the echinocandin caspofungin (CAS) and micafungin (MIC), and the polypepidermin b (Amb) and liposomal amphotericin b (LAMB). Furthermore, PMN were simultaneously stimulated with lipopolysaccharides (LPS) or zymosan. Afterwards, PMNs were analyzed by flow cytometry regarding activation, degranulation, and phagocytosis. Additionally, a dichotomous assay was used to detect reactive oxygen species (ROS). IL-8 synthesis was measured by enzyme-linked immunosorbent assay (ELISA). Secondly, a murine model was used to investigate the influence of MIC and POS on the clinical course of IPA in vivo. Therefore, mice were treated with antifungals and inoculated with C. albicans. Afterwards, mice were analyzed concerning fungal burden and pulmonary damage (albumin ELISA) with neutrophic animals serving as controls.

**Results:** In vitro, pretreatment with POS lead to enhanced activation (CD62L: 44% +/- 8 vs 13 +/- 2, p<0.05), increased degranulation, andROS generation (ROS 2880 rfu +/- 2384 vs 8528 +/- 161, p<0.05), whereas zymosan triggered IL-8 synthesis was reduced by trend. In contrast, ISA pretreated PMN showed decreased expression of activation markers. Moreover, ISA impaired degranulation and LPS triggered generation of ROS (6980 rfu +/- 1338 vs 28730 +/- 6893, vs p<0.05). FLU and VOR did not show a significant influence on PMN effector functions in vitro. MIC pretreatment resulted in enhanced expression of activation marker CD62L but reduced expression of CD11b, and decreased degranulation. Additionally, phagocytosis (27% +/- 4 vs 44 +/- 1, LPS, p<0.05) as well as generation of ROS (22660 rfu +/- 3286 vs 41180 +/- 2584, zymosan, p<0.05), and IL-8 synthesis were substantially impaired. GAS showed an increased neutrophagosis (75% +/- 6 vs 44 +/- 5, LPS, p<0.05), whereas degranulation and LPS triggered generation of ROS were reduced by trend. Pretreatment with conventional AmB resulted in activation of almost all effector functions besides impaired phagocytosis (43% +/- 3 vs 59 +/- 3, LPS, p<0.05). In contrast, LAMB did not significantly alter any effector functions. In vivo, treatment with POS resulted in a reduced fungal burden as expected but led to reduced albumin concentration in BAL (111 ng/ml +/- 46 vs 380 +/- 31, p<0.05) indicating a decreased pulmonary damage. Despite significant influence on PMN effector functions in vitro, MIC did not affect clinical course IPA in vivo.

**Summary/Conclusions:** CD62L and POS induce PMN activation, whereas ISA and MIC inhibit PMN effector functions in vivo. CAS shows variable modification on PMN. Possibly independent from its antifungal effects, POS reduces pulmonary damage in mice suffering from IPA in vivo. Further studies are needed to distinguish the obviously multidimensional immunomodulatory effects of different antifungal agents and to clarify their relevance in clinical practice.

---

MIC pretreatment resulted in enhanced expression of activation marker CD62L but reduced expression of CD11b, and decreased degranulation. Additionally, phagocytosis (27% +/- 4 vs 44 +/- 1, LPS, p<0.05) as well as generation of ROS (22660 rfu +/- 3286 vs 41180 +/- 2584, zymosan, p<0.05), and IL-8 synthesis were substantially impaired. GAS showed an increased neutrophagosis (75% +/- 6 vs 44 +/- 5, LPS, p<0.05), whereas degranulation and LPS triggered generation of ROS were reduced by trend. Pretreatment with conventional AmB resulted in activation of almost all effector functions besides impaired phagocytosis (43% +/- 3 vs 59 +/- 3, LPS, p<0.05). In contrast, LAMB did not significantly alter any effector functions. In vivo, treatment with POS resulted in a reduced fungal burden as expected but led to reduced albumin concentration in BAL (111 ng/ml +/- 46 vs 380 +/- 31, p<0.05) indicating a decreased pulmonary damage. Despite significant influence on PMN effector functions in vitro, MIC did not affect clinical course IPA in vivo.

**Summary/Conclusions:** CD62L and POS induce PMN activation, whereas ISA and MIC inhibit PMN effector functions in vivo. CAS shows variable modification on PMN. Possibly independent from its antifungal effects, POS reduces pulmonary damage in mice suffering from IPA in vivo. Further studies are needed to distinguish the obviously multidimensional immunomodulatory effects of different antifungal agents and to clarify their relevance in clinical practice.

Summary/Conclusions: CD101, a novel echinocandin, was protective against fungal challenge in immunosuppressed mouse models of candidiasis, aspergillosis, and PCP. These data suggest that CD101 may provide benefit as an antifungal prophylaxis in patients with hematological diseases at risk for infection. The efficacy of SC-administered CD101 demonstrated in the candidiasis and aspergillosis models suggests potential utility in the outpatient setting for treatment or prophylaxis.

Methods: A retrospective review of our Hospital’s Leukaemia database (IRB approved) was made for clinical characteristics and outcomes in surgically managed IFI patients diagnosed between Jan 2005 and Dec 2015. IFI was defined by EORTC/MSG 2008 criteria.

Results: Among 795 acute leukemia patients diagnosed during this period, we found 19 patients with IFI who had undergone surgical interventions (15 proven, 1 probable and 3 possible IFI). The details of the IFI, surgical interventions, antifungal treatments and perioperative complications are summarized in Table 1. Most commonly performed surgical intervention was either open thoracotomy or video assisted thoracoscopic surgery for wedge resection or lobectomy. Nine of the 15 proven IFI patients had overall benefit from the pro-

cedure through optimization of antifungal therapy with MIC/sensitivities, arrest of aspergilloma related massive bleeding and/or complete resolution of the IFI allowing further chemotherapy or transplantation. Of these, 7 patients were alive and well at the time of data collection and 2 had died. Among the survivors, the mean duration of the survival post-surgery was 57.7 months (range 9–118.3 months). The 2 patients who died also had benefited from the procedure and had survived for 6.5 and 47 months post-surgery but both succumbed to septic events unrelated to the IFI during subsequent chemotherapy. Of the remaining 6 patients (out of the 15 proven IFI), 3 had temporary clinical and/or radiological improvement only but succumbed 2 to 6 months post-surgery due to unrelated septic events, 2 died due to progression of the IFI and 1 lacked information to draw any conclusions. The patient with probable IFI diag-

nosed during induction was able to proceed with further chemotherapy post-

surgery but succumbed to CNS relapse of leukaemia 8 months later. Of the 3 patients with possible IFI, 2 were able to proceed with transplantation and 1 with chemotherapy post-surgery, but all the 3 patients succumbed to leukaemia and/or unrelated septic events.

Summary/Conclusions: Major surgical interventions are feasible in selected leukaemia patients with IFI. In carefully selected patients they can yield valuable information to guide anti-fungal therapy or enable therapeutic outcomes allowing patients to proceed with curative chemotherapy and stem cell transplantation.

P647

INFECTIONS IN MULTIPLE MYELOMA ARE FREQUENT AND PREDOMINANTLY CAUSED BY BACTERIA: RESULTS OF A 12-YEAR SURVEY FROM A SINGLE CENTER

M. Von Lilienfeld-Toal1,*, M. Klaus1, H. Sayer2, S. Scholl1, T. Ernst1, I. Hilgendorf1, O. Yomade1, A. Klink1, K. Schilling1, A. Hochhaus1, A. Brioli1, L.O. Mügge3

1Universitätsklinikum Jena, Jena, 2Helios Klinikum Erfurt, Erfurt, 3Heinrich-Braun-Klinikum, Zwickau, Germany

Background: The outcome of patients with multiple myeloma (MM) has improved dramatically in the past years, mainly due to a better control of the disease. However, it is not clear what influence this has on treatment- or disease-related complications such as infections. Recent data even suggested an increased rate of infections in patients with MM, possibly associated with the use of novel drugs.

Aims: To determine the rate and the type of infections in MM patients undergoing treatment and to evaluate possible disease- or treatment-related risk-factors.

Methods: All patients with MM treated at our institution between 2003 and 2014 were included in this retrospective analysis after approval by the institu-
tional review board. Data on age, sex, diagnosis, comorbidities, treatment modalities, and infectious complications were recorded. Each type of therapy (e.g., high-dose therapy versus conventional therapy) defined a patient-case (duration per patient-case: beginning of therapy until the beginning of another type of therapy) and infections were recorded per case. To determine risk-
factors, generalized estimating equations comparing cases were used.

Results: Four-hundred seventy-nine patients (male: 272, 57%) accounted for 1690 cases (median number of cases per patient 3, range 1-15). At presentation in our institution, median age was 62 (35-89) years, and most patients had advanced disease (Stage III according to Salmon-Durie classification in 364 patients, 76%) and an IgG-paraprotein (255 patients, 53%). Type of therapy given were as follows: 534 (32%) conventional long-term chemotherapy, 514 (30%) induction-type chemotherapy, 237 (14%) chemotherapy for stem-cell mobilisation, 310 (18%) high-dose melphalan with stem-cell transplantation and 95 (6%) supportive care only. One-hundred sixty-six patients (35%) with 285 patient-cases never experienced an infection during chemotherapy and/or melphalan. However, the majority of patients experienced at least one episode of infection throughout their treatment, accounting for 773 infections in 627 patient cases (37% of all patient cases). Most (559, 72%) infections were of bacterial origin including 156 cases with pneumonia (9% of all patient cases). Herpes zoster was noted in 37 patient cases. Relapse (OR 1.9, 95% CI 1.5-2.5, p<0.001) and high-dose chemotherapy (OR 11.3, 95% CI 8.4-15.3, p<0.001) were associated with a higher risk of infection whereas time of treat-
ment (2003-2008 versus 2009-2014) or use of novel drugs did not influence the rate of infection.

Summary/Conclusions: More than 60% of MM patients experience at least one episode of infection during their course of treatment. These infections are mostly of bacterial origin and strongly associated with high-dose chemotherapy or relapse. Novel drugs do not seem to influence the rate of infection. Unfortu-
nately, despite the general improvement in the care of patients with MM, no difference in the rate of infections could be detected in recent years.

P648

HUMAN L-FICOLIN POLYMORPHISMS CONTRIBUTE TO SUSCEPTIBILITY TO INFECTIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

U. Schnetzke1, M. Fischer1, A. Hoehhaus1, S. Schofl1
1Klinik für Innere Medizin II, Abteilung für Hämatologie und Internistische Onkologie, Universitätshospital Jena, Jena, Germany

Background: In neutropenic patients with acute myeloid leukemia (AML) bacterial infections and sepsis are a leading cause of mortality. Several studies propose a contribution of individual single nucleotide polymorphisms (SNPs) of the innate immune system to the course of infections. Human ficolins represent recognition molecules of the lectin pathway of complement especially ficolin-2 (L-ficolin) is emerging as an important component of the lectin pathway in the circulation. Ficolins share structural and functional characteristics with C1q from the classical pathway of the complement that acts with Pentraxin 3 (PTX3) that helps the innate immune system targeting pathogens like bacteria or viruses. In the context of hematopoietic stem cell transplantation polymorphisms of PTX3 have been identified as an independent risk factor for developing pulmonary aspergillosis.

Aims: We sought to investigate the impact of L-ficolin and PTX3 SNPs on the occurrence of infectious events such as sepsis and pneumonia, including invasive fungal disease (IFD), in 186 adult patients with newly diagnosed AML following anthracycline-based induction chemotherapy. In addition to our studies on membrane receptors, this work represents an important extension on soluble molecules of the innate immune system and their potential implication on infections.

Methods: Genotyping of L-ficolin and PTX3 SNPs (rs17514136, rs17549193, rs1800450 and rs3816527, rs2305619, rs1840680) was performed by TaqMan assay. Multiple logistic regression analyses were applied to evaluate the association between SNPs of the polymorphisms and the occurrence of infectious events.

Results: Two L-ficolins SNPs were identified as risk factors for developing sepsis and/or pneumonia. Patients harboring rs17514136GG or GG (n=100 or 22) revealed a significantly higher risk for developing sepsis (odds ratio [OR]: 1.88; 95% confidence interval [CI]: 1.01–3.37, p=0.039) or pneumonia (OR: 2.79; 95% CI: 1.16–6.9, p<0.003). A similar risk profile could be demonstrated for patients carrying rs17549193TTCT or TT. No association was found between SNPs of the PTX3 gene and the analysed infectious events.

Summary/Conclusions: To our best knowledge, this study represents the first analysis demonstrating that polymorphisms of human L-ficolin (rs7309123, rs17549193) represent an independent risk factor of developing sepsis and/or pneumonia in patients with AML undergoing induction chemotherapy. Interestingly, no association of PTX3 SNPs and infectious events such as IFD was found in this non-transplant setting. In conclusion, a genetic risk profile based on membrane bound and soluble molecules of the innate immune system might be helpful in identifying patients prone for infectious events.

TIMING OF DEFIBROTIDE INITIATION POST-DIAGNOSIS OF HEPATIC VENO-OCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME AFTER PRIMARY CHEMOTHERAPY: EXPLORATORY ANALYSIS OF AN EXPANDED-ACCESS PROTOCOL

N. Kernan1, P. Richardson2,*, B. Triplett3, S. Grupp4, J. Antin5, W. Liang6, R. Hume6, W. Tappe6, R. Soffer7
1Pediatric Bone Marrow Transplantation Service, Memorial Sloan Kettering Cancer Center, New York, New York, 2Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 3Bone Marrow Transplantation and Cellular Therapy, St. Jude Children’s Research Hospital, Memphis, 4Pediatric Oncology, The Children’s Hospital of Philadelphia, Philadelphia, 55Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, 6Jazz Pharmaceuticals, Inc., Palo Alto, 7Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

Background: Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT); however, VOD/SOS can occur after chemotherapy. To date, HSCT VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States.

Aims: To perform an exploratory post hoc analysis of the impact of timing of initiation of defibrotide after VOD/SOS diagnosis in patients developing VOD/SOS after primary chemotherapy without HSCT (off label).

Methods: In an expanded-access protocol for patients with VOD/SOS post-HSCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25mg/kg/d (4 divided doses of 6.25mg/kg) was given a median of 22 days after the diagnosis of VOD/SOS. In the post-chemotherapy subgroup, survival was analyzed post hoc from the day VOD/SOS was diagnosed (days 0–30 after start of chemotherapy) through follow-up, which was collected for 100 days post-chemotherapy. For these exploratory analyses, survival rates in the post-chemotherapy subgroup were estimated from time of VOD/SOS diagnosis to start of defibrotide for (1) all patients before/after days 1, 2, 3, 4, 7, and 14, using Fisher’s exact test and (2) patients starting defibrotide on a particular day: 0, 1, 2, 3, 4, 5, 6, 7, 8–14, and ≥15, by Cochran-Armitage test for trend across days. Causes of treatment delay were not assessed.

Results: In the final dataset, 137 patients developed VOD/SOS after primary chemotherapy. Of these, 87 patients (41 with MOD) developed VOD/SOS by day 30 after the start of chemotherapy. In the latter group, 79.3% (69/87) were aged ≤16 years. In 26.4% (2387) of post-chemotherapy patients, defibrotide was started the day of diagnosis; in 89.7% (78/87), by Day 7. In the population of patients with primary chemotherapy, 85.4% (27/32) patients provided informed consent. In this post-diagnosis in both the overall group and MOD subgroup (Figure), earlier initiation was associated with higher Day +100 survival rates for all days, which was significant at a number of timepoints. The trend test for particular initiation days...
also showed a significant trend over time for higher Day +100 survival with earlier defibrotide initiation post-diagnosis in both the overall group and MOD subgroup (*P* < .05). In the overall post-chemotherapy population, adverse events (AEs) and serious AEs occurred in 66% and 40% of patients, respectively. Aside from multi-organ failure, the most common AE of any severity was hypotension (9.5%). Possibly related AEs lead to discontinuation in 7.3%; most common was gastric hemorrhage (3.7%).

**Summary/Conclusions:** In this exploratory analysis of final study data in the subgroup of patients developing VOD/SOS after chemotherapy, earlier defibrotide initiation post-VOD/SOS diagnosis was associated with improved Day +100 survival, confirmed by the Cochran-Armitage test (*P* < .05), even in the small MOD subgroup. This time-dependent relationship was consistent with that found in the HSCT subgroup from this study. No specific day appears to provide a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed.

**ADAMTS-13 REGULATES NEUTROPHIL RECRUITMENT IN A MOUSE MODEL OF INVASIVE PULMONARY ASPERGILLOSIS**

A. Hasibeder1,*, S. Prüfer2, K. Ebner3, S. Reuter1, P. Aranda Lopez1, I. Scharrer1, F. Banno4, M. Stassen 2, H. Schild 2, K. Jurk3, M. Bosmann3, H. Beckert1, M. Radsak1

1IIIrd Dept. of Medicine, 2Institute for Immunology, 3Center for Thrombosis and Hemostasis, Johannes Gutenberg-University Medical Center, Mainz, Germany, 4Department of Molecular Pathogenesis, National Cerebral and Cardiovascular Center, Suita, Japan

**Background:** Von Willebrand factor (VWF) is produced as multimers of various sizes and is secreted as an acute phase protein during inflammation. The main mechanism regulating the size and prothrombotic activity of VWF is the specific proteolytic activity of ADAMTS-13 (a disintegrin and metalloprotease with ThromboSpondin type 1 repeats-13) which is diminished under several pathological conditions.

**Aims:** To determine the relevance of this regulatory pathway for the innate inflammatory response by polymorphonuclear neutrophils (PMN), we employed a mouse model of invasive pulmonary aspergillosis (IPA) where PMN functionality is crucial for fungal clearance and survival.

**Methods:** IPA was induced by intratracheal application of *Aspergillus fumigatus* (*A. f.* conidia in wildtype (129/Sv/Pas) or ADAMTS-13 deficient (*Adamts13*−/−) mice, and VWF deficient (*Vwf*−/−) mice or respective controls (B6). Some mice were sacrificed 24 h after infection. Fungal load was assessed as colony forming units (CFU) after plating and culturing lung homogenates on Sabouraud agar plates. For histological analysis paraffin sections of the lungs were stained with H&E, mouse complement component C3d and VWF antibody. Bronchoalveolar lavage fluid (BALF) was analyzed for cell count (bead-based by flow cytometry or by an animal blood counter), ELISA was performed for albumin amount and cytokines were analyzed by a multiplex assay. Bone marrow-derived PMN were isolated by magnetic cell sorting using biotin labeled Ly6G/C specific antibody. PMN functions were analyzed for degranulation, oxidative burst activity and CD62L shedding by flow cytometry. Fungal killing of PMN in vitro was assessed by a XTT assay. Chemotactic properties of *A. f.*-activated and control serum from wildtype and knock-out mice was evaluated by migration of purified human PMN, isolated by dextran sedimentation and Histopaque® centrifugation, in a transwell assay.

**Results:** While infected neutropenic mice developed lethal IPA, all wildtype mice survived the infection. Interestingly, *Adamts13*−/− mice displayed more severe signs of disease with a lethal course in about 24% of the animals. Examination of the lungs revealed a higher fungal burden along with increased signs of acute lung injury and levels of pro-inflammatory cytokines in ADAMTS-13 deficient mice. Histology sections demonstrated a more pronounced perivascular leukocyte infiltration in support of a dysregulated inflammatory response in *Adamts13*−/− mice. Importantly, we observed no general defect in the activation of neutrophil effector functions in response to conidia or hyphae in vitro. Furthermore, innate inflammatory response to IPA was not altered in VWF deficient (*Vwf*−/−) mice compared to wildtype (B6) control.

**Summary/Conclusions:** Therefore, we conclude that the proteolytic regulation of VWF by ADAMTS-13 or ADAMTS-13 by itself is an important mechanism to control PMN recruitment in acute inflammatory processes, such as fungal pneumonias.
Myelodysplastic syndromes - Biology

P652
IDENTIFICATION OF THE SPECIFIC HEMATOPOIETIC STEM CELL POPULATIONS RESPONSIBLE FOR FAILURE TO HYPMETHYLATING AGENTS IN MYELOODYSTIC SYNDROMES
I. Garfán-Gómez1, 2, A. Alfonso1, Y. Ogoot1, H. Yang1, G. Montalban-Bravo1, A.C. Yu2, S. Silver2, K. Clise-Dwyer1, G. Garcia-Manero1, S. Colla1
1Leukemia, The University of Texas MD Anderson Cancer Center, 2McGovern Medical School, The University of Texas Health Science Center, 3Stem Cell Transplantation & Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Myelodysplastic syndromes (MDS) are hematopoietic disorders characterized by the ineffective production of mature blood cells of one or more lineages and by the risk of evolution to acute myeloid leukemia. The current standard of care for MDS patients is the treatment with hypomethylating agents (HMA); however, response to drugs from this family occurs in just about half of the patients and is accompanied by high rates of therapy failure. Failure to HMA in MDS is a poorly understood process associated to increased risk of disease progression and to a dismal prognosis and cannot be, thus far, predicted or prevented.

Aims: Given that MDS are stem cell disorders, our aim was the identification and molecular characterization of the specific hematopoietic stem/progenitor cell (HSPC) population in which the relapse-driver clones arise. This is an essential step for the development of effective monitoring and early intervention protocols for HMA failure.

Methods: Using flow cytometry immunophenotyping, we quantitatively analyzed the different cell subpopulations within the CD34+CD38- and CD34+CD38+ HSPC compartments in 122 sequential MDS bone marrow samples obtained from 93 patients at different stages of HMA treatment.

Results: In line with earlier reports suggesting the presence of alterations in myeloid progenitor frequencies in MDS, our flow cytometry data stratified untreated patient samples in two groups representative of two abnormal differentiation patterns. These data suggest that each abnormal differentiation pattern arises from defects in different HSC populations and has a differential impact in the number and functionality of downstream progenitor cells (R). Additionally, a deeper immunophenotypic analysis of recently defined HPC functional fractions showed decreased erythroid and megakaryocytic potential in CMP (2-fold each, p<0.05) and megakaryocytic-erythroid progenitor (MEP) populations (-3.8-fold erythroid, -7.6-fold megakaryocytic; p=0.07, p=0.04, respectively) from CMP pattern patients but not in GMP pattern patients. HSPC frequency-monitoring of 69 samples collected from 36 patients throughout therapy showed persistence of both abnormal differentiation patterns even during clinical remission. Furthermore, specific HSC populations were differentially expanded upon HMA failure with leukemic progression in the two groups of patients. In CMP pattern MDS, LT-HSC frequency significantly increased after relapse (10.4-fold; p<10^-5), whereas the LMPP frequency sharply increased (8-fold; p<10^-4) in GMP pattern patients. The fact that a proliferative switch occurred in different HSC subpopulations confirmed that the two subgroups are distinct entities with different hierarchical origins.

Summary/Conclusions: Overall, our data provide evidence of the existence of biologically different MDS subtypes which are caused by separate differentiation defects and progress through the expansion of characteristic HSC populations.

Figure 1. Working flow cytometry immunophenotyping, we quantitatively analyzed the different cell subpopulations within the CD34+CD38- and CD34+CD38+ HSPC compartments in 122 sequential MDS bone marrow samples obtained from 93 patients at different stages of HMA treatment.

P653
FUNCTIONAL STUDY ON THE COOPERATION OF ASXL1 AND RUNX1 MUTATIONS FOR LEUKEMIC TRANSFORMATION
R. Bera1, D.-C. Liang1, M.-C. Chiu1, Y.-J. Huang1, L.-Y. Shih1, A. Unnikrishnan1,*, A.V. Ngoc Quynh1, R. Pickford2, A. Nunez1, L. Hesson1
1Prince of Wales Clinical School & Lowy Cancer Research Centre, Prince of Wales Hospital, Sydney, Australia 2Bioanalytical Mass Spectrometry Facility, UNSW Sydney, 3Haematology Department, Prince of Wales Hospital, Sydney, Australia

Background: Our previous studies showed that RUNX1 and ASXL1 mutations were frequently co-existed in chronic myelomonocytic leukemia (CMMML) (EHA 2015) and clonal evolution of RUNX1 and/or ASXL1 occurred most frequently in chronic myeloid leukemia (CML) with myeloid blast crisis (EHA 2016). The molecular pathogenesis of cooperation of RUNX1 and ASXL1 mutations has not been reported yet.

Aims: We aimed to determine the functional role of collaborative association of RUNX1 and ASXL1 mutations for secondary acute myeloid leukemia (sAML) transformation.

Methods: For in vitro study, we overexpressed RUNX1-WT/MT (R135T) in K562 cells which harboring ASXL1-MT (Y591X) and co-expressed with ASXL1-WT/MT (R693X) in murine 32D cells. After stable expression, functional properties were examined by using immunoblot, co-immunoprecipitation, quantitative RT-PCR, flow cytometry, cell proliferation, colony formation and gene expression microarray analyses. C57BL/6 mice were used for bone marrow transplantation (BMT) experiments for in vivo study.

Results: We found that RUNX1-MT augmented cell proliferation, colony formation, HOXA gene expression and inhibited megakaryocytic differentiation in ASXL1-MT K562 cells compared to RUNX1-WT or empty vector control. The cooperation of RUNX1 and ASXL1 mutations or the knocked down of ASXL1 cooperated with RUNX1-MT inhibited apoptosis and impaired differentiation in 32D cells. Nine months post BMT mice with the combined RUNX1 and ASXL1 mutations, but not RUNX1-MT or ASXL1-MT alone, developed disease characterized by marked splenomegaly, hepatomegaly, and leukocytosis with a shorter latency. We found that RUNX1-MT stabilized hypoxia-inducible factor 1A (HIF1-α) and increased its target gene expression such as HIF1-α (inhibitor of DNA binding 1). Clinical samples analyses showed that ID1 expression increased in both RUNX1-MT and ASXL1-MT or the combined mutations of RUNX1 and ASXL1 compared to control samples. We also examined the impact of RUNX1 and ASXL1 mutations on sAML-free survival of 104 Patients with CMMML, in whom 11 had co-occurrence of RUNX1 and ASXL1, 39 had either mutated ASXL1 or RUNX1 and 54 patients were negative for both mutations. We found that patients carrying co-existed mutations had a shorter sAML-free survival (median 16.1 months, 95% CI 0.0-60.1 months) than those carrying either mutated gene alone (median 23.0 months, 95% CI 17.8-28.2 months) or negative for both mutated genes (median not reached, 59.2% ± 8.8% at 5 years) (P=0.023).

Summary/Conclusions: The present study demonstrated that clinical and functional evidence for a collaborative association of RUNX1-MT and ASXL1-MT for sAML transformation. We identified HIF-1α targeting a new pathway which may be critical for leukemic progression of RUNX1/ASXL1-mutated myeloid malignancies.

A NOVEL MASS SPECTROMETRY METHOD REVEALS THE INTRACELLULAR PHARMACOKINETICS OF AZACYTIDINE THERAPY IN VIVO
A. Unnikrishnan1, A.V. Ngoc Quynh1, R. Pickford2, A. Nunez1, L. Hesson1, E. Punnampadam2,*, A. Emery1, A. Arora1, A. Wang3
1Prince of Wales Clinical School & Lowy Cancer Research Centre, 2Bioanalytical Mass Spectrometry Facility, UNSW Sydney, 3Haematology Department, Prince of Wales Hospital, Sydney, Australia
Background: The cytidine analog 5'-Azacitidine (AZA, Fig A), a DNA demethylating agent, is the primary drug for the treatment of high-risk Myelodysplastic Syndrome (MDS) and Chronic Myelomonocytic Leukaemia (CMLL), and response is associated with improved survival benefits. However, only ~50% of treated patients will ever respond to AZA and the molecular basis for poor response is poorly understood. It is unclear whether non-responders to therapy have different rates of AZA uptake into their cells and/or AZA incorporation into nucleic acids compared to AZA responders, nor whether these might relate to DNA methylation in vivo.

Aims: We aimed to develop an analytical method capable of simultaneously detecting all the subcellular fractions of AZA (Fig B) within the bone marrows of patients undergoing AZA therapy, while also assessing DNA and RNA methylation levels. This would provide the most comprehensive snapshot of the intracellular pharmacokinetics of AZA therapy in vivo as a first step towards better understanding AZA resistance.

Methods: We have developed a new method utilising mass spectrometry to accurately quantify all the different subcellular fractions of AZA within the same sample (Fig C). Using an Orbitrap mass spectrometer with very high mass resolution, we have achieved the first mass separation of DAC and AZA from all naturally occurring isotopes of deoxycytidine and cytidine respectively (a difference of less than 1 Da), thus enabling accurate quantification. We utilised subcellular fractionation to obtain purified quantities of DNA- and RNA-incorporated nucleotides, as well as free unincorporated nucleotides present in the cytoplasm. We developed a reduction reaction to reduce the spontaneous hydrolysis of nucleotides, as well as free unincorporated nucleotides present in the cytoplasm.

Results: Using our new method, we report for the first time direct simultaneous quantification of: (1.) DNA-incorporated DAC, (2.) intracellular, free DAC, (3.) methyl deoxycytidine in DNA, (4.) RNA-incorporated AZA, (5.) intracellular, free AZA, and (6.) methyl cytidine in RNA within the same sample. We demonstrate an inverse correlation between the amount of DAC incorporated into DNA and DNA demethylation. However, no such correlation was observed between AZA incorporation and RNA demethylation (Fig D). The sensitivity and resolution of our method also enabled, for the first time, a comprehensive survey of the total intracellular pharmacokinetics of AZA in vivo in patients undergoing a standard cycle of treatment. We discovered that the bone marrow cells of AZA responders (n=4) incorporated more DAC into DNA compared to non-responders (n=4). DAC incorporation was also inversely proportional to DNA methylation levels, with greater DNA demethylation observed in the responders compared to non-responders. Furthermore, we observed two patterns in AZA non-responders, with DAC-incorporation and DNA demethylation occurring in some individuals (n=2), while in non-responders (n=2) showed low or no DAC incorporation and no DNA demethylation (Fig E). Our method also enabled us to directly prove that low DAC incorporation was not a result insufficient AZA accumulation intracellularly, as cytoplasmic measurements of unincorporated AZA and DAC were higher in the non-responders with the lowest levels of DNA-incorporated DAC. Additionally, in these non-responders, there was also concomitant increase in AZA incorporation into RNA.

Figure 1.

Summary/Conclusions: We have developed a new method that has enabled the first comprehensive analysis of the intracellular pharmacokinetics of AZA therapy in vivo. Our results have revealed that while AZA responders incorporated AZA efficiently into DNA, leading to DNA demethylation, there were two modes of primary AZA resistance: in some non-responders, low levels of AZA incorporation into DNA likely derives from cell cycle quiescence, resulting in low amounts of DNA demethylation. However, in other non-responders who showed DAC incorporation into DNA and demethylation, resistance arises from as-yet-unknown mechanisms not connected with AZA metabolism.

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematological disorders at high risk of progression to acute myeloid leukemia (AML). Due to recent high-throughput sequencing studies, the mutational dynamics and clonal evolution during disease progression have just begun to be understood. However, large longitudinal sequencing genomic studies are still required.

Aims: To analyze the relationship between the dynamics of gene mutations and cell pathways they are involved in with the progression from MDS to sAML in order to study the mechanisms underlying disease evolution.

Methods: Sixty-eight serially collected samples from 34 MDS/CMLL patients evolving to sAML were studied by a combination of whole-exome sequencing (WES) and targeted-deep sequencing (TDS). Each patient was studied at two different time-points: at the time of diagnosis (MDS/CMLL stage) and after sAML progression (disease evolution, leukemic phase). At initial presentation of the disease, diagnoses were as follows: 18 RAEB-1/2, 9 RCMD and 7 CMML. Initially, WES was carried out on 40 diagnosis/progression-matched samples. Driver mutations were identified, after variant calling by a standardized bioinformatics pipeline, by using the novel tool “Cancer Genome Interpreter” (https://www.cancergenomeinterpreter.org). Secondly, in order to validate mutations and precise variant allele frequencies (VAFs) estimation, TDS using a custom MDS/AML-related capture enrichment panel (illumina®) of 117 genes was performed in 30 out of 40 of the initial cohort. Moreover, a total of 28 paired samples from a cohort of 14 patients were analyzed by TDS.

Results: Combining both WES and TDS approaches, a total of 143 mutations in 50 different genes were identified at the sAML stage, with most of them (118 mutations) already present at the MDS stage, at clonal or sub-clonal levels.

Most of the recurrently mutated genes were SRSF2 (28%), TET2 (24%), SF3B1 (21%), ASXL1 (21%), TET2 (23%) and NRAS (21%). However, it should be noted that 68% genes were mutated only in less than 10% of the patients, highlighting the great heterogeneity that exists in the mechanisms of disease evolution during disease. To study the clonal evolution during disease progression we compared VAFs of mutations detected at both time-points (sAML to MDS/CMLL stage) in each patient. We identified 4 different clonal dynamics: mutations that were initially present but increased VAF (type-1), decreased (type-2), were newly acquired (type-3) or persisted with similar allelic burden (type-4) at sAML stage. Interestingly, most of type-1 mutations were detected in STAG2 gene. Thus, mutational burden of STAG2 were markedly increased (6/8 patients) at sAML progression. Moreover, type-3 mutations, only detected at the sAML-stage, were predominantly identified in FLT3 (3/4) and NRAS (5/6).

Conversely, type-4 mutations were present in MDS-related genes such as SRSF2 (8/12), SF3B1 (3/6) and TET2 (8/12). Most of mutations in these genes showed no changes during progression to sAML.

Summary/Conclusions: Progression from MDS to sAML could be explained by different mutational processes, as well as by the occurrence of unique and complex changes in the clonal architecture of the disease during the evolution. Mutations in genes such as STAG2, FLT3 or NRAS could play an important role during disease progression.

PROGRESSION OF MDS TO AML FEATURES GAIN OF SINGLE DRIVER MUTATIONS WITH CONSEQUENT CHANGES IN CLONAL COMPOSITION IN A CASE OF PROGRESSION OF MULTIPLE CLONES WITH MUTATIONS IN IDENTICAL GENES

1Unidad de Diagnóstico Molecular y Celular del Cáncer, IBMC-Centro de Investigación del Cáncer (USAL-CSIC), Salamanca, 2Research Program on Biomedical Informatics, IMIN Hospital del Mar Medical Research Institute and Drivelat Pompeu Fabra, Barcelona, 3IBSAL, Hematology Department, Hospital Universitario de Salamanca, Salamanca, 4IBIOMED, University of León, 5Hematology Department, Hospital de León, León, 6Hematology Department, Hospital del Barco, Ponferrada, Léon, 7Hematology Department, Hospital Santa Bárbara, Soria, 8Hematology Department, Hospital Nuestra Señora de Sonsoles, Ciudad Real, 9Hematology Department, Hospital General de Segovia, Segovia, Spain
Background: Myelodysplastic syndromes (MDS) to acute myeloid leukemia (AML) associates with acquisition of genetic aberrations. Similar aberrations may occur in the development of primary AML, particularly in the context of a clonal hematopoiesis of indeterminate potential. Thus, in-depth knowledge of the genetics and clonal composition of MDS and paired AML samples allows insights into MDS progression in particular and AML development in general.

Aims: Here, we assessed mutations in serial samples of patients with MDS and progression to AML by next generation (NGS) and single-cell sequencing to identify mutations and clonal changes associated with AML development.

Methods: Mononuclear cells from 21 bone marrow (BM) samples of 8 patients with MDS and progression to AML were studied for mutations by an NGS panel (Agilent HaloPlex, Illumina MiSeq) comprising 98 genes relevant in hematologic neoplasms, and for copy number variations (Affymetrix CytoScan HD). All AML have been split, except one with del(5q). Samples were collected during MDS, at AML diagnosis and under treatment. Variants were verified by Sanger and pyrosequencing or fragment analysis in NM and CD3+ cells (germline).

Clonal assignment of variants was verified by single-cell mutation analysis using a Single-Cell Printer.

Results: Applied criteria and verifying variants by orthogonal methods in blasts and CD3+ cells, a median of 3 variants (range, 1-6) in the MDS and 4 (range, 1-6) in the AML samples were deemed pathogenic. During MDS, all patients except one had mutations in genes involved in RNA-spooling (SRSF2, ZRSR2, SF3B1), or epigenetic regulation (DNMT3A, ASXL1, EZH2). Additional mutations existed in FLT3, NRAS, PTEN, STAG2, CEBPA, RUNX1 or WT1. Subclonal mutations (i.e. variant allele frequency (VAF) <10%) were present in only two MDS samples. Towards AML, patients acquired a median of 1 (range, 0-2) new mutation in FLT3, CSF3R, KRAS, NRAS, PHF6, IDH1 or WT1. The VAF shifts from MDS to AML indicated cooperativity of mutations on clonal outgrowth, e.g. gain of CSF3R p.T618I was accompanied by a chromosome 19q-loss resulting in hemizygosity of a preexisting CEBPA mutation; or acquisition of a FLT3-TKD mutation was associated with upgrowth of a RUNX1 mutation. Changes in mutations or VAFs also changed in a subclone, e.g. in one patient, mutations in the same genes occurred under decitabine treatment by gaining two distinct FLT3 mutations. In another patient, who achieved complete remission after induction chemotherapy, but relapsed with MDS, which again progressed to AML, mutations were lost or gained, while a STAG2 mutation was detectable at all time. Interestingly, identical genes were recurrently mutated in different clones within single patients, e.g. progression to AML associated with acquisition of a WT1 mutation in an NRAS mutated MDS clone and with the generation of further subclones harboring distinct combinations of WT1 and NRAS mutations. The co-occurrence of the specific WT1 and NRAS mutations in the different clones was demonstrated by mutation analyses of 72 single patient cells.

Summary/Conclusions: Mutations in MDS are few in number, but enriched in genes involved in RNA-spooling or epigenetic regulation; gain of single driver mutations leads to clonal outgrowth and thus, AML. Subsequent treatment can change the mutational and clonal profile. Mutations in identical genes occur in different clones, as confirmed by single-cell analyses; this suggests a fertile ground (e.g. microenvironment) for such mutations in a patient and may lead to (a therapeutically exploitable) competition of clones.

Antonio e Biagio Hospital, Alessandria, 13Dept of Hematology, University of Florence, Florence, Italy

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of diseases characterized by a clonal and ineffective hematopoiesis, as well as the tendency to develop iron overload, mainly due to red blood cell transfections. Iron overload has been described to increase ROS production and progressively worsen hematopoiesis. In mitochondria, iron is a fundamental component of cytochromes belonging to the oxidative phosphorylation (OXPHOS), which is considered the main source of cellular energy. Mitochondria are also the main site of ROS production. In this regard, cancer energetic metabolism is an emerging issue that could represent an attracting therapeutic target.

Aims: The aim of the study was to investigate the energetic metabolism in MDS patients and to understand the impact of iron overload on the energy production.

Methods: We selected 37 samples from patients with MDS with or w/o iron overload (7 RA, 5 RARS, 9 RCMd, 4 RAEB-I, 2 RAEB II and 10 sAML). In addition we analyzed 86 samples from healthy subjects stratified according to (20-103 years) and a control group of patients with thalassemia with iron overload. In all these samples, we evaluated the ATP/AMP ratio, as marker of energy status, the OXPHOS activity, in term of oxygen consumption and ATP synthesis, the lactate dehydrogenase (LDH) activity, as marker of anaerobic glycolysis, and malondialdehyde (MDA), as marker of lipid peroxidation. The same parameters have been analyzed also after iron chelation with deferasirox (DFX) and after incubation of the cells with DFX and DFO.

Results: Our study clearly demonstrated that mitochondrial function is altered in MDS, leading to a strong energetic defect and an increase in oxidative stress, far beyond the expected parapathological decrease resulting from ageing. The OXPHOS efficiency is highly reduced in MDS compared to controls, determining an impairment of the ATP/AMP ratio, which is 2.4 in young controls, 0.75 in elderly controls and it is 0.2 in b-thalassemia and MDS patients. By contrast, LDH activity increased in the MDS patients (6mU/mg) with respect...
MONOBLASTS MAY SUPPRESS ANTITUMOR IMMUNE RESPONSES AND BE ASSOCIATED ON MONOCYTES IN CMML PATIENTS. VSIG4-EXPRESSING MONOCYTES AND BLASTS. IN CD14+CD11b+ MONOCYTES FROM MDS AND AL-MDS PATIENTS WAS HIGHER THAN IN THOSE FROM CONTROLS, BUT VSIG4 expression WAS NOT DETECTED ON CD34+ BLASTS. IN CD14+CD11b+ MONOCYTES FROM MDS AND AL-MDS PATIENTS, VSIG4 WAS STRONGLY EXPRESSED ON CD68+CD206+ TUMOR-ASSOCIATED MACROPHAGES (TAMs). FURTHERMORE, THE EXPRESSION LEVELS OF VSIG4 ON CD14+ MONONUCLEAR CELLS FROM MDS PATIENTS WAS SIGNIFICANTLY REGULATED IN COMPARISON WITH THOSE FROM CONTROLS. 2) TWO MDS CELLS EXpressed both VSIG4 mRNA AND ITS CELL-SURFACE PROTEIN. VSIG4 EXPRESSION ON MDS CELLS, AND ON MONOCYTES AND MONOBLASTS FROM MDS AND CMML PATIENTS, RESPECTIVELY, WAS SIGNIFICANTLY UPREGULATED BY CO-CULTIVATION WITH HS-5 SUP, LEN, AND POM, BUT NOT WITH CYTARABINE OR AZACITIDINE. THIS EXPERIMENT WAS REPEATED WITH 12 MDS CASES, FROM WHICH LDH DECREASED FROM 88 TO 77 IN MDS. BY CONTRAST, IN HEALTHY SAMPLES THE IRON CHELATION Diminished a REDUCTION OF OXPHOS ACTIVITY, WITH A CONSEQUENT IMPAIRMENT OF ATP/RATIO AND AN INCREASE OF ANAEROBIC GLYCOLYSIS FLUX. LIPID PEROXIDATION IS SIGNIFICANTLY REDUCED BY DFX AND 23% WITH DFX (P VALUE <0.001 FOR BOTH). SIMILAR REDUCTION IS OBSERVED IN B-HELASSEMIA. BY CONTRAST, MDA LEVELS INCREASED IN HEALTHY SUBJECTS INCUBATED WITH DFX. CURIOUSLY, ALL THESE ABNORMALITIES ARE MORE PROMINENT IN MDS WITH IOL COMPARED TO MDS WITHOUT IOL AND ARE SIGNIFICANTLY WORSE IN MDS WITHOUT IOL COMPARED TO ELDERLY NONMDS. FURTHERMORE, THE TREATMENT OF PATIENTS WITH DFX PROMOTES SIMILAR FINDINGS AS IN VITRO INCUBATION.

**SUMMARY/CONCLUSIONS:** IN SUMMARY OXPHOS ACTIVITY AND THE ENERGETIC STATUS ARE HIGHLY IMPAIRED IN MDS COMPARED TO ELDERLY SUBJECTS. MDS CELLS USED O2 TO PRODUCE ROS INSTEAD OF ATP. THIS IS TYPICAL OF AGE BUT IS SIGNIFICANTLY INCREASED IN MDS COMPARED TO ELDERLY CONTROLS AND IT IS FURTHER INCREASED BY IOL. DFX IS ABLE TO RESTORE MITOCHONDRIAL ACTIVITY AND ATP PRODUCTION IN ALL THE PATIENTS ANALYZED AFTER IN VIVO OR IN VITRO TREATMENT.
on cytomorphological characteristics, but it remains a challenge in some patients who do not fulfill diagnostic criteria. Flow cytometry (FC) immunophenotyping can be an important tool for MDS diagnosis, but a lack of standardisation and subjectivity of the analysis hinder its applicability.

**Aims:** To develop a methodology for FC immunophenotyping that allows us to establish the differential diagnosis between MDS patients and non-clonal cytopenias using a myeloid maturation database.

**Methods:** Bone marrow samples from 55 MDS patients, and 51 controls with cytopenias of several origins (immune disease, hypersplenism, drug toxicity) were analysed by FC. We elaborated a Myeloid Maturation Database using the Infinicyt® v1.7 software (Cytognos, Spain). From all bone marrow controls, we merged files stained with a 4-colour combination (CD16-FITC/CD13-PE/CD45-APC/CD11b-APC). We selected myeloid population from the merged file and drew a maturation path. We obtained a maturation diagram that displays the fluorescence intensity of each parameter measured along the maturation stages. Then, for patients and controls, we obtained the fluorescence intensities whose median values exceeded ±2SD range in comparison with the stored database values (Figure 1). We elaborated a score, considering the relevant changes in fluorescence intensities (deviations) in the four markers analysed (CD16, CD13, CD45, CD11b) and in the four maturation stages, with a punctuation from 0 to 16.

**Results:** We found a mean of 1.9 deviations (fluorescence intensities values exceeded ±2SD) in controls, and a mean of 4.5 deviations in patients. Our test resulted reliable for differential diagnosis between controls and patients (curve ROC analysis, AUC=0.748; p=0.016). We found that with a cut-off of 4.5 deviations, we obtained a high specificity in the diagnosis of MDS (100%) but a low sensitivity (45%). With a high suspicion of MDS (specificity 90%), we can consider patients with scores above 3.5, thus achieving higher sensitivity (59%). Additionally, the number of immunophenotyping changes correlated well with prognostic risk. We confirmed that the higher the risk, the greater impact on deviations from the normal pattern (average of 3.7 at low risk, 4.5 at intermediate risk; 6.8 at high risk) (Figure 2).

**Summary/Conclusions:** The maturation database (using the maturation analysis from Infinicyt® software) was useful to discriminate between MDS patients and non-clonal cytopenias, proving to be a reliable diagnostic test, also with prognostic implications. The application of this database as a diagnostic tool has the advantage that the result is independent of the observer. Inclusion of more myeloid markers and incorporation of erythroid parameters could increase sensibility in differential diagnosis.
Background: Epigenetic drugs are currently used for the treatment of several hematologic malignancies, but their pharmacological mechanism remains poorly understood. For DNA methyltransferase and histone deacetylase inhibitors (DNMTi and HDACi) several mechanisms of action have been proposed, mostly based on candidate gene approaches. However, less is known about their genome-wide transcriptional and epigenomic consequences.

Aims: To investigate the effects of epigenetic treatment on transcription and chromatin, we profiled genome-wide transcription start sites (TSS) activities and identified epigenetic changes following the treatment with inhibitors against DNMTi, HDACi, or both.

Methods: Genome-wide analysis of transcription start sites (TSS) (Cap analysis of gene expression (CAGE) sequencing), methylation status (whole-genome bisulphite sequencing) and chromatin dynamics (Chromatin-immunoprecipitation (ChIP) sequencing) was performed. DNMTi and HDACi treatment was performed by using a mouse neuroblastoma xenograft model. Functional assays were used to investigate the mechanisms of LTR reactivation, a neuroblastoma mouse xenograft model to confirm the LTR reactivation in vivo.

Results: Following the treatment with inhibitors against DNMTi, HDACi, or both, we observed the activation of thousands of cryptic, currently non-annotated transcription start sites (treatment-induced non-annotated transcripts, TINATs). These TINATs arose most commonly from LTR12 elements, particularly LTR12C (ca. 50% of all TINATs). The resulting transcripts frequently splice into protein-coding exons and encode truncated or chimeric open-reading frames which translated into currently uncharacterized protein isoforms with predicted abnormal functions or immunogenic potential, the last one based on uncharacterized candidate gene approaches. However, less is known about their genome-wide transcriptional and epigenomic consequences.
start of treatment was 21 months (95% CI=19-24); CR: 25 months (95%CI=20-30); PR: 27 months (95%CI=20-30); and SD: 17 months (95% CI=14-19) (p=0.006). We compared OS between mCR vs CR (p=0.193, HR 0.796 [95% CI=0.765-1.122]), mCR vs PR (p=0.572; HR =0.564 [95% CI=0.378-0.840]) or mCR vs SD (p=0.243; HR =1.242 [95% CI=0.863-1.788]), without any statistical difference (Fig. 1A). Median progression-free survival (PFS) was 14 months (95%CI=13-16); CR: 16 months (95%CI=13-21); PR: 11 months; mCR: 10 months (95%CI=5-15); and SD: 10 months (95%CI=9-12) (p=0.013). No statistical differences were observed between PFS in patients who achieved mCR vs PR (p=0.410; HR 1.816 [95% CI=0.439-7.612]) and SD (p=0.7743; HR 1.059 [95% CI=0.752-1.491]), but PFS was increased in those patients who achieve CR when compared to mCR (p=0.013; HR 0.665 [95% CI=0.482-0.918]) (Fig. 1B).

Aims: This ongoing, phase 2, multicenter, open-label study followed by a long-term extension (ext) study evaluates the effects of luspatercept in pts with low-risk MDS. Endpoints include long-term safety and tolerability, erythroid response (IWG Hi-E), pharmacodynamic and iron metabolism biomarkers, and pt-reported quality of life (QoL).

Methods: Inclusion criteria: MDS IPSS low or int-1, age ≥18 yr, Hgb <10 g/dL (if <4U RBC/8 weeks), no prior HMA, and no current lenalidomide or erythropoiesis-stimulating agent (ESA). The dose-escalation phase of the study is completed. An expansion cohort of up to 56 patients was added to this phase of the study to evaluate response to luspatercept in pts who would not qualify for the phase 3 MEDALIST trial (for regularly transfused ring-sideroblast positive [RS(+)] patients with EPO >200U/L). These include pts with low transfusion burden (LTB, <4U RBC/8 weeks) and either 1) RS(+) (≥15% in bone marrow) with baseline EPO ≤200U/L or 2) RS(-) and any EPO level. RS(-) pts were additionally treated w/4U RBC/8 weeks. Pts are treated every 3 weeks subcutaneously for up to 5 doses (titration up to 1.75mg/kg) in the base study (NCT01749510) and are then eligible for long-term treatment up to 5 additional years (NCT02268383).

Results: Data: (as of 09Sep2016) were available for 73 base and 42 ext study pts. Pts treated and 22 ext pts were LTB, 41 base ext center. The high transfusion burden (HTB, >4U RBC/8 weeks). Median (range) age (yr) was 72 (27-90), 53% pts had prior ESA, 51% pts had baseline EPO <200 U/L. Median (range) Hgb (g/dL) for LTb pts was 8.6 (6.4-10.1). Median (range) RBC transfusion burden (U/8 weeks) for HTB pts was 6 (4-18). 71% base and 86% ext pts were RS(+). IWG Hi-E response rates for pts treated with ≥0.75mg/kg in the base and ext studies, respectively, were 62% (18/29) and 83% (19/23) for RS(+)(t) pts with EPO <200 U/L and 46% (5/11) and 87% (8/9) for RS(+)(t) pts with EPO 200-500 U/L. RBC-TI rates for pts treated with >0.75mg/kg in the base and ext studies, respectively, were 66% (13/19) and 71% (10/14) for RS(+)(t) pts with EPO <200 U/L and 33% (3/9) and 60% (3/5) for EPO 200-500 U/L. Preliminary RS(-)(t) response rates (IWG Hi-E and RBC-TI) by subgroup will also be presented at the meeting. Luspatercept was well tolerated, with related grade 3/serious adverse events (in 3 pts) as of 28Nov2016 of blast cell count increase, myalgia, and worsening of general condition. The most common related AdEs (≥2 pts) were diarrhea, fatigue, headache, hypertension, arthralgia, bone pain, injection site erythema, myalgia, and peripheral edema.

Summary/Conclusions: Lower-risk MDS patients treated long-term with luspatercept demonstrated robust and sustained increases in Hgb and decreases in transfusion burden and a high rate of RBC-TI. A Phase 3 study of luspatercept in regularly-transfused RS(+) patients with lower-risk MDS according to IPSS-R is ongoing (MEDALIST study; NCT02631070).

**P667**

**LUSPATERCEPT INCREASES HEMOGLOBIN AND REDUCES TRANSFUSION BURDEN IN PATIENTS WITH LOWER-RISK MYELODYSPLASTIC SYNDROMES (MDS): LONG-TERM RESULTS FROM PHASE 2 PACE-MDS STUDY**

1Marien Hospital Düesseldorf, 2Universitätsklinikum Düsseldorf, Düsseldorf, 3III. Department of Medicine, Hematology and Medical Oncology, Technical University of Munich, Klinikum rechts der Isar, Munich, 4Onkologischer Schwerpunkt am Oskar-Helene-Heim, Berlin, 5OncoResearch Lenzerfelden Ug, Hamburg, 6University Hospital Bonn, Bonn, 7Universitätsklinikum Frankfurt, Goethe University, Frankfurt/Main, 8Johannes Gutenberg-Universität, Mainz, Germany, 9Aqeva Pharma Inc, Cambridge, 10Celgene Corporation, Summit, United States, 11Universitätsklinikum Carl Gustav Carus, Dresden, Germany

**Background:** Management of anemia is a common therapeutic challenge in patients (pts) with MDS. Luspatercept (ACE-536), a fusion protein containing GDF11 reducing aberrant Smad2/3 signaling and promoting late-term extension (ext) study evaluates the effects of luspatercept in pts with low-risk MDS. Endpoints include long-term safety and tolerability, erythroid response (IWG Hi-E), RBC transfusion independence (RBC-TI, ≥8 weeks), duration of Hi-E, pharmacodynamic and iron metabolism biomarkers, and pt-reported quality of life (QoL).

**Methods:** Inclusion criteria: MDS IPSS low or int-1, age ≥18 yr, Hgb <10 g/dL (if <4U RBC/8 weeks), no prior HMA, and no current lenalidomide or erythropoiesis-stimulating agent (ESA). The dose-escalation phase of the study is completed. An expansion cohort of up to 56 patients was added to this phase of the study to evaluate response to luspatercept in pts who would not qualify for the phase 3 MEDALIST trial (for regularly transfused ring-sideroblast positive [RS(+)] patients with EPO >200 U/L). These include pts with low transfusion burden (LTB, <4U RBC/8 weeks) and either 1) RS(+) (≥15% in bone marrow) with baseline EPO ≤200 U/L or 2) RS(-) and any EPO level. RS(-) pts were additionally treated w/4U RBC/8 weeks. Pts are treated every 3 weeks subcutaneously for up to 5 doses (titration up to 1.75mg/kg) in the base study (NCT01749510) and are then eligible for long-term treatment up to 5 additional years (NCT02268383).

**Results:** Data: (as of 09Sep2016) were available for 73 base and 42 ext study pts. Pts treated and 22 ext pts were LTB, 41 base ext center. The high transfusion burden (HTB, >4U RBC/8 weeks). Median (range) age (yr) was 72 (27-90), 53% pts had prior ESA, 51% pts had baseline EPO <200 U/L. Median (range) Hgb (g/dL) for LTb pts was 8.6 (6.4-10.1). Median (range) RBC transfusion burden (U/8 weeks) for HTB pts was 6 (4-18). 71% base and 86% ext pts were RS(+). IWG Hi-E response rates for pts treated with >0.75mg/kg in the base and ext studies, respectively, were 62% (18/29) and 83% (19/23) for RS(+)(t) pts with EPO <200 U/L and 46% (5/11) and 87% (8/9) for RS(+)(t) pts with EPO 200-500 U/L. RBC-TI rates for pts treated with >0.75mg/kg in the base and ext studies, respectively, were 66% (13/19) and 71% (10/14) for RS(+)(t) pts with EPO <200 U/L and 33% (3/9) and 60% (3/5) for EPO 200-500 U/L. Preliminary RS(-)(t) response rates (IWG Hi-E and RBC-TI) by subgroup will also be presented at the meeting. Luspatercept was well tolerated, with related grade 3/serious adverse events (in 3 pts) as of 28Nov2016 of blast cell count increase, myalgia, and worsening of general condition. The most common related AdEs (≥2 pts) were diarrhea, fatigue, headache, hypertension, arthralgia, bone pain, injection site erythema, myalgia, and peripheral edema.

**Summary/Conclusions:** Lower-risk MDS patients treated long-term with luspatercept demonstrated robust and sustained increases in Hgb and decreases in transfusion burden and a high rate of RBC-TI. A Phase 3 study of luspatercept in regularly-transfused RS(+) patients with lower-risk MDS according to IPSS-R is ongoing (MEDALIST study; NCT02631070).

**Figure 1.**

**Summary/Conclusions:** Although mCR and CR result in the same OS, PFS is increased in patients achieving CR when compared with mCR. These data indicate that mCR should be considered as a valid endpoint in clinical trials.
survival advantage when compared with conventional therapies and has also shown activity in IPSS lower-risk patients. However, about 40% of patients do not respond and most patients lose response within 2 years. Treatment options for MDS patients failing hypomethylating agents therapy are scarce and overall survival (OS) is extremely short.

Aims: Objectives of this study were to describe in a cohort of real life MDS patients treated with AZA, the reasons causing treatment discontinuation, and to evaluate the clinical outcome after the end of AZA therapy.

Methods: Unselected patients recorded in the MDS Registry of Fondazione Italiana Sindrome Midollinoplastiche (FISIM) and treated with AZA from January 2009 to June 2014 were considered for the analysis. All types of conventional pancytopenia and unexplained cytopenias allowed of AZA were allowed. Clinical response, cause of discontinuation, salvage treatments and OS from discontinuation of AZA were the major end points.

Results: Between January 2009 to June 2014 1799 newly diagnosed MDS patients were enrolled in the Registry, and 418 received AZA; 269 as 1st line treatment (64%), 11 patients (3%) received 2nd line treatment (28%) and 34 as a line ≥3rd (8%). Median age at diagnosis was 73 years (range 18-91); 260 patients (62%) were male. WHO diagnosis was RA or RARS (n=27, 6%), RCMD with or without RS (n=62, 15%) and RAEB (n=126, 30%), RAEB-2 (n=189, 45%), other subtypes (n=15, 4%). At start of AZA therapy IPSS score was low in 14 (3.4%), int-1 in 97 (23.2%), int-2 in 163 (43.8%); high in 67 patients (16%), and not available in 57 patients (13.6%). Patients received a median of 7 courses of treatment (range 1-63). Seventy-three % of the whole cohort (418 pts) were alive at 1 year from beginning of AZA therapy and median OS was 23 months. (25 for IPSS lower-risk MDS and 21 for IPSS higher risk MDS). OS after discontinuation of AZA was 8 months. Clinical responses according to IWG criteria were available in 344 (418 patients, 81%): 22 patients (6%) achieved a complete haematological response, 77 (22%), a partial response, 86 (25%) had stable disease while 136 (40%) did not respond. Response was achieved after a median of 6 cycles. A median follow up of 16 months (range 7-35) in 37 (9%) patients AZA therapy was still ongoing while in 381 (91%) the treatment has been discontinued. Interruption of treatment was due to loss of response in 59 (16%) patients, AML evolution in 154 (40%), death in 43 (11%), toxicity or poor compliance in 39 (10%), allogeneic transplant (HSCT) in 12 (3%), other reasons in 22 (6%), not reported in 52 patients (14%). Of the 381 patients who discontinued AZA, 15 (4%) were managed with intensive AML-like chemotherapy, 22 (6%), received an allogeneic HSCT, 27 (7%) low-dose chemotherapy (7%), 22 (6%) erythroid stimulating agents, 18 (5%) other treatments and 277 (72%) patients no further treatment or only supportive therapy.

Summary/Conclusions: Our data confirm that AZA therapy is effective for MDS patients, both with higher and lower IPSS risk disease. Response rate is consistent with what previously reported, with a median OS of 23 months. Interestingly, at 16 months, 91 % of patients had discontinued treatment, either for progression or loss of response and only in 10% of cases for reported toxicity. Only 28% of patients received any kind of salvage therapy and overall survival after AZA discontinuation was poor (8 months).

P668 COMBINATION OF DEEP PHENOTYPING AND TARGETED NEXT GENERATION SEQUENCING AS A DIAGNOSTIC TOOL IN CHILDREN WITH SUSPECTED MDS E. Louka1,*, A. Hamblin2, G. Buck1, H. Drew2, P. Ware2, P. Ancil1, S. Background: Paediatric Myelodysplastic Syndromes (MDS) are a rare and heterogeneous group of disorders distinct from adult MDS. They may present with symptoms of anaemia, life threatening infection or evolving leukaemia; however, they may also present as unexplained cytopenias or with multisystem disease of unclear aetiology. Diagnosis can represent a huge challenge for clinicians, even in highly specialised centres and this can delay the delivery of the most appropriate treatment. Hence an accurate diagnosis is crucial in selecting the most appropriate management, including surveillance and follow up.

Aims: To devise a clinical grade diagnostic targeted NGS panel and combine the results with extensive clinical phenotypic information to obtain a diagnosis in children referred with suspected MDS.

Methods: Children (0–18yrs) were referred from 14 UK centres with a diagnosis of suspected MDS and/or sustained cytopenias with morphological features of myelodysplasia. Extensive phenotypic information including family history, detailed clinical examination and disease course details were collected and captured on an online database using the Human Phenomiser tool. A customised targeted NGS panel was designed using the Illumina design studio containing 42 genes, 916 amplicons and 301 exons; selected through literature reports and well described mutations in Paediatric MDS and potential overlap Bone Marrow failure syndromes (BMFS). Coverage of each base within target regions was assessed for every sample on each sequencing run using Covemri software. Library preparation was performed using an Illumina TrueSeq Custom Amplicon panel, followed by sequencing on an Illumina MiSeq. Data analysis was performed using our established bioinformatic pipelines (Hamblin A: Blood 2014 124:2373).

Results: In total 59 patients (females= 29, males 30) have been screened and 3 subgroups identified based on the original suspected clinician diagnosis at presentation: MPN/JMML (n= 15), de novo MDS (n=9) and idiopathic cytopenias of undetermined significance, (ICUS) with some features of dysplasia (n= 35). Mutations were detected in 24/59 patients (40%, Table 1). Of these, NGS results confirmed the original clinical diagnosis in 15 cases (62.5%); established the diagnosis for the first time in 6 cases (25%); and led to a change in diagnosis (from autoimmune neutropenia to Shwachman-Diamond Syndrome) in 1 case leading to a significant change in patient management. In two already known cases, it allowed monitoring of the disease molecular signature. As expected, BMAS pathway mutations were common in the JMML/MPN (100%) and de novo MDS patient subgroups (33%). Additional mutations in epigenetic modifiers, spliceosome mutations as well as second BMAS pathway hits were also detected in 40% of JMML patients and in one case within the de novo MDS group; this finding was associated with poor outcome. Within the heterogenous ICUS patient group, pathogenic mutations were identified in 5 (13.6%) cases with BMFS genes (SBDS, ELANE, TP53). In contrast to the other MDS/MPN cases, in this group, no BMAS pathway mutations were detected.

Summary/Conclusions: Targeted NGS together with detailed phenotyping is a useful tool for the diagnosis of suspected MDS and unexplained cytopenias in children, with 40% of patient showing a disease-associated mutations. Results were available within 6-8 weeks in most cases enabling both rapid initial diagnosis and, in some cases, appropriate molecular markers for monitoring of clonal evolution and response to therapy. For the children who remain without a clinical diagnosis, whole genome sequencing (WGS) may identify pathogenic mutations and this is currently underway.
Myeloma and other monoclonal gammopathies - Clinical 3

Background: The majority (88.2%) received SC bortezomib, 18 (11.8%) received at least 1 cycle of PAD. The median age was 55 years (range 28-71), 139 (91%) received 4-6 cycles of PAD. More detailed subtyping of the lymphocyte phenotypes is ongoing and may reveal potential predictive biomarkers for immunomodulatory drugs such as lenalidomide and checkpoint inhibitors.

Results: Between April 2011 and January 2014 153 patients were enrolled (median age 55, range 28-71 years), 139 (91%) received 4-6 cycles of PAD. The overall response rate to PAD was 82.4% (≥VGPR: 41.2%). Responses were similar irrespective of ISS or genetic risk (standard: ≥VGPR 37.5%, PR 40.9%, adverse: ≥VGPR 53.5%, PR 34.9%). Post-PBSCH, 63 (41.2%) patients achieved ≥VGPR, and 44 (28.8%) patients achieved PR of whom 36 proceeded to ASCT. After a median follow-up of 44 months from registration, median overall PFS was 22.5m (95% CI: 18.1-25.3). For those who achieved ≥VGPR, median PFS from PBSCH was 8.9m (95% CI: 4.6-13.3) and 25.7m (95% CI: 13.7-37.6) for MRD+ (N=25) and MRD- (N=16) patients at D100 post-PBSCH respectively. 2y-PFS 28.0% (95% CI: 19.4-45.6) and 56.3% (95% CI: 32.0-80.6) respectively. PR patients proceeding to ASCT had a median PFS of 17.2m (95% CI: 14.2-20.2) and 23.1m (95% CI: 16.8-29.4) for those who were MRD+ (N=20) and MRD- (N=7) at D100 respectively, 2y-PFS 23.0% (95% CI: 0-100) and 42.9% (95% CI: 6.2-79.6) respectively.

Summary/Conclusions: This is the first study to report outcomes of patients stratified to ASCT by depth of response. The overall PFS for the study is shorter than other published trials, most likely due to the inferior outcome for MRD+ patients. More detailed subtyping of the lymphocyte phenotypes is ongoing and may reveal potential predictive biomarkers for immunomodulatory drugs such as lenalidomide and checkpoint inhibitors.

Figure 1.
Background: Lytic lesions occur in the majority of patients with multiple myeloma (MM) and represent one of the criteria for starting therapy. In the past, whole-body X-ray (WBX) represented the method of choice for detecting skeleton abnormalities; today, magnetic resonance imaging (MRI), positron emission tomography (PET) and computed tomography (CT) have been adopted for their higher power in detecting extra-medullary localizations and their higher sensitivity. Nevertheless, which technique would be really the best one is still matter of current discussion.

Aims: Our single-center retrospective study was designed to compare PET-CT with other imaging techniques (WBX, vertebal column CT and MRI) at the diagnosis and during the follow-up of MM patients. Finally, we assessed a possible predictive/prognostic role of the PET-CT in terms of quality of response and survival.

Methods: We enrolled 160 patients with diagnosed symptomatic (N=149) or smoldering multiple myeloma (N=11) observed at the AOUOP, Pisa, Italy, between January 1996 and December 2015. Eighty-three were male and 77 female; the median age was 70 years (range, 28-85), and half of them presented with low ISS risk score. Forty-five subjects were not eligible to high-dose therapy; 64% of them received bortezomib- and 23% melphalan-based regimens. Patients eligible to high-dose therapy received VAD, TAD or VTD and then one (88%) or two (12%) autologous transplants. At the relapse, lenalidomide (57%) or anthracyclines (40%) were administered.

Summary/Conclusions: Our study showed that PET-CT and MRI would represent the techniques of choice in the assessment of bone involvement in MM patients in view of their high and comparable sensitivity. Moreover, PET-CT allowed detecting skeletal involvement in 18% of cases negative by WBX, in 37% of those CT-negative, and in 10% of those MRI-negative. Sensitivity of PET-CT was superimposable to that of MRI (90%), and higher than that of WBX (60%) and CT (73%). Nevertheless, the specificity was lower for PET-CT and MRI (40%) in respect of CT (51%) and WBX (71%). Analogously to that observed at diagnosis, PET-CT during follow-up showed distinct advantages in terms of sensitivity compared to X-rays (83% vs 60%, respectively). In contrast, PET-CT sensitivity was comparable to that of CT and MRI. As at diagnosis, the specificity was higher for WBX (70%) than for CT, RM and PET-CT (40% for all of these). When PET-CT was correlated to the quality of response, it was significant only in the not transplanted cohort (>PR rate in PET-negative cases vs 27% vs 23% in the PET-positive group; p=0.016). Nevertheless, PET-CT positivity either at diagnosis or during follow-up did not impact on long-term OS and PFS.

results: Overall, we compared 160 PET-CT, 233 WBX, 106 CT, and 85 MRI exams. At diagnosis, PET-CT allowed detecting skeletal involvement in 18% of cases negative by WBX, in 37% of those CT-negative, and in 10% of those MRI-negative. Sensitivity of PET-CT was superimposable to that of MRI (90%), and higher than that of WBX (60%) and CT (73%). Nevertheless, the specificity was lower for PET-CT and MRI (40%) in respect of CT (51%) and WBX (71%). Analogously to that observed at diagnosis, PET-CT during follow-up showed distinct advantages in terms of sensitivity compared to X-rays (83% vs 60%, respectively). In contrast, PET-CT sensitivity was comparable to that of CT and MRI. As at diagnosis, the specificity was higher for WBX (70%) than for CT, RM and PET-CT (40% for all of these). When PET-CT was correlated to the quality of response, it was significant only in the not transplanted cohort (>PR rate in PET-negative cases vs 27% vs 23% in the PET-positive group; p=0.016). Nevertheless, PET-CT positivity either at diagnosis or during follow-up did not impact on long-term OS and PFS.

Summary/Conclusions: Our study showed that PET-CT and MRI would represent the techniques of choice in the assessment of bone involvement in MM patients in view of their high and comparable sensitivity. Moreover, PET-CT allowed detecting skeletal involvement in 18% of cases negative by WBX, in 37% of those CT-negative, and in 10% of those MRI-negative. Sensitivity of PET-CT was superimposable to that of MRI (90%), and higher than that of WBX (60%) and CT (73%). Nevertheless, the specificity was lower for PET-CT and MRI (40%) in respect of CT (51%) and WBX (71%). Analogously to that observed at diagnosis, PET-CT during follow-up showed distinct advantages in terms of sensitivity compared to X-rays (83% vs 60%, respectively). In contrast, PET-CT sensitivity was comparable to that of CT and MRI. As at diagnosis, the specificity was higher for WBX (70%) than for CT, RM and PET-CT (40% for all of these). When PET-CT was correlated to the quality of response, it was significant only in the not transplanted cohort (>PR rate in PET-negative cases vs 27% vs 23% in the PET-positive group; p=0.016). Nevertheless, PET-CT positivity either at diagnosis or during follow-up did not impact on long-term OS and PFS.
Results: There were 78 patients in Group 1 and 52 patients in Group 2. Patients in Group 2 had higher baseline dFLC, bone marrow plasma cells (BMPc). Mayo stage and were more likely to have active MM compared to patients in Group 1. Table 1 lists baseline characteristics of the patients in Groups 1 and 2. Patients in Group 1 had higher rate of renal involvement. cPCs were detectable in 22% (n=28) of patients at the time of ASCt. More patients in Group 1 had detectable cPCs than in Group 2 (31% vs 8%; p<0.002), likely due to clearance of cPCs with treatment. Data on cPCs at diagnosis in the induction group was available in 14 patients, of whom 57% (n=8) had detectable cPCs vs 31% in the direct ASCt group (p=0.06). 6 of the 8 (75%) patients cleared cPCs with induction therapy. There were no significant differences in patients who had detectable and undetectable cPCs before transplant, including organ involvement, baseline dFLC, BMPc, and Mayo Stage (data not shown).

In Group 2, both progression free survival (PFS) (10.5 months vs 58 months, p<0.0001) and overall survival (OS) (16 months vs not reached, p<0.0001) were worse in patients who had detectable cPCs compared to those without cPCs (Figure 1). This difference was not seen in Group 1 (OS: not reached vs 98 months, p=0.96; PFS 43 vs 52 months, p=0.74). In multivariate analysis, adjusting for Mayo Stage and induction chemotherapy, there was a trend towards worse OS in patients with detectable cPCs (p=0.06).

Figure 1. Patients receiving induction chemotherapy before ASCt

Summary/Conclusions: cPCs are cleared after induction treatment in majority of AL patients. Patients who have detectable cPCs prior to proceeding to ASCt after induction have worse PFS and OS than patients without cPCs. The other hand, presence of cPCs was not found to be an adverse prognostic factor in patients proceeding directly to ASCt. This may be due otherwise excellent prognosis in this group, with absence of other high-risk features that are seen in patients who require induction. A limitation of our study is lack of data on cPCs at diagnosis in all patients who received induction therapy.

P674

RENAI IMPAIRMENT IN MYELOMA - PATIENT CHARACTERISTICS, TREATMENT MODALITIES, STEM CELL TRANSPLANTATION & OUTCOMES FROM THE AUSTRALIAN AND NEW ZEALAND MYELOMA REGISTRY

Background: Renal impairment (RI) is a poor prognostic factor in multiple myeloma (MM). Analysis of disease characteristics, therapy & outcomes can improve treatment & prognosis.

Aims: To assess (1) characteristics of patients with RI at diagnosis - severity of RI, age, risk factors, high risk features, stage, disease manifestations & performance status, and (2) treatment including induction therapy & autologous stem cell transplant (ASCT) and outcomes.

Methods: Data from newly diagnosed MM patients enrolled in the Australian and New Zealand Myeloma Registry from 1 Feb 2013 to 31 Dec 2016 were analysed.

Results: Of 867 patients, 775 had eGFR available at diagnosis: 34% (267/775) had eGFR <60ml/min (22% at 30-60 ml/min; 6% at 15-30 ml/min; 6% at <15 ml/min). Mean age of patients with RI (<60 ml/min) was 72 vs 64 years without RI. Diabetes melitus (DM), a major cause of chronic kidney disease (CKD), was more prevalent in patients with RI: 17% of patients with eGFR <30 ml/min compared with 8% >30 ml/min. Patients with RI (<30 ml/min) and DM had a similar response to first-line therapy compared to RI without DM (PR, 75% vs 82%, p=0.56), with no difference in OS (26 vs 37 mths, p=0.68) or PFS (24 mths, p=0.82). High risk features of FISH (del17p, t(14;16), t(14;16), amp1q21, del13q) & high LDH were more prevalent in RI compared with eGFR 46-30 ml/min vs 46-30 ml/min (Fig 1). However, patients with eGFR >30 ml/min had better OS than RI patients with eGFR <30 ml/min (p=0.03) & OS (HR 0.28, 95%CI 0.08-1.01, p=0.05) compared with no ASCT. The improvement was also seen in severe RI (<30 ml/min), with a longer PFS (HR 0.21, 95%CI 0.05-0.86, p=0.03) & OS (HR 0.10, 95%CI 0.01-0.82, p=0.03) with ASCT.
BCL-2 inhibitor, induces cell death in multiple myeloma (MM) cells, particularly those with the t(11;14) translocation.

**Aims:** The objectives of the study are to evaluate safety, PK, recommended phase two dose, and preliminary efficacy of VEN monotherapy in relapsed/refractory (R/R) MM.

**Methods:** Patients (pts) with relapsed/refractory (R/R) MM received VEN monotherapy in this phase 1 study. Daily VEN was given at 300–1200mg in dose escalation cohorts and 1200mg in the safety expansion. Pts with disease progression (PD) on VEN monotherapy could receive VEN plus dexamethasone and remain on study.

**Results:** As of 19Aug2016, 66 pts were enrolled. Median age was 63 years (36–80) and 36 (46%) pts had t(11;14). Median number of prior lines of therapy was 13 (range: 1–15): 46 (70%) pts were refractory to bortezomib, 20 (30%) to carfilzomib, 57 (77%) to lenalidomide, 35 (53%) to pomalidomide, and 52 (79%) were refractory to the last prior therapy. Median time on VEN monotherapy was 2.5 months (range: 0.2–23); 17 pts received VEN plus dexamethasone after PD for a median (range) of 1.53 (0.5–23) months. Fifty-five (83%) pts discontinued, with 41 due to PD. Common adverse events (AEs) were nausea (47%), diarrhea (36%), vomiting (21%) and grade 3/4 hematologic toxicities [thrombocytopenia (32%), neutropenia (27%), anemia (23%), leukopenia (23%)]. Common serious AEs were pneumonia (8%), sepsis (5%), cough, hypotension, pain, and pyrexia (3% each). There were no events of TLS. Six deaths were reported due to PD, and 1 each due to lung disorder and brain hemorrhage following trauma. Overall response rate (ORR) for all pts on VEN monotherapy was 21% (14/66); 10 (15%) achieved very good partial response (VGPR) or better [2 stringent complete response (sCR), 3 CR, 5 VGPR]. For all pts, median time to progression (TTP) was 4.7 months (range: 5–34). A clear difference in responses was seen among pts with t(11;14) vs without [ORR, 40% vs 6%; ≥VGPR, 27% vs 6%]. For pts with t(11;14), median TTP was 6.6 months [vs 1.9 months for pts without (t(11;14)] and median DoR was 9.7 months. A high BCL2:BCL2L1 (BCL-X) gene expression ratio was observed in 10/44 (23%) baseline tumor samples, enriched in pts with (t(11;14)) compared with not (t(11;14)) (38% vs 5%) and associated with clinical response; 80% (8/10) of pts [all t(11;14)] with a high BCL2:BCL2L1 ratio achieved ≥PR with a median TTP of 11.5 months. Among pts with (t(11;14)) who were refractory to the last therapy, ORR was 42% (11/26); for t(11;14) pts refractory to both bortezomib and lenalidomide, ORR was 40% (8/20) and 50% (3/6), respectively. No difference was seen in ORR for (t(11;14) pts with high-risk del(17p) versus those without the deletion [40% (2/5) vs 40% (10/25)].

**Summary/Conclusions:** VEN has an acceptable safety profile with promising single-agent anti-myeloma activity in pts with R/R MM positive for (t(11;14)) who failed multiple prior lines of therapy.

**P676**

AN OPEN-LABEL, PHASE 1B STUDY (MMY1001) OF DARATUMUMAB COMBINED WITH CARFILZOMIB, LENALIDOMIDE, AND DEXAMETHASONE (KRd) IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM)

S.Z. Usmani1,*, A. Charī2, S.Lonial3, B. Weiss4, R.L. Comenzo5, K. Wu6, E.H. van Beers1, B. van der Holt4, H. Visser5, M. Hansson6, A.W. van der Velden7, J. van den Dungen8, M. Vermeulen9, J. Koenders9, H.B. Vervoord10, M. Stevens-Kroef10, A. Jakubowiak11, S. Zweegman1, P. Sonneveld1, Bioinformatics, SkylineDx, 2Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, 3Department of Internal Medicine, Albert Schweitzer Hospital, Dordrecht, 4Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, 5Division of Hematology and Transfusion Medicine, Skåne University Hospital, Lund, Sweden, 6Department of Internal Medicine, Martini Hospital, Groningen, 7Department of Clinical Genetics, Erasmus MC, Rotterdam, 8Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands, 9Norwegian University of Science and Technology, Trondheim, Norway, 10Department of Virology, UVI University Medical Center, Amsterdam, Netherlands

**Background:** Multiple myeloma (MM) affects mostly elderly people with a median age of 69 years at diagnosis, with 35-40% of patients older than 75. Overall survival (OS) is variable: of patients aged 66-79, 9% survive less than 3 months and 23% survive longer than 10 years. Recently the revised ISS (rISS) has been proposed as a prognostic marker that incorporates ISS, FISH and LDH. Another marker, the SKY92 prognostic classifier, first described in 2002, was developed in younger, transplant eligible multiple myeloma (MM) patients who were included in the HOVON-65/GMMG-HD4 trial. The SKY92 classifier was thoroughly validated in eight independent cohorts, at the time of its initial publication, and since. **Aims:** Here, we validated the SKY92 gene expression classifier and rISS in elderly, non-transplant eligible patients included in the HOVON-87/NMSG-18 trial (Zweegman et al. Blood 2016;127(9):1109-1116).

**Methods:** In this trial, melphalan, prednisone, thalidomide (MPT) plus thalidomide maintenance was compared with melphalan, prednisone, lenalidomide (MPR) plus lenalidomide maintenance. The MMprofiler™ CE IVD assay was used to obtain SKY92 scores, classifying a patient as high-risk or standard-risk. In addition, the international staging system, LDH, FISH and rISS were analyzed.

**Results:** The 178 patients in the analysis for which enough bone marrow was available to perform GEP, had a median age of 73 years. At the time of data collection, 31.5% had MM for less than 12 months. There were 25 of 178 patients as high-risk (14%). The median OS for the 25 patients classified as SKY92 high-risk was shorter than the median OS of standard-risk patients: SKY92 high-risk 21 months versus SKY92 standard-risk 35 months (hazard ratio (HR)=3.0, 95% confidence interval (CI)=1.7-5.3; p<0.01); Figure 1 shows the proportion of patients with high-risk ISS-Ill is 8%, which is comparable to the 10% identified in the initial report of the rISS. Interestingly, the proportion of SKY92 high-risk patients is larger (14%), whereas the median OS associated with these patients is shorter (21 vs 25 months). The SKY92 classifier performed better compared to the rISS as high-risk marker for OS. The 2-year OS rate using the SKY92 classifier was significantly lower than patients verified by rISS (35% vs 45%). The 2-year progression free survival (PFS) rate was similar for SKY92 high-risk and rISS-III (16% and 17%, respectively). In the multivariate analysis, SKY92, rISS and deletion of 13q were independently associated with OS. Inde-
Background: The number of multiple myeloma patients has grown with aging populations, and with increasing age the number of comorbidities increases as well. Clinically, it is well known that comorbidity in multiple myeloma patients decreases performance status, increases risk of therapy-related complications and may lead to life-threatening conditions. Currently, the literature on comorbidity in multiple myeloma is very limited and based on small case series. Clinical trials rarely include elderly, frail patients due to eligibility criteria. Population-based studies provide valuable information on survival outcomes in relation to presence/absence of comorbidities in newly diagnosed real-life multiple myeloma patients in the general population.

Aims: To evaluate the prevalence of comorbidities and to study the impact of comorbidities on survival among patients with newly diagnosed multiple myeloma.

Methods: All newly diagnosed patients with multiple myeloma from January 1st, 1985 to December 31st, 2013 in Sweden were included in the study. Using the Swedish Patient Registry, all discharge diagnosis and discharge listings were gathered from each patient from January 1st, 1985. Comorbid conditions were defined as chronic illnesses which demand life-long treatment or follow-up. Only those diagnoses made prior to multiple myeloma were used. Using ICD 8, 9 and 10 codes, comorbid diseases were identified. Kaplan-Meier curves were used to estimate survival. Risk of death was compared among multiple myeloma patients with a comorbid condition to those without a comorbidity, using Cox’s proportional hazards regression (adjusting for age, gender, year of diagnosis, and other comorbidity conditions).

Results: A total of 13,718 patients with multiple myeloma were included in the study and 21 groups of comorbidities were identified. The most common diseases were cancer, hypertension, heart failure, ischemic heart disease and atrial fibrillation. Among all patients, 55% had no prior history of comorbidity, 23% had one comorbidity, 12% had two comorbidities, and 10% had three or more comorbidity conditions. Survival was negatively influenced by the number of comorbidities (Figure 1). The risk of death was significantly increased in patients with atrial fibrillation (HR=1.08; 95% CI 1.00-1.16), heart failure (HR=1.50; 95% CI 1.40-1.61), stroke (HR=1.20; 95% CI 1.11-1.30), psychological disease (HR=1.27; 95% CI 1.16-1.39), chronic lung disease (HR=1.22; 95% CI 1.12-1.32), diabetes (HR=1.14; 95% CI 1.04-1.36), peripheral vascular disease (HR=1.26; 95% CI 1.12-1.42), cancer (HR=1.10; 95% CI 1.04-1.16), dementia (HR=1.65; 95% CI 1.38-1.99), paralysis (HR=1.44; 95% CI 1.15-1.80), inflammatory bowel disease (HR=1.38; 95% CI 1.08-1.74), end stage renal disease (HR=1.57; 95% CI 1.03-2.04), and cirrhosis (HR=1.64; 95% CI 1.10-2.43).

Summary/Conclusions: In this large, population-based study including almost 14,000 patients, we have shown that comorbidities are common among newly diagnosed multiple myeloma patients and that comorbidities are associated with an inferior survival. Importantly, the number of comorbidities showed a dose-response relationship with inferior overall survival. For example, the median overall survival for patients with 3 or more comorbidities was reduced by more than 50% compared to patients without comorbidities. The importance of comorbidities should be taken into account when evaluating patients and deciding on treatment strategies for individuals with multiple myeloma.
DETECTION OF NEW EMERGING CLONES DURING TREATMENT BY NGS ALLOWS A BETTER RISK PREDICTION ON MULTIPLE MYELOMA PATIENTS

Background: Multiple myeloma (MM) is a genetically complex disease, characterized by the presence of multiple clones with differing degrees of drug sensitivity at the time of diagnosis. Consequently, therapeutic response of MM patients is unpredictable and extremely variable, and although the treatments introduced over the last decade have significantly improved the outcome of these patients, most patients eventually relapse. Deep sequencing methods have contributed to increase the knowledge about the clonal heterogeneity of the disease and helped to establish the three evolution patterns at relapse: linear and branching clonal evolution, and no clonal changes. Aims: To analyze the diversity and relative dominance of different clones and their evolution throughout the course of disease by NGS of the immunoglobulin repertoire in MM patients. To evaluate if the presence of different clones is associated with increased risk.

Methods: Immunoglobulin repertoire was analyzed by NGS in bone marrow samples from 180 MM patients included in three GEM clinical trials (NCT00461747, NCT00443235 and NCT01237249). The two first clinical trials involved patients younger than 65 years old, and were analyzed with ChocoSeq methodology, the later one involve patients older than 65 years old, and were analyzed with a local NGS method recently validated (Martínez-López et al, Laukema 2017). A clonotype was identified when at least 400 identical sequencing reads were obtained, or it is present at a frequency of >1%.

Results: Of the 180 MM patients studied, 57 (32%) shows the presence of more than one clone throughout the clinical course of the disease. The identification of new evolving clones was only possible in the GEM10 clinical trial with the Local NGS method; in this clinical essay, 6% (4/71) of patients shows the development of different clones during treatment. We show that the frequency of the predominant clone at diagnosis of these four patients decreased with treatment, but the frequency of the new ones increased and the patients progressed. When more than one clone is present at diagnosis, the relative dominance of the clones varies throughout the course of disease in an unpredictable manner. There were no differences in median MRD values between patients with one clone or more than one clone (0.0082% and 0.0055% respectively). The presence of more than one clone was not associated with high-risk cytogenetics. The presence of more than one clone at diagnosis does not condition the prognosis in any of the patients and treatments analyzed. Median PFS was 38 and 58 months for patients with one clone or more one clone, respectively (HR=1.43, p=0.28).

Summary/Conclusions: The analysis of the IG repertoire by the local NGS method during treatment is able to identify and quantify new emerging clones during the treatment that were not detectable at diagnosis. The new clones contributed to increase the MRD levels in the follow-up samples. The presence of different clones at diagnosis is not associated with higher risk of progression, high risk cytogenetics or higher MRD values.

PANOBINOSTAT INDUCES CD38 UPRGRADING AND AUGMENTS THE ANTI-MYELOMA EFFICACY OF DARATUMUMAB

Background: Immunotherapy with the anti-CD38 monoclonal antibody (mAb) daratumumab is increasingly being utilized in myeloma patients with relapsed/refractory (R/R) disease after prior treatment with immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs). However, the efficacy of daratumumab is limited by low expression of CD38 on myeloma cells. We investigated the use of the histone deacetylase inhibitor (HDACi) panobinostat to modulate target antigen expression on myeloma in favor of potent mAb-mediated recognition and destruction. We show that panobinostat augments CD38 expression specifically on myeloma cells and demonstrate powerful synergy with anti-CD38 mAb daratumumab.

Aims: Determine the impact of panobinostat on upregulation of CD38 expression on myeloma cells in order to enhance the efficacy of daratumumab.

Methods: Myeloma cells were treated with titrated doses of panobinostat (0, 10, 25 nM) and expression of CD38 and a panel of additional target molecules including SLAMF7, as well as accessory ligands analyzed by flow cytometry at 24, 48 and 72 hours. Antibody-dependent cellular cytotoxicity (ADCC) against panobinostat treated and untreated myeloma cells was analyzed at 4 and 20 hours after addition of PBMC at an effector to target ratio of 25:1 in the presence of daratumumab or an isotype control antibody.

Results: Myeloma cells treated with panobinostat (n=12 patients) with panobinostat (10 vs 25 nM) and observed a uniform increase in CD38 expression in each case by flow cytometry. Upregulation of CD38 was already detectable after 24 hours, peaked after 48 hours of exposure to panobinostat and was higher at the 25 nM compared to the 10 nM dose. At 48 hours, the mean fluorescence intensity (MFI) of CD38 expression in panobinostat and untreated myeloma cells was 271, respectively (136, p=0.563). Median GS was not reached for patients with one clone, and was 81 months for patients with more than one clone (HR=1.43, p=0.28).

Summary/Conclusions: The analysis of the IG repertoire by the local NGS method during treatment is able to identify and quantify new emerging clones during the treatment that were not detectable at diagnosis. The new clones contributed to increase the MRD levels in the follow-up samples. The presence of different clones at diagnosis is not associated with higher risk of progression, high risk cytogenetics or higher MRD values.

FINAL RESULTS OF PHASE (PH) 1/2 STUDY OF CARFILZOMIB, POMALIDOMIDE, AND DEXAMETHASONE (KPD) IN PATIENTS (PTS) WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM): A MULTI-CENTER MMRC STUDY

Background: In the era of increased use of 1st-line and maintenance lenalidomide (LEN), there is growing need for effective 2nd-line therapies (tx) for LEN-refractory pts. The combination of carfilzomib (CFZ), pomalidomide (POM), and dexamethasone (DEX) has shown promising activity in advanced RRMM, including for pts refractory to LEN (Shah et al. Blood. 2015).

Aims: In this Ph 1/2 study, KPD was evaluated in RRMM, with a focus on pts who are LEN-refractory but proteasome inhibitor (PI)-naive/sensitive.

Methods: LEN-refractory disease was required for 2nd-line KPD and LEN-refractory exposure for ≥2 cycles. Ph 1 dose escalation to determine MTD. Ph 1 dose escalation to determine MTD. Ph 2 dose escalation to determine MTD.

Results: As of 12/1/16, 65 pts have been enrolled, with efficacy and safety data available for 64 pts; 4 at DL1 (20mg/m2 CFZ, 3mg POM), 29 at DL2 (20mg/m2 CFZ, 4mg POM), 40 at DL3 (20/27mg/m2 CFZ, 4mg POM), and 2 at DL4 (20/36mg/m2 CFZ, 4mg POM). Median age was 63 y, median time from diagnosis 5.1 y, median prior tx lines 2, and 94% had refractory disease. Cytogenetic data were available for 59 pts; 33% were high risk per IMWG. There were 9 dose-limiting toxicities, all asymptomatic cytopenias: 6 pts with grade (G) 3 neutropenia and 1 with G4 thrombocytopenia. The MTD was established at DL3. In 64 pts, G3/4 hematologic toxicities included neutropenia (25%) and lymphopenia (14%), and non-hematologic toxicities (all grades) included fatigue (51%), dyspnea (42%), and gastrointestinal (45%). PRs were rapid with a ≥PR rate of 63% after 1 cycle and 77% after 4 cycles. After a median of 20.9 cycles (range, 1.7–49), ≥PR (n=54, 85%), ≥CR (n=35, 56%), and ≥NCR (n=20, 35%) were achieved. Complete response (CR) and ≥CR complete response (nCR) 20%. In the 1st population (N=55, 51% LEN-refractory, 28% progressing on LEN maintenance), ≥PR was 84% with 30 treated at MTD. After median follow-up of 21 (1–49) mo, median progression-free survival (PFS) for all 64 pts enrolled was 16.8 mo and 2-y overall survival (OS) was 76.8% with 20 pts remaining on treatment. For standard-risk (n=38) vs high-risk pts (n=21), ≥PR was 89% vs 81%, ≥nCR was 24% vs 10%, median PFS was 22.3 vs 10.6 mo, and 2-y OS was 90.8% vs 56.0%.

Summary/Conclusions: KPD is well tolerated and highly active (≥PR 84%) with encouraging PFS (median 16.8 mo) in an RRMM pt population that was mostly LEN-refractory and PI-naive/sensitive. The results support planned evaluation of KPD with daratumumab in RRMM, particularly for high-risk pts.
and del(17p).

Responses in high achieving a VGPR or better. Median TTP (11.6 months) were achieved at least a PR (ORR 59%), with 6 patients (22%) expressing achieved at least a PR (ORR 59%), with 6 patients (22%) achieving VGPR or better (66%) achieving VGPR or better. Sixteen of 27 patients with low BCL2 levels were expressors were independent of cytogenetic status.

Figure 1.

Results: The ORR was 68% (44/65) for all evaluable patients and 89% (31/35) in patients who had 1-3 prior therapies (31/35). A broad range of BCL2, BCL2L1 and MCL1 expression was observed, however higher BCL2 levels were detected in patients who achieved a partial response (PR) or better (median: 3.01 vs 0.87, p<0.01). Additionally, higher BCL2 levels were observed in patients who had 1-3 prior lines of therapy compared to 4 or more lines of therapy (median: 3.03 vs 0.94, p<0.01). In contrast, no association was observed between BCL2L1 or MCL1 gene expression and response or number of prior therapies. Bootstrapping and aggregating thresholds from trees was used to estimate a threshold value for BCL2 expression that would provide optimum selection of patients to have a response. On average, seventeen of 18 patients with high BCL2 expression (≥3.0) achieved at least a PR (ORR 94%), with 12 patients (66%) achieving VGPR or better (Figure 1). Sixteen of 27 patients with low BCL2 expression achieved at least a PR (ORR 59%), with 6 patients (22%) achieving a VGPR or better. Median TTP (11.6 vs 5.7 months) and DoR (10.2 vs 5.7 months) were significantly higher (p=0.01) in patients with low BCL2 expression. Responses in high BCL2 expressors were independent of cytogenetic status as determined by interphase FISH analysis, including t(11;14), t(4;14), del(13q) and del(17p).

Summary/Conclusions: Targeting BCL-2 and MCL-1 with the combination of VEN, BTZ and dexamethasone provides a unique approach for MM treatment. Efficacy results in tumors expressing high BCL2 levels, including 94% ORR, provide supportive evidence for the evaluation of this combination regimen in the ongoing phase 3 study (NCT02755597) in R/R MM.

P683
THE IMPACT OF THE INTRODUCTION OF BORTEZOMIB ON DIALYSIS INDEPENDENCE IN MULTIPLE MYELOMA PATIENTS WITH RENAL FAILURE: A NATIONWIDE DUTCH POPULATION-BASED STUDY
B. Oortgiesen1,*, R. Azad1, M. Hemmelder2, R. Kibbelaar3, N. Veeger4, J. de Vries5, E. van Roon1,*, M. Hoogendoorn5
1Department of Clinical Pharmacy & Pharmacology, 2Department of Nephrology, Medical Centre Leeuwarden, 3Department of Pathology, Pathology Friesland, 4Department of Epidemiology, 5Department of Hematology, Medical Centre Leeuwarden, Leeuwarden, 6Department of Pharmacy, University of Groningen, Groningen, Netherlands

Background: Renal insufficiency is common at presentation in patients with multiple myeloma (MM) and associated with a poor survival. Approximately 10% of the patients require dialysis. Studies have shown that the novel agent bortezomib has a positive effect on recovery of renal function in MM patients with renal insufficiency.

Aims: The aim of this study is to determine the effect of the revised guideline, including the introduction of bortezomib as first line treatment in MM patients with dialysis dependence, on renal function recovery.

Methods: All patients on renal replacement therapy (RRT) in the Netherlands are registered in the Dutch registry Renine. Data on age, gender, start date of RRT, type and dates of RRT or hospital, primary renal diagnosis, date of death and cause of death are collected. In this nationwide population-based study, we selected all patients with MM registered in Renine between January 2002 and January 2016. No information regarding therapy of MM is provided in Renine. In March 2010, bortezomib was advised as first-line treatment in patients suffering from MM with renal impairment in the Dutch guidelines. Therefore, we divided our cohort in two periods: before the bortezomib guideline (January 1, 2002 till March 29, 2010) and after introduction of the bortezomib guideline (March 29, 2010 till January 1, 2016). Kaplan-Meier and Cox proportional hazards modelling were used to identify significant indicators for dialysis independency.

Results: A total of 700 patients were included in the study (422 patients pre-bortezomib and 278 after bortezomib introduction). In the period after the introduction of bortezomib 15% of patients became dialysis independent compared to 8% in the pre-bortezomib period (HRadj=2.1 (95% CI 1.0–4.2), Figure 1). In addition, patients who started dialysis in the period after bortezomib introduction became dialysis independent more rapidly than in the pre-bortezomib period (1.2 compared to 1.7 years, p<0.001). Age < 75 years (vs. ≥ 75 years) and light chain deposition disease (LCDD) as the primary renal disease (vs. myeloma) were significantly associated with achieving dialysis independence (HRadj=2.1 (95% CI 1.0–4.2) and HRadj=5.7 (95% CI 2.5–13.2), respectively).
Background: The immunomodulatory agent pomalidomide is active in patients with relapsed/refractory multiple myeloma, including those who failed prior lenalidomide and bortezomib. Phase II clinical trials showed that pomalidomide is also effective in primary AL amyloidosis. After this drug was marketed for multiple myeloma (in Italy since September 2015), it became routinely accessible also to patients with myeloma-associated AL amyloidosis, a particularly fragile population.

Aim: Aim of this study is to report the efficacy of pomalidomide and dexamethasone in patients with multiple myeloma-associated AL amyloidosis.

Methods: The databases of the Pavia Amyloid Research and Treatment Center were searched for patients with a diagnosis of multiple myeloma and AL amyloidosis. In all cases, endomyocardial biopsy (EMB) was performed and patients received 28-day cycles of pomalidomide (4mg from day 1 to 21) and dexamethasone (20/40mg weekly). All patients gave written informed consent for their clinical data to be used for research purposes, in accordance with the Declaration of Helsinki. Thirty patients were treated to date. Hematologic and organ response were assessed according to the International Society of Amyloidosis criteria.

Results: Median age was 65 years (range: 34-85 years) and 22 (73%) patients were men. Heart involvement was present in 13 patients (43%) and kidney involvement in 18 (60%). Forty (13%) patients were in Mayo Stage I, 17 (57%) in stage II and 9 (30%) in stage III. Fifteen (50%) patient were in renal stage I, 8 (27%) and 3 (23%) were in renal stage II and III respectively and 5 (16%) patients were on dialysis at the time of P Dex initiation. Median bone marrow plasma cell infiltrate was 20% (range: 12-90%). Twenty-three (76%) patients were refractory to all previous lines of therapy. Median time from diagnosis to treatment first line therapy was 71 months (IQR: 35.5-209 months). Adverse events were observed in 5 (17%) of subjects: skin rash and confusion in one patient each and mild increase in serum creatinine in 3 (10%), resolved with the decrease of the dose of pomalidomide. The median number of prior treatment regimens was 2 (range 1-11). All patients previously received lenalidomide and an alkylating agent, only 3 patients were not exposed to bortezomib, due to severe peripheral nervous system involvement, 10 (33%) underwent autologous stem cell transplant and 9 (30%) received previous thalidomide-based regimens. The median number of P Dex cycles performed was 4 (range: 1-11). Median follow-up of living patients was 6 months (IQR: 3.5-16 months) and 13 (43%) patients died due to progressive disease. Fourteen patients (47%) achieved at least partial response, with 1 complete remission (CR), and very good partial responses (VGPR) in 2 cases (6%). Cardiac responses were observed in 1 of 5 patients with measurable NT-proBNP (20%), but this can be underestimated due to the pomalidomide-related increase of NT-proBNP, and renal response in 3 of the 11 evaluable patients (27%).

Summary/Conclusions: The combination of pomalidomide and dexamethasone is well tolerated and effective in multiple myeloma-associated AL amyloidosis and can be a valuable rescue option in this high-risk population.

P686
WHEN PERFORMANCE OF CYTOGENETICS MATTERS: A POPULATION-BASED STUDY IN THE NETHERLANDS ON NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

M. Brink1, 2, O. Visser1, M.C. Minnema2, S. Zweegman3, P. Sonneveld4, A.G. Dimmohamed4
1Department of Research, Comprehensive Cancer Center the Netherlands, 2Department of Hematology, University Medical Center Utrecht, Utrecht, 3Department of Hematology, VUMc, Amsterdam, 4Department of Hematology, Erasmus MC Cancer Institute, 5Department of Public Health, Erasmus University Medical Center, Rotterdam, Netherlands

Background: It was recently shown in both clinical and population-based series that unperformed cytogenetics (UPCs) in intensively treated patients with acute myeloid leukemia was independently associated with poor prognosis, as compared to patients with performed cytogenetics.

Aims: Therefore, we set out to assess whether UPCs is associated with poor outcome in young patients with symptomatic multiple myeloma (MM) who have received induction chemotherapy.

Methods: We identified 359 newly diagnosed patients with MM <66 years in the nationwide population-based Netherlands Cancer Registry (NCR). UPCs was used to indicate that no sample was sent in for cytogenetic analysis. Performed cytogenetics were grouped by Revised International Staging System (R-ISS), i.e. high-risk (presence of translocations (4;14) or (14;16) or deletion 17p) or standard-risk (presence of other aberrations or no aberrations). Only patients treated with induction chemotherapy, defined as treatment with VCD, PAD, BD or TAD +/- subsequent high dose melfalan and autologous stem cell transplantation (ASCT), were included for analyses. In total, 319 (89%), median age 60 years, 62% male were treated with induction chemotherapy, 39 patients otherwise or had no therapy. The primary endpoint was progression-free survival (PFS), defined as time from start of first line induction chemotherapy to progression or death, whichever comes first. Patients alive without progression were censored at February 1st, 2016.

Results: With a total of 2230 (1903) patients with VCD, PAD, BD or TAD +/- subsequent high dose melfalan and autologous stem cell transplantation (ASCT), were included for analyses. In total, 319 (89%), median age 60 years, 62% male were treated with induction chemotherapy, 39 patients otherwise or had no therapy. The primary endpoint was progression-free survival (PFS), defined as time from start of first line induction chemotherapy to progression or death, whichever comes first. Patients alive without progression were censored at February 1st, 2016.

Summary/Conclusions: Our data show that cytogenetics testing is performed in 70% of MM patients <66 years. Although response rates were similar for patients in the UPC, standard- and high-risk groups, PFS was better in the standard-risk group. Patients with unperformed cytogenetics had the poorest outcomes. The reasons are unclear, but a plausible explanation for not performing cytogenetics could be the patients’ worse clinical condition at presentation which requires immediate therapy. For the abovementioned outcome measures, data of calendar year 2015 will be added and presented at the European Hematology Association.
Background: To contextualize the benefit of novel agents such as daratumumab (DARA) monotherapy for the treatment of patients with heavily pre-treated and highly refractory multiple myeloma (MM), it is critical to understand the real-world outcomes of this patient population on current standard of care (SOC) therapy. To determine the comparative effectiveness of DARA vs real-world SOC, an adjusted comparison was conducted utilizing data from the DARA monotherapy trials and the International Myeloma Foundation (IMF) chart review.

Methods: Data for patients treated with DARA 16mg/kg monotherapy were available from clinical trials MMY2002 (n=106) and GEN501 (n=42), while patients treated with SOC therapies were derived from the IMF chart review of patients with MM who had ≥3 prior lines of therapy and were double refractory to a proteasome inhibitor (PI) and an immunomodulatory drug (IMiD) (n=550, original 510, additional Swedish patients 40). Patients from the IMF cohort who moved into further treatment lines after the line therapy where they fulfilled inclusion criteria, contributed information to the analysis for multiple lines of therapy, with baseline defined as the date of initiation of the actual treatment line, resulting in a total of 963 treatment lines from 550 patients from the IMF cohort. The relative survival effect of DARA versus SOC was estimated using multivariate Cox regression analyses. The methodology utilized individual patient data to compare overall survival (OS). The covariates included age, gender, prior lines of therapy, albumin, β2-microglobulin, prior exposure to pomalidomide and carfilzomib, and prior refractory status. Clustering of observations at the treatment-line level within patients was controlled for using the robust sandwich estimate for the covariance matrix. Statistical significance testing was performed using a two-tailed P-value of <0.05, and all comparisons between treatment groups were reported with hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: After adjustment for differences in baseline characteristics (ICMS included in the multivariate model between the DARA and SOC groups, results showed a significant improvement in favor of DARA compared with SOC for OS (HR=0.42 [95% CI 0.31–0.57]). When limiting the comparative analysis to European patients from the IMF cohort (n=341), results for OS are very similar (HR=0.40 [95% CI: 0.28-0.58]).

Summary/Conclusions: Findings from the regression analyses using the updated IMF dataset were consistent with results from the previous analysis and suggest that DARA is associated with significant gains in OS compared with SOC therapies for patients with heavily pre-treated and highly refractory MM. Findings for a European subset from the IMF dataset were similar to results from the entire cohort.

References

Results: From the 497 patients included, 77 (15%) patients died within 2 years from diagnosis due to active MM. When we compared this latter cohort with the remaining patients, the profile of the high risk group was characterized (Table 1) by a higher proportion of patients >75 years, advanced ISS and RIS stage, higher β2-microglobulin (β2-M) levels (>3.5 and 5.5mg/dl) and abnormal LDH; increased incidence of high-risk cytogenetic features (HR CA), CD45- clonal plasma cells, and lower incidence of CD27 + MM phenotype. The event was defined as death related to active MM within 2 years from diagnosis, either because of disease progression or early death due to absence of response.

Background: Multiple Myeloma (MM) is predominantly a disease of the elderly and the outcome of these patients is poorer than that of transplant candidates. It is well established that those considered frail or unfit have a dismal prognosis, however, even within fit patients, such as those included in clinical trials, there is substantial proportion of early deaths (within the first 2 years after diagnosis). Identification of this “high-risk” fit elderly patients could contribute both to the design of innovative clinical trials, and to avoid the emotional and economical burden of ineffective treatments. The aim of this study was to identify and validate a score to predict early deaths. The endpoint was defined as death related to active MM within 2 years from diagnosis.

Methods: 497 NDMM not transplant candidates treated in two prospective GEM-PETHEMA trials were included in the study: GEM05MAS65 (n=260) used frontline treatment with either bortezomib-melphalan-prednisone (VMP) or bortezomib-thalidomide-prednisone followed by maintenance with bortezomib, thalidomide or bortezomib, prednisone; the GEM2010MAS65 (n=239) compared induction with sequential or alternating cycles of VMP + lenalidomide and dexamethasone. The event was defined as death related to active MM within 2 years from diagnosis, either because of disease progression or early death due to absence of response.

Aims: To analyze the factors associated with early death (within first 2-years) due to active MM in elderly newly diagnosed (NDMM) patients fit enough to be included in clinical trials with optimized therapy with proteasome inhibitors and IMiDs.

Methods: 497 NDMM not transplant candidates treated in two prospective GEM-PETHEMA trials were included in the study: GEM05MAS65 (n=260) used frontline treatment with either bortezomib-melphalan-prednisone (VMP) or bortezomib-thalidomide-prednisone followed by maintenance with bortezomib, thalidomide or bortezomib, prednisone; the GEM2010MAS65 (n=239) compared induction with sequential or alternating cycles of VMP + lenalidomide and dexamethasone. The event was defined as death related to active MM within 2 years from diagnosis, either because of disease progression or early death due to absence of response.

Table 1.
unsR (duration of response (≥PR) <6 months) to the baseline score we were able to build a new score in which the unsR had a 3 points weight. A score ≥ 4 identify a subgroup of patients with high probability of death within 2 years despite optimized treatment.

Summary/Conclusions: The risk of early death due to active disease in elderly patients was related to four independent prognostic factors: age >75y, high LDH levels, advanced ISS, and presence of HR CA. A score ≥ 4 identify a subgroup of patients with high probability of death within 2 years despite optimized treatment.

MPL ACTIVATION DIRECTLY INDUCES FIBROCYTE DIFFERENTIATION TO CAUSE MYELOFIBROSIS
T. Maekawa1, Y. Osawa1, T. Izumi1, S. Nagao1, K. Takano1, Y. Okada1, N. Tachi1, M. Teramoto1, T. Kawamura1, T. Horouchi1, R. Saga1, S. Kato1, T. Yamamura1, J. Watanabe1, A. Kobayashi1, S. Kobayashi1, K. Sato1, M. Hashimoto2, S. Suzu2, F. Kimura1
1Division of Hematology, Department of Internal Medicine, National Defense Medical College, Tokorozawa, Saitama, 2Center for AIDS Research, Kumamoto University, Kumamoto, Japan

Background: Myelofibrosis (MF) may be caused by various pathogenic mechanisms, such as elevated circulating cytokine levels, cellular interactions, and genetic mutations. However, the underlying mechanism of MF remains unknown. A recent study showed that the neoplastic clone of fibrocytes, spindle-shaped fibroblast-like blood cells derived from monocyte lineage, was essential in primary MF pathogenesis; serum amyloid P, which suppressed fibrocyte differentiation, markedly improved survival and MF in a murine xenograft model (JExp Med 2016; 213: 1723-1740). Regarding cytokines, the thrombopoietin (TPO) signaling pathway was assumed to be closely associated with promoting MF. Mice transplanted with TPO-overexpressing bone marrow cells showed symptoms such as MF and splenomegaly (Blood 1997; 90: 4369-4383). Romiplostim (Rom), a TPO-receptor agonist, induced MF in rats and some immune thrombocytopenic purpura patients (Blood 2005; 114: 3749-3756). Fibrocytes and TPO played certain roles in MF pathogenesis, but the nature of their relationship remains unknown.

Aims: We investigated the relationship between myeloproliferative leukemia protein (MPL, TPO receptor) activation and fibrocyte differentiation in promoting MF. The secondary goal was to discover a unique fibrocyte marker in monocyte or macrophage population.

Methods: Murine fibrocyte cell lines were established from transgenic mice harboring the temperature-sensitive large T-antigen gene of simian virus 40 under IL-3 and M-CSF conditions. Murine fibrocyte cell lines and human peripheral blood mononuclear cells (PBMCs) were cultured with or without Rom to evaluate if MPL activation promoted fibrocyte differentiation, and the ratio of spindle-shaped cells was calculated. Rom was administered on day 1 and 8 to induce an MF-like phenotype in C57BL/6J mice, and clodronate liposomes (CLs; day -4, -1, 4, and 7) were used to eliminate monocytes and macrophages.

Results: Flow cytometric analysis revealed that all murine fibrocyte cell lines stained positive for fibrocyte cell markers, including collagen I, CD45, CD34, CD11b, and CD68. Murine fibrocyte cell lines expressed MPL and responded to Rom or murine TPO to differentiate into mature fibrocytes, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-3 and M-CSF alone. Rom also increased the number of mice splen cell fibrocyte colonies in the presence of IL-3 and M-CSF, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-3 and M-CSF alone. Rom also increased the number of mice spleen cell fibrocyte colonies in the presence of IL-3 and M-CSF. The administration of 1mg/kg of Rom once a week induced an MF-like phenotype in all mice within 2–3 weeks and increased the number of fibrocytes in the spleen. Treatment with CLs eliminated fibrocyte precursors and prevented severe MF and splenomegaly. Human cultured fibrocytes also expressed MPL, and Rom increased the number of spindle-shaped fibrocytes induced from human PBMCs. The SLAMF7high MPLhigh subpopulation was clearly separated from the SLAMF7low MPLlow population in human CD14+ monocytes. A significantly higher frequency of fibrocyte differentiation was observed in the SLAMF7high MPLhigh population. The number of SLAMF7high MPLhigh cells was significantly greater in MF patients than in healthy donors. Conversely, their numbers did not increase in MF patients treated with ruxolitinib.

Summary/Conclusions: MPL activation directly induced fibrocyte differentiation from monocytes and macrophages expressing MPL, and the elimination of these cells reversed the MF phenotype. Our findings confirmed a link between fibrocytes and the TPO/MPL signaling pathway and indicated that the combination of MPL and SLAMF7 could be a useful fibrocyte marker in monocytes or macrophages.

ENGRAFTMENT OF PRIMARY MYELOFIBROSIS BONE MARROW-DERIVED CD14+ MONOCYTES IN NOD-SCID-γ MICE
T. Manshour1, Z. Estrov1, D. Pilling2, G.E. Bueso-Ramos2, S. Prijic1, K.J. Newberry1, S.M. Post1, X. Zhang1, Y. Zhang1, H.M. Kantarjian1, S. Verstovsek1
1Leukemia Department, The University of Texas/ MD. Anderson Cancer Center, Houston, 2Department of Biology, Texas A&M University, College Station, 3Department of Hematopathology, The University of Texas/ MD. Anderson Cancer Center, Houston, United States

Background: Progressive bone marrow (BM) fibrosis in patients with PMF is thought to arise from non-hematopoietic stromal cells stimulated by overpro-
duced growth factors. However, in other tissues and organs, fibrosis is associated with the accumulation of fibrocytes, which express markers of both hematopoietic and stromal cells. Recently, we have reported that clonal neoplastic fibrocytes play a role in the induction of BM fibrosis in primary myelofibrosis (PMF) (Verstovsek, J Exp Med. 2016). We demonstrated that the BM of PMF patients harbors more neoplastic, functionally distinct fibrocytes and fewer MSCs than hematologically normal bone marrow (BM). In addition, we detected an overabundance of fibrocytes in the BM and spleen of an established PMF mouse model and a xenograft mouse model of PMF created using BM-derived low-density cells from patients with PMF.

Aims: Fibrocytes, which make up <1% of BM cells, differentiate from a sub-population of monocytes and are recruited to sites of organ damage where they regulate tissue repair. We hypothesized that clonal neoplastic CD14+ monocytes may play a role in the induction of BM fibrosis in PMF.

Methods: To test this hypothesis, we transplanted NSG mice (NOD/Scid NoD.Cg-prkdcscid Il2rgtm1wjl/SZJ) with sorted CD14+ monocytes from patients with JAK2V617F-positive PMF or donors with hematologically normal BM.

Results: Here, we show that BM-derived CD14+ cells from patients with JAK2V617F-positive PMF or donors with hematologically normal BM engrafted in NSG mice. Transplanted NSG mice with PMF BM-derived CD14+ monocytes developed a myelofibrosis-like phenotype with reticulin fibrosis and abundant neoplastic (JAK2V617F) fibrocytes in the BM and spleen. Two months after transplantation, we detected a subpopulation of hDA45+ and hDC68+ cells within the hLA+ population of BM cells. In addition, we found dysplastic megakaryocytes in the BM and spleen of the PMF CD14+ transplanted mice. Immunohistochemistry of paraffin embedded BM sections did not detect hDA3, hDC19 or hDC34 cells. However staining with anti-human CD42b antibodies detected human megakaryocytes, suggesting that the dysplastic megakaryocytes detected in PMF CD14+ transplanted NSG mice are human-derived.

Summary/Conclusions: Taken together, our data suggest that neoplastic CD14+ monocytes contribute to the induction of BM fibrosis in PMF. What role CD14-derived megakaryocytes play in the pathogenesis of PMF remains to be determined.

Background: Somatic mutations on calreticulin (CALR) gene are found in a majority of patients with JAK2C-wt or CALR-mutated MPN. Hence, elucidation of alpha-granule formation and neutrophil-megakaryocyte plasticity in CALR-mutated neoplastic MPNs is of great clinical importance.

Aims: We aimed to recapitulate the MPN phenotypes and examine the impact of CALR ins5 on human hematopoietic cell differentiation in vitro.

Methods: We employed iPSCs (iPSC) established from a healthy individual harboring a 5-base insertion CALR ins5 and a FA patient and a healthy individual harboring a 5-base insertion CALR ins5 on human hematopoietic cell differentiation. Aims: CALR ins5-dependent megakaryopoiesis was examined by therapeutic compounds.

Results: A number of differentially expressed proteins were identified with the most frequent being members of the RAS GTPase family and oxidative stress response proteins. Subsequent analysis found that calreticulin (CALR), known to be involved in calcium homeostasis and apoptotic signaling, was overexpressed in JAK2V617F-null fibrocytes compared with JAK2 wild-type and independently of the JAK2V617F allele burden. Finally it was demonstrated, in a Ba/F3 cell model, that increased calreticulin expression was directly linked to production of CALR ins5 and could be regulated by JAK2 kinase inhibitors.

Summary/Conclusions: In conclusion, these results reveal proteome alterations in MPN fibrocytes depending on the genotype and phenotype of patients, highlighting new oncogenic mechanisms associated with JAK2 mutations and overexpression of calreticulin.

Background: Systemic mastocytosis (SM) is a myeloid neoplasm defined by abnormal growth and pathologic accumulation of neoplastic mast cells (MC) in various internal organs. The indolent variant of SM (ISM) is associated with an almost normal life expectancy. By contrast, the prognosis in advanced SM, including SM with associated hematologic neoplasm (SM-AHN), aggressive SM (ASM), and MC leukemia (MCL) is poor with short survival times. Most patients with SM express the D816V-mutated variant of KIT, which confers resistance against several tyrosine kinase inhibitors (TKI), including imatinib. DCC-2618 is a novel switch control inhibitor that has been described to block the kinase activity of KIT.

Aims: The aims of this study were to evaluate the effects of the switch control inhibitor DCC-2618 on proliferation and survival of neoplastic MC and other neoplastic and non-neoplastic cell types that may play a role in advanced SM and often expand in AHN patients.

Methods: To this end, we used different human MC lines (HMC-1, HMC-1.2, ROSA13K[TW], ROSA13K[TW]B6, ROSA13K[TW]B6, MCFP-1.1, MCFP-1.2, MCFP-1.3 and MCFP-1.4) and primary neoplastic MC obtained from patients with SM. In addition, the acute myeloid leukemia (AML) cell lines

KLF1 expression required for the erythroid cell differentiation in CALR ins5 cells. Finally, we showed that the treatment of ruxolitinib greatly reduced megakaryocytic differentiation in both CALR ins5 and wt HPCs, demonstrating that ruxolitinib does not possess preferential targeting of CALR ins5 cells.

Summary/Conclusions: We have established an in vitro model system that recapitulates the megakaryocytosis caused by mutant CALR, which should be useful tool for the examination of therapeutic strategies against MPN patients harboring CALR mutation.

QUANTITATIVE PROTEOME HETEROGENEITY IN MYELOPROLIFERATIVE NEOPLASM SUBTYPES AND ASSOCIATION WITH JAK2 MUTATION STATUS

Guillem Yust1, C. Vladian P2, J. Mondet1, I. Plo1, P. Mossuz1,4

1TIMC-IMAG Laboratory - TheREX team, GRENoble, France, 2Institute for Medical Research, Belgrade, Serbia, 3INSERM, UMR1170. Gustave Roussy, Paris, 4Laboratoire d’Hématologie cellulaire - Institut de Biologie et Pathologie, GRENoble, France

Background: Apart from well-known genetic abnormalities, several studies have reported variations in protein expression in Philadelphia negative (Ph-) Myeloproliferative Neoplasm (MPN) patients that could contribute towards their clinical phenotype.

Aims: In this context, a quantitative mass spectrometry proteomics protocol was used to identify differences in the granulocyte proteome with the goal to characterize the pathogenic role of aberrant protein expression in MPNs.

Methods: LC MS/MS (LTQ Orbitrap) coupled to iTRAQ labeling showed significant and quantitative differences in protein content among various MPN subtypes. Variability in proteome phosphorylation (PTM) and cell cycle were assessed in CALR wt and JAK2V617F MPN. Using the expression of CALR wt HPC, implying that

DGCC-2618 is a novel switch control inhibitor that has been described to block the kinase activity of KIT.

Aims: The aims of this study were to evaluate the effects of the switch control inhibitor DCC-2618 on proliferation and survival of neoplastic MC and other neoplastic and non-neoplastic cell types that may play a role in advanced SM and often expand in AHN patients.

Methods: To this end, we used different human MC lines (HMC-1, HMC-1.2, ROSA13K[TW], ROSA13K[TW]B6, ROSA13K[TW]B6, MCFP-1.1, MCFP-1.2, MCFP-1.3 and MCFP-1.4) and primary neoplastic MC obtained from patients with SM. In addition, the acute myeloid leukemia (AML) cell lines
MOLM-13, MV4-11, KG-1 and U-937, the eosinophilic leukemia cell line EOL-1, human cultured umbilical vein endothelial cells (HUVEC), the microvascular human endothelial cell line HMVEC and primary neoplastic cells obtained from patients with AML, chronic myelomonocytic leukemia (CMMML) and (clonal or reactive) hypereosinophilia were used. Cell proliferation was quantified by 3H-thymidine uptake. Apoptosis was determined by flow cytometry and light microscopy. The phosphorylation-status of KIT and BTK was analyzed by Western blotting. The effects of DCC-2618 on histamine secretion in basophils (BA) were analyzed by histamine release assay.

Results: DCC-2618 was found to block the proliferation of all MC lines tested, with lower IC50 values measured in KIT D816V-negative HMC-1.1 cells (12±0.3 nM) and ROSAΔITD cells (4±1 nM) than in KIT D816V-positive HMC-1.2 cells (123±36 nM), ROSAΔITD cells (168±65 nM), and the multi-resistant MC line MCPV-1. The DCC-2618-metabolite DP-5439 showed comparable growth-inhibitory effects in all cell lines tested. DCC-2618 was also found to inhibit proliferation of primary neoplastic MC obtained from patients with classical SM, AML with AS-ANH and MCL (IC50: 83-460 nM). DCC-2618 induced apoptosis and blocked tyrosine phosphorylation of KIT in all MC lines tested. We were also able to show that DCC-2618 inhibits proliferation and survival in the eosinophilic leukemia cell line EOL-1 (IC50: 1.8±1.3 nM) and the FLT3 ITD-mutated AML cell lines MV4-11 (IC50: 147±80 nM) and MOLM-13 (IC50: 132±95 nM). In addition, DCC-2618 was found to block proliferation in primary leukemia cells in patients with monoblastic AML and CML which are the most prevalent types of AHN in advanced SM. DCC-2618 was also found to inhibit growth of cultured human vascular endothelial cells, suggesting that the drug may also counteract SM-related angio genesis. Finally, DCC-2618 was found to inhibit anti-IgE-induced histamine release from normal BA in a dose-dependent manner (IC50: 1±10 µM).

Summary/Conclusions: DCC-2618 is a new potent switch control TKI that counteracts growth and survival of neoplastic MC, leukemic monocytes, AML blasts, eosinophils, and endothelial cells in vitro. Whether DCC-2618 is able to block growth of neoplastic MC and other involved lineages in patients with advanced SM is currently being ascertained in a clinical trial (NCT02571036).

P694
DISTRIBUTION OF MUTATIONS IN DRIVER AND NON-DRIVER GENES ACCORDING TO CLONAL HEMATOPOIESIS IN ESSENTIAL THROMBOCYTHESIS AND POLYCYTHEMIA VERA

A. Senín1,2,*, B. Bellosillo2,3, C. Fernández-Rodríguez2,3, L. Camacho2,3, J. Martínez-López1,1
1Hematology, Hospital 12 de Octubre, Madrid, Spain
2Hematology, Hospital del Mar-IMIM. Universitat Autònom de Barcelona
3Group of Applied Clinical Research in Hematology. Cancer Research Program, IMIM, Pathology Department, Hospital del Mar-IMIM. Universidad de Barcelona, Madrid, Spain

Background: Essential thrombocythemia (ET) and polycythemia vera (PV) are clonal myeloid disorders that originate from a multipotential hematopoietic stem cell. Although most women with PV and ET have mutations in JAK2V617F, the proportion of patients presenting clonal hematopoiesis by X chromosome inactivation patterns (XCIP) is variable and its relationship with the presence of non-driver mutations is not well known.

Aims: To study the distribution and dominance of driver and non-driver mutations in development of clonal hematopoiesis.

Methods: One hundred and twenty-six women (PV n=33, ET n=93) with an informative result of XCIP based on HUMARA analysis were included in the study. HUMARA analysis was performed by studying the degree of methylation of exon 1 in granulocytes and lymphocytes. Somatic mutations were studied in DNA extracted from granulocytes by NGS using a panel of 51 myeloid-related genes.

Results: Median age of patients at the time of HUMARA analysis was 64 years (range:21-92). Mutations in JAK2 were present in 62% of them, CALR in 11%, MPL in 8%, and 14% were triple negative (TN). Non-driver mutations were detected in 9 patients (17 PV and 28 ET). The most frequently mutated genes were TET2 (16%), DNMT3A (8%), ASXL1 (5%), SF3B1 (5%), EZH2 (2%) and RUNXI (2%). The mutation with the highest variant allele frequency (VAF) was considered the dominant mutation and it corresponded to a driver mutation in 92 patients (JAK2 n=70, CALR n=13, MPL n=8) and a non-driver mutation in 9 patients (TET2 mutations in 4 JAK2-mutated patients with mutations in TET2. CBL, DNMT3A or EZH2). In 12 cases the VAF of the driver mutation (JAK2 n=2, CALR n=1, MPL n=2) was similar to the non-driver mutation, being TET2 the codominant mutation in 6 of them. HUMARA analysis was clonal in 66 patients and polyclonal in 60 patients (62%). Mutations were most frequently observed in ET (72% vs 76% in PV, p=0.0027). Clonal HUMARA was observed in 90% of MPL-mutated patients in comparison with 58% in JAK2-mutated, 42% in CALR-mutated and 11% in TN (p<0.0001). Two patients with TN ET showing clonal hematopoiesis had TET2 mutations. In JAK2-mutated women, the mutant allele load was significantly higher (7.9±8.3% vs 3.3±5% in clonal cases vs non-clonal cases, p=0.02) and in PV than in ET (76% vs 47%, p=0.01). Eighty percent of patients with non-driver mutations showed HUMARA clonality vs 37% of patients without non-driver mutations (p<0.0001). The mutated genes significantly associated with a higher frequency of clonal hematopoiesis were TET2 (p=0.007) and SF3B1 (p=0.029).

P695
RUXOLITINIB/NILOTINIB/PREDNISOLONE COMBINATION: A PROMISING NOVEL TREATMENT FOR MYELOFIBROSIS

A. Arenas1, R. Ayala1, M. Gallardo1, J. Martínez-López1,2
1Hematology, Hospital 12 de Octubre, Madrid, Spain
2Hematology, Hospital del Mar-IMIM. Universitat Autònoma de Barcelona

Background: Myelofibrosis (MF) is the myeloproliferative neoplasm chromosome Ph- negative with worst prognosis. MF is characterized by stem cell-derived clonal myeloproliferation and reactive cytokine-driven inflammatory bone marrow fibrosis. Ruxolitinib is the first line treatment for MF. It was associated with significant reduction in symptomatic splenomegaly and improved constitutional symptoms. In a previous work (Arenas et al. Blood Volume 122, Issue 21 (ASH Annual Meeting Abstract)) we identified a set of promising synergistic drugs combinations for a ruxolitinib. Nilotinib and prednisolone were selected from them.

Aims: The aim of this work is the study the effect of the combination of ruxolitinib, nilotinib and prednisolone in hematopoietic progenitor cells from patients with MF.

Methods: A ruxolitinib, nilotinib and prednisolone dose-response curves and synergistic studies were performed in hematopoietic progenitors CD34+ from five MF patients. We studied the molecular effect of single drugs and in combination on SET2 cell line with western blot. To adress the antiangiogenic activity of the drugs and their combinations, we pre-incubated HS27 cultures with 100nM of ruxolitinib, 1 µM of nilotinib, 1 µM of prednisolone or their combination during 1 h. After that, we added 2mg/mL TGF-β during 24h to induce fibrogenesis. Finally, the collagen I expression was evaluated by immunocytochemistry (ICC).

Results: The effects of ruxolitinib, nilotinib and prednisolone resulted in an EC50 value of 55nM, 6.6µM and 13.1µM, respectively. A combination index (CI) of less than 1 indicated synergy. All combination had a synergistic behavior (Table 1); moreover, there were two combinations whose CI from all samples was less than 1 (ruxolitinib+nilotinib+prednisolone) in 9/10 samples and in 7/10 samples of the driver mutation in the JAK/STAT signaling pathway was inhibited: the phosphorylation of STAT5 was inhibited by ruxolitinib in 83±20% (p-value<0.05) regarding to control at 30 min and it was maintained at 3 hours (p-value<0.05). The combinations 32nM ruxolitinib plus 1.6 µM nilotinib (RN) and 32nM ruxolitinib plus 1.6µM prednisolone (RNP) inhibited more than 50% of the phosphorylation of STAT5 at 30 min and maintained at 3 hours. The MAPK signaling pathway was inhibited at 30 min, the phosphorylation of ERK was inhibited in 77±16.4%.
% (p-value<0.05) by ruxolitinib, 42.6±14.4 % by RN and 70.8±11.2 % by RN (p-value<0.001). The inhibition was maintained at 3 hours by ruxolitinib (71.3±18.9 %, p-value<0.05). The Akt/Pi3K signaling pathway seemed to begin to inhibit at 3 hours by ruxolitinib (57.5±25.2 %), nilotinib (38.4±26.8 %), RN (30.5±24.03 %) and RNP (37.4±16.5 %). Then, the anti-bisperucogenic activity of the drugs and their combinations were studied. Nilotinib reduced the mRNA expression of COL1 by 48.1±29.9 % (p<0.05) and prednisolone (RNP: 37.8±19.1 % (p-value<0.05). These results were corroborated by IHC: the inhibition of expression of collagen I was more intense if the HS27 were treated with nilotinib or RN (figure 1).

Summary/Conclusions: In conclusion, ruxolitinib, nilotinib, prednisolone and their combinations had a synergistic behavior to control the proliferation of myelofibrosis cells. In MF patients, moreover, they had anti-fibrotic activity in fibroblast cells. For these reasons, the combined ruxolitinib/nilotinib/prednisolone could be a promising therapy to MF and support an ongoing clinical trial in MF patients.

P696
INTERLABORATORY ASSESSMENT OF MUTATION DETECTION IN MYELOID MALIGNANCIES BY TARGETED NEXT-GENERATION SEQUENCING
1Pathology, Hospital del Mar, Barcelona, 2Hematology, Hospital 12 de Octubre, Madrid, 3Hematology, Hospital Universitari i Politècnic La Fe, Valencia, 4Rigshospitalet, Copenhagen, 5Department of Haematology, Herlev Hospital, Herlev, 6Department of Haematology, Örebro University Hospital, Örebro, 7Department of Haematology, Udde- valla Hospital, NU Hospital Organization, Uddevalla, Sweden, 8Department of Haematology, Hospital del Mar, Barcelona, 9CIMA LAB Diagnostics, Pamplona, 10Hematology, Hospital Universitario Virgen del Rocio, Seville, 11Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, 12Hematology, Hospital Regional Universitario de Málaga, Málaga, 13Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, 14Hematology, Hospital 12 de Octubre, Madrid, Spain

Background: Next-generation sequencing (NGS) technology is being implemented in clinical practice for assessing the mutational status of myeloid neoplasms. The Working Group on Molecular Biology from the Spanish Society of Hematology has performed an interlaboratory assessment of gene mutation analysis by targeted NGS using myeloid panels.

Aims: To assess the technical performance of mutation detection by targeted NGS using myeloid panels.

Methods: The technical comparison was established on two rounds with samples previously analysed using NGS panels, Sanger sequencing and/or fragment analysis. First, four DNA samples (S1-S4) from AML patients were shared among the centers. In the second round 17 relevant mutations in 7 genes. Each center performed library preparation, sequencing and blind variant analysis following their own routine methodology. Detected variants and data regarding main methodological parameters were collected. Detection rate was calculated as the number of laboratories with positive detection out of the number of laboratories that sequenced the particular gene region.

Results: Eight different gene panels were used for library preparation (pre-detected in 10 labs and custom in 4). The predominant approach was amplicon enrichment (11/14, 78.6%) and only 3/14 laboratories (21.4%) used capture-based methods.

Sequencing was performed with Illumina devices in 9/14 laboratories and Ion Torrent platforms in 5/14. Alignment and variant calling was performed with MiSeq Reporter (n=3), Torrent Suite (n=4) or panel-adjusted or laboratories and there is controversy as previous

Myeloproliferative Neoplasms (MPNs) result from genetic and epigenetic dysregulation. Epigenetic therapies, such as Vorinostat (SAHA, MK-0677), a histone deacetylase inhibitor, have been tested as a therapeutic strategy in these patients. Examining the epigenetic landscape in MPN may provide new insights into predicting therapeutic response and therefore enhance the clinical utility of these agents. Probably the best described epigenetic mechanism is DNA methylation (DNAm); in which methyl groups are added to DNA (71.3±18.9 %, p-value<0.05) with combination with ruxolitinib (30.5±24.03 %) and ASXL1E635fs. Then, the antifibrotic activity of the drugs and their combinations were studied. Nilotinib reduced the mRNA expression of COL1 (39.8±1.9 %) (p-value<0.05). Its combination with ruxolitinib (RN: 37.8±19.1 %) (p-value<0.05) was more intense if the HS27 were treated with nilotinib or RN (figure 1).

Summary/Conclusions: The combined ruxolitinib/nilotinib/prednisolone could be a promising therapy to MF and support an ongoing clinical trial in MF patients.

P697
METHYLATION AGE IN MPN PATIENTS AS A CORRELATE FOR DISEASE STATUS, ALLELE BURDEN AND THERAPEUTIC RESPONSE
1Blood Cancer Research Group, Centre for Cancer Research and Cell Biology, Queens University Belfast, Belfast, United Kingdom, 2Department of Haematology, Uppsala University Hospital, Uppsala, Sweden, 3Department of Haematology, VU University Medical Centre, Amsterdam, Netherlands, 4Department of Haematology, Guy’s and St Thomas’ NHS Foundation Trust, London, 5Department of Haematology, Russells Hall Hospital, Dudley, 6Department of Haematology, Cardiff University, Cardiff, United Kingdom, 7Department of Interdisciplinary Medicine (Haematological Department), Viborg Hospital, Viborg, 8Department of Haematology, Herlev Hospital, Herlev, 9Department of Haematology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, 10Department of Haematology, Odense University Hospital, Odense, 11Department of Internal Medicine (Haematological Department), Viborg Hospital, Viborg, 12Department of Haematology, Örebro University Hospital, Örebro, 13Department of Haematology, Udde- valla Hospital, NU Hospital Organization, Uddevalla, Sweden, 14Department of Haematology, Herlev Hospital, Herlev, 15Department of Haematology, Roskilde Hospital, Roskilde, Denmark, 16Centre for Medical Education, School of Medicine, Dentistry and Biomedical Sciences, Queens University Belfast, Belfast, United Kingdom

Background: Myeloproliferative Neoplasms (MPNs) result from genetic and epigenetic dysregulation. Epigenetic therapies, such as Vorinostat (SAHA, MK-0677), a histone deacetylase inhibitor, have been tested as a therapeutic strategy in these patients. Examining the epigenetic landscape in MPN may provide new insights into predicting therapeutic response and therefore enhance the clinical utility of these agents. Probably the best described epigenetic mechanism is DNA methylation (DNAm); in which methyl groups are added to DNA at CpG sites regulating chromatin compaction and gene expression/repression. DNAm is known to be altered by ageing and can reflect the effect of diet, lifestyle or disease on cellular processes. Therefore ‘methylation age’ (MA) may be a more accurate reflection of disease than ‘chronological age’ (CA), which is merely a description of how long a person has been alive. Weidner et al (Genome Biology. 2014) described how the measurement of DNAm levels at CpG sites within 3 genes, ASYA ITGAXZ, PDE4C enabled the determination of a biomarker that reflected the individual.

Aims: The aim of our study was correlate MA with disease status, mutational burden and therapeutic response in a cohort of MPN patients treated with Vorinostat.
Methods: MA was calculated following pyrosequencing of bisulfite converted DNA from 40 MPN patients on an investigator initiated non-randomised open label phase II multicentre study of Vorinostat (EudraCT #2007-005360-49). Paired samples were analysed at trial entry and after 3 months of therapy to calculate their individual MA scores. Validation of methods used and ageing signature calculation was carried out using cell line and healthy volunteer material.

Results: Samples from 18 Essential Thrombocythaemia (ET) and 22 Polycythemia Vera (PV) patients (23 F/17 M) with a mean age of 62 years (range 29-81) were assessed. JAK2V617F was detected in 77.5% (n=31/40). Complete clinical response (CR) was achieved in 8 patients, partial (PR) in 17, and in no response (NR) in 15 patients. MA was on average 8.3 years younger than CA (range -43.4 to +41.6) at time of trial entry and 8.2 years younger (range -36.5 to +33.3) after therapy. This difference between MA and CA was greater in ET patients compared to PV, both at trial entry (-14.0 years vs -3.7) and after therapy (-13.0 years vs -4.3). A statistically significant link between JAK2 allele burden and MA was seen: compared to patients with low or no JAK2 allele burden, patients with high JAK2 (>60% at baseline) had an older MA at trial entry (64.2 years vs 44.5, p=0.0007) and after therapy (64.3 years vs 44.6, p=0.0015). This difference was also seen when PV or ET patients were examined separately. Patients with a high JAK2 allele burden tended to have a MA closer to their CA at trial entry (-0.6 years vs -15.3, p=0.0122) and after 3 months therapy (-0.5 years vs -16.2, p=0.0072). Although the cohort size was small, within the ET group, NR compared to PR was associated with a younger MA after therapy (41.4 years vs 56.3, p=0.0156). Within PV, NR compared to PR was associated with a MA that was older than CA both before (+9.2 years vs -14.2, p=0.0346) and after therapy (+7.4 years vs -13.9, p=0.0347).

Summary/Conclusions: Our results suggest a link between MA and JAK2 allele burden in MPN patients, suggesting that allele burden alone has a role in clinical phenotype and disease evolution but in the overall methylation landscape of the mutated cells. However, the role of MA with respect to therapeutic response needs to be clarified with further studies required to show its full impact.

P698
ELUCIDATING THE AGE INCREASED HEMATOPOIETIC CELL-INTRINSIC AND EXTRINSIC MECHANISMS IN MYELOPROLIFERATIVE NEOPLASMS INITIATION AND PROGRESSION
N. R. Tata1,*, S. Radek1
1Department of Biomedicine, University Hospital Basel, Basel, Switzerland

Background: The number of detectable somatic mutations increase with age, but this increase is surpassed by the rise in the incidence of cancer in older people. The underlying mechanisms for this disparity remain to be elucidated. Myeloproliferative neoplasm (MPN) is an ideal malignancy model disease to study clonal hematopoiesis, disease initiation and progression during natural aging because the majority of the relevant mutations (such as JAK2 V617F) are catalogued, the disease evolves and progresses slowly allowing the collection of serial samples, and an inducible transgenic mouse models for the disease have been established. Nonetheless, the prevalent occurrence of such clonal events in aged individuals brings up the question, which age-associated disease have been established. Nonetheless, the prevalent occurrence of such clonal events in aged individuals brings up the question, which age-associated mechanisms attributable for increased prevalence of myeloid malignancies will be essential for the development of strategies for early detection and therapeutic targeting of myeloid malignancies.

Aims: The goal of this proposal is to identify age associated hematopoietic cell-intrinsic and cell-extrinsic factors that determine initiation and progression of MPN at young versus old age in mouse models carrying a JAK2-V617F or JAK2-V617F mutation.

Methods: To assess the effect of aging on MPN initiation and progression we studied the young and aged inducible transgenic mouse models of MPN. Integrated omics analysis was performed on MPN initiating stem and progenitor cells. Results: Our results suggest that age related changes in expression patterns resemble in a way that can be found in aged wildtype mice. The mutation profile in patients with pediatric MPN appear to be less complex than in older MPN patients. We are currently investigating the relative contributions and collaborations of age-associated cell intrinsic and extrinsic changes in HSCs and BM niche in the course and severity of MPN in mouse models carrying a JAK2-V617F mutation, and in naturally aged donors and recipients of bone marrow transplantations.

Summary/Conclusions: Our study provided novel molecular and cellular mechanisms underlying increased incidence of MPN manifestation in old age. The implications of this work goes beyond the MPN malignancy and the concept that small subset of aged myeloid cells may serve as a model to the wider scientific community to study other types of malignancies. This knowledge ultimately will help to define novel strategies to delay or target the onset of MPN in an aging individual.
P700

COMBINATION THERAPY OF POMALIDOMIDE PLUS RUXOLITINIB IN MYELOFIBROSIS: RESULTS FROM COHORT 1 OF THE MPNSG-0212 TRIAL (NCT01644110)

1University Hospital of Ulm, Ulm, Germany; 2University of Bochum, Minden, Germany; 3RWTH Aachen University, University Medical Center, Aachen, Germany; 4University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 5Jena University Hospital, Jena, Germany; 6University Hospital of Freiburg, Freiburg, Germany; 7University Hospital of Mainz, Mainz, Germany; 8University Hospital of Munich, Munich, Germany; 9Hematology and Oncology Practice, Augsburg, Germany; 10University Medical Center Magdeburg, Magdeburg, Germany; 11University Tübingen, Tübingen, Germany; 12University of Cologne, Cologne, Germany

Background: Therapeutic options to address anemia in patients (pts) with Myelofibrosis (MF) are limited. In our MPNSG-0109 trial investigating pomalidomide (POM) in MF with cytopenia, anemia was improved in 14-29% of pts treated with 0.5-2mg POM once daily (QD) (Schlenk RF, Stegelmann F et al. Leukemia 2016).

Aims: To evaluate synergistic effects of POM plus ruxolitinib (RUX), we are currently investigating the combination therapy within the MPNSG-0212 trial (NCT01644110).

Methods: The MPNSG-0212 is designed as multicenter, single-arm phase-IIb trial with a target population of 38 pts in the first cohort. Primary endpoints are response rate after 12 cycles (28 days each) according to IWG-MRT (Tefferi et al., Blood 2006) and red blood cell (RBC) transfusion independence criteria (Gale et al., Leuk Res 2011). Secondary endpoints are safety, quality of life, progression-free, and overall survival. Main inclusion criterion is MF with anemia (Hb <10 g/dL and/or RBC transfusion dependency). While POM is given as 0.5-2mg POM once daily (QD) (Schlenk RF, Stegelmann F et al. Leukemia 2016), the available options are limited.

Results: Safety and efficacy data from 38 pts are presented. Median age of the pts was 67 years (range, 46-83): 19 pts (50%) previously received hydroxyurea, RUX, EPO, POM, and/or corticosteroids. Median hemoglobin (Hb) level at study entry was 8.6 g/dL (range, 5.4-11.7); 11 pts (29%) were RBC-transfusion-dependent. Median spleen size by ultrasound was 17.9 cm (range, 12.6-28). At baseline, 30 pts (79%) had constitutional symptoms, 11 pts (29%) had hepatosplenomegaly, and 7 pts (18%) presented with cytopenias (anemia and thrombocytopenia). Currently, JAK1/2 inhibitor RUX is the only available therapy for pts with MF. Although RUX has been shown to reduce splenomegaly and symptoms in pts with MF, it is associated with dose-limiting cytopenias and is not indicated for pts with platelets <50,000/µL. PAC is an oral kinase inhibitor with specificity for JAK2, FLT3, and CSF1R. In the phase 3 PERSIST-2 study of PAC vs BAT (including RUX) in pts with MF and BL thrombocytopenia, PAC was significantly more effective in terms of spleen volume reduction (SVR; P=0.001) and appeared to have a better benefit/risk profile vs BAT.

Aims: This analysis examines outcomes for pts with MF treated with RUX in the phase 3 PERSIST-2 study.

Methods: Pts with MF and BL platelet count ≤100,000/µL were randomized (N=311) 1:1:1 to PAC 400mg once-daily (QD), PAC 200mg twice-daily (BID), or BAT. BAT included any physician-selected treatments for MF, as well as no additional treatment. The primary endpoints were the rates of pts achieving ≥35% SVR (by mRVI) and ≥50% reduction in total symptom score (TSS; MPN-SAF TSS 2.0) at week 24. Efficacy analyses used the intent-to-treat efficacy (ITT-E) population, which included all pts with randomization date allowing them to contribute data for a week 24 endpoint. Crossover from BAT to PAC was allowed after week 24 or splenic progression.

Results: RUX was the most commonly received active BAT. 44 (45%) BAT pts received RUX (Figure) and 32 (33%) received only RUX. Of the 44 pts who received RUX on study, 17 (39%) had BL platelet counts <50,000/µL and would not have been candidates for RUX by approved indication (or study protocol).

Conclusions: RUX is a well-tolerated and active agent in MF pts with cytopenia. Further trials are warranted to evaluate the role of RUX in MF.
RTX starting doses were based on baseline platelet (PLT) counts (5 mg bid [≥50 to <100 ×10^9/L], 15 mg bid [100 to 200 ×10^9/L], or 20 mg [>200 ×10^9/L]). Pts were ≥18 y; there was no maximum age limit. The primary endpoint was safety and tolerability of RTX. Secondary endpoints included changes in spleen length and symptoms. Following crossover to PAC in 22 RTX-treated pts, 19 remained on treatment at the time of data cut-off.

**Figure 1.**

**Summary/Conclusions:** In the phase 3 PERSIST-2 study of PAC vs BAT in pts with MF and BL thrombocytopenia, although 19% of RUX-treated pts achieved a 50% reduction in TSS, RUX-treated pts rarely achieved SVR ≥35% at week 24. Rates of grade 3/4 AEs were higher with PAC vs RUX treatment, though the majority of RUX-treated pts began with 5 mg dosing. Rates of dose reductions and discontinuations due to AEs with PAC BID and RUX were similar. Following crossover to PAC in 22 RUX-treated pts, 19 remained on treatment at the time of data cut-off.

**Figure 1.**

**Summary/Conclusions:** This analysis included the largest cohort of elderly pts with MF treated with RTX to date. Consistent with the study by Latagliata et al., RTX was safe and effective in pts ≥75 y, with pts achieving reductions in splenomegaly and symptoms similar to those in the overall population. Consistent with the study by Latagliata et al., our study provides further evidence that RTX is safe and effective in elderly pts with MF.
Background: Accurate disease risk stratification is crucial for transplant decision making in myelofibrosis (MF). However, several prognostic models are available, it is unknown if they are equivalent in the way they distribute patients into risk groups and in their discriminatory power to predict survival.

Aims: We have compared the performance of the International Prognostic Scoring System (IPSS), dynamic IPSS (DIPSS), DIPSS-plus, and Rumi’s score in a series of 544 MF patients aged 70 years or younger at time of diagnosis.

Methods: The Spanish Registry of Myelofibrosis is a nationwide, longitudinal registry contributed by centers associated to the Grupo Español de Enfermedades Mieloproliferativas Filadelfia negativas (GEMFIN). From January 2000 to January 2016, a total of 544 adult patients aged ≤70 years with primary MF (n=335) or secondary MF (n=209) had been included in the registry. Cases of the prefibrotic form of MF were not considered. Comparison of the relative power of each prognostic model to discriminate levels of risk was estimated by means of the Harrell’s concordance index (C-index) and the R² explained variation. All the statistical analyses were performed with IBM SPSS 22.0 and Stata 11.

Results: In the intermediate-2 group, patients with intermediate risk were diagnosed with MF at ages ≥55 years, and patients with intermediate risk were diagnosed with MF at ages ≥65 years.

Summary/Conclusions: In our contemporary series of MF patients only the highest risk prognostic current prognostication systems have a median survival below the 5-year threshold recommended for considering transplantation. Patient selection for transplantation is quite dependent on which prognostication model is used for disease risk stratification.
PMF seem to be the main contributors to infectious risk. In 11% of the cases. Advanced age, a previous infectious event and diagnosis of their negative prognostic association. Interestingly, RUX dosage, spleen summary/conclusions: response and hematological toxicities during treatment were not associated with infectious risk.

Methods: Clinical and laboratory data of MF pts treated with RUX are retrospectively collected from the database of 21 Italian Hematology Centers. Infections were defined according to the CTCAE.

Results: Overall, 373 pts received RUX between June 2011 and June 2016. At RUX start the clinical features were (median): age 68 years (27-89); >65y, 62%; male, 57%; Hb, 10.8g/dL (7-16.7); Hb <10g/dL, 40%; PLT, 246×10^9/L (33-1887); PLT <100×10^9/L, 10%; spleen enlargement, 97%; spleen length ≤10cm, 65%; constitutional symptoms, 52%. International Prognostic Score System (IPSS) was intermediate-1 (15%), intermediate-2 (46%), high (39%). JAK2V617F mutation was detected in 255 out of 313 evaluated pts (81%). Karyotype was unfavorable in 15 out of 203 evaluable pts (7%). Previous infectious complications were recorded in 31 pts (8%). After a median RUX exposure of 20 months (range, 1-56), 101 pts (27%) experienced 129 infectious events of types was unfavorable in 15 out of 203 evaluable pts (7%). Previous infectious complications were recorded in 31 pts (8%). After a median RUX exposure of 20 months (range, 1-56), 101 pts (27%) experienced 129 infectious events, for an incidence rate of 14.9 cases for 100 pts/year. The rate of infections tended to decrease over time: 54% occurred within 6 months of therapy, 15% between 6 and 12 months, 9% between 12 and 18 months (p=0.0001). Respiratory tract infections were more frequently observed (73 events, 57%). Cutaneous, urinary tract and gastrointestinal infective events were diagnosed in 15%, 10% and 7% of cases, respectively. In 14 cases fever of unknown origin was recorded (Figure 1). Etiological agents were isolated in 14 cases (11%); bacteria in 9 cases (gram+ 56%, gram- 22%, C. difficile diarrhea 22%) and fungi in 2 cases (pulmonary aspergillosis and oesophageal candidiasis). Mycobacterium tuberculosis was isolated in 3 cases. Herpes-virus reactivations occurred in 12 cases (9%). No patients reactivated hepatitis B virus. At last follow-up, 88 pts (24%) have died, in 10 cases (11%) due to infectious complication. Among baseline features, age≥65 years at RUX start (p=0.0001), previous infection (p=0.001), primary vs secondary MF (p=0.021) and high IPSS (p=0.029) significantly correlated with higher infectious risk. Notably, no differences were observed according presence of large (≥10cm) splenomegaly, higher (>20) total symptoms score, presence of cytopenias, Charlson comorbidity index (>2) and body mass index (>21 and >30). In multivariate analysis, PMF diagnosis (HR 1.6 CI95% 1.07-2.5), age≥65 years (HR 2.1 CI95% 1.3-3.3) and previous infection (HR 3 CI95% 1.7-5.4%) confirmed their negative prognostic association. Interestingly, RUX dosage, spleen response and hematological toxicities during treatment were not associated with infectious risk.

Summary/conclusions: Infections occurred in around one-third of RUX-treated pts; the rate of infections tended to decrease over time, and were fatal in 11% of the cases. Advanced age, a previous infectious event and diagnosis of PMF seem to be the main contributors to infectious risk.

Figure 1.

TREATMENT AND MANAGEMENT OF PATIENTS WITH MPNS-FINDINGS FROM THE INTERNATIONAL MPN LANDMARK SURVEY

Methods: This cross-sectional, internet-based survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK and was administered to pts with MPNs and to physicians treating pts with MPNs. Pts and physicians were recruited independently. We describe disease-management strategies in these pts.

Results: Overall, 699 pts (MF, n=223; PV, n=174; ET, n=302) and 219 physicians completed the survey. In line with treatment guidelines, main therapies used by pts were ruxolitinib (54%), aspirin (40%), and HU (28%) in MF; phlebotomy (PLB, 70%), aspirin (66%) and HU (42%) in PV; and aspirin (73%), HU (48%), and anagrelide (15%) in ET (Figure 1). Most physicians reported prescribing the following: ruxolitinib (76%), transfusion (54%), and HU (53%) in MF; aspirin (79%), HU (77%) and PLB (67%) in PV; and aspirin (80%), HU (67%), and anagrelide (52%) in ET. Many physicians (51% MF, 47% PV, 49%
ET) chose watchful waiting to manage >25% of their pts at diagnosis; 22% of untreated pts had moderate to high (quartiles 3-4) overall symptom burden. Physicians primarily recommended treatment for pts experiencing severe symptoms (72% MF, 68% PV, 72% ET) or symptomatic splenomegaly (71% MF, 61% PV, 39% ET). PLB was mainly used to treat pts with PV. Of those who received PLB (n=155), 71% were very or somewhat satisfied; 25% were very satisfied. A small number of physicians felt that PLB had a negative impact on their QOL. Similarly, 37% of physicians felt that PLB had a negative impact on pt QOL; PLB alone was insufficient for disease control in 38% of pts. Pts stopped PLB because physician deemed it no longer necessary (62%), pts felt worse after treatment (10%), and visit frequency was inconvenient (8%). Physician-reported reasons for stopping PLB were that visit frequency was inconvenient (38%), pts felt worse after treatment (35%), and lack of intravenous access (33%). HU use was assessed in pts with PV or ET. Of those who received HU (PV, n=95; ET, n=145), 78% and 74%, respectively, continued to receive HU; 19% and 22% were dissatisfied with HU therapy. Main reasons for stopping HU were lack of efficacy (29% PV, 13% ET) and toxicity (10% PV, 27% ET). Overall, 78% of physicians reported that up to 25% of their pts showed inadequate efficacy or intolerance of HU. Main measures of treatment success among pts were physician feedback (73% MF, 75% PV, 75% ET) and blood counts (72% MF, 67% PV, 74% ET). Lack of efficacy, side effects, and discontinuation were key reasons for changing therapy.

Summary/Conclusions: Many pts with MPNs are managed with watchful waiting at diagnosis. Although most of these pts have a low symptom burden, 22% have a moderate to high burden, highlighting the need for proactive and standardized symptom assessments at diagnosis and over the course of treatment. Interestingly, a proportion of physicians and pts felt that phlebotomy had a high negative impact on pt QOL. Overall, pts consider physician feedback and blood counts to be important indicators of treatment success.

**P707 SUCCESSFUL LONG-TERM MAINTENANCE OF PV PATIENTS WITH A MONTHLY SCHEDULE OF ROPEGINTERFERON ALFA-2B: AN UPDATE FROM THE PEGINIVERA STUDY**

1Krankenhaus der Elisabethinen Linz, Linz, 2AZOP Orphan Pharmaceuticals AG, Vienna, 3Department of Internal Medicine IV, Klinikum Wels-Grieskirchen, Wels, 4Third Medical Department, Hanusch Hospital, Vienna, 5Dep. Internal Medicine IV, Haematology & Oncology, Innsbruck Medical University, Innsbruck, Austria, 6Department of Hematology, Oncology and Rheumatology, Center of Integrated Oncology Cologne Bonn, University Hospital of Bonn, Bonn, Germany, 7CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, 8Hematology and Hemostaseology, Medical University Vienna, 9Sozialmedizinisches Zentrum Ost - Donauspital, Vienna, 1011th Medical Department, Salzburger Cancer Research Institute, Paracelsus Medical University, Salzburg, Austria, 11Aprova CRO, Brno, Czech Republic

Background: Ropeginterferon alfa-2b is a novel long-acting monopegylated interferon alpha (IFNa) with Orphan designation in Europe and the U.S. Reduced dosing frequencies and favorable tolerability accompanied by robust clinical responses in patients with polycythemia vera (PV) have been reported over the first few years of treatment. Successful long-term, potentially lifelong maintenance with high rates of adherence, compliance and treatment outcome remain important goals to be elucidated.

Aims: PEGINIVERA phase III (NCT: 2010-018768-18), is a prospective, open-label, multicenter study investigating efficacy and safety of ropeginterferon alfa-2b in long-term treatment of patients with confirmed diagnosis of PV, pre-treated or naïve to cytoreductive therapy.

Methods: All patients responding well to the initial bi-weekly administration schedule and participating in the study for longer than one year, had the option to switch to a “once every 4 weeks” schedule. The 2-week regimen (defined as the time period when all criteria for switching were fulfilled but the patient continued the 2-week regimen) was compared to the 4-week regimen (for a duration of 6 months after switch). The present analysis was focused on maintenance of efficacy.

Results: Data from the last available analysis include 29 patients remaining on study with a median treatment duration of 213 weeks. All 29 patients have completed at least 2 years of treatment (5 patients are in the 39th year, 7 in the 43rd year, 10 in the 50th year and 7 in the 69th year of treatment). Baseline characteristics of the study cohort during long-term maintenance treatment and efficacy follow-up data were already presented earlier (Gisslinger et al. 2015). All of the 29 patients were switched to dosing once every 4 weeks. Median treatment duration at time of switch was 104 weeks (Q1-Q3: 69-124 weeks). All 29 patients remained on the 4-week schedule with a median observation period of 2 years thereafter. Study results reflect excellent safety and tolerability profile of ropeginterferon alfa-2b in this setting. The percentage of patients maintaining their best haematological response according to ELN before (i.e. after median 104 weeks of treatment) and 6 months after switching to the 4-week regimen was consistent at 51.7%. Further, need for phlebotomy during the 6 months after switching did not increase (consistent 7/29 patients). Changes in haematological parameters and spleen size were minimal and without clinical relevance. Similarly, the percentages of patients maintaining their best molecular response were 62.1% and 58.6%, respectively (non-significant). Importantly, the majority of patients on ropeginterferon alfa-2b long-term treatment, developed a sustained reduction of mutant JAK2 allele burden to below 10%, a feature that can only be achieved by IFNα based therapies.

Summary/Conclusions: In summary, all patients remaining on ropeginterferon alfa-2b after a median of 2 years of initial treatment were successfully switched to a more convenient monthly long-term maintenance schedule, thereafter no patients discontinued, and all patients could be maintained on this schedule for currently another 2 years (trial still ongoing). These data underscore the expected long-term efficacy with regard to haematological, clinical and molecular parameters and the excellent safety/tolerability of ropeginterferon alfa-2b. Long-term maintenance treatment of PV patients using ropeginterferon-alfa 2b monthly is feasible, efficacious and well tolerable. Continuous patient-individual adaption of dosing regimen, including dose and dosing schedule, is recommended.

**P708 NO IMPROVEMENT IN SURVIVAL OVER TIME FOR PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS PATIENTS WHO TRANSFORM TO ACCELERATED OR BLAST PHASE**

C. Mccnarama1*, J. Kennedy 1, T. Panzarrella2, G. Daher-Reyes1, R. Alblooshi1, J. Ramanana1, A. Aruda1, J. Ho1, N. Siddiqui1, J. Claudio1, R. Devin1, T. Stockley3, M. Sukhail3, M. Thomas3, S. Chan 1, D. Maze4, A. Schimmer1, A. Schuh1, H. Sibai1, K. Yee1, S. Kamel-Reid1, M. Minden1, V. Gupta1

1Department of Medical Oncology and Hematology, 2Department of Biostatistics, 3Advanced Medical Diagnostics Laboratory, Princess Margaret Cancer Centre, Toronto, Canada

Background: The outcome of patients with Philadelphia negative myeloproliferative neoplasms (MPN) who transform to acute leukemia is abysmal. There have been no advances in targeted therapy for this cohort of patients or individualized treatment based on genomic information. Furthermore, no large studies have investigated the impact of molecular profiling on clinical outcome in patients with accelerated or blast phase of MPN.

Aims: To describe the clinical outcomes of patients with MPN who transform to accelerated or blast phase and evaluate the impact of genomic alterations on outcomes.

Methods: Eligibility criteria included: Prior diagnosis of Philadelphia negative MPN according to WHO 2008 criteria; evidence of transformation to accelerated (10-19% blasts in peripheral blood or bone marrow) or blast phase (≥20% blasts) and seen at Princess Margaret Cancer Center between January 1998 and February 2017. The primary endpoint was overall survival (OS); defined as the time from transformation to death or last follow-up. Secondary endpoints included survival based on curative versus non-curative approach and treatment over time. In addition the impact of mutations will be correlated with clinical outcomes and survival.

Results: One hundred and eighty-seven patients who transformed to accelerated or blast phase with a prior diagnosis of MPN were identified at our institution. The outcome of patients with Philadelphia negative myeloproliferative neoplasms (MPN) who transform to acute leukemia is abysmal. There have been no advances in targeted therapy for this cohort of patients or individualized treatment based on genomic information. Furthermore, no large studies have investigated the impact of molecular profiling on clinical outcome in patients with accelerated or blast phase of MPN.
Other Non-malignant hematopoietic disorders

P709

MASITINIB FOR TREATMENT OF SEVERELY SYMPTOMATIC INDOLENT SYSTEMIC MASTOCYTOSIS: ADDITIONAL EFFICACY ANALYSES FROM THE RANDOMIZED, PLACEBO-CONTROLLED, PHASE 3 STUDY: MASITINIB FOR TREATMENT OF SEVERELY SYMPTOMATIC INDOLENT SYSTEMIC MASTOCYTOSIS (ISM) WHO ARE UNRESPONSIVE TO EXISTING, OPTIMAL SYMPTOMATIC TREATMENTS. IN THE LANCET (FEB 11:389[10069]:612-620), LORHALLY AND COLLEAGUES REPORTED A SIGNIFICANT AND CLINICALLY MEANINGFUL TREATMENT BENEFIT FOR MASITINIB (6MG/KG/DAY OVER 24 WEEKS) VERSUS PLACEBO, PRIMARY ANALYSIS BASED ON CUMULATIVE RESPONSE (>75% IMPROVEMENT FROM BASELINE, TIMEFRAME 8-24, COMPRISING 5 VISITS AT 4-WEEK INTERVALS) IN AT LEAST ONE OF FOUR SEVERE BASELINE SYMPTOMS (PRURITUS, FLUSHES, DEPRESSION, OR FATIGUE) USING REPEATED MEASURES METHODOLOGY FOR RARE DISEASES (I.E., A LONGITUDINAL ANALYSIS WITH RESPECT TO SYMPTOMS AS OPPOSED TO PATIENT RESPONSE RATE AT A SINGLE POINT IN TIME). ELIGIBLE PATIENTS WERE AGED 18-75 YEARS AND HAD ISM ACCORDING TO WHO CLASSIFICATION CRITERIA THAT WERE SLIGHTLY WIDER THAN THE WHO CLASSIFICATION.

Aims: To aid interpretation of this study's prospectively declared primary endpoint via comparison with additional efficacy analyses based on a cohort restricted to the WHO classification of ISM and more conventional patient-centric response endpoints.

Methods: Randomized, placebo-controlled, phase 3 study that included 135 severely symptomatic ISM patients, including the subvariant smoldering systemic mastocytosis (71 mastinib, 64 placebo). 80% of whom satisfied the WHO classification.

Results: Masitinib showed a significant improvement over placebo according to its pre-specified primary endpoint (mITT population), with a cumulative response of 18.7% versus 7.4%, respectively, odds ratio (OR) of 3.6 [95%CI 1.2-10.8], P=0.008 (with re-randomization). This outcome was confirmed in the WHO patient subgroup: 17.8% versus 8.0%, respectively, OR=3.25 [0.97-10.88], P=0.0317. Computing the primary analysis (mITT) according to cumulative response per patient (GEE model) was also positive: 26.7% versus 12.8%, respectively, OR=2.48 [1.16-5.31], P=0.0212, as was analysis according to individual patient response (Pearson chi-square): 40.3% versus 24.2%, respectively, P=0.0062. Response (per patient) on all severe baseline symptoms for at least one visit was: 16.4% versus 8.1%, respectively, P=0.0062. Finally, analysis of sustained response in all severe baseline symptoms across multiple visits was highly discriminatory between treatment arms: for patients with 3 severe baseline symptoms, masitinib generated a 12.5% response rate (≥75% improvement in each symptom) for 3 out of 5 visits, versus no response for placebo; and for patients with 2 severe baseline symptoms masitinib generated a response rate of 21.1%, 15.8% and 10.5% over at least 1, 2, and 3 visits, respectively, versus no response for placebo.

Summary/Conclusions: These post-hoc analyses confirm the clinical relevance, durability, and generalizability of the positive primary endpoint from study AB06006. Findings therefore support the conclusion that masitinib generates a significant therapeutic benefit in patients with severely symptomatic ISM who were unresponsive to optimal symptomatic treatments.

P710

THERAPY RESPONSE AND LONG-TERM OUTCOME OF 71 ADULT PATIENTS WITH HEMATOLOGICAL MALIGNANCY-ASSOCIATED HEMOPHAGOCYTIC LYMPHOPHISTIOCYTOSIS: A SINGLE INSTITUTION EXPERIENCE

M. Machaczka1,2,*, K. Kosior3, E. Pawlikowicz4, M. Wolan5, M. Gajewski5, M. Klimkowska3

1Department of Haematology, Medical University of Warsaw, Warsaw, Poland, 2Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN, USA, 3Department of Hematology, Medical University of Warsaw, Warsaw, Poland, 4Department of Hematology, University Medical Centre, Utrecht, The Netherlands, 5Department of Medicine, University of Kansas Medical Center, Kansas City, Kansas, USA.
Background: Hemophagocytic lymphohistiocytosis (HLH) is a devastating disorder of uncontrolled immune activation characterized by clinicopathological evidence of extreme inflammation. Hematological malignancy-associated HLH (m-HLH) has the worst outcome in comparison with any other form of HLH. m-HLH can occur as the first manifestation of an occult malignancy, before start or during the treatment of known malignancy, or as the sign of a malignancy relapse or transformation to the more aggressive disease form.

Aims: The aim of the present study was to analyze the response to HLH therapy and overall survival of adult patients with m-HLH.

Methods: From 2008 and onwards, data on adult patients referred to the Hematology Center Karolinska with suspected HLH were prospectively collected. Review concerned records of 142 adults with suspected HLH, hospitalized between Jan 2009 and Dec 2016. Of those, 71 patients with hematological malignancy were diagnosed with HLH and included to the present study. Hematological malignancy was defined as a neoplasm of lymphoid or myeloid origin. In all studied patients, the diagnosis of HLH was based on the HLH-2004 criteria. Infection as a possible additional trigger of HLH was carefully studied in all our m-HLH patients. EBV and CMV DNA were routinely examined in whole blood, using RT quantitative PCR; other viruses (e.g. adenovirus, HSV, VYZ, HHV6, influenza) were studied based on indications. Blood and urine cultures were performed in order to reveal any bacterial or fungal infections. Tests for fungal antigens, tuberculosis, and parasites were also performed if indicated. HLH treatment categories have included proapoptotic chemotherapy (etoposide, corticosteroids, IVIG) and T cells (corticosteroids, cyclosporine A).

Results: Seventy-one adults, aged 22–84 years, were diagnosed with aggressive m-HLH during the 8-year period. Lymphoid malignancy was diagnosed in 42 patients and myeloid malignancy in 29 patients. Fifty-four (76%) patients developed HLH as a first manifestation of unknown malignancy, during progressive disease, or malignancy relapse. The remaining 24% patients developed HLH during chemotherapy. In 14 patients, HLH therapy started before confirmation of HLH diagnosis, based on suspicion of HLH (mean 6.7±8.4 days; median 2 days; range 1–31 days). Seventeen patients started HLH therapy at the day of HLH diagnosis. In 36 patients HLH therapy started after confirmation of HLH diagnosis (mean 15.9±14.3 days; median 5 days; range 1–242 days). Forty of 71 (56%) patients with active HLH died, of which 20 had signs of progressive malignancy, 16 patients had generalized infection (bacterial - 12 patients, viral - 3 patients, fungal - 4 patients; some patients had more than one type of infection), 5 patients had coagulopathy - central nervous system bleeding. Thirty-one (44%) patients responded to HLH therapy and achieved remission of HLH. However, only 13 of 71 (18%) patients with m-HLH were still alive after a median follow-up time of 50 months, despite the attempted treatment in 67 (94%) cases. The probability of overall survival (OS) from 6, 12, 24 and 60 months after HLH diagnosis was 39, 20, 15 and 15%, respectively. The patients who developed m-HLH with concomitant infection during chemotherapy had significantly longer OS (p=0.03) compared to patients who had HLH solely attributed to malignancy (Figure 1).

Summary/Conclusions: HLH in the context of malignancy is still considered a challenging adult hematological disease. m-HLH is a highly lethal disorder in adults. The patients who develop m-HLH with concomitant infection during chemotherapy show better survival than those who had HLH solely attributed to malignancy. Although poor outcome in some patients with m-HLH is related to malignancy progression, in some patients the lack of effective M-HLH therapy may further impede adequate treatment of malignancy.
Background: Erythrocytoses are characterized by an elevated red cell mass. The most widely studied disease is Polycythemia Vera (PV), however, other types of erythrocytoses can be either inherited (Congenital Erythrocytosis–CE) or disorders due to acquired factors (idiopathic erythrocytosis (IE), secondary erythrocytosis related to lung, cardiac or renal disorder). Next generation sequencing (NGS) has been used to analyse the presence of mutations in 28 genes (enlarged hypoxia pathway and other candidate genes).

Methods: We created and developed a national network in France to analyze the genomic abnormalities in patients suspected of CE. The selection of patients was performed based on the criteria defined in the French expert panel. DNA was extracted from patient blood and genomic exome (ENCODE) sequencing was performed by flow cytometry. Molecular analysis was performed by Sanger or Next generation sequencing.

Results: Out of 140 patients, 132 were included in the analysis and 8 were excluded due to poor quality. 60% of the patients were females. The median age was 46 years (range 1-85 years). The most frequent presenting symptoms were: headache (n=37, 25.9%), fatigue (n=21, 14.6%), atypical idiopathic arthritis (n=13, 8.9%), systemic lupus erythematosus (n=10, 6.8%), myalgia (n=10, 6.8%), and Raynaud phenomenon (n=5, 3.4%). The median follow-up was 4.8 years (range 0.1-21 years).

Conclusions: CE is a chronic disease with a variable course characterized by an increased red cell mass and a high risk of thromboembolic and haemorrhagic complications. The diagnosis of CE remains challenging, as there is no proper diagnosis can be made, no prognosis or advice can be provided to the patient, and no curative treatment exists.

Methods: To date, samples from 140 patients have been recorded, among whom 46 have been genetically studied using NGS approach. Genomic abnormalities were identified in 14 of those patients (13 males and 1 female; median age 50 y. (12-71) with unknown significance have been derived, including 4 in PHD genes, 5 in HIF genes, 4 in LNX genes (SH2B3) and 1 in JAK2 gene. In patients with variants, a familial history of erythrocytosis was noted in 3. No independent thrombotic complication was reported in 15 patients. In 2 patients (one with a JAK2 variant and one with a KIT variant), the erythropoietin was low, whereas for the others, the erythropoietin was normal. Of note, the median age of the patients was surprisingly high, suggesting that the diagnostic was not previously performed due to the absence of available tests. Functional studies were performed on PHD2 variants: a significant decrease in the hydroxylase activity was noted for one variant, but not for the others. On the other hand, a decrease in the stability along time of the PHD2 protein was observed for two variants, underscoring the different mechanisms involved in the impairment of the PHD2 activity.

Summary/Conclusions: In conclusion, monoallelic variants in genes related to familial hemolytic-lymphohytic cytostasis are useful tool to explore mutations in CE, but it is essential to identify, collect and analyze the genomic abnormalities in patients suspected of CE.
University of Padova, 1Department of Medicine –DIMED, Clinica Medica 1, 2Department of Medicine, University of Padua, 3Department of Oncology, Azienda “Santobono-Pausilipon”, Pausilipon Hospital, 4Department of Pediatric Haematology-Oncology, Department of Pediatric Haematology-Oncology, Napoli, 5Department of Pediatric Haematology-Oncology, University Hospital of Parma, Parma, 6Department of Pediatric Haematology-Oncology, University Hospital of Bolzano, Bolzano, 7Department of Reproduction and Growth, University Hospital Sant’Anna in Ferrara, Ferrara, 8Department of Haematology, Oncoematologia Pediatrica, Policlinico G. B. Rossi, Verona, 9Department of Pediatric Haematology-Oncology, University of Catania, Catania, 10Department of Haematology, Ca’Foncello Hospital, Treviso, Italy

Background: Erythrocytosis, (i.e. increased levels of hemoglobin / hematocrit (Hb/Htc) >95 percentile for age and sex), is rarely found in pediatric or adolescent age. Presence of familial cases, presentation at birth or presence of known mutations, as well as exclusion of secondary causes identifies primary (PE) or congenital secondary forms (CE). However, many cases still lack evident etiological definition (idiopathic E.). Moreover, natural course and treatment are still anecdotal reported.

Aims: Here we present our experience in a large and heterogeneous series of children with absolute erythrocytosis. The aims is to identify a possible clinical and diagnostic approach to children with erythrocytosis

Methods: All children with E. who lacked evidence of reactive origin were consecutively referred to our laboratory for molecular evaluation. Molecular analysis of the main involved genes (VHL, HIF2A, EPOR, JAK2, PHD2) was performed by allele specific PCR, PCR on direct DNA sequencing. Erythopoietic Colony Essay (ECC) was performed on peripheral blood with and without cytokines. Clinical features and treatment choices were reported by referring clinicians (table 1).

Table 1.

Results: Patients were group according to the definitions of absolute Erythrocytosis. A total of 44 pediatric cases were identified (less than 18 years old). There were 7 families, where 5 adults were also found polyglobulic. However, in only 4 families a defect was identified (2 VHL, and 2 Hb variants). One Hb positive case was found sporadic. Most Hb variants were not symptomatic, while all other familiar cases had splenomegaly and vascular symptoms. Among non familial, non genetic cases, 5 children were affected by Down Syndrome; 4 children had severe renal or cerebral disease. In one 4 year old girl, with a polymorphic VHL variant, who presented with arterial hypertension, a small size ganglionneuroma was found after a 5yrs follow-up. In 21 cases non causes could be identified. They were mostly male (n18); presented at adolescent age with advanced puberal status (n17); many were symptomatic (6). Only one 9 year old girl was diagnosed with polycytemia vera (JAK2V617F positive). Treatment varied according to physician decisions and presence of vascular symptoms, 6 children received ASA and 11 were phlebotomised. In two older patients severe vascular complications were observed (arterial thrombosis), even with Htc<45%.

Summary/Conclusions: This series shows the heterogeneity of Erythrocytosis as found in pediatrics. Extensive clinical and genetic analysis are required but still a large number of cases lack clear definitions. The usefulness of antiaggregation and phlebotomy is not proved.

O. Oncocentro Pediatria, Institute of Maternal and Child Health IRCSS Burlo Garofolo, Trieste, Italy

Background: The most frequent Autoimmune Neutropenia (AIN) in childhood is the primary type (p-AIN), whereas in adults AIN is mostly represented by secondary neutropenias, which can be associated to infection, drug administration, immunodeficiency, neoplasms, bone marrow transplantation or other autoimmune disorders.

Aims: To describe clinic and laboratory findings in children affected by AIN secondary to other autoimmune diseases (s-AIN).

Methods: This registry study analyzes 26 patients affected by s-AIN enrolled in the Italian neutropenia registry of A.I.E.O.P. (Associazione Italiana di Onco-Ematologia Pediatrica) over a 15-year time-span: this cohort, the largest ever described, was compared to 263 patients affected by p-AIN enrolled in the Registry in the same period.

Table 1. Results: Specific characteristics of s-AIN patients are presented in Figure 1. The prevalence of former preterm babies among p-AIN (and not s-AIN) patients was significantly higher than in a cohort of 487 consecutively hospitalized children (p=5.29e-02). The median age of onset of AIN was 0.77 year and 10.07 year in p-AIN and s-AIN respectively (p=1.105e-12). The prevalence of selected IgA deficiency was 3% in p-AIN and 13.6% in s-AIN children; both prevalences were significantly higher than that (0.21%) of a group of 470 controls (p=0.0009 in p-AIN and p=7.239e-12 in s-AIN). Median value of neutrophils was lower in p-AIN (0.45 x 10^9/L) than in s-AIN 0.63 x 10^9/L (p = 0.03); median value of lymphocytes was significantly reduced (p=6.29e-11) in s-AIN (1.58 x 10^9/L) vs p-AIN (4.36 x 10^9/L) group. Leukopenia (p=1.80e-07) and severe infections (p=0.0001) occurred more frequently in s-AIN; mononcytosis (p=0.039) and spontaneous remission (p=3.21e-11) in p-AIN. GCSF was used in 6% of the p-AIN patients and in 1% of the s-AIN patients (p=0.0045). Neutropenia appeared contemporarily to other autoimmune manifestations in 11/26 s-AIN patients (42.3%), appeared firstly in 8/26 patients (30.7%) (median and mean time of appearance of other autoimmune signs: 440 and 987 days respectively) and later in 7/26 patients (26.9%) (median and mean time of appearance of s-AIN: 588.5 and 886.3 days respectively). Evans Syndrome (ES) and autoimmune thyroiditis (AT) were the most common secondary autoimmune diseases (11 and 7 patients, respectively), whereas 7 s-AIN patients presented not previously reported associations: 3 with GH deficiency, 2 with coeliac disease (CD), 1 with autoimmune hepatitis (AH) and 1 with autoimmune-encephalitis. In 6 children s-AIN was associated with more than one defined autoimmune disease and in 4 children with undefined autoimmune signs characterized by arthralgia and ANA positivity. Finally, only 2/26 patients presented spontaneous remission: a boy who recovered from ES and one patient, affected by both AT and CD who, after starting gluten-free diet, recovered from s-AIN (and not from AT). A third girl suffering from both AH and bi-lineage ES (thrombocytopenia + AIN) has been maintained, 30 months after the stop therapy, a stable remission from AH and thrombocytopenia (but not from s-AIN).

Summary/Conclusions: p-AIN is in the vast majority of cases a benign and self-limiting disorder typically occurring under 2-3 years old whereas s-AIN is a more severe disease, usually appearing after the first 5 years of life, usually associated to lymphocytopenia and with a highly frequent tendency to become chronic.

P718 PAROXYSMAL NOCTURNAL HEMOGLOBINURIA TREATMENT DURING PREGNANCY

M. Vinogradova1,*, A. Kulagin2, T. Kirsanova1, N. Klimenchenko3, R. Shmakov3

1hematology, Federal Scientific Center for Obstetrics, Gynecology and Perina- tolology, Moscow, 2hematology, 1st Saint Petersburg State Medical University, Saint Petersburg, 3obstetrics, Federal Scientific Center for Obstetrics, Gynecol- ogy and Perinatology, Moscow, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a life-threatening disorder with a high risk of thrombosis. Targeted therapy radically changed the prognosis in PNH. Therefore issues of reproductive health in PNH patients are becoming very important. Recently the management of PNH during pregnancy has been challenging because of the high risk of maternal morbidity and frequent pregnancy loss. The combination of targeted therapy with eculizumab and anticoagulants made it possible not only to increase the survival rate, but also to improve the quality of life.

Aims: We compared the pregnancy outcomes in PNH patients on eculizumab treatment and retrospective data on pregnancies of patients on symptomatic therapy only.

Methods: Since 1999 we have analyzed 32 pregnancies in PNH patients. 17 patients (group 1) from 2013 exposed to eculizumab during pregnancy with anticoagulants. Other 15 women (group 2) received only symptomatic therapy. The median of PNH granulocyte clone at that time was 74.7% (23-99). PNH diagnosed before the pregnancy in all cases. 64.3% of them had previously received immunosuppressive treatment of aplastic anemia. 18.7% patients registered venous thromboses before conception. 92.9% of patients had been using eculizumab prior to becoming pregnant, mean duration of therapy was 21 months (4-44). Anticoagulation with low molecular weight heparin was used in 85.7% pregnancies.

Results: Clinical manifestations of hemolysis significantly regressed during eculizumab treatment: normalization of LDH was registered in 76.5% patients. Without eculizumab LDH level increased in all pregnant patients. No maternal death and thrombotic events have been observed. 42.9% of patients required a dose adjustment due to breakthrough hemolysis (a dose increase and/or more frequent use of eculizumab). Pregnancy complications were less frequent with eculizumab: abortion threat 35.3% vs 85.7%, fetal growth retardation syndrome 7.1% vs 21.4%, preeclampsia 5.9% vs 14.3%. Transfusion rate was higher without eculizumab (86.7% vs 41.2%). Pregnancies resulted in the birth in 100% patients exposed eculizumab and 42.9% on supportive treatment. Mean birth weight 2560 g (450-3550). Most of newborns (87.5%) are healthy, 83.3% of them received breastfeeding without complications both on eculizumab and without it.

Summary/Conclusions: We can conclude that pregnancy outcomes in PNH patients with eculizumab are much better than with symptomatic therapy only. Our data demonstrate the possibility of safe therapy with eculizumab in preg- nant women. Pregnancy does not worsen the prognosis of PNH in the case of targeted and adequate supportive therapy. There is no difference in health between infants born by mothers with PNH and the newborns from general population.
Platelet disorders: Clinical

P719
LONG-TERM RESPONSE TO ORAL ELIGLUSTAT IN TREATMENT-NAÏVE ADULTS WITH GAUCHER DISEASE TYPE 1: FINAL EFFICACY AND SAFETY RESULTS FROM A PHASE 2 CLINICAL TRIAL AFTERTW YEARS OF TREATMENT
E. Lukina1, N. Watman2, M. Dragosy3, H. Lau4, E. Avila Arregui5, H. Rosenbaum6, Y. Wu7, S. Gaemers7, M.J. Peterschmitt8
1National Research Center for Hematology, Moscow, Russian Federation, 2Hospital Ramos Mejia, 3IMAI-Research, Buenos Aires, Argentina, 4New York University School of Medicine, New York, United States, 5Instituto Mexicano del Seguro Social Hospital de Especialidades, Col. La Raza, Mexico, 6Ram Bam Medical Center, Haifa, Israel, 7Sanofi Genzyme, Cambridge, United States

Background: In Gaucher disease type 1 (GD1), deficient lysosomal acid β-glucosidase activity leads to accumulation of glucosylceramide, primarily in macrophages (Gaucher cells), which deposit in the spleen, liver, and bone marrow, leading to thrombocytopenia, anemia, hepatosplenomegaly, and skeletal disease. Hematologists often identify and manage the disease. Intravenous enzyme replacement therapy (ERT) with recombinant acid β-glucosidase has been the mainstay of therapy for GD1. Eliglustat is an oral substrate replacement therapy approved as first-line treatment for adults with GD1 with poor, intermediate, or extensive CYP2D6-metabolizer phenotypes (>90% of patients). Phase 3 trials demonstrated safety and efficacy of eliglustat in naïve patients (Mistry et al. JAMA. 2015) and safety and stability in patients switching from long-term ERT (Cox et al. Blood. 2017). We report the final 5-year results of an open-label Phase 2 trial (NCT00382180, Sanofi Genzyme) in previously untreated adults with GD1. These data build on 1-, 2-, and 4-year data showing sustained improvements in hematologic parameters, organ volumes, disease-related biomarkers, and measures of bone health (Lukina et al. Blood Cells Mol Dis. 2014).

Methods: Adult GD1 patients who had splenomegaly with thrombocytopenia and/or anemia received 50 or 100mg eliglustat twice daily (equivalent to 42 or 84mg eliglustat) during the first 6 months, followed by dose adjustment to a maximum of 75mg OD (East Asians, 12.5mg OD or 25mg every other day) in pediatrics aged 1-5 years, 50mg (non-East Asians), and 75mg (East Asians) in adults. Efficacy outcomes included changes in hemoglobin, platelets, spleen and liver volumes, disease-related biomarker levels, skeletal manifestations, and achievement of therapeutic goals for anemia, thrombocytopenia, splenomegaly, and hepatomegaly (Pastores et al. Semin Hematol. 2004; Lukina et al. Blood. 2010).

Results: Of 26 enrolled patients, 19 completed the trial and 7 withdrew: 2 on the first day of treatment due to asymptomatic nonsustained ventricular tachycardia detected during the monitoring (plasma levels of eliglustat were undetectable); 1 after 1 year due to progression of a bone lesion (retrospectively identified at baseline); 1 chose to withdraw after 2 years; and 3 due to pregnancy. After 8 years of eliglustat, mean (±SD) hemoglobin level and platelet count increased by 2.1±1.7 g/dL (from 11.3±1.6 to 13.4±1.3 g/dL) and 110% (from 67.5±21.1 to 130.7±59.8 x109/L), respectively. Mean spleen and liver volumes (multiples of normal, MN) decreased by 68% (from 17.3±10.4 to 5.1±3.5 MN) and 31% (from 1.6±0.5 to 1.1±0.3 MN), respectively. All patients met ≥3 of 4 long-term therapeutic goals (spleen, 100% of patients; liver, 100%; hemoglobin, 93%; platelets, 53%) by 7-8 years. Median chitotriosidase levels decreased by 84%, CCL-18 by 82%, and glucosylsphingosine (Lyso GL-1) by 88%; plasma GL-1 normalized. Total mean lumbar spine bone mineral density increased by 0.12 g/cm2; mean Z-score increased by 0.88 (from -1.27±0.12 to -0.39±1.13) and mean T-score by 0.95 (from -1.64±0.17 to -0.69±1.31). Eliglustat was well-tolerated. All quality of life measures (SF-36, fatigue severity score [FSS], disease activity score) showed improvement over time. Most adverse events in this long-term trial were mild or moderate in severity (98%, 342/348) and considered unrelated (94%, 328/348) to treatment.

Summary/Conclusions: After 8 years of treatment with eliglustat, clinically meaningful improvements in hematologic, visceral, biomarker, and bone parameters continued or were maintained among patients in this Phase 2 trial. No new safety concerns emerged.

P720
REAL WORLD EVIDENCE ON DRUG UTILIZATION PATTERNS OF ERTOMOBAG IN ADULT PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP) via an Information Technology (IT) [ELTROMBOPAG] IN SELECTED COUNTRIES IN THE EUROPEAN UNION (EU) STUDY
E.O. Gutiérrez1,*, N. Revilla1, R.M. Campos2, A. Miñano3, F. Velasco4, N. González5, R. Ferrer6, 6Novartis Pharma AG, Basel, Switzerland, 7Hospital Universitario de Burgos Avda. Islas Baleares s/n, Burgos, Spain

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by isolated thrombocytopenia, with platelet counts <100x109/L. Ertomobag is an oral small-molecule nonpeptide thrombopeoitin-receptor agonist that has shown high efficacy and a safety profile consistent with the management of patients with chronic ITP (aged ≥1 year) who are refractory to other treatments (eg, corticosteroids, immunoglobulins). The recommended ertomobag dose in patients with chronic ITP is 25mg once daily, OD (East Asians, 12.5mg OD or 25mg every other day) in pediatricians aged 1-5 years, and 50mg OD (East Asians, 25mg OD) in adults and pediatrics aged 6-17 years at initiation, followed by dose adjustment to a maximum of 75mg OD based on platelet counts. REVIEU study was conducted in accordance with risk management plan in five European Union (EU) countries to document ertomobag utilization patterns in real-world practice. Here, we report the exploratory descriptive data on the subset of adult patients (aged ≥18 years) with ITP as primary diagnosis.

Aims: To evaluate the real-world data to determine drug utilization patterns among adult patients with ITP receiving ertomobag within five EU countries.

Methods: REVIEU study was a multinational, multicenter, retrospective, medical chart review in patients with a documented past treatment with ertomobag between the period immediately after first approval/launch in May 2010 and September 2014 (ie, dispensed at least once by the pharmacy and patient received at least one dose) for whatever reason. Patients who participated or were participating in a randomized ertomobag clinical trial were excluded.

Table 1.

Table 1. Proportion of patients with platelet counts by ITP disease phase, dose, and by ITP disease phase and ertomobag dose are reported in Table 1.

Results: Overall, 287 adult patients with ITP (chronic >12 months), 75.3%; persistent [3-12 months], 10.8%; acute [<3 months], 13.6%; unknown (n=1) were included, majority in Spain (n=128) followed by Italy (n=67), Greece (n=36), France (n=29), and Germany (n=27). Ertomobag was the first treatment with no prior ITP therapies in 12 (4.2%) [acute, 10.3%; persistent, 6.5%; chronic, 2.8%] patients. A total of 99 (34.6%) patients received one prior therapy (corticosteroids, 79 [27.6%], 128 (44.8%) patients received two prior therapies (corticosteroids+immunoglobulins, 114 [39.9%]). 43.7% of patients received three prior therapies (corticosteroids, immunoglobulins, and splenectomy). In total, the majority of patients received at least one prescription of corticosteroids (252, 88.1%) followed by immunoglobulins (180, 62.9%), and splenectomy (64, 22.4%) prior to ertomobag initiation. Patients received an average daily dose of ertomobag 45.6mg (chronic ITP, 44.6mg; persistent ITP, 43.1mg; acute ITP, 53.0mg) during the study. Overall, dose changes were reported in 749 adult ITP prescriptions (down-titration, 53.7%; up-titration, 43.7%; no change in dose, 2.7%). 49.1% of dose changes were reported during the first 6 months of treatment (35% in first 3 months). The main reasons for dose change included: disease improvement (30.4%), no treatment response (26.8%) and others (27.1%). Disease improvement accounted for down-titration in 51.2% (206/402) and up-titration in 4.6% (15/327), and no treatment response for up-titration in 54.4% (178/327) and down-titration in 5.0% (20/402) of adult patients with ITP. Without ITP responders with platelet counts by ITP disease phase and by ertomobag dose are reported in Table 1.

Summary/Conclusions: The majority of adult patients with ITP (75.3%) were diagnosed with chronic ITP, and were treated with ertomobag as second-line or greater therapy after corticosteroids and immunoglobulins, in line with the approved indication. Ertomobag was also prescribed in 24.4% of adult patients with acute and persistent ITP. The starting dose followed the summary of product characteristics (SmPC) recommendations in the majority of cases and dose modifications were generally according to platelet counts. Data from REVIEU study have shown that ertomobag use in the real world setting is largely consistent with the EU label and is considered part of ITP medical therapies.

P721
BIOLGICAL CHARACTERIZATION OF ITP PATIENTS THAT ARE NON-RESPONDERS TO TRADITIONAL THERAPIES
N. Revilla1, R.M. Campos2, A. Miñano3, F. Velasco4, N. González5, R. Ferrer6,

1Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain, 2Charité Universitätssmedizin Berlin, Berlin, Germany, 3Hôpital Haut Lévêque Centre FMagendie Avenue de Magellan, Bordeaux, France, 4Hospital Clínico Universitario Virgen de la Victoria Campus Universitario de Teatinos s/n, 5Hospital Regional Universitario de Málaga Avenida Carlos Haya s/n, Málaga, Spain,
Background: A previous study has suggested a mechanism of Fcγ receptors (FcγR)-independent platelet clearance in immune thrombocytopenia (ITP) (1). Antibody-mediated platelet desialylation may lead to platelet clearance in the liver via hepatic Ashwell–Morell receptors, providing a potential explanation for refractoriness to classical therapies (steroid, IVIG and splenectomy).

Aims: The aim of this study was to analyze the biological features of ITP patients refractory to conventional therapies.

Methods: We performed a prospective study in 8 patients with primary ITP not responding to standard therapies (corticosteroids, IVIG and/or splenectomy) as well as in 8 patients with non-refractory ITP (control group). Mean platelet size, surface expression of platelet glycoprotein (GP) IIb, and the activation marker CD62 were examined by flow cytometry (FC) analysis, as well as desialylation of platelet membrane gangliosides using fluorescent-conjugated Ricinus Communis Agglutinin I (RCA-1), a lectin that binds to galactose residues underlying sialic acids. Patients’ sera was also incubated with normal human platelets to analyze Agglutinin I (RCA-1), a lectin that binds to galactose residues underlying sialic acids.

Results: A total of 546 pts received either R or E between Dec 2009 and Dec 2015. Of these, 106 (19.4%) underwent TPO-RA switch. Table 1 summarizes outcome after switch. Overall 69/106 (65%) of pts achieved, regained or maintained response upon switching. Either one TPO-RA switch sequence was equally effective (p=0.682). Outcome was not associated with gender, age at 1st TPO-RA treatment, splenectomy status. However, number of lines of previous therapies was lower responders (p=0.020): response to the 2nd TPO-RA (80% responders) compared to those who were non-responders to 1st TPO-RA (49% responders, p=0.001). It could be speculated that lack of response to either one of the two available TPO-RA identifies a subgroup of pts least likely to respond when switching to the second available TPO-RA. Pts switched for non-efficacy reasons are more likely to maintain a response upon switching (p=0.030). The so far unexplained and unprecedented phenomenon of wide platelet fluctuation appears to be linked to the removal of the spleen, the physiological platelet reservoir organ.

THROMBOEMBOLIC EVENT MANAGEMENT AND OUTCOMES IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (cITP) DURING TREATMENT WITH ELTROMBOPAG (EPAG): RESULTS FROM THE EXTEND STUDY

M.N. Saleh1,*, J.B. Busse2, R.S. Wong3, B. Meddeb4, A. Salama5, O. Ovacik6, S. Atkinson6, E. Quebe-Felah6, A. Kheifi6
1Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, AL, 2Pediatric Hematology/Oncology, Weill Cornell Medicine, New York, United States, 3Sir YK Pao Centre for Cancer & Department of Medicine and Therapeutics, Chinese University of Hong Kong, Hong Kong, 4Hôpital Aziza Othmana, Tunis, Tunisia, 5Charité-Universitätsmedizin, Berlin, Germany, 6Novartis Pharma AG, Basel, Switzerland, 7Hôpital Farhat Hached, Sousse, Tunisia

Background: EPAG is an oral thrombopoietin receptor agonist approved for treatment of previously treated patients (pts: eg corticosteroids, immunoglobulins) with cITP aged ≥1 yr. The EXTEND study, a global, open-label, extension study of pts with cITP who received EPAG or placebo in prior EPAG studies, evaluated long-term safety and tolerability of EPAG. In EXTEND, 19 (6.3%) pts receiving EPAG experienced a total of 24 thromboembolic events (TEEs; composite of pulmonary embolism, MI, stroke, TIA). Objective of this analysis was to assess thromboembolic and other serious adverse events (SAEs) in pts receiving EPAG.

Methods: Among 1167 pts treated with EPAG at least once and 126/248 (51%) pts maintained continuous platelet counts ≥50×109/L (range, 2 days to 8.8 yrs) and mean daily dose was 50.2 (range, 1-38%) splenectomized; 49% aged 18-49 yrs. Median exposure duration was 2.4 yrs (range, 2 days to 8.8 yrs). An additional 10 pts continued EPAG treatment after diagnosis, 7(6.7%) patients presented severe (non-ICH) ICH bleeding, ICH was more likely incurred in severe bleeding patients with ICH (P=0.001, OR=4.724, 95% CI 1.845-12.092), gum or oral mucosal bleeding (P<0.001, OR=2.941, 95% CI 1.658-5.216) and epis-taxis (P=0.027, OR=1.865, 95% CI 1.074-3.238). Compared to severe (non-ICH) bleeding, ICH was more likely incurred in severe bleeding patients with ICH (P=0.001, OR=1.682, 95% CI 1.271-2.234), female patients (P=0.010, OR=2.148, 95% CI 1.200-3.844), complication of pulmonary disease (P=0.001, OR=4.724, 95% CI 1.845-12.092), female patients (P=0.001, OR=4.724, 95% CI 1.845-12.092), gum or oral mucosal bleeding (P<0.001, OR=2.941, 95% CI 1.658-5.216) and epistaxis (P=0.027, OR=1.865, 95% CI 1.074-3.238).

Summary/Conclusions: This analysis shows that most pts who experienced a TEE had resolution of the event after medical/surgical treatment, most commonly anticoagulant therapy, regardless of whether EPAG was discontinued, interrupted or continued. The decision to restart EPAG following a TEE should be made on a case-by-case basis, with caution (including frequent platelet count monitoring) and only if the benefit is expected to outweigh any risk. If anticoagulation therapy is instituted (as in most cases), it is possible the bleeding risk may shift the risk-benefit to maintenance of EPAG treatment.
patients with severe bleeding. At the end of follow-up, the estimated 10-year cumulative rate of no remission among patients with severe bleeding was higher than that among patients without severe bleeding (P=0.017, RR=1.608, 95% CI, 1.052-2.456). The estimated 10-year cause-specific mortality related to fatal bleeding in patients with severe bleeding was higher than that in patients without severe bleeding (P=0.001, RR=9.886, 95% CI, 1.806-54.098). The estimated 10-year mortality among ICH patients was higher than that among severe (non-ICH) patients (P=0.009, RR=4.543, 95% CI, 1.317-15.668).

Summary/Conclusions: Platelet count <10×10⁹/μL, female patients, complication of pulmonary disease, gum or oral mucosal bleeding and epistaxis are significant predictive factors for severe bleeding in the elderly. Severe bleeding in elderly ITP was associated with more failure of response to treatment, increased long-term risk of no remission and mortality related to fatal bleeding.

P725

ATORVASTATIN IMPROVE THE PROGNOSIS OF ADULT PATIENTS WITH CORTICOSTEROID-RESISTANT IMMUNE THROMBOCYTOPENIA VIA ENHANCING BONE MARROW ENDOTHELIAL CELL FUNCTION

Y. Kong¹, X.-N. Cao¹,¹, X.-H. Zhang¹, M.-M. Shi¹², Y.-Y. Lai¹, Y.-Q. Sun¹, Y. Wang¹, L.-P. Xu¹, Y.-J. Chang¹, X.-J. Huang¹²
¹Peking University People’s Hospital, Peking University Institute of Hematology, ²Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Immune thrombocytopenia (ITP) is generally considered to be an autoimmune disorder characterized by increased peripheral platelet destruction and reduced platelet production. Corticosteroids represent the standard first-line therapy for achieving responses in around 80% of patients. However, for those corticosteroid-resistant ITP patients, who exhibit either no response (NR) to corticosteroids or corticosteroid-dependent, the pathogenesis remains poorly understood and the management is challenging. Emerging evidence from mouse studies has suggested that the cross-talk between megakaryocytes (MKs) and bone marrow endothelial progenitor cells (EPCs) in the bone marrow (BM) microenvironment regulates MKs maturation and thrombopoiesis. We recently reported that the impaired BM EPCs, which could be quantitatively and functionally improved by atorvastatin in vitro, induced the occurrence of poor graft function following allo-transplantation (Blood, 2016, 128:2988-2999). However, little is known about the functional role of BM EPCs and how to improve impaired BM EPCs in patients with corticosteroid-resistant ITP.

Aims: To determine whether quantitative and/or functional abnormalities of BM EPCs are involved in the occurrence of corticosteroid-resistant ITP. Moreover, to investigate the effects of atorvastatin and N-Acetyl-L-cysteine (NAC, a ROS scavenger) on the number and function of cultured BM EPCs derived from patients with corticosteroid-resistant ITP and its underlying molecular mechanisms. Finally, to evaluate the efficacy and safety of atorvastatin and NAC to adult patients with corticosteroid-resistant ITP.

Methods: Twenty-three patients with corticosteroid-resistant ITP, 30 patients with newly diagnosed ITP and 17 healthy donors (age 18-55) were enrolled from 2016 to 2017 at Peking University Institute of Hematology. BM EPCs were cultured as previously reported. Atorvastatin and NAC were administrated to the 5-day cultivated BM EPCs in corticosteroid-resistant ITP patients until tested on day 7. The number and function of BM EPCs were evaluated pre- and post-treatment by cell counting, DiI-Ac-LDL and FITC-lectin (sWGA) double staining, migration, cell proliferation, tube formation, levels of reactive Oxygen Species (ROS) and apoptosis. Proteins expressions for p38, ERK, JNK, Akt were measured by flow cytometry and western blot. Subsequently, a single-center pilot study was performed to evaluate the efficacy and safety of atorvastatin and/or NAC in corticosteroid-resistant ITP patients. The primary endpoints were complete response (CR), response (R), and overall response (OR). Secondary end points were time to response (TTR) and adverse events.

Results: Human bone marrow EPCs were demonstrated as the spindle shape and the similar expression of CD34, VEGFR2 and CD133 at day 7 of cultivation among BM EPCs. We enrolled three cohorts of subjects: increased and dysfunctional BM EPCs, which were characterized by impaired proliferation, migration, angiogenesis, and higher levels of ROS and apoptosis, were revealed in corticosteroid-resistant ITP patients compared to those in newly diagnosed ITP. Activation of p-p38 was detected in BM EPCs from corticosteroid-resistant ITP patients. Furthermore, the number and function of BM EPCs derived from corticosteroid-resistant ITP patients were enhanced by atorvastatin or NAC treatment in vitro through down-regulation of the p38 mitogen-activated protein kinase (MAPK) pathway. In the single-center pilot study, a total of 12 corticosteroid-resistant ITP patients were recruited to receive either the combination of atorvastatin and NAC or alone. At day 28, the CR, R and OR rate was 63.6% (7/11) (3/12), 41.7% (5/12) and 66.7% (8/12), respectively. In patients who achieved CR and R, the median (range) TTR was 24 days (7-51 days), with no apparent adverse events.

Summary/Conclusions: The number and the function of BM EPCs were improved by atorvastatin and NAC treatment with or without corticosteroid and NAC in vitro and in vivo quantitatively and functionally improved BM EPCs derived from corticosteroid-resistant ITP patients through down-regulation of the p38 MAPK pathway. Although the sample size of clinical study is small, with a relatively short follow-up period by now, our data suggest that atorvastatin and NAC are effective and safe in the management of corticosteroid-resistant ITP patients. Therefore, further prospective multicenter randomized clinical trials with larger sample size are needed in the future.

P726

PLATELET DESIALYLATION IS A KEY MECHANISM AND A THERAPEUTIC TARGET IN THROMBOCYTOPENIA DURING SEPSIS: AN OPEN-LABEL, MULTICENTER, RANDOMIZED CONTROLLED TRIAL

X. Li¹, M.-F. Li², X.-L. Li³, S.-Y. Geng¹, L. Huang², M. Hou¹, L.-Y. Liu², J. Peng¹
¹Department of Hematology, Qilu Hospital, Shandong University, Jinan, China, Jinan, ²Yantai Yuhuangding Hospital Affiliated to Qingdao University, Yantai, China, ³Infectious Disease Hospital of Yantai, Yantai, China, ⁴Yantaihan Hospital of Yantai, Yantai, China, Yantai, China

Background: Sepsis is a systemic, deleterious host response to infection leading to severe sepsis, and possibly septic shock as defined by the Surviving Sepsis Campaign guidelines. Thrombocytopenia is a common finding in sepsis. Studies in murine models suggested that platelet desialylation was an important mechanism of thrombocytopenia during sepsis. Desialylation-induced platelet removal could possibly be circumvented by adding sialidase inhibitors during sepsis. Oseltamivir, also known as Tamiflu, is a viral sialidase inhibitor that prevents the release of progeny virions. Several studies suggests the feasibility that oseltamivir can be used for the treatment of infection-associated thrombocytopenia.

Aims: To determine whether thrombocytopenia is associated with increased platelet desialylation in septic patients, and whether oseltamivir is an effective treatment to increase platelet counts in severe sepsis.

Methods: We first performed a prospective, multicenter, observational study that enrolled septic patients with or without thrombocytopenia to determine the association between platelet desialylation and thrombocytopenia in patients with sepsis. Next, we conducted an open-label, randomized controlled trial in which the patients who had severe sepsis with thrombocytopenia (platelet counts ≤50×10⁹/L) were randomly assigned to receive an antimicrobial therapy alone (control group) or antimicrobial therapy plus oseltamivir (oseltamivir group). The study flowchart is shown in Fig. 1. Both groups received appropriate antimicrobial agents and standard medical support based on the guidelines issued by the Surviving Sepsis Campaign. The oseltamivir group additionally received 5 full days of oseltamivir therapy. The oseltamivir was administered orally or through a feeding tube at a dose of 75mg once every 12 hours. Time from randomization to the administration of oseltamivir was less than 24 hours. The antimicrobial agents were continuously administered until 3 days after the resolution of the physiological abnormalities related to the systemic inflammatory response syndrome (SIRS). The primary outcomes were platelet desialylation level at study entry, and overall platelet response rate within 14 days post-randomization. Secondary outcomes included platelet recovery time, the occurrence of bleeding events, and the amount of platelets transfused within 14 days post-randomization. The percentages of platelets positive for Ricinus communis agglutinin I (RCA-I), Erythrina cristagalli lectin (ECL) or Saccurni Triticum vulgare lectin (sWGA) analyzed by flow cytometry represented the levels of platelet desialylation. Platelet response was defined as platelet counts returning to or above 100×10⁹/L. Platelet recovery time was calculated as the date of randomization to the date when platelet counts were >100×10⁹/L. Written informed consents were obtained from the study participants prior to inclusion in the study.

Figure 1.
Results: The platelet desialylation levels increased significantly in the 127 septic patients with thrombocytopenia compared to the 134 patients without thrombocytopenia. A platelet response was achieved in 45 of the 54 patients in the oseltamivir group (83.3%) compared with 34 of the 52 patients in the control group (65.4%; P=0.045). The median platelet recovery time was 5 days (interquartile range 4-6) in the oseltamivir group compared with 7 days (interquartile range 5-10) in the control group (P=0.003). The amount of platelets transfused decreased significantly in the oseltamivir group compared to the control group (P=0.044). The multivariate analysis by Cox proportional hazards models showed that the Sequential Organ Failure Assessment (SOFA) score and platelet recovery time were independent indicators of oseltamivir therapy.

Summary/Conclusions: Thrombocytopenia was associated with increased platelet desialylation in septic patients. The addition of oseltamivir could significantly increase the platelet response rate, shorten platelet recovery time and reduce platelet transfusion. Chinese Clinical Trial Registry, ChiCTR-IPR-16008542.

SAFETY AND EFFICACY OF LONG-TERM OPEN-LABEL DOSING OF SUBCUTANEOUS (SC) ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA (ITP)
J. Bussel1,*, M. Tarantino2, V. Blanchette3, A. Raj4, J. Despotovic5, D. Beam6, J. Roy7, X. Wang8, B. Mehta8, M. Eisen8
1Weill Cornell Medicine, New York, 2The Bleeding and Clotting Disorders Institute, Peoria, United States, 3Hospital for Sick Children, Toronto, Canada, 4Pediatric Blood and Cancer Disorders Clinic, Louisville, 5Texas Children’s Hematology Center, Houston, 6Cook Children’s Medical Center, Forth Worth, United States, 7Children’s Health Queensland & Pathology Queensland, Saint Lucia QLD, Australia, 8Amgen Inc., Thousand Oaks, United States

Background: Children with ITP for ≥6 months who completed a romiplostim phase 1/2 or phase 3 parent study could enroll in this open label long term extension study

Aims: To evaluate the safety and efficacy of long-term romiplostim in children with ITP.

Methods: Patients enrolled at 28 sites in the US, Canada, Spain, and Australia. All patients received SC romiplostim once weekly. The initial dose was the final dose from the parent study or 1 µg/kg for patients previously receiving placebo; dose was then adjusted from 1-10 µg/kg to target platelet counts of 50−200×10^9/L. Incidence of adverse events (AEs) was the primary endpoint.

Results: As of 24 Feb 2016, 66 patients entered this study; 65 received romiplostim for up to 6.2 years. At baseline, median (min–max) age was 11 (3–18) years; 56% were female; 61% were white, 14% African American, 14% Hispanic/Latino, 9% Asian, and 3% other; 9.1% had prior splenectomy. Median (min–max) baseline platelet count was 27.5 (2–458)×10^9/L. Median (min–max) treatment duration was 100 (5–321) weeks. Median (min–max) average weekly romiplostim dose was 4.8 (0.1–10.0) µg/kg, which included escalation to a stable dose. After ~week 200 (n=8 patients), the median dose was observed to fluctuate. All 65 patients received their doses per protocol >90% of the time; 18 patients missed ≥1 dose due to noncompliance for a total of 41 times. Reasons for discontinuing treatment (n=8, required other therapy (n=4), noncompliance (n=3), administrative decision (n=3), per protocol (n=1), and AE (n=2) (asthenia, headache, dehydration, and vomiting in one patient and anxiety in the other, per investigator, none of the AEs were treatment-related); 43 (65%) patients continued in the study. Fifty-two serious AEs occurred in 17 patients, 3 deemed treatment-related (anemia, epistaxis, and thrombocytopenia). Bleeding AEs occurred in 56 patients; 5 deemed treatment-related (gingival bleeding, petechiae, injection site bruising, injection site hematoma, and epistaxis). No thrombotic events were reported. There were no peripheral blood abnormalities warranting a bone marrow examination. No patients had anti-TPO neutralizing antibodies. From week 2 on, median platelet counts remained >50×10^9/L; platelet counts were >100×10^9/L at most timepoints, despite an observed decrease in the median dose from 4-5 µg/kg to 2-3 µg/kg around week 160 (Figure). Nearly all (94%, 61/65) patients had a platelet response (median platelet counts for a month ≥50×10^9/L). Nine (14%) patients (5 boys and 4 girls, none with prior splenectomy) entered remission (Table), defined here as platelet counts ≥50×10^9/L for 24 weeks with no ITP treatments. Twenty-three (35%) patients received rescue medications.

Summary/Conclusions: Over 6 years of data from this ongoing open-label extension study of romiplostim in children with ITP show that >90% of children achieved a platelet response with romiplostim. The safety profile was overall tolerable, similar to that in past studies. Some children (9/66) with longstanding ITP entered remission after receiving romiplostim.

**IMPACT OF VENETOCLAX ON THE QUALITY OF LIFE OF CLL PATIENTS RELAPSED/REFRACTORY TO B-CELL RECEPTOR (BCR) SIGNALING PATHWAY INHIBITOR TREATMENT**

W. Wierda¹, K. Shaikh, J. Potluri², L. Noe³, R. Kamalakar³, J. Gdovin², R. Humerickhouse⁴, M. Verdugo⁴

¹The University of Texas MD Anderson Cancer Center, Houston, ²AbbVie Inc, North Chicago, United States

**Background:** The prognosis for patients with CLL after B-Cell Receptor inhibitor (BCR) failure is very poor. Patients with R/R CLL who discontinue and/or progress on BCRi treatment tend to have poor clinical outcomes. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.

**Aims:** To assess whether VEN has an impact on health related quality of life (HRQoL) among CLL patients R/R to BCRI treatment and receiving VEN monotherapy.

**Methods:** The study enrolled patients with CLL who had previously received treatment with ibritinib and/or idelalisib, have relapsed on treatment, or experienced progression after discontinuation of either agent. Patients are to receive VEN monotherapy for up to two years, or until discontinuation due to disease progression, unacceptable toxicity, or any other reason. Patient-reported HRQoL measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), Week 24, and every 12 weeks thereafter. Mean change from BL to each assessment through Week 48 are reported here. Clinical relevance was based on minimum important difference (MID) of values from BL to each assessment. A change of 5-10 points is considered a “small” change on the EORTC-QLQ-C30. The lower bound of 5 points was used for MID acceptance on both measures.

**Results:** Clinically meaningful improvements from BL were observed early and were sustained through week 48 in VEN treated patients in the EORTC-QLQ-C30 global health status and the role, social, and emotional functioning scales. Furthermore, early and sustained improvements in fatigue through week 48 were seen in both EORTC-QLQ-C30 and EORTC-QLQ-CLL16 (Table 1).

<table>
<thead>
<tr>
<th>Table 1.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Table 1:</strong> Comparison of deltas from baseline to each assessment through Week 48.</td>
</tr>
</tbody>
</table>

**Summary/Conclusions:** This interim analysis provides preliminary evidence that demonstrates CLL patients R/R to BCR inhibitors receiving VEN monotherapy experienced improvement in several key aspects of functioning and HRQoL. These results may be important to consider when making therapeutic choices in R/R CLL following relapse or progression on BCR inhibitors.

**P729**

**THE ROLE OF PSYCHOLOGICAL VARIABLES FOR TYROSIINE KINASE INHIBITORS (TKI) DISCONTINUATION IN CHRONIC MYELOID LEUKAEMIA (CML) PATIENTS: IMPLICATION FOR MEDICAL DECISION MAKING PRACTICE**

S. Buat½, J. Corteletti², Cutica¹, E. Orlandi¹, E. Chiara³, E. Buceii², A. Iurlo², G. Pravettoni¹

¹Department of Oncology and Hematology, University of Milan, ²Hematology-BMT Unit, IRCCS Ca’ Granda Policlinic Foundation Hospital, Milan, ³Department of Oncology Hematology, IRCCS Policlinic San Matteo Foundation Hospital, Pavia, Italy

**Background:** Treatment-free remission (TFR) is an emerging goal for CML patients (pts) that reach a sustained deep molecular response (DMR), as it can reduce the risk of long-term toxicities that impair quality of life, and mitigate the costs associated with long-term TKI therapy. Therapy discontinuation may represent a great challenge for patients and different factors (not only clinical) may play a role in medical decision, such as psychological and emotional variables. In this respect, it is essential to consider pts’ concerns and preferences regarding the discontinuation option.

**Aims:** This study was aimed at investigating psychological (emotional and cognitive) and clinical factors related with the attitude to opt for discontinuation of therapy in CML pts.

**Methods:** This is an observational, prospective, no-drug related study conducted in 3 Italian centers with large experience in CML treatment. A detailed battery of questionnaires focusing on health behaviour, risk taking and personality was administered.

**Results:** One hundred and twenty pts were enrolled (56% males; mean age=50, SD=1.2). Median duration of the disease was 8 years (range 1-39y). 62/120 pts were receiving Imatinib first line. The idea of stopping TKI is appealing in only 31% of pts. In 11% of them there was a high probability of response upon restarting a TKI. Pts are more likely to stop their TKI if the risk of relapse is no more than 30% (% Mean=±33.62; SD=±33.46). Main worries related with the choice to stop TKI are fear of possible disease recurrence, (60.5%), fear of drug resistance if the disease relapses (44.5%) and fear to disappoint family or friends (28.9%). Older pts (>40 years) are more concerned about relapse and subsequent lack of response than younger (x²=9.65, p=0.02). Finally, pts with higher passive risk taking attitude (who are more reluctant and undecided in everyday-life decisions) seemed to be more afraid to lose disease control in CML. ANOVA showed a significant difference (p<0.05) between the two groups (53% vs 31%).

**Summary/Conclusions:** Many studies have confirmed the feasibility and safety of stopping TKI therapy in selected pts, with the potential to drastically modify clinical practice in CML management in the next future. TKI discontinuation appears appealing and challenging at the same time for many CML pts. This study, for the first time, analyses how and when pts would consider this option including implications for health care providers in clinical practice, using both a clinical and psycho-cognitive perspective.

**BUDGET IMPACT ANALYSIS OF BIOSIMILAR RITUXIMAB (CT-P10) FOR THE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKAEMIA IN THE 28 EU MEMBER STATES**

F. Renicz¹,², L. Gulács³,², P. Bajil³,², M. Pętek³,², V. Brodyszki³,²

¹Department of Health Economics, Corvinus University of Budapest, ²HTA Consulting Budapest, Budapest, Hungary

**Background:** In December 2016, the European Medicines Agency’s Committee for Medicinal Products for Human Use has recommended granting marketing authorization to biosimilar rituximab (CT-P10) in all indications of the reference product, including chronic lymphocytic leukaemia (CLL). Compared to the originator rituximab, CT-P10 was estimated to cost 30% less. The aim of this study was to assess a potential price reduction for offering a more affordable treatment option for CLL patients across Europe.

**Aims:** To assess the budget impact of the introduction of CT-P10 into the treatment of CLL in the 28 EU member states. Moreover, we provide an estimation for the number of additional CLL patients that can be treated with CT-P10 from the cost savings.

**Methods:** A budget impact analysis was performed to evaluate the one-year cost outcomes under two scenarios with and without the availability of CT-P10. The budget impact was calculated as the difference in costs between the two scenarios. For the major European markets, five-year cost savings were also estimated. Market uptake of CT-P10 was assumed to be 30%. A third party payer’s perspective was adopted, and only drug costs were considered. Based on expert opinion, it was assumed that when CT-P10 is entering the market it will be at 50-70% of the official list price of originator rituximab in each country. Costs of administration and monitoring were not incorporated in the calculations, as it can be assumed that these are equal for the reference product and CT-P10. The initial number of patients treated with rituximab was estimated from IMS sales data on total annual consumption of originator rituximab in 2016. Other model parameters such as patients’ average body surface area and treatment rate of rituximab among CLL patients, were derived from the published literature. One-way sensitivity analysis was undertaken to test the robustness of model assumptions.

**Results:** Over a one year time horizon, the cumulative budget impact of adopting CT-P10 is estimated to be €17.80 million in the 28 EU member states (30% discount in drug prices compared to the originator rituximab). Countries responsible for the majority of the cost savings are Germany (€4.06 million), Italy (€3.15 million), France (€2.41 million), Spain (€1.34 million), the UK (€1.34 million), Poland (€0.80 million), Austria (€0.66 million), the Netherlands (€0.59 million), Finland (€0.49 million) and Sweden (€0.43 million). If the cost savings were used to treat additional CLL patients with CT-P10, a total of 1,624 patients could be treated annually throughout Europe. The potential cost savings were in a direct correlation with the price and market uptake of CT-P10. Applying a 40% and 50% discount in drug prices compared to the originator rituximab, cost savings are projected to €23.73 and €29.67 million, from which further

Madrid, Spain, June 22 – 25, 2017
AN INVESTIGATION INTO THE NEEDS AND PRIORITIES OF PATIENTS WITH MULTIPLE MYELOMA DURING REMISSION—IMPLICATIONS FOR RE-DESIGNING PATIENT-CENTRED HEALTHCARE SYSTEMS

D. De-Silva1,2, J. Land2, M. Heinrich2, J. Galinsky3, Y. Reyal4, N. Rabin2, A. Mehta2, K. Yong1

1UCL Cancer Institute, 2Department of Behavioural Science and Health, University College London, London, 3Myeloma UK, Edinburgh, 4Haematology, St George's Hospital, 5Haematology, University College London Hospital, London, United Kingdom

Background: Therapeutic advances in multiple myeloma (MM) mean that patients have extended periods of remission without need for active anti-myeloma therapy. This provides an opportunity to review how these patients are managed and design patient-centred healthcare systems. Remote monitoring systems have been implemented for other cancer patients in remission.

Aims: We aimed to explore patient needs during stable remission from MM and design patient-centred models of healthcare systems. We investigated factors influencing patient acceptability of remote monitoring.

Methods: Patients with stable MM in a treatment-free interval selected from outpatient clinics at a tertiary centre completed a survey which explored the acceptability of various methods of remote monitoring. Subsequently semi-structured interviews were conducted by an independent researcher to investigate factors influencing this preference. Interviews were carried out until saturation of themes, transcribed verbatim and thematic analysis was performed using open coding by a doctor, physiotherapist and psychologist.

Results: 78 patients were surveyed; the most acceptable alternative was a telephone clinic (with doctor 77%, nurse 69%). 19 interviews were conducted exploring patient preferences for the introduction of telemonitoring (TM) replacing clinic face-to-face (FTF) consultations with a doctor. Median age was 61 years (range 46–76), and 9 were male. 18 patients were in 1st remission; 16 had most recently received high dose therapy and autograft, 3 had post autograft consolidation.

The centre was not the local hospital for 18 patients interviewed. The majority were accepting of TM as an alternative to FTF clinics due to the burden of travel, associated cost and clinic waiting times. These affected patients’ physical and psychological well-being, with TC perceived as less burdening. Patients acknowledged reduced needs during remission compared to treatment phase and felt TC would benefit redistribution of consultant time for patients on active therapy. So they suggested this service change would be more beneficial for healthcare resourcing rather than them personally. Interpretation of blood results by clinicians was regarded as central to monitoring disease, and for some who were unaware of clinical symptoms, the only way a relapse would be detected. General preference was for bloods to be done locally, leading to concerns that patients in rural areas were unsure how to monitor their own MM, hence valued the knowledge of their medical team. Doctors were perceived to have more expertise than nurses and this influenced preferences regarding who undertook TC. As a result, patients sought reassurance they could see a doctor if they had any concerns after TC with a nurse. Patients valued familiarity with the centre where they were treated due to prior positive experience and the importance of being seen at a tertiary centre renowned for its expertise in MM. This influenced acceptability of TC as long as they remained under the centre’s care with preference for continuity of staff involved. Whilst TC was acceptable for patients in remission, some were concerned about how relapse would be managed and expressed preference for FTF when being told they had relapsed.

Summary/Conclusions: Nurse led TCs are an acceptable alternative to FTF consultations for monitoring patients in remission from MM. Design of healthcare systems incorporating TCs need to have robust systems for accessing blood test results, for managing relapse, ready access to doctors and reassurance about the competence and knowledge of practitioners involved.

THE THERAPEUTIC UTILITY OF A SYSTEMATIC PROTOCOL FOR GERIATRIC ASSESSMENT IN ONCOHEMATOLOGIC PATIENTS

C. Terán,1 A. Hormigo2, R. Cordoba1, M. Jarana3, M. Perez3, C. Plaza3, P. Llamas1

1Hematology, 2Geriatrics, 3Oncohealth, Fundacion Jimenez Diaz, Madrid, Spain

Background: The prevalence of hematological malignancies has increased over time especially in the older population. In the era of immunochemotherapy and targeted therapy, it is important to have a multidisciplinary and comprehen- sive evaluation in order to allow differentiation of those patients who need intensive therapeutic measures or a more conservative approach. To choose the best treatment for these patients, a geriatric hematology program has been launched.

Aims: Evaluate the utility of the comprehensive geriatric assessment (CGA) in patients with hematologic malignancies on the initial therapeutic decision making. Determine frailty prevalence and short - mid term prognostic impact using a screening tool for its identification.

Methods: Patients diagnosed with hematologic malignancies were followed prospectively. Patients age 70 and over were referred to hematological nursing consultation. 68 screening tool was used to identify frailty risk. Patients with a score of 8 or 9 were referred for further consultation in Hematology Oncology Clinic for carrying out the CGA. In the comprehensive geriatric assessment, the clinical information obtained included: physical, mental, social and nutritional assessments, as well as an additional screening on geriatric syndromes. The regular medication was reviewed based on the STOPP/START criteria. The interventions were classified into 3 categories according to the Balducci classification: 1) Fit, 2) Fragile and 3) Poor prognostic.

Results: We have included 32 patients in the last 9 months, with an average age of 81 (71-89) years. 56% of the patients were female. The main hematological malignancy referred was high grade non-Hodgkin lymphoma (59%). At the time of the evaluation, 87% had ECOG 0 and 17% had ECOG 1, 80% had a score 0. The social, functional and mental profiles are shown in Table 1. According to polypharmacy and comorbidities, data are shown in Table 2. The distribution of patients by frailty scales, are described in Table 3. 56% of the patients were classified as robust, 35% fragile and the rest with poorly prognosis. After the evaluation we recommended nutritional measures, control of the polypharmacy and physical exercise. Of the included patients, 22 had been reviewed at 6 months staying alive 95%. 24% required hospitalization after the initial assessment and 13% went to the emergency department.
Methods: We used nationwide, register-based case-control study design to investigate the role of CT imaging in the etiology of childhood leukemia. We identified all childhood (0-15 years) leukemia cases from 1990 to 2011 (N=10935) in Finland and randomly selected thrice as many controls (N=3279) from the Population Registry, individually matched by gender and year of birth. The cases were 81% (N=885) acute lymphoblastic leukemias and 13% (N=142) acute myeloid leukemias. We collected data on all pediatric CT scans from 1975–2011 from the databases of all five university hospitals in Finland and randomly selected thrice as many controls (N=3279) from the Population Registry, individually matched by gender and year of birth. The aim of this analysis was to compare HRU with ixazomib-Rd doublet therapy and continuous treatment until progression. With more complex regimens and longer treatment duration, costs of treatment and healthcare resource utilization (HRU) are expected to increase, with IV agents having a greater impact on treatment burden than oral agents. The oral proteasome inhibitor ixazomib is approved in the US, EU, and multiple countries worldwide, in combination with lenalidomide-dexamethasone (Rd), for the treatment of RRMM patients (pts) following at least 1 prior therapy. Approval was based on the phase 3 TOURMALINE-MM1 study of ixazomib-Rd vs placebo-Rd, which demonstrated significantly improved progression-free survival (PFS; median 20.6 vs 14.7 months, HR 0.74) with ixazomib-Rd, with limited additional toxicity and no adverse impact on patient-reported quality of life (QoL; Moreau et al, N Engl J Med 2016).

Aims: HRU was an exploratory endpoint of the TOURMALINE-MM1 trial. The aim of this analysis was to compare HRU with ixazomib-Rd vs placebo-Rd, incorporating all non-protocol additional medical care encounters such as inpatient and outpatient admissions and their duration, as well as time lost from work or other activities by pts and their caregivers. HRU was an exploratory endpoint of the TOURMALINE-MM1 trial. The aim of this analysis was to compare HRU with ixazomib-Rd vs placebo-Rd, incorporating all non-protocol additional medical care encounters such as inpatient and outpatient admissions and their duration, as well as time lost from work or other activities by pts and their caregivers.
Results: Overall, 152 (42%) pts on the ixazomib-Rd arm had 316 hospitalization events, compared to 156 (43%) pts (3,355 events) in the placebo-Rd arm. Exposure-adjusted hospitalization rates (0.530 and 0.564 per pt-year [ppy], respectively) and mean length of stay (10 and 10.8 days) were similar between the ixazomib-Rd and placebo-Rd arms (Table 1). Rates of outpatient visits were also similar between arms; 217 (60%) pts on the ixazomib-Rd arm had 197 (median 4) compared to 198 (55%) pts and 194 visits (median 5) on the placebo-Rd arm. Exposure-adjusted outpatient visit rates were 3,305 and 3,355 ppy, respectively (Table 1). On the ixazomib-Rd arm, 46 (13%) pts missed a total of 527 (median 7) days of work or other activity, compared to 51 (14%) pts and 580 (median 8) days on the placebo-Rd arm. Similarly, 16 (4%) pts on the ixazomib-Rd arm missed 4128 (median 5) days of work or other activity on the ixazomib-Rd arm, compared to 24 (7%) pts’ caregivers and 110 (median 4) days on the placebo-Rd arm.

Summary/Conclusions: The ixazomib-Rd triplet regimen did not add to the HRU burden compared to the placebo-Rd doublet, while prolonging PFS. This is consistent with the limited additional toxicity burden and the reported lack of an adverse impact on QoL with ixazomib-Rd. In contrast to findings reported for injected agents (Armoiry et al, J Clin Pharm Ther 2011; Gaultney et al, J Clin Pharm Ther 2013; Baz et al, Support Care Cancer 2015), this all-oral triplet regimen did not increase time lost from work, caregiver burden, or the number of inpatient/outpatient visits.

P737

EFFECT OF IMPROVEMENT OF SURVIVAL, POPULATION AGING AND IMWG '14 CRITERIA ON INCIDENCE AND PREVALENCE OF MULTIPLE MYELOMA

V. Martinez-Robles1,*, B. Ballina1, S. Cerda1, N. de las Heras1, M. Fuertes1, L. Villalobos1, J.A. Rodriguez-Garcia1, E. Fernando1

1Hematología, Complejo Asistencial Universitario de León, LEON, Spain

Background: There are some variables that can modify Multiple Myeloma incidence of New Diagnosed (NDMM) and prevalence over the time: Past decade shows a new demographic data in our society: the increment of expectancy of life and an excellent performance status. In the last years we have assisted to an amazing improvement in the management and expectancy of life of Multiple Myeloma (MM) patients. Recent changes in criteria recommendation by IMWG ‘14 to begin treatment in NDMM patients can increment its incidence. New expensive but very effective and well tolerated antimyeloma (antiMM) agents are in the center of attention of Hematologic and Public Healthcare Systems. There are data of improvement of survival that can increment of prevalence.

Aims: We have analysed our data base and calculate incidence by sex, age and three 5-years periods of time at diagnosis and obtain tendencies to get ready for next decade of ageing people with best antimyeloma agents. We have analysed prevalence of MM patients on last 7 years with cutoff date on 1st of November (2010 to 2016).

Methods: We retrospectively analysed the incidence of patients with new diagnostic of Multiple Myeloma (NDMM) from 1998 to 2012. (Fig.1). Then we divide the cohort in several groups: sex and age at diagnosis (3 groups: <65, 65-75 and >75) and in four 5-year (quinquennium) periods of time (1998-2002, 2003-07, 2008-12, 2013-2016). (Fig. 2). We have calculated the incidence per 100000 inhab/year using census data of our Local Registry of Tumours of our Public Health Area. Characteristics of patients: n=346. M/F: 206/140. Median age at diagnosis: 74 years (Range: 39-100).

Results: A) INCIDENCE RATES (see Table). In the past IMW (Roma-14#PO197) we reported incidence rates form 1998 to 2012. We observed a constant increase of Annual Average of incidence from 4.57 cases/100000 inhabitants/ year from the 1st period to 6.15 in the last. Adjusted by Age Incidence increase from 14 to 18.5 cases in the O65 group. From 2013 to Nov-2016 global and adjusted by age incidence remains similar to last years data with 80 new cases in the 4 year-period (5.9 cases for global population and 17.2 cases for over65 population). After IMWG ‘14 criteria to begin treatment in NDMM the incidence was similar to the last 7 years (2008-12 period) incidence with 37 NDMM cases (25 O65y group).

B) PREVALENCE RATES (PrevR).

- 2012. 77 pts alive. PrevR: 22.2 /100000 inhabit;
- 2014. 84 pts alive. PrevR: 24.4/100000 inhabit;

Table 1.

Summary/Conclusions: Although we don’t observe substantial changes on incidence rates of NDMM, we have noted an important rise on prevalence rates of more than 40% from 2010 to 2016 (21.2 to 30.3 pts alive /100000 inhabit.) Several new antiMM drugs are available in the therapeutic arsenal and probably increases the prevalence rates.
Background: Although most children affected by Acute Lymphoblastic Leukemia (ALL) are cured with current protocols, relapses still occur in the bone marrow as well in extramedullary sites, mainly the central nervous system (CNS).

Aims: The goal of this study was to report the results of the largest series of patients treated with hematopoietic stem cell transplantation (HSCT) for isolated extramedullary relapse (iEMR). We evaluate the role of HSCT in the treatment of extramedullary relapses.

Methods: From 1990 to 2015, 281 children (1-18 years) underwent HSCT for ALL iEMR from 19 centers, members of the Italian Pediatric Onco-Hematology Association (AIEOP).

Results: Of the 281 patients (203 male, 78 female) 167 presented relapse confined to CNS, 73 to testis, 14 to mediastinum, 11 to CNS + other sites and 73 to testis. HSCT was performed from one of these; if not, the single center decided to perform autologous HSCT (Auto HSCT) or haploidentical HSCT (Haplo HSCT).

Results: Of the 281 patients (203 male, 78 female) 167 presented relapse confined to CNS, 73 to testis, 14 to mediastinum, 11 to CNS + other sites and 73 to testis. HSCT was performed from one of these; if not, the single center decided to perform autologous HSCT (Auto HSCT) or haploidentical HSCT (Haplo HSCT).

Summary/Conclusions: The optimal treatment for isolated extramedullary relapse (EMR) is still controversial. To address this issue, we collected data of patients treated with hematopoietic stem cell transplantation (HSCT) for ALL iEMR from 19 centers, members of the Italian Pediatric Onco-Hematology Association (AIEOP).

Methods: From 1990 to 2015, 281 children (1-18 years) underwent HSCT for ALL iEMR from 19 centers, members of the Italian Pediatric Onco-Hematology Association (AIEOP).

Results: Of the 281 patients (203 male, 78 female) 167 presented relapse confined to CNS, 73 to testis, 14 to mediastinum, 11 to CNS + other sites and 73 to testis. HSCT was performed from one of these; if not, the single center decided to perform autologous HSCT (Auto HSCT) or haploidentical HSCT (Haplo HSCT).

Summary/Conclusions: In this study we present the largest series of patients with ALL iEMR treated with HSCT with a very long follow up. Comparison with published chemotherapy (CH) studies is challenging as favorable, early responses are followed by early and very early relapse: in fact the use of HSCT seems to abrogate the impact of some “classical” negative risk factors. Our results suggest that both autologous and allogeneic HSCT are effective treatments for ALL iEMR. Data from contemporary trials, that include MRD assessment to better stratify the patients, will further clarify the role of HSCT in the treatment of extramedullary relapses.

PREDICTIVE FACTORS FOR DEVELOPING VENO-OCCLUSIVE DISEASE/SINUOSIDAL OBSTRUCTION SYNDROME (VOD/SOS) DIAGNOSED AFTER DAY 21: ANALYSIS OF FINAL DATA FROM AN EXPANDED-ACCESS PROGRAM

D. Marin1, R. Champlin1, H. Kantarjian3, E. Jabbour3

1Stem Cell Transplantation and Cellular Therapy, St. Jude Children’s Research Hospital, Memphis, 2Pediatric BMT Therapy, The Children’s Hospital of Philadelphia, Philadelphia, 3Memorial Sloan-Kettering Cancer Institute, New York, 4Jazz Pharmaceuticals, Inc., Palo Alto, United States

**Background:** Inotuzumab ozogamicin (IO) is a CD22 monoclonal antibody attached to calicheamycin and targets B lymphocytes in early stages of development. In a randomized study of IO compared with conventional salvage therapy in patients with refractory relapsed B-ALL, patients treated with IO had higher complete response rates (81% vs 29%, p<0.001), and a greater proportion of patients proceeded to allogeneic hematopoietic stem cell transplantation (SCT) (41% vs 11%, p<0.001). However, patients treated with IO prior to SCT were also noted to have higher rates of veno-occlusive disease (VOD) compared to the SCT group without IO exposure (11% vs 1%) (Kantarjian NEJM 2016).

In efforts to further investigate this finding, we reviewed treatment outcomes for patients with and without IO exposure.

**Methods:** We performed a nested control comparison of patients treated during the years when they were being treated with IO on a number of clinical trials at our institution.

**Results:** Between 6/2010 and 10/2016, 251 patients with B-ALL with a median age of 35 years (range, 4-70 years) received an allogeneic matched sibling (n=85), matched- or 1-antigen mismatched unrelated (n=90), haplo-identical (n=38), or cord blood donor SCT (n=38) in CR1 (n=103), CR2+ (n=105), or with active disease (n=43). Patients received largely myeloablative regimens (BMT) or reduced intensity myeloablative (RI-MAB) regimens. Patients treated with IO after BMT, vs those treated from 1995 to 2000.

**Summary/Conclusions:** Fatal VOD is a rare occurrence. However, IO exposure prior to SCT increases the risk for any VOD. Furthermore, IO exposure followed by a double allograft preparative regimen increases this risk nearly 6-fold, and should be avoided in these patients.
P742

A COMPARISON OF CLINICAL OUTCOMES BETWEEN MATCHED SIBLING DONOR (MSD) AND UNRELATED DONOR (URD) STEM CELL TRANSPLANTATION IN ADULT PATIENTS WITH SEVERE APLASTIC ANEMIA

1Hematology, Yeouido St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, 2Hematology, Catholic Blood and Marrow Transplantation Center, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, 3Hematology, Incheon St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Allogeneic stem cell transplantation (SCT) using HLA-matched unrelated donor (URD) has been usually regarded as a suboptimal option in patients with severe aplastic anemia (SAA), who have failed to immunosuppressive treatment (IST). However, recent improved outcomes of URD SCT lead to its extended role for treating those lacking HLA-matched sibling donor (MSD).

Aims: Through this study, we intended to verify the possibility of URD SCT as a front-line treatment for SAA patients.

Methods: We compared outcomes of consecutive SAA patients who received SCT from 8/8 well-matched URD (WM-URD; n=61) and partial (6/8 or 7/8) matched URD (PM-URD; n=33) with 8/8 matched MSD (n=126) at our institution between Mar 2002 and Dec 2016. Patients receiving MSD and URD SCT were conditioned with fludarabine (180mg/m²) + cyclophosphamide (100mg/kg IV) plus rabbit ATG (10mg/kg IV), and total body irradiation (fractionated 800cGy) + cyclophosphamide (100-120mg/kg IV) with/without rabbit ATG (2.5mg/kg IV), respectively.

Results: Median age of the WM-URD and the PM-URD groups were significantly lower compared to that of the MSD group (29 yrs, 31 yrs, and 39 yrs; P<0.01, respectively). When we adjusted other clinical and transplant-related factors, which include age and IST failure, using multivariate analysis, we found that the incidence of acute and chronic GVHD of the WM-URD and PM-URD groups were significantly higher compared to those of the MSD group (42.6% and 63.6% vs 9.5%; P<0.01, and 44.8% and 33.3% vs 8.9%; P<0.01, respectively).

When we compared the incidence of transplant-related mortality (TRM) (10.7% vs 7.4% vs 7%; P=0.53) and overall survival rate (OS; 89.3% vs 92.5% at 6 yrs; P=0.52) between the WM-URD and the MSD groups, there were no significant difference. However, trends of higher TRM incidence in either WM-URD (18.2% vs 7.4% at 6 yrs; P=0.05) and lower OS rate (81.8% vs 92.5% at 6 yrs; P=0.05) were observed between the UM-URD and the MSD groups. There was no primary graft failure in both WM-URD (0% vs 18.3%; P=0.01) and PM-URD (0% vs 18.3%; P=0.02) groups were significantly lower compared that of the MSD group.

When we adjusted other clinical and transplant-related factors, which include age and IST failure, using multivariate
analysis, the OS rate of the WM-URD group was not significantly different (HR 1.45, 95% CI: 0.52-4.09; P=0.48), whereas that of the PM-URD group was significantly lower (HR 2.85, 95% CI: 1.01-8.02; P=0.04), compared to that of the MSD group.

Summary/Conclusions: Our study showed that there was no significant difference in OS rate between the WM-URD and the MSD groups. As high incidence of GVHD remains a problem in the former group, strategies to reduce it are needed in future protocols.

P743

HAPLOIDENTICAL ALLOGENEIC STEM CELL TRANSPLANT IN SEVERE THALASSEMAIA PATIENTS
S. Hongeng1,2, S. pakakasama3, U. anurathapan3, B. Andersson2
1Peditiatrics, Ramathibodi hospital, Mahidol University, Bangkok, Thailand, 2Stem cell transplantation, MD Anderson Cancer Center, Houston, United States

Background: Thalassemia free survival after allogeneic stem cell transplantation (SCT) is about 80–90% with either matched related or unrelated donors. However, the probability of finding a HLA-compatible donor is less than 50%. We explored the use of a mismatched related ("Haplo-") donor.

Aims: To evaluate the outcome of SCT with Haplo donors in severe thalassemia patients

Methods: All patients received two courses of pre-transplant immunosuppressive therapy (PTIS) with fludarabine (Flu) 40mg/m2/d together with dexamethasone (Dxm) 25mg/m2 for 5 d to facilitate engraftment. After two courses of PTIS, a reduced-toxicity conditioning regimen of rabbit anti-thymocyte globulin (ATG) 1.5mg/kg/d on days SCT -12,-11,-10, Flu 35mg/m2 on days SCT -7,-6,-5,-4 was given followed by T-cell replete peripheral blood progenitor cells (PBPC). GVHD prophylaxis consisted of cyclophosphamide (Cy) 50mg/kg on days SCT +3 and +4 (Post-Cy), and on day SCT +5 tacrolimus or sirolimus was started together with a short course of mycophenolate mofetil.

Results: Fifty-one patients underwent haplo-SCT. Their median age was ten years (range, 2 to 28 years). Forty-nine patients engrafted with 100% donor chimerism. Two of five patients with high titers of donor-specific anti-HLA antibodies suffered primary graft failure. Median time to neutrophil engraftment was 14 days (range, 11 to 18 days). Eight patients developed mild to moderate, reversible veno-occlusive disease, while twelve patients developed acute GVHD grade II, that quickly responded to steroid therapy. Only seven patients developed limited chronic GVHD. Projected overall and event-free survival rates at two years are 95% and 94%, respectively. The median follow up time is 18 months (range;10 to 50 months).

Summary/Conclusions: This haplo-SCT protocol may yield excellent outcomes for thalassemia patients, and provide a treatment option for patients lacking a HLA-matched donor.

P744

AUGMENTATION OF FLUDARABINE AND BUSULFAN-BASED MYELOABLATIVE REGIMEN WITH THIOTEPA IMPROVES OUTCOMES WITH NO ADDDED TOXICITY IN ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKAEMIA
V.S. Sheikh1, N. Boaz1, S. Girisu1, B. Avni1, R. Or1, M. Shapiro1
1Stem cell transplant, HADASSAH, Jerusalem, Israel

Background: Allogeneic stem-cell transplantation (HSCT, allo-SCT) is the most effective way to control leukemia relapse for patients with acute myeloid leukemia (AML). Busulfan and Cyclophosphamide (Bu/Cy), the current standard of care, in allogeneic transplant for acute myeloid leukemia (AML), is limited by increased treatment related mortality. Myeloablative doses of Busulfan (12-8mg/kg) with Fludarabine (160mg/m²) (Flu-Bu), has reduced toxicity, however with the limitation of increased relapses. We have tried to improve outcome of Flu-Bu regimen by augmentation with Thiopeta (10mg/kg). Here we compared outcomes of 45 such patients (getting augmented regimen, Flu-Bu with the addition of Thiopeta, (group 2), to 44 patients who received Fludarabine, Busulfan myeloablative reduced toxicity regimen (group 1), during the same period.

Aims: The primary objective of the report was to compare the toxicity and incidence of relapse between the two regimens. Secondary objective was to compare overall survival (OS), and disease-free survival (DFS), the non-relapse mortality (NRM), engraftment kinetics, incidence of acute and chronic graft-versus-host disease (GVHD), and comparison between high and low-risk patients amongst the two groups.

Methods: 89 patients with AML were retrospectively analyzed. 44 patients were conditioned with Flu-Bu (group 1) and 54 patients augmented with Thiopeta (Flu-Bu-TT, group 2). The transplant conditioning regimen, (augmented myeloablative) consisted of 30mg/m² intravenous Fludarabine for 5 days (total dose 150mg/m²), for matched related donors or for 6 days (180mg/m²), for unrelated or mismatched donors, intravenous Busulfan (3.2mg/kg/day for 4 days, total dose 12.8mg/kg), and intravenous Thiopeta 5mg/kg for 2 days (10mg/kg). The conventional myeloablative regime was identical, however without the addition of Thiopeta.

Results: Toxicities were comparable, with mucositis in 7 patients (15%) in group 1 and 8 patients (17%) in group 2, (p=1.0), severe sepsis in 4 (9%) in group 1 and 3 (6%) in group 2, (p=0.7), severe venoocclusive disease in 2% of group 1 and 4% of group 2, (p=1.0) and comparable non-relapse mortality (NRM) in group 1 and 2, (p=0.7). 5-year disease free survival (DFS), median follow up of 5 years, was significantly better in group 2, 38% for group 1, and 62% in group 2, (p=0.02) and 5-year overall survival showed trend towards benefit in group 2 (62% vs 42%, p=0.06). 14/30 (46%) patients in group 1 relapsed, as compared to 4/31 patients, (12%, p=0.005) in group 2, considering NRM as competing risk.

Figure 1.

Summary/Conclusions: In conclusion, the outcome of augmented regimen (DFS and OS) is superior Flu-Bu regime, mainly due to reduction in relapses, with comparable toxicities and could eventually replace Bu/Cy.

P745

PROGNOSTIC TOOLS CAN PROVIDE PERSONALIZED OUTCOMES PREDICTION AFTER ALLOGENEIC HCT IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES
C. cho1,2, S. devlin2, P. hilden2, M. maloy1, M. horowitz3, J.D. rizzo3, B. logan3, P. barba3, R. o’reilly5, S. donath4, M. parades3
1Adult Bone Marrow Transplant Service, Department of Medicine, 2Department of Biostatistics and Epidemiology, Memorial Sloan Kettering Cancer Center, New York, NY, 3Medical College of Wisconsin and Center for International Blood and Marrow Transplant Research, Milwaukee, WI, United States, 4Department of Hematology, Hospital Vall d’Hebron, Universitat Autonoma de Barcelona, Barcelona, Spain, 5Bone Marrow Transplant Service, Department of Pediatrics, Memorial Sloan Kettering Cancer Center, New York, NY, United States

Background: Current prognostic indices for allogeneic HCT (alloHCT) outcomes often focus on a limited set of factors, be they patient characteristics, disease features, or transplant approaches. We sought to evaluate two comprehensive prognostic models in a large sample of patients undergoing alloHCT with CD34 selection (CD34 alloHCT).

Aims: To evaluate two comprehensive prognostic models: The first combining the HCT-Cumorbidity Index (HCT-CI) and Disease Risk Index (DRI); the second applying the Center for International Blood and Marrow Transplant Research (CIBMTR) One Year Survival Outcomes Calculator, which uses large-scale multicenter data reported to the CIBMTR to provide patient-specific predictions on survival 1 year after first alloHCT.

Methods: This retrospective analysis included adult recipients of first alloHCT with CD34+ selected PBScs from 7/8 to 8/8 donors for AML, ALL, or MDS at a single center between 1/2000 and 12/2015. The Kaplan-Meier (KM) method estimated OS and RFS. The cumulative incidence method for competing risks estimated relapse and nonrelapse mortality. We evaluated univariate association between variables of interest and OS/RFS using the log-rank test. Cox regression models assessed the adjusted effect of covariates on OS/RFS.

We then determined predicted 1 year OS for each patient using the CIBMTR Calculator. Patients were divided into groups based on predicted OS probability.
in intervals of 5% +/- 2% (e.g., 65 +/- 2% probability of survival at 1 year). Corresponding observed 1 year OS was then estimated for each group by the KM method. A kernel smoother was used to visually display the average of observed 1 year survival estimates over the continuous range of predicted OS.

**Results:** 506 patients with AML (n=290), ALL (n=72), or MDS (n=144) were included. Of these, 470 patients (AML=263, MDS=141, ALL=66) had full data available for the CIBMTR Calculator. On univariate and multivariate analyses, DRI, HCT-CI, and age correlated with significant differences in OS/RFS, while donor HLA match correlated with a significant difference in OS. Stratifying patients based on a composite of DRI (low/intermediate vs high/very high) and HCT-CI (0-2 vs 3+) revealed significant differences in OS/RFS between the 4 groups (Fig. 1). Compared with a reference group of patients with both low/intermediate DRI and low HCT-CI, those with high DRI and low HCT-CI were at greater risk of death (HR 2.50; 95% CI 1.55-4.05), more so than patients with a higher HCT-CI but still low/intermediate DRI (HR death 1.80; 95% CI 1.34-2.43; HR relapse/death 1.68; 95% CI 1.26-2.24). Within each comparator group, predicted and observed survival, KM estimates of 1 year OS fell within range of that predicted by the CIBMTR Calculator in almost all groups (Fig. 1). In one group, patients had lower observed 1 year OS than predicted (76%, 95% CI 62-93%, vs 85 +/- 2%, p<NS). In this group, 29/30 patients (97%) had intermediate or high DRI; 59% had poor prognostic ALL by NCGN criteria (n=12, 44%) or other adverse features such as minimal residual disease pre-HCT (n=4, 15%).

**Figure 1.**

**Summary/Conclusions:** Based on a large cohort of patients who underwent CD34 alloHCT for acute leukemia or MDS, we demonstrate that DRI is a major determinant of outcome. The CIBMTR Survival Outcomes Calculator predicts 1 year prognosis with relative precision, though some disease-risk features not reflected in the Calculator may affect outcomes in patients with otherwise good prognosis. Taken together, these prognostic models can assist in predicting outcomes and identifying patients most likely to benefit from CD34 alloHCT. Furthermore, applying the CIBMTR calculator analysis in individual centers may help identify patients with worse outcomes than predicted and guide patient and/or HCT selection.

**THROMBOTIC MICROANGIOPATHY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: IS THERE A PROTECTIVE ROLE FOR URSO OXYCHOLIC ACID?**

1Clinical Hematology, H.Universitario Virgen del Rocío, Seville, 2Clinical Hematology, ICO-Duran i Reynals, Barcelona, 3Clinical Hematology, H.Universitario de Salamanca, Salamanca, 4Hematology, H.Universitario Virgen del Rocío, Seville, 5Hematology, H Santa Creu i Sant Pau, 6Hematology, H.Clinic, Barcelona, 7Hematology, H.Clinico, Valencia, 8Hematology, H.Universitario de Salamanca, Salamanca, 9Hematology, H.Clinico, Valencia, 10Hematology, Hospital Clinic, Barcelona, 11Hematology, H.Clinico, Valencia, Spain

**Background:** Thrombotic microangiopathy (TMA) after allogeneic stem cell transplantation (alloSCT) may be a severe complication associated with high mortality. Since there is no standard treatment it would be helpful to have efficacious prophylactic measures. Some data support the beneficial effect of ursodeoxycholic acid (UDA) to prevent endothelial-cell damage.

**Aims:** We retrospectively analysed a total of 671 patients undergoing to reduced intensity conditioning (RIC) alloSCT, comparing the occurrence of overall TMA according with the use or not of UDA.

**Methods:** Both uni and multivariate analysis were performed including patient and transplant-related variables at the moment of transplant to analyse the risk of developing TMA.

**Results:** Cumulative incidence for overall TMA was 4.8 (3.4-6.6) at 1 month, 10.1 (7.9-12.5) at 100 days, and 12.7 (10.3-15.4) at 180 days (Fig. 1). On univariate analysis, TMA was more frequent in lymphoid malignancies, Flu darabine-melphalan based conditioning, unrelated donor, mismatched donor, prophylaxis with sirolimus-tacrolimus (SRL/TKR), prior transplant and non-UDA patients. The probability of overall TMA at 180 days in UDA patients was 9.6% (95% CI: 5.9-14.3), versus 14.7% (95% CI: 11.7-18.1) in non-UDA patients. On multivariate analysis the risk factors which remained statistically significant were unrelated donor and the use of SRL/TKR, whereas the use of UDA significantly decreased the risk of TMA (HR:0.4, 95% CI:0.2-0.8, p:0.01). Moreover, in the subgroup of SRL/TKR, 100 days-cumulative incidence of TMA was 11.8% (95% CI: 6.9-18.1) versus 25.6% (95% CI: 17.9-33.9) depending on the use or not of UDA, respectively (p:0.005), whereas in the subgroup of CNL/MTX 100d- Cumulative incidence of TMA was 3.4% (95% CI: 0.6-10.6) vs 12.1% (95% CI:7.1-18.6) with and without UDA, respectively (p:0.05).

**Summary/Conclusions:** In conclusion the use of UDA decreases the risk of TMA after alloSCT regardless of type of immunoprophylaxis.

**Table 1.**
Results: Characteristics of patients are shown in Table 1. With a median follow-up for patients alive of 39 months (3–221), the median estimated survival in months and the % at +1 year and +2 years was: 114 months, 70% and 62% overall survival (OS); 23 months, 57% and 49% event free survival (EFS); 6 months, 35% and 26% GRFS1; 11 months, 46% and 38% GRFS2. 147 (24%) and 218 (35%) hadn’t any event in GRFS1 and in GRFS2 respectively. In GRFS1, event’s incidence was: 90 (15%) for III-IV aGVHD, 170 (27%) for cGVHD, 152 (25%) for relapse and 57 (9%) for death; In GRFS2 was 90 (15%), 65 (11%), 174 (28%) and 65 (11%) respectively. Considering those patients with cGVHD as event in GRFS1, 105 of them hadn’t the event as cGVHD at the same time in GRFS2 (since they had cGVHD requiring systemic treatment but not severe cGVHD). For these patients, the alternative event in GRFS2 was: 72 without any event, 22 relapsed and 11 died. In the multivariate analysis, factors associated with better outcomes were: for GRFS1 diagnosis (p=0.04; benefit in NHL/HL/CLL p=0.02, HR 0.71; C195% 0.53-0.95), >4 prior lines (p=0.03, HR 1.5, C195% 1.04-2.04), early EBMT stage (p<0.001 with early as reference); intermediate p=0.02, HR 1.5, C195% 1.2-1.9; advance p<0.001, 2.0, 1.5-2.6), in vivo T-cell depletion (p=0.02, 0.6, 0.39-0.92) and haploidentical donor (p=0.04 with HLA identical as reference, no significance 1 or 2 mismatch [p=0.18], haploidentical p=0.02, 0.43, 0.25-0.74). Only early EBMT disease stage maintained significance in GRFS2 (p=0.001 with early as reference; intermediate p=0.005, 1.5, 1.1-1.9; advance p<0.001, 1.9, 1.4-2.6).

Summary/Conclusions: In our study the percentage of the GRFS endpoint was similar to previously reported. Comparing both proposed definitions, the GRFS2 endpoint define a higher population of patients without any event; so that it is possible that t morbidity is misdiagnosed. The EBMT disease score was the factor with more impact in both; it is interesting to point that although the group, haploidentical donor is associated with better GRFS1.

P748
EFFICACY AND SAFETY OF DEFIBROTIDE IN THE TREATMENT OF HEPATIC VENO-OCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME FOLLOWING HEMATOPOIETIC STEM CELL TRANSPLANTATION: FINAL SUBGROUP RESULTS
1Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 2Division of Pediatric Blood and Marrow Transplantation, University of Minnesota, Minneapolis, 3Bone Marrow Transplantation and Cellular Therapy, St. Jude Children’s Research Hospital, Memphis, 4Pediatric BMT Service, Memorial Sloan Kettering Cancer Center, New York, 5Pediatric Oncology, The Children’s Hospital of Philadelphia, Philadelphia, 6Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, 7Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 8Memorial Sloan-Kettering Cancer Institute, New York, 9Jazz Pharmaceuticals, Inc., Palo Alto, United States

Background: Hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is a potentially life-threatening complication of conditioning regimens for hematopoietic stem cell transplant (HSCT) and may also occur following chemotherapy without HSCT. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Diagnosis has traditionally been based on the Baltimore criteria or modified Seattle criteria. Defibrotide is approved for treating severe hepatic VOD/SOS post-HSCT in the European Union and for treatment of hepatic VOD/SOS with renal/pulmonary dysfunction post-HSCT in the United States. The defibrotide expanded-access protocol was designed to provide access to defibrotide prior to its approval in the United States and to collect additional data on safety and efficacy in a broader patient population, including those with and without MOD, and following HSCT or chemotherapy without HSCT.

Aims: This is an analysis of defibrotide efficacy and safety in the subgroup of patients developing VOD/SOS following HSCT, using final data from the expanded-access protocol.

Methods: The original expanded-access protocol required VOD/SOS diagnosis by at least one criterion or biopsy post-HSCT, with evidence of MOD (27%) or pulmonary dysfunction). The study was amended to also include patients without MOD (off-label), with VOD/SOS per modified Seattle criteria, and/or with VOD/SOS following chemotherapy without HSCT (off-label). After patients provided informed consent, defibrotide treatment (25/mg/kg/d in 4 divided doses of 6.25/mg/kg) was recommended ≥21 days.

Results: This analysis of final data is based on 1000 patients enrolled from 2007–2016 who had confirmed VOD/SOS following HSCT and had received ≥1 dose of defibrotide. Of these patients, 512 (51.2%) had MOD. The median age was 14 years (range 0.10–77.0), with 570 patients (57.0%) aged ≤16 years, (28.9% of whom had MOD) and 430 patients (43.0%) aged >16 (231 [45.1%] of whom had MOD). Among pediatric patients, 28.2% were aged <1–23 months, 52.5% aged 2–11 years, and 19.3% aged 12–16 years. Primary diseases in ≥10% of the overall HSCT group were acute lymphocytic leukemia (19.8%), acute myelogenous leukemia (26.1%), and neuroblastoma (10.5%). Kaplan-Meier estimated Day +100 survival was 58.8% (95% confidence interval [CI], 55.7%–61.9%) in the overall HSCT group (Figure), with rates of 49.5% (95% CI, 45.0%–53.8%) in patients with MOD and 68.9% (95% CI, 64.5%–72.9%) in patients without MOD. In patients aged ≥16 years, Kaplan-Meier estimated Day +100 survival was 67.9% (95% CI, 63.8%–71.6%) and 47.1% (95% CI, 42.3%–51.8%) in patients aged >16 years (Figure). In the overall HSCT population, 210 patients (21.0%) had ≥1 treatment-related adverse event (TRA). TRAEs occurring in ≥2% of patients were pulmonary hemorrhage (4.6%), gastrointestinal hemorrhage (3.0%), epistaxis (2.3%), and hypotension (2.0%).

Figure 1.
Summary/Conclusions: This final analysis of the defibrotide expanded-access protocol demonstrates favorable Day +100 survival (58.9%) in patients with confirmed VOD/SOS following HSCT, and 49.5% in those with MOD, a complication typically associated with dismal outcomes. Survival and safety findings, consistent with prior clinical trials, provide supportive evidence for the clinical utility of defibrotide for treatment of VOD/SOS in patients with and without MOD.

P749
GENERATION OF IMMORTAL MURINE HEMATOPOIETIC STEM/PROGENITOR CELL LINES FROM TRANSGENIC MICE
E. Doma1, A. Höbl1, V. Sexl1
1Pharmakologie und Toxikologie, Veterinärmédizinische Universität Wien, Wien, Austria

Background: Research on hematopoietic and leukemic stem cells (LSCs) is currently limited as these cells are infrequent and their immortalization is hardly achievable.

Aims: We aimed to establish a long term ex-vivo culture system that allows maintenance and expansion of LSK (lin-, Sca-1-, c-Kit+) cells.

Methods: We adapted a technique described by the L. Carlson lab and transduced high-purity sorted murine LSKs with Lhx2, a LIM-homeobox transcription factor, which has been reported to facilitate ex vivo expansion of immature hematopoietic cells.

Results: Lhx2 expressing hematopoietic progenitor cell (HPC(LSK)) lines require SCF (stem cell factor) and IL-6 and they can be maintained in a feeder-independent culture for more than 6 months. They preserve LSK markers despite continuous proliferation. HPC(LSK) cells repopulate lethally irradiated mice and re-establish T and B hematopoietic cell pool. HPC(LSK) cells were established from a range of transgenic mice, underlying the overall applicability of this model. Using this system, we established LSC lines that express BCR/ABL(p210), MLL-AF9,Nras12/2 or Flt3-ITD; Nras12/2. These LSCs home to the bone marrow, differentiate into all lineages and drive myeloid leukemia in mice.

Summary and Conclusions: We created a robust method of expanding hematopoietic stem/progenitor cells. They are immortalized and can be expanded indefinitely. This tool allows analysis of the molecular mechanisms controlling self-renewal in hematopoietic and LSCs as well as drug screening. Our system may represent a breakthrough in (cancer) stem cell biology and assist in the development of new therapeutic avenues to combat LSCs.

INHIBITING BCL2 AND NK CELLS IMPROVES STEM CELL TRANSPLANT OUTCOMES.
J. Davis1,2, Y. Jiao3,4, R. Koldej1,2, N. Huntington3,5, D. Ritchie1,2,6
1The ACRF Translational Research Laboratory, The Royal Melbourne Hospital, 2Department of Medicine, The University of Melbourne, 3Department of Molecular Immunology, The Walter and Eliza Hall Institute, Melbourne, Australia, 4School of Medicine, Tsinghua University, Beijing, China, 5Department of Medical Biology, The Walter and Eliza Hall Institute, 6Department of Clinical Oncology and Haematology, The Royal Melbourne Hospital, Melbourne, Australia

Background: Allogeneic haematopoietic stem cell transplantation (alloHSCT) is the most effective means of preventing relapse of blood cancers, in particular AML. The curative potential of alloHSCT is largely due to the immune mediated killing of NK cells. NK cell apoptosis in human cells is inhibited by Venetoclax (ABT-199), a BCL2 antagonist approved in the treatment of AML, resulted in NK cell apoptosis in human cells in vivo.

Aims: We extended our observations in vivo. We used a MHC-mismatched mouse model of alloHSCT, where donor BM and T cells from BALB/c (H2Kd) mice were injected into irradiated C57BL/6 WT recipients to show that pharmacological inhibition of BCL2 in WT mice with just two doses of ABT-199 resulted in rapid depletion of NK cells. Our preliminary data indicates that alloHSCT WT recipient mice pre-treated with ABT-199 develop full donor engraftment even in the setting of significant RIC, with minimal GVHD.

Summary/Conclusions: Recipient NK cell inhibition may therefore represent a means by which to deliver alloHSCT more safely by reducing conditioning intensity and GVHD.

P751
MESENCHYMAL STEM CELL IRRADIATION INTERFERES WITH THE ADIPOGENIC/OSTEOGENIC DIFFERENTIATION BALANCE IMPROVING THEIR HEMATOPOIETIC-SUPPORTING ABILITY
S. Preciado Perez1, 2, S. Munton1, A. Rico1, R. Ortega1, I. Misiewicz-Krzeminska1, L. Millán-Vega1, N. Dias-Ramos1, T. Ramadori1, C. Roman1, C. Rodriguez1, M. Diez-campeelo1, M. López-Parr1, A. Redondo1, L. I. Sanchez Abarca1, M. C. Del Cañizo1, F. Sánchez-Guijo1
1IBCSAL-Hospital Universitario de Salamanca, Salamanca, Spain

Background: Mesenchymal stromal cells (MSC) are precursors of adipocytes and osteoblasts in the bone marrow (BM) niche, and key regulators of the hematopoietic process. After HSC transplantation, MSC remain of host-origin. Total body irradiation has been widely used in conditioning regimen and MSC are shown to be radio-resistant. Nevertheless, the functional effects of irradiation on BM-MSC have not been extensively explored.

Aims: The main objective was to evaluate the effects of irradiation on the MSC in their hematopoietic-supporting capacity.

Methods: Ten BM samples were obtained from healthy donors after informed consent. MSC were obtained and characterized following standard procedures to derive conditions. MSC were treated with ABT-199 develop full donor engraftment even in the setting of significant RIC, with minimal GVHD.

Summary and Conclusions: We created a robust method of expanding hematopoietic stem/progenitor cells. They are immortalized and can be expanded indefinitely. This tool allows analysis of the molecular mechanisms controlling self-renewal in hematopoietic and LSCs as well as drug screening. Our system may represent a breakthrough in (cancer) stem cell biology and assist in the development of new therapeutic avenues to combat LSCs.
Background: Prolonged isolated thrombocytopenia (PT), is a serious complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT) and defined as the engraftment of all peripheral blood cell lines other than platelet (PTL) count ≤20×10^9/L or dependence on PLT transfusions for more than 60 days after allo-HSCT. Several clinical risk factors have been proposed to be associated with PT after allo-HSCT. However, the underlying mechanisms remain to be elucidated. Emerging evidence from mouse studies has suggested that effective hematopoiesis depends on a particular bone marrow (BM) microenvironment in which hematopoietic stem cells reside. MSCs represent a key cellular component of the BM microenvironment, which are potential progenitors for osteoblasts, adipocytes, chondrocytes, and marrow stromal cells. The functions of megakaryocytopoiesis and thrombocytopoiesis result from the interactions between hematopoietic progenitor cells, cytokines, and marrow stromal cells derived from MSCs or MNCs directly. However, the functional role of BM MSCs in the patients with PT has never been reported. Moreover, approaches for improving the dysfunction of BM MSCs in patients with PT are lacking.

Aims: To evaluate the number and function of BM MSCs in patients with PT post-allo-transplant. Moreover, to investigate the approach to enhance the number and function of BM MSCs derived from patients with PT and its underlying molecular mechanisms in vitro.

Methods: Three cohorts were included: patients with PT (N=25), patients with good graft function (GGF, N=12), defined as persistent successful engraftment after allotransplant, and transplant donors as normal controls (N=10). BM MSCs were cultured as previously reported. All experiments were carried out using BM MSCs derived from passages 2–4. The number and functions of BM MSCs were evaluated by fibroblasts colony-forming unit (CFU-F) assay, cell proliferation, alamarBlue®-assayed activity of nitric oxide synthase (NOS). Reactive oxygen species (ROS) levels were evaluated by flow cytometry. Protein expression for p-p38, p38, p-p53, p53 was measured by flow cytometry and western blots. To further investigate the potential effect for repairing the dysfunctional BM MSCs, N-Acetyl-L-cysteine (NAC) and the SMAC mimetic that actively antagonizes all IAPs. AT406 were utilized to the BM MSCs for PT patients. After 2 days in vitro culture, the number of SAβ-positive cells was counted, the intracellular levels of ROS and p-p38 were evaluated in BM MSCs by flow cytometry.

Results: Human BM MSCs were demonstrated as spindle shape and typical immunophenotype of MSCs at day 21 of cultivation among subjects with PT, GGF and normal controls. Cultures from all normal BM samples produced confluent layers of adherent cells composed of spindled shaped cells. 2 of the 12 GGF BM and 15 of the 25 PT BM failed to produce any adherent layers within 3 weeks of culture. BM MSCs derived from PT patients expanded more slowly and appeared flattened and larger. Proliferative capacity and CFU-F counts of BM MSCs from PT patients were significantly reduced compared to those of GGF patients and normal controls. Moreover, increased levels of ROS, which was associated with increased number of SAβ-positive cells, were identified in BM MSCs from PT patients. Intracellular p-p38 level was significantly elevated in PT patients compared to those in GGF patients. After NAC treatment in vitro, the number of SAβ-positive cells was decreased whereas the number of senescent cells, the intracellular levels of ROS and p-p38 were reduced markedly in BM MSCs from PT patients.

Summary/Conclusions: In summary, the current study demonstrated the number and the function of BM MSCs were abnormal in PT patients following allo-HSCT. The reduced proliferation in vitro combined with decreased ROS level and reversed the senescence phenotype through down-regulation of the p38 MAPK pathway. Our results indicate that the dysfunctional BM MSCs may play an important role in the pathogenesis of PT following allo-HSCT and NAC represents a promising therapeutic approach for repairing the impaired BM MSCs in PT patients post-allo-transplant.

GRAFT-VERSUS HOST DISEASE (GVHD) DEVELOPMENT AFTER BONE MARROW TRANSPLANTATION IS NOT INFLUENCED BY TH9 CELLS

T. Reisser,1 S. Mučhe,1 J. Scheurer1, K.-M. Debatin1, G. Strauss1

Departments of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany

Background: Th9 cells are a recently defined subset of T helper cells (Th) characterized by the massive production of IL-9. Th9 cells mediate immune responses against helminth infections, exhibit anti-tumor immunity against solid tumors and mediate allogeneic transplant tolerance but they also contribute to immunopathology in allergy and autoimmunity.

Aims: Currently, the role of Th9 cells for GVHD induction and the graft-versus-tumor effect is largely unknown. Therefore, we first explored, whether Th9 cells are induced during GVHD development in two different MHC-mismatched bone marrow transplantation (BMT) models and secondly analyzed, whether transplantation of in vitro-generated Th9 cells mediates GVHD.

Methods: We transplanted allogeneic BM and spleen cells from B6 SJL mice (CD45.1, H-2b) into B6Δ2F1 mice (CD45.2, H-2bd) or in B6.12m12 mice (CD45.2, major targets, we utilized B6→B6ΔMHC-mismatched BMT model. Th9 cells were induced in vitro from spleen cells from mice lacking Th9 cells derived from B6-cIAP-/- or XIAP-/- animals compared to B6-WT T cells, the allo-recipients (BALB/c) showed similar GVHD. Same results were also observed in another B6→F1 model. Furthermore, in vitro studies showed that XIAP-/- and cIAP-/- T cells had comparable proliferation and cytokine secretion as WT-T cells. These data suggested that the increase in GVHD mortality following treatment with AT-406 is not due to its effects on donor T cells. To further dissect the increased mortality after AT-406 treatment, we hypothesized that the absence of IAPs in hosts may impact on GVHD. To test this, cIAP-/- and XIAP-/- and WT-B6 animals were lethally irradiated and transplanted with syngeneic (B6) or allogeneic (BALB/c) T cells. Compared to WT recipients, both cIAP-/- and XIAP-/- animals showed increased mortality (p<0.001) and worse gastrointestinal (GI) GVHD. To explore whether IAPs regulate GVHD through their expression exclusively in host hematopoietic cells, we generated [B6→B6Ly5.2], [cIAP-/-→B6Ly5.2] and [XIAp-/-→B6Ly5.2] chimeras and utilized them as recipients in 2nd allo-BMT in XIAp-/- and WT-B6 donors. This approach allowed us to compare equivalent GVHD mortality to [B6→B6Ly5.2] chimeras. Consistently, dendritic cells (DCs) from XIAP-/- and cIAP-/- animals showed similar functions as WT-B6 in vitro, suggesting that IAP expression in host hematopoietic cells is not critical. Next, to test the role of IAPs in non-hematopoietic GVHD target tissues, we tested the reverse approach, by expanding IAP-deficient T cells in vivo and allotransplantation into BALB/c mice and generated [B6→cIAP-/-Ly5.2] and [B6→XIAP-/-Ly5.2] chimeras, where IAPs are absent only in the non-hematopoietic host cells. The allogeneic [B6→cIAP-/-Ly5.2] and [B6→XIAP-/-Ly5.2] chimeras demonstrated a significantly worse survival compared to WT [B6→Ly5.2] recipient (p<0.01). To determine the potential mechanisms for exacerbating GVHD, we analyzed expression of pro-inflammatory cytokines and the expression of cell surface molecules like CD25, CTLA-4 and GITR. The expression of Bcl-2 in allo-XIAP-/- animals was significantly increased.

Summary/Conclusions: These data suggest that enhanced apoptosis in the target tissues in the absence of IAPs contributes to greater GVHD severity. Thus expression of functional IAPs in target host tissues is crucial for reducing the damage from GVHD.
during GVHD. After in vitro differentiation of Th9 cells from naïve T cells we obtained more than 60% of IL-9 producing cells after 5 days of culture. Th9 cells differ in their cytokine profile (IL-9+, IFN-g-, IL-13-) from Th1 and Th2 cells. Transplantation of in vitro-generated Th9 cells together with allogeneic BM cells did not induce GVHD in the MHC-disparate recipient mice, while the transplantation of unselected T cells or in vitro-generated Th1 cells induced GVHD and resulted death in about 60% of the animals. Although no GVHD development was detected, Th9 cells migrated into lymphoid organs and GVHD target organs such as spleen and lung. Surprisingly, when the cytokine phenotype of the transplanted Th9 cells were analyzed after ex vivo isolation from spleen and liver at different time points after transplantation, the cells lost their IL-4 production and acquired TNF-a and IFN-g. Furthermore, moving to a plasticity of Th9 cells after adoptive transfer. Systemic increase of TNF-a and IFN-g in the serum of mice receiving Th9 cells, however, was not detected.

**Summary/Conclusions:** Th9 cells are not induced during GVHD development and the adoptive transfer of in vitro-generated Th9 cells does not induce GVHD. However, the transplanted Th9 cells home to spleen and GVHD target organs and start to produce TNF-a and IFN-g without strong systemic increase in these cytokines. Since TNF-a and IFN-g are cytokines associated with an anti-tumor cytotoxicity and Th9 cells are known to eliminate solid tumors, future experiments will define whether in vitro-generated Th9 cells can be used as a cellular therapy for anti-tumor responses in BM-transplanted hosts.

**IMPROVED HSC ENGRAFTMENT IN A MOUSE MODEL OF HEMATOPOIETIC STEM CELL GENETIC THERAPY MEDIATED BY MSCS**

M. Fernandez-Garcia1,2,*, M. L. Lamana 1,2, M. Hernando-Rodríguez 1,2, A. Morales Hernandez 1,2,*, A. Martinat2, S. McKinney-Freeman2

**Aims:** To study the effect of MSCs on HSC engraftment in a clinically relevant model of hematopoietic genetic therapy.

**Methods:** We have studied the effect of MSCs co-infection in a mouse model of HSC gene therapy with risk of engraftment failure in Fancnani anemia mice (Fanca--/--).

**Results:** In these experiments, the infusion of low numbers of WT LSK cells (1,000 LSK) in Fanca--/-- mice resulted in 30% graft failure, which was prevented when MSCs were co-infused. Furthermore, when 1,500-3,000 Fanca--/-- LSK cells transduced with a therapeutic lentiviral vector (PGK-FANCA-wPRE) were transplanted, the infusion of similar cell doses resulted in more than 50% of engraftment failure, which decreased to 30% only when more than 10,000 gene-corrupted LSKs were infused. Once again, Ad-MSCs co-infusion decreased graft failure in after the infusion with the same number of gene-corrupted LSK cells.

**Summary/Conclusions:** Taken together, our results demonstrate the potential of Ad-MSCs to avoid graft failure in a clinically relevant model of hematopoietic genetic therapy with risks of engraftment failure.

**P756**

**EFFECT OF POMALIDOMIDE ON T CELL POLARIZATION IS MEDIATED DURING EPIGENETIC MODIFICATIONS.**

I. Alvarez Laderas-1, J. J. Piruat 1, T. Caballero Velázquez 1, M. Ceballos 2, J.-Y. Lim1,*, D.-B. Ryu1, S.-E. Lee1, G. Park2,3, C.-K. Min1,3

**Methods:** Treatment of naïve T cells with pomalidomide induces epigenetic modifications during T cell polarization which might favor the process of differentiation of CD45RA+ cells depending on the cytokines present in the medium. We next studied whether or not the effect of pomalidomide in T cell polarization might be mediated by epigenetic mechanisms: in the presence of Th1 promoting conditions there was a significant increase of the activation marker H3K4me3 at the TBET promoter and a significant decrease in H3K27me3 upon exposure to pomalidomide. Furthermore, exposure to pomalidomide led to an increased expression of T-bet as assessed by western-blot in naïve CD45RA+ cells activated with anti-CD3 plus anti-CD28 and supplemented with IL-12, IFN-γ and anti-IL-4. By contrast, in Th2 polarization conditions, pomalidomide increased the levels of TNF-a and IL-4 and IL-10 in the Th2 polarizing culture while, under Th2 promoting conditions, a significant increase in H3K4me3 at the promoter of FANCA was observed after exposure to pomalidomide.

**Summary/Conclusions:** Pomalidomide favours both Th1 and Th2 cell differentiation of CD45RA+ cells depending on the cytokines present in the medium. Treatment of naïve T cells with pomalidomide induces epigenetic modifications during T cell polarization which might favor the process of differentiation of the naïve T cells.

**MESENCHYMAL STEM CELLS (MSCS) ATTENUATE CUTANEOUS SCLERODERMATOUS GRAFT-VERSUS-HOST DISEASE (SCL-GVHD) THROUGH INHIBITION OF IMMUNE CELL INFLTRATION IN A MOUSE MODEL.**

J.-Y. Lim1,*, D.-B. Ryu1, S.-E. Lee1, G. Park2,3, C.-K. Min1,3

**Aims:** To study the therapeutic effect of mesenchymal stem cells in a murine sclerodermatous GVHD (Scl-GVHD) model that is characterized by skin thickening and lung fibrosis.

**Methods:** We have studied the therapeutic effect of mesenchymal stem cells (MSCs) in a mouse model of cutaneous GVHD that is characterized by skin thickening and lung fibrosis.

**Results:** In these experiments, the infusion of low numbers of WT LSK cells (1,000 LSK) in Fanca--/-- mice resulted in 30% graft failure, which was prevented when MSCs were co-infused. Furthermore, when 1,500-3,000 Fanca--/-- LSK cells transduced with a therapeutic lentiviral vector (PGK-FANCA-wPRE) were transplanted, the infusion of similar cell doses resulted in more than 50% of engraftment failure, which decreased to 30% only when more than 10,000 gene-corrupted LSKs were infused. Once again, Ad-MSCs co-infusion decreased graft failure in after the infusion with the same number of gene-corrupted LSK cells.

**Summary/Conclusions:** Taken together, our results demonstrate the potential of Ad-MSCs to avoid graft failure in a clinically relevant model of hematopoietic genetic therapy with risks of engraftment failure.
Although C57BL/6N (N) and C57BL/6J (J) mice are derived from the same parental C57BL/6 strain, there are key genotypic and phenotypic differences between these sub-strains. However, more than 58% of studies published involving C57BL/6 mice do not indicate the specific sub-strain employed. J mice have a five-exon deletion in the Nicotinamide nucleotide transhydrogenase (Nnt) gene that results in a non-functional protein. NNT is involved in the resolution of oxidative stress in the mitochondria. Hematopoietic stem cells (HSCs) can reconstitute the entire hematopoietic system after transplantation into hosts whose hematopoietic compartment has been ablated. This is clinically exploited as HSCs transplantation (HSCT) to treat hematologic diseases and represents the only curative therapy for many disorders. During HSCT, HSC are subject to dramatic increases in both intra and extracellular reactive oxygen species (ROS), which compromises their self-renewal, differentiation, and survival. The absence of a functional Nnt gene in J-HSC may curtail their ability to resolve elevated ROS post-transplant.

Aims: As elevated oxidative stress compromises hematopoietic stem and progenitor cell (HSPC) function, here we thoroughly interrogated the frequency and function of HSPCs in J and N bone marrow (BM).

Methods: N and J peripheral blood (PB) and BM (n=9) was interrogated by flow cytometry for the absolute frequencies of all major hematopoietic lineages and HSPC compartments, respectively. 5000 J or N CD45.2 HSPCs (Lin-Scal+c-Kit+ cells) were transplanted along with 5000 competitor CD45.1 HSPCs into lethally irradiated mice to test for competitive in vivo hematopoietic repopulating activity and ROS levels post-transplant. The lineage potential and repopulating activity of multi-potent progenitors (MPP2: Lin-Scal+c-Kit+Flt3+CD48+CD150+, MPP3: Lin-Scal+c-Kit+Flt3-CD48+CD150-, MPP4: Lin-Scal+c-Kit+Flt3-CD48+CD150-) was also tested by transplanting 2000 MPPs from J or N mice into sub-lethally irradiated mice and examining the PB of recipients every 3-4 days for 34 days post-transplant. Sensitivity of HSPCs to oxidative stress was tested by examining ROS levels and the in vitro colony forming unit (CFU) potential of HSPCs isolated from N and J mice treated with pI:pc.

Results: The frequency of the major PB lineages and bone marrow HSPC compartments was identical in J and N mice. However, J-HSPCs displayed compromised short-term (4-12 weeks post-transplant) hematopoietic repopulating activity relative to N-HSPCs that was driven by a delay in lymphoid reconstitution. No differences were found in donor contribution to bone marrow HSPC compartments at 20 weeks post-transplant. However, donor-derived MPPs and CLPs displayed a two-fold increase in ROS levels in recipients of J-HSPCs versus N-HSPCs at 20 weeks post-transplant. MPPs are responsible for repopulation of the hematopoietic system during this early window post-transplant. Different MPP subpopulations can be defined (MPP2, MPP3 and MPP4) according to their self-renewal potential and specific lineage potential. MPP3s and MPP4s are the first MPP subpopulations to reconstitute the lymphoid lineage after transplantation. J-MPP3s and J-MPP4s displayed less in vivo repopulating activity than N-MPP3s and N-MPP4s. It is known that pI:pc treatment increases ROS levels in HSCs. We found about two-fold higher ROS levels in HSPCs isolated from pI:pc treated J mice than N mice with the exception of the myeloid progenitor compartments (CMP, GMP and MEO). J-HSPCs also generated fewer and smaller CFU than N-HSPCs when isolated from pI:pc treated mice. These data indicate that J-HSPCs cannot resolve oxidative stress as efficiently as N-HSPCs, which may be due to lower self-renewal potential after exposure to oxidative stress. Short-term J-lymphoid-biased progenitors (e.g. MPPs and CLPs) were especially sensitive to increasing ROS, which very likely drives the short-term loss of in vivo repopulating activity.

Summary/Conclusions: Based on these data, we hypothesize that loss of the Nnt gene in C57Bl/6J mice sensitizes HSPCs to oxidative stress, which compromises their short-term in vivo hematopoietic repopulating activity.

**GWAS RESULTS IN RED BLOOD CELL PHENOTYPES AND THEIR RELATIONSHIP WITH THROMBOSIS**

1Thrombosis and Hemostasis Unit, Hospital de Sant Pau, 2Unit of Genomics of Complex Diseases, Institut d’Investigació Biomèdica Sant Pau. (IIB-Sant Pau). 3Hematology, Hospital de Sant Pau, Barcelona, Spain, 4Cardiovascular Medicine Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, 5Department of Medicine, Universitat Autonoma de Barcelona, Barcelona, Spain

**Background:** Venous thromboembolism (VTE) is a complex and multifactorial disease with a estimated heritability of 60%. Intermediate phenotypes of VTE have been used to identify genetic risk factors. We previously reported a genetic correlation of 5 erythrocyte phenotypes with VTE.

**Aims:** To identify single nucleotide polymorphisms (SNPs) influencing the phenotypic variance of erythrocyte parameters, especially those related to VTE, in Spanish families from the Genetic Analysis of Idiopathic Thrombophilia (GAIT2) Project.

**Methods:** Genome-wide association analyses (GWAS) with ~10M SNPs were performed for eighteen erythrocyte phenotypes in 935 subjects belonging to 35 extended families with thrombosis of GAIT2. The erythrocyte phenotypes evaluated were: Hemoglobin (Hb), red blood cell count (RBC), hematocrit (Ht), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), red blood cell distribution width (RDW), reticulocyte (RET), low fluorescence reticulocyte (LFR), middle fluorescence reticulocyte (MFR), high fluorescence reticulocyte (HFR), reticulocyte fluorescence index (IRF), haptoglobin (HP), serum iron (Fe), total iron binding capacity (TIBC), saturation index (SI), serum ferritin (FT) and serum transferrin receptor (TFR).

**Results:** We identified 12 SNPs showing association with the 5 erythrocyte phenotypes previously related to VTE (Table 1). Interestingly, the rs56036145 (FVIIIa/TF), Fxa, plasmin and plasma kallikrein. These data reinforce our previous report of genetic correlation of TFR with VTE. The most significant SNP-associations were reported.

**Table 1. Top SNP-associations with erythrocyte phenotypes related to VTE from GWAS in GAIT2.**

G: genetic correlation with VTE; Chr: Chromosome.

**Summary/Conclusions:** Several genetic variants involved in the variance of erythrocyte phenotype levels were identified by GWAS. Of note, TFR was associated with a SNP in TFPI2 that might influence the variance of both TFR levels and VTE risk. These data could be useful to investigate genes related to red blood cell parameters and VTE.

**ESSENTIAL THROMBOCYTHEMIA (ET) AND POLYCYTHEMIA VERA (PV) PATIENTS SHOW AN INCREASED THROMBUS FORMATION IN A DYNAMIC MODEL OF PLATELET ADHESION**

A. Vignoli, F. Marchesi, M. Marchetti, S. Gamba, C. Giaccherini, C. Verzoni, L. Russo, S. Tesserolo, G. Finazzi, P.E. van der Meijsen, F. Swieringa, H. ten Cate, J.W. Heemskerk, A. Rambaldi, A. Falanga

Madrid, Spain, June 22 – 25, 2017

haematologica | 2017; 102(s2) | 307
Background: ET and PV are characterized by a high incidence of arterial and venous thrombosis. Platelet (PLT) count is not an independent risk factor for thrombosis in these conditions. However, no information is available on patient PLT qualitative properties, i.e. the PLT thrombus formation capacity in a dynamic condition.

Aims: We wanted to evaluate, in a group of ET and PV patients, the PLT thrombus formation capacity by an ex-vivo dynamic model of PLT adhesion under flow conditions, and to establish the influence of JAK2-V617F/Calreticulin (CalR)/MPL mutations, hematological parameters, and ongoing therapies.

Methods: One hundred-thirty patients, i.e. 78 ET (32 M/46 F; median age=61 years, range 28-86) and 52 PV (26 M/26 F; median age=65 years, range 38-87), were enrolled after informed consent. For the adhesion assay, peripheral venous whole blood was drawn in sodium citrate, recalciﬁed in the presence of heparin, and perfused over a collagen-coated surface for 4 min. at a shear rate of 1,000 s⁻¹. PLTs were then stained with an anti-Cd26/P-selectin-ﬁtC Alexa Fluor 647, and annexin V-Alexa Fluor 67 to detect pro-coagulant phosphatidylserine expression. After staining, phase contrast and ﬂuorescence images of adherent PLTs were taken in random ﬁelds using an EVOS® microscope. Results are expressed as the means±SEM of the % of area covered by all PLTs (% coverage), or as the % of adherent PLTs positive for phosphatidylserine. Main hematological parameters, therapies, and mutational status were recorded.

Results: PLT adhesion was signiﬁcantly (p<0.01) greater in either ET (45±3±1%) and PV patients (48±9±1%) compared to healthy controls (37±5±1%), while no difference was found between ET and PV patients. The analysis according to the mutational status shows that ET PLT adhesion was highest in JAK2-V617F mutation carriers (n=4; coverage: 47±7±2%, p<0.001 vs controls), followed by CalR-positive patients (n=21; coverage: 45±5±3%, p<0.05 vs controls, p=n.s. vs JAK2-V617F), while PLT adhesion of MPL-positive (n=3; coverage: 32±1±2%) or triple negative (n=13; coverage: 42±6±5%) ET patients was not statistically different from controls. In PV, no statistically significant difference was observed between subjects with >50% versus those with <50% JAK2-V617F allele burden. According to our treatment, we observed that ET patients treated with the combination of aspirin+hydroxyurea presented the lowest PLT adhesion, while in PV no signiﬁcant diﬀerence was observed between subjects on aspirin alone or phosphatidyserine. Main hematological parameters, therapies, and mutational status were recorded.

Summary/Conclusions: ET patients who are not on anticoagulation. Further sub group analysis of this cohort and efforts to improve reporting of anticoagulation associated bleeding is underway.

INCIDENCE OF VENOUS THROMBOEMBOLISM IN PATIENTS UNDERGOING LOWER LIMB SURGICAL REVASCULARIZATION: IS THROMBOPROPHYLAXIS WARRANTED?

A. Baranwal1, S. Singh1, A. Yanamadala1, P. Smith1,*, E. Colaiuta1
1MacNeal Hospital, Berwyn, United States

Background: The incidence of postoperative deep vein thrombosis (DVT) or consequent pulmonary embolism (PE) in patients undergoing lower extremity surgical revascularization procedures is not well studied. The need for routine anticoagulation for DVT/PE prophylaxis after the lower limb surgical revascularization remains controversial.

Aims: The purpose of this study is to retrospectively evaluate the incidence of postoperative DVT/PE in patients undergoing lower limb surgical revascularization.

Methods: Charts for patients undergoing lower limb surgical revascularization, from 01/01/2010 to 12/31/2015, were evaluated for DVT/PE. DVT/PE within three months of the revascularization was considered to be a postoperative DVT/PE. Patients undergoing multiple procedures were counted as different cases if they were on different days. Multiple procedures on a patient on the same day were considered a single case. Patients with hypercoagulable states or previous history of DVT were excluded. Descriptive statistics and t-test was used to analyze incidence of DVT/PE and assess the importance of postoperative thromboprophylaxis.

Results: Between 1/1/2010 to 12/31/2015, 360 patients were found to have undergone lower extremity surgical revascularization. Study population included 200 males and 160 females. Mean patient age was 69.54 years. One patient had a previous history of DVT and was excluded. Overall, of the 359 patients, five (1.4%) were recognized to have a new DVT/PE within 3 months of the surgery. One patient developed DVT in the contralateral limb, and one developed it in the arm. Patients were recognized to have a new DVT/PE, on an average, at 7.6 days after the surgery. A one sided t-test demonstrated that the average
postoperative day for recognition of DVT/PE was significant greater than 3.5 (7.6 vs 3.5, \textit{p}val=0.048). Patients developing DVT/PE did not differ by obesity or age when compared with non-DVT/PE population.

**Summary/Conclusions:** There have been only a few studies to assess the incidence of DVT/PE in patients undergoing lower limb surgical revascularization. In our study population, 1.4% of patients had evidence of DVT/PE. This constitutes a low risk of venous thromboembolism. The 2012 American College of Chest Physicians (ACCP) guidelines for prevention of venous thromboembolism in nonorthopedic surgical patients (Chest 2012; 141(2)Suppl;e227s-e277s), requires the use of pneumatic compression devices (PCDs), over no prophylaxis, to prevent DVT/PE in low risk patients. Since, patients with lower limb surgeries are not a good candidates for PCDs, pharmacological thromboprophylaxis with low dose heparin may be warranted. Given that bleeding is a potential complication in these patients, it might be prudent to start thromboprophylaxis 3-5 days after the surgery. Further studies are needed to assess the bleeding risks of postoperative thromboprophylaxis after surgical revascularization procedures.
