Abstract

Immune checkpoint inhibitors targeting programmed cell death protein 1 (PD-1) and programmed death-ligand 1 (PD-L1) have improved the survival of patients with non-small cell lung cancer (NSCLC). Still, many patients do not respond to these inhibitors. PD-L1 (CD274) expression, one of the factors that influences the efficacy of immune checkpoint inhibitors, is dynamic. Here, we studied the regulation of PD-L1 expression in NSCLC without targetable genetic alterations in EGFR, ALK, BRAF, ROS1, MET, ERBB2 and RET. Analysis of RNA sequencing data from these NSCLCs revealed that inferred IFN-\(\gamma\), EGFR and MAPK signaling correlated with CD274 gene expression in lung adenocarcinoma. In a representative lung adenocarcinoma cell line panel, stimulation with EGF or IFN-\(\gamma\) increased CD274 mRNA and PD-L1 protein and membrane levels, which were further enhanced by combining EGF and IFN-\(\gamma\). Similarly, tumor cell PD-L1 membrane levels increased after coculture with activated peripheral blood mononuclear cells. Inhibition of the MAPK pathway, using EGFR inhibitors cetuximab and erlotinib or the MEK 1 and 2 inhibitor selumetinib, prevented EGF- and IFN-\(\gamma\)-induced CD274 mRNA and PD-L1 protein and membrane upregulation, but had no effect on IFN-\(\gamma\)-induced MHC-I upregulation. Interestingly, although IFN-\(\gamma\) increases transcriptional activity of CD274, MAPK signaling also increased stabilization of CD274 mRNA. In conclusion, MAPK pathway activity plays a key role in EGF- and IFN-\(\gamma\)-induced PD-L1 expression in lung adenocarcinoma without targetable genetic alterations and may present a target to improve the efficacy of immunotherapy.

Introduction

After years of limited progress in the treatment of advanced non-small cell lung cancer (NSCLC), a major leap forward has been made with the introduction of programmed cell death protein 1 (PD-1)/programmed death-ligand 1 (PD-L1) targeting immune checkpoint inhibitors. These have greatly improved the overall survival of patients with advanced NSCLC, especially patients without targetable genetic alterations, accounting for almost 60% of NSCLC [1–3]. Patients with PD-L1-positive tumors generally respond better to PD-1-targeted immune checkpoint inhibition. However, discrepancies between observed PD-L1 expression and the benefit from treatment often occur [4]; even in a preselected patient population with >50% PD-L1-positive tumor cells, only 45–55% of patients respond to therapy [5]. The limited value of tumor PD-L1 as a biomarker may be caused by the highly dynamic expression of PD-L1 due to the influence of multiple factors [6]. The best characterized inducer of PD-L1 expression in NSCLC is the pro-inflammatory cytokine IFN-\(\gamma\), which is secreted by T cells [7,8]. PD-L1 on tumor cells binds to PD-1 on T cells, disrupting T cell function and thereby preventing an effective tumor immune response [9]. Oncogenic driver mutations, such as mutations in EGFR, ALK and BRAF, are known inducers of PD-L1 expression in NSCLC cells. In these oncogene-activated cells, the PI3K/mTOR, JAK/STAT and MAPK pathways are the main drivers of PD-L1 expression [10–13].
Interestingly, EGFR wild-type NSCLC tumors have higher levels of PD-L1 and tumor infiltrating lymphocytes, and respond better to PD-1/PD-L1-targeted therapy compared with EGFR mutant NSCLC [1,2]. However, there are only limited data about the regulation of PD-L1 expression in NSCLC without targetable genetic alterations [14–16]. A better understanding of PD-L1 regulation may provide a rationale to combine immune checkpoint inhibitors with other targeted agents. In the present study, we aimed to identify pathways regulating CD274 (PD-L1) expression in this NSCLC subtype by using RNA sequencing data from The Cancer Genome Atlas (TCGA) lung adenocarcinoma and squamous cell lung carcinoma datasets. We functionally validated our findings using adenocarcinoma cell lines and cocultures with peripheral blood mononuclear cells (PBMCs). Our results indicate that growth factor-dependent MAPK signaling plays an important role in basal and IFNγ-induced PD-L1 expression of lung adenocarcinoma without targetable genetic alterations.

Materials and methods

TCGA data retrieval and analysis

TCGA RNA sequencing V2 and mutation data for lung adenocarcinoma and squamous cell carcinoma [17,18] were obtained from the cBioportal for Cancer Genomics [19] on 14 October 2018. We selected 230 adenocarcinoma and 178 squamous cell carcinoma samples with complete RNA sequencing and whole exome sequencing data. Data were analyzed and visualized using R (available from https://www.r-project.org/) and the R studio interface 1.1.453 (available from https://www.rstudio.com/) and ggplot2 package for R 3.5.1 (available from http://ggplot2.tidyverse.org). Our analysis was performed in 159 lung adenocarcinoma and 166 squamous cell lung carcinoma samples without targetable alterations in EGFR, ALK, ROS1, BRAF, ERBB2, MET or RET [20]. TCGA RNA sequencing data were normalized in two steps. Each expression value was first log10-transformed and then Z-score normalized by subtracting the mean expression of each gene and dividing by the standard deviation. Next, MAPK pathway activation was inferred according to the methods of previously described gene signatures for rat sarcoma (RAS) and MEK activation [21,22]. Inferred pathway activities were calculated as described in the original articles. IFNγ signaling was inferred using IRF1 and STAT1 mRNA levels; STAT3 signaling by using STAT3 gene expression. The correlation of CD274 (PD-L1) mRNA level with these signature scores was calculated using Spearman correlation. To complement this analysis, gene set enrichment analysis (GSEA) was performed on the same samples, using the hallmark PI3K and IFNG signatures in addition to the previously mentioned signatures. Furthermore, we used the C6 oncogenic signaling MEK and EGFR signatures and an alternative PI3K signature. However, the authors doubt whether their signatures, developed for estrogen receptor-positive breast cancer, can be used for other tumor types (http://software.broadinstitute.org/gsea/index.jsp [23,24]). GSEA was performed with 1000 permutations with Z-score normalized CD274 gene expression as a continuous phenotype label. Genes were ranked based on the Pearson Metric.

Cell culture

The human NSCLC cell lines HCC827, H292, A549, H358 and H460 were obtained from the American Type Culture Collection (ATCC, Manassas, VA, USA). H322 was obtained from Sigma-Aldrich (St Louis, MO, USA). All cell lines are from the adenocarcinoma histological subtype, except H292, which is an adenocarcinoma-like mucoepidermoid carcinoma. Cells were quarantined until screening for microbial contamination and mycoplasma was performed and proven to be negative. Cells were tested and authenticated using short tandem repeat profiling. Cells were grown in RPMI with 10% FCS, with 2 mM glutamine added for H322 cells. All cells were incubated in a humidified atmosphere with 5% CO₂ at 37 °C.

Antibodies and treatments

The details of antibodies used for flow cytometry and Western blotting are provided in Supplementary material, Table S1. Western blotting detection was performed using Lumi-Light Western blotting substrate (Roche Diagnostics, Basel, Switzerland). Cells were treated under normal culture conditions with EGF, HGF, IFNγ (each from R&D Systems, Minneapolis, MN, USA), erlotinib (LC Laboratories), cetuximab (Merck KGaA Darmstadt, Germany), selumetinib (AZD6244, Axon Medchem, Reston, VA, USA), XL147 (LC Laboratories), everolimus (Selleckchem, Houston, TX, USA), BMS911543 (Selleckchem) and actinomycin D (Sigma-Aldrich).

siRNA transfection

Cells were transiently transfected with an siRNA targeting STAT3 (Eurogentec, Liege, Belgium) or a negative control siRNA (12935300, Invitrogen, Carlsbad, CA, USA) using oligofectamine (11252011, Invitrogen) in Opti-MEM (51985, Invitrogen) according to the manufacturer’s instructions. Twenty-four hours after transfection, cells were treated with indicated ligands and treatments. After a total of 48 h, STAT3 knockdown efficiency and proteins of interest were analyzed by Western blotting or flow cytometry. All experiments were performed in triplicate.

Flow cytometric analysis

Cells were harvested using trypsin and kept on ice in PBS with 2% FCS during the entire protocol. After staining, cells were kept in PBS with 2% FCS until
analysis. Cells were incubated with anti-PD-L1 antibodies at 10 μg/ml for 45 min. Bound antibody was detected by incubating cells with goat anti-mouse IgG at a 1:50 dilution for 45 min. Measurements were performed on a BD Accuri C6 flow cytometer (BD Biosciences, Franklin Lakes, NJ, USA). Data analysis was performed with FlowJo v10 (Tree Star, Ashland, OR, USA) and surface receptor expression was expressed as mean fluorescence intensity (MFI). Measurements were corrected for background fluorescence and unspecific binding of the secondary antibody. Unless stated otherwise, all experiments were performed in triplicate.

Western blot
Lysates from cells were made using mammalian protein extraction reagent with protease and phosphatase inhibitors diluted 1:100 (Thermo Fisher Scientific, Waltham, MA, USA). Proteins were separated using SDS-PAGE. Target proteins were detected with the appropriate antibodies and images were captured using a digital imaging system (Bio-Rad, Hercules, CA, USA). All bands were observed around the size specified in supplementary material, Table S2A. Densitometric quantitation of target proteins was calculated using ImageJ relative to loading controls β-actin or GAPDH depending on the target protein size (see supplementary material, Table S2B for data).

Viability assays
H292 (8000 cells/well), H358 (20,000 cells/well), A549 (2000 cells/well), H322 (10,000 cells/well) and H460 (2000 cells/well) cells were plated in 96-well plates in their respective media and after 6 h erlotinib or selumetinib was added in concentrations ranging from 0.01 to 10 μM. After 96 h, cells were fixed in 3.7% formaldehyde and stained using crystal violet. After washing, bound crystal violet was dissolved using 10% ethanoic acid and absorption measured at 590 nm. Cell survival was calculated as a percentage of untreated control. All proliferation assays were performed three times in triplicate.

RNA sample collection and qRT-PCR
Total RNA was extracted using Trizol reagent (Invitrogen) and possible DNA contamination was removed using TURBO DNase amp (Life Technologies, AM2238). RNA was then reverse transcribed to cDNA with M-MLV reverse transcriptase (Thermo Fisher Scientific, 28025013). Real-time PCR was performed using IQ SYBR Green Supermix (Bio-Rad, 1708886) according to the manufacturer’s instructions. The following primers were used: CD274 forward 5'-CAATGTTACCAGCACACTGAGA-3', reverse 5'-GCCATAAATAAGATGGCTCCCAGAA-3'; GAPDH forward 5'-CCCCATCTCCACCTTTGGAC-3', reverse 5'-CCACCACCGTGTGCTGTAG-3'. The relative gene expression was calculated using the double delta CT method and GAPDH as a loading control [25]. All qPCR experiments were performed three times in duplicate.

Coculture experiments
Human PBMCs were isolated from whole blood by Ficoll-Paque density centrifugation (Ficoll-Paque PLUS, GE Healthcare Life Sciences, Marlborough, MA, USA) from peripheral blood donated by healthy volunteers. The acquired PBMCs were activated for 72 h using human T-activator CD3/28 beads (Thermo Fisher Scientific) and 100 IU/ml IL-2 (Proleukin, Novartis, Basel, Switzerland) in the presence of tumor cells. Separately, tumor cells were seeded into 96-well plates at a density of 1 × 10^4 cells/well for 48 h. Then, the pre-activated PBMCs were added into the coculture system at a 5:1 ratio of PBMCs to tumor cells. During coculture, cells were treated with EGF (20 ng/ml), erlotinib (10 μM) and selumetinib (10 μM). After 24 h of coculture, cell-free supernatant was collected for IFNγ analysis by ELISA (Sino Biological, Beijing, PR China). Cells were harvested for flow cytometric measurement of membrane PD-L1. In separate experiments, tumor cells were cultured in cell-free supernatant from activated PBMCs. Membrane PD-L1 levels were determined after 24 h using flow cytometry.

Statistics
Cell line experiments were assessed for differences with unpaired two-tailed Student’s t-test or two-way ANOVA followed by Bonferroni post-hoc or Dunnett’s test. Results are represented as means ± SD. A P value < 0.05 was considered statistically significant. Statistical analyses were performed using GraphPad Prism software (version 6.0 GraphPad software).

Results
MAPK pathway activation correlates with CD274 gene expression in lung adenocarcinoma
To study which EGFR-related signaling pathways regulate CD274 expression in NSCLC without targetable genetic alterations, we collected RNA sequencing data of 159 lung adenocarcinoma and 166 squamous cell lung carcinoma samples from TCGA, excluding samples with driver mutations in EGFR, ALK, BRAF, ROS1, MET, ERBB2 and RET. Activating KRAS mutations were present in 75 of the lung adenocarcinoma and in one of the squamous cell carcinoma samples. Activation of the MAPK pathway was determined using validated signatures for RAS or MEK activation [21,22]. MAPK pathway activation scores were significantly higher in KRAS mutant samples (see supplementary material, Figure S1A). In addition, there was a moderate correlation between RAS and MEK activation scores (see supplementary material, Figure S1B). Interestingly, in adenocarcinomas, but not in squamous cell carcinomas,
RAS and MEK activation scores correlated with CD274 gene expression (Figure 1A, Table 1). Subset analysis showed that these correlations were strongest in KRAS wild-type lung adenocarcinomas (Figure 1B and supplementary material, Figure S1C). STAT3 mRNA levels did not correlate with CD274 in any subset (Table 1). In both histological subtypes, mRNA levels of STAT1 and IRF1, important mediators of IFNγ, correlated with CD274 (Figure 1C and supplementary material, Figure S1D), CD8A (rs = 0.73, \( r_s = 0.72 \)), and IFNG (rs = 0.71, \( r_s = 0.74 \)), respectively. Inferred MEK and RAS activities were not significantly correlated with STAT1 (rs = 0.12, \( p = 0.27 \); \( r_s = 0.1 \), \( p = 0.36 \)). Interestingly, a combined score for MAPK and IFNγ signaling, created by adding up 0 to 1 rescaled MEK activation scores and STAT1 levels, correlated more strongly with CD274 mRNA levels (see supplementary material, Figure S1E). GSEA using RAS, MEK and the hallmark IFNG signatures largely confirmed these findings. In addition, GSEA of the PI3K hallmark signature suggested a link between PI3K/mTOR signaling and CD274 (see supplementary material, Table S3). This suggests that activation of the MAPK, PI3K/mTOR and IFNγ pathways is related to increased CD274 mRNA levels in lung adenocarcinomas without targetable genetic alterations.

EGF increases IFNγ-induced PD-L1 expression in NSCLC cells without targetable genetic alterations

A panel of lung adenocarcinoma cell lines without targetable genetic alterations, including a KRAS wild-type (H322), three KRAS mutant (A549, H358 and H460) and a KRAS wild-type adenocarcinoma-like mucoepidermoid carcinoma cell line (H292) [26], was selected to further investigate the relationship between EGFR and IFNγ pathway activation with PD-L1 expression. Membrane PD-L1 was observed in all cell lines, irrespective of KRAS mutation status (see supplementary material, Figure S2A). The highest levels were found in H292, H358 and H460 cells. Levels were comparable with PD-L1 membrane levels of HCC827 EGFR mutant NSCLC cells (see supplementary material, Figure S2A). We wondered whether IFNγ and EGF, known activators of the EGFR, PI3K/mTOR and MAPK pathways, would increase PD-L1 levels in our panel. Treatment with EGF or IFNγ for 24 h using physiologically relevant concentrations (20 ng/ml) [27,28] increased membrane PD-L1 in both KRAS wild-type and KRAS mutant cells (Figure 2A,B). Moreover, exposure of cells to EGF combined with IFNγ resulted in a further increase in PD-L1 compared with IFNγ alone. Prolonged incubation up
EGFR inhibition prevents EGF- and IFNγ-induced PD-L1 upregulation

To analyze the regulation of membrane PD-L1 by EGFR and STAT1 signaling, H292 and H358 cells were treated with EGF and IFNγ in the presence of anti-EGFR monoclonal antibody cetuximab or EGFR small molecule inhibitor erlotinib. Interestingly, cetuximab and erlotinib prevented not only EGF-induced but also IFNγ-induced upregulation of CD274 mRNA levels, which was reflected in reduced membrane and total PD-L1 protein levels (Figure 3A,B and supplementary material, Figure S3A). Data from multiple experiments showed that erlotinib reduced basal PD-L1 membrane levels in H358 but not H292 cells (see supplementary material, Figure S3B). Erlotinib had a similar effect on EGF- and IFNγ-induced PD-L1 membrane levels in two other cell lines but not in the erlotinib-resistant H460 cell line, as expected (see supplementary material, Figure S4A). EGFR inhibition effectively reduced EGFR-dependent MAPK and PI3K/mTOR signaling and modestly decreased IFNγ-induced upregulation of (p)STAT1 (Figure 3B). These results indicate that EGFR- and IFNγ-induced CD274 mRNA and PD-L1 protein and membrane levels are dependent on EGFR-mediated signaling.

MAPK pathway inhibition prevents PD-L1 induction by EGF and IFNγ

Next, we assessed the involvement of MAPK and PI3K/mTOR signaling in PD-L1 upregulation. Selumetinib, an inhibitor of MEK1/2, almost completely suppressed induction of CD274 mRNA by EGF and IFNγ in H292 and H358, and diminished the induction of protein and membrane levels (Figure 4A,B and supplementary material, Figure S3A). Moreover, selumetinib decreased basal PD-L1 membrane levels in H292 and H358 cells (see supplementary material, Figure S3B). Selumetinib effectively inhibited MEK1/2 activity, as reflected in the reduction in pERK1/2 levels, and had a moderate effect on pSTAT1 levels. The effect of selumetinib on membrane PD-L1 was confirmed in additional cell lines (see supplementary material, Figure S4A). PI3K inhibitor XL147 and mTORC1 inhibitor everolimus partially suppressed EGF- and IFNγ-induced PD-L1 in H292 cells, but they had no effect on the induction of membrane PD-L1 (Figure 4A,B). At these concentrations, both drugs effectively inhibited PI3K/mTOR pathway activity, as indicated by reduced pAKT and pS6 levels (Figure 4B). We pursued studying the MAPK pathway because of its major influence on PD-L1 expression. A wide range of selumetinib and erlotinib concentrations was used to determine if lower drug concentrations also reduce PD-L1 expression. After 24 h, even the lowest selumetinib concentration (0.1 μM) strongly reduced pERK levels, as well as PD-L1 protein and membrane expression levels of H292 and H358 cells in both control and EGF- and IFNγ-stimulated cells (see supplementary material, Figure S3C). Treatment with this selumetinib concentration for 96 h resulted in a growth reduction of 30–50% (see supplementary material, Figure S3D), indicating that PD-L1 expression can be manipulated with a MAPK activity inhibitor using concentrations that only partially reduce cell growth. In line with these results, selumetinib had a similar moderate effect on growth in the other three cell lines (see supplementary material, Figure S3C).
MAPK signaling in growth factor- and cytokine-induced PD-L1 expression

Figure 2. EGF and IFNγ induce PD-L1 in NSCLC cell lines. (A and B) NSCLC cell lines without targetable genetic alterations treated with 20 ng/ml EGF, 20 ng/ml IFNγ or both. After 24 h, PD-L1 membrane expression was measured using flow cytometry (Student’s t-test; ns = not significant, *p < 0.05, **p < 0.01 compared with IFNγ, n = 3–11, combined data from all other figures). (C) Membrane PD-L1 levels measured using flow cytometry in cells treated with EGF and IFNγ for 24 or 72 h. Data are represented as MFI/mean corresponding control MFI, n = 3. (D) PD-L1 mRNA levels measured using RT-qPCR on H292 and H358 treated with 20 ng/ml EGF or IFNγ or both for 24 h. Data were analyzed using the double delta CT method and GAPDH as a loading control. (E) Western blotting of protein extracts from H292 and H358 treated with 20 ng/ml EGF, 20 ng/ml IFNγ or both for 1, 24, 48 and 72 h. Actin was used as a loading control. Con, untreated control.

S4B). Similar results were observed with erlotinib. In conclusion, MAPK pathway inhibitors suppress EGFR- and IFNγ-induced CD274 mRNA and PD-L1 protein and membrane expression at concentrations that have a small effect on growth.

HGF induces surface PD-L1 via the MAPK pathway
We investigated whether activation of the MAPK pathway via HGF receptor (cMET) has a similar effect on PD-L1 as MAPK activation by EGFR. Overexpression of cMET and its ligand HGF occur
Figure 3. EGFR inhibition prevents EGF- and IFNγ-induced PD-L1 expression. H292 and H358 cells were treated with 20 μg/ml cetuximab or 10 μM erlotinib with and without cotreatment with 20 ng/ml EGF, 20 ng/ml IFNγ or both for 24 h. (A) Membrane PD-L1 measured using flow cytometry (two-way ANOVA with Dunnett’s multiple comparisons test; **p < 0.01, ***p < 0.001 compared with untreated control). (B) Cellular protein levels measured using Western blotting. Actin was used as a loading control. Data from a representative experiment are shown. C, untreated control; E + I, EGF + IFNγ.

frequently in lung adenocarcinoma tumors [29]. Moreover, upon binding of HGF, cMET is known to activate PI3K/mTOR, MAPK and JAK/STAT pathways, similar to EGFR [30]. HGF enhanced PD-L1 expression and augmented IFNγ-induced PD-L1 expression in the cMET-positive H292 and H358 cell lines (Figure 4C). Combining HGF and EGF had no additional effect on membrane PD-L1 levels compared with single EGF or HGF treatment. Also, in this case, selumetinib effectively prevented HGF-induced effects on PD-L1 levels in both cell lines, whereas erlotinib only showed efficacy in H292 cells. Taken together, these results demonstrate that, irrespective of the upstream growth factor receptor, MAPK pathway activation is essential for PD-L1 membrane expression.

MAPK pathway inhibition does not interfere with IFNγ-induced MHC-I upregulation

Expression of MHC-I is critical for tumor cell antigen presentation and the anti-tumoral immune response [31]. Because both MAPK and IFNγ signaling can influence MHC-I expression, we wondered whether EGFR and MEK1/2 blockade could interfere with its expression in our cell lines [32–34]. IFNγ, but not EGF, increased MHC-I membrane expression in four of five cell lines (Figure 4D and supplementary material, Figure S4C). Moreover, MAPK pathway inhibition using erlotinib and selumetinib did not influence IFNγ-induced upregulation of MHC-I expression, suggesting that MHC-I-mediated tumor cell antigen presentation will not be impaired by these drugs.

MAPK signaling increases stability of CD274 mRNA

To investigate the role of STAT signaling in MHC-I and PD-L1 expression after IFNγ or EGFR treatment, we inhibited STAT1 and STAT3, major transcription factors downstream of IFNγ and EGFR signaling, respectively [6,35]. Suppression of STAT1 signaling using JAK2 inhibitor BMS911543 prevented IFNγ-induced PD-L1 and MHC-I expression, but not EGF-induced PD-L1 expression (Figure 5A and supplementary material, Figure S5A). Also, inhibition of STAT3 using an siRNA had no influence on PD-L1 regulation by MAPK signaling (see supplementary material, Figure S5B). Therefore, we hypothesized that the MAPK pathway may regulate PD-L1 at a post-transcriptional level. KRAS mutations were recently shown to be involved in post-transcriptional regulation of basal PD-L1 levels through modulation of CD274 mRNA stability [36]. To study whether MAPK signaling controls the stability of IFNγ-induced CD274 mRNA, KRAS wild-type and mutant cells were pretreated with IFNγ followed by the addition of the transcriptional blocker actinomycin D [37]. Blocking transcription for 90 min halved CD274
Selumetinib effectively decreases growth factor- and IFNγ-induced PD-L1 expression. H292 and H358 cells were treated with 10 μM XL147, 10 μM everolimus or 10 μM selumetinib, with and without cotreatment with 20 ng/ml EGF, 20 ng/ml IFNγ or both for 24 h. (A) Flow cytometry of membrane PD-L1 (two-way ANOVA with Dunnett’s multiple comparisons test, *p < 0.05, ***p < 0.001 compared with ligand-stimulated control). (B) Western blot of cellular protein levels. Actin was used as a loading control. Data are from a representative experiment (n = 2). (C) Membrane PD-L1 and (D) MHC-1 levels measured by flow cytometry of H292 and H358 cells treated with 10 μM erlotinib or 10 μM selumetinib, with and without cotreatment with 20 ng/ml EGF, 20 ng/ml HGF, 20 ng/ml IFNγ or a combination for 24 h. In (C), two-way ANOVA with Dunnett’s multiple comparisons test, *p < 0.05, **p < 0.01, ***p < 0.001 compared with ligand-stimulated control. (D) Student’s t-test, **p < 0.01. ns, not significant; C, untreated control; XL, XL147; Ev, everolimus; Selu, selumetinib. H+E+I, HGF + EGF + IFNγ.
Figure 5. MAPK signaling increases CD274 mRNA stability. (A) Membrane PD-L1 using flow cytometry and cellular protein levels by Western blotting in cells treated with BMS911543 in the presence of 20 ng/ml EGF and IFNγ for 24 h. Blot from a representative experiment (n = 2). (B) RT-qPCR of CD274 mRNA levels (PD-L1) in H292 and H358 cells initially treated with IFNγ for 24 h, then with 5 μg/ml actinomycin D for 10 min, followed by 20 ng/ml IFNγ, 20 ng/ml EGF or 10 μM selumetinib for 80 min. Data were analyzed using the double delta CT method and GAPDH as a loading control (two-way ANOVA with Tukey’s test, *p < 0.05, **p < 0.01, ***p < 0.001). Con, untreated control; E+I, EGF + IFNγ; ActD, actinomycin D.

MAPK pathway inhibition decreases PBMC-induced PD-L1 surface expression

To study the relationship between immune cell activation and PD-L1 expression of tumor cells, we performed cocultures of PBMCs and NSCLC cells. After 24 h coculture, membrane PD-L1 and MHC-I were strongly induced in tumor cells (Figure 6A,B). Conditioned medium from activated PBMCs contained IFNγ (30 ng/ml) in comparable levels to our other experiments and also strongly induced membrane PD-L1, indicating that IFNγ may be involved in PBMC-induced PD-L1 (see supplementary material, Figure S6A). Similar to our previous experiments, EGF further enhanced tumor cell MAPK pathway activity and PD-L1 expression, which was counteracted by erlotinib and selumetinib, without influencing MHC-I (Figure 6A,B and supplementary material, Figure S6A). Our results indicate that MAPK pathway inhibition can reduce tumor cell PD-L1 in a more complex coculture system, without interfering with MHC-I induction in tumor cells, potentially improving the immunogenicity of these cells.

Discussion

In this study we revealed a correlation between MAPK pathway activation and CD274 expression in lung adenocarcinomas without targetable genetic alterations using TCGA RNA sequencing data. Subsequently, we demonstrated the importance of MAPK signaling in the upregulation of PD-L1 by growth factors and IFNγ in lung adenocarcinoma cell lines, which was mediated through CD274 mRNA stability and STAT1 activation (Figure 6C). Inhibition of the MAPK pathway prevents growth factor-, IFNγ- and PBMC-induced PD-L1
MAPK signaling in growth factor- and cytokine-induced PD-L1 expression

Figure 6. Erlotinib and selumetinib prevent PBMC-induced PD-L1, but not MHC-I expression, in NSCLC cells. (A) H292 and H358 cells were cocultured with 72 h pre-activated PBMCs from healthy volunteers at a ratio of five PBMCs per tumor cell. During coculture, cells were treated with 20 ng/ml EGF, and 10 μM erlotinib or 10 μM selumetinib. Membrane PD-L1 was measured by flow cytometry after 24 h (two-way ANOVA with Bonferroni’s multiple comparisons method, **p < 0.01, ***p < 0.01 compared with control + pre-activated PBMCs). (B) Membrane MHC-I measured using flow cytometry (two-way ANOVA, *p < 0.05, **p < 0.01 compared with control). R, resting PBMCs; A, activated PBMCs. (C) Proposed model for the role of IFNγ and MAPK signaling in PD-L1 regulation in lung adenocarcinoma. IFNγ derived from tumor infiltrating immune cells induces CD274 transcription in tumor cells through activation of JAK/STAT signaling. CD274 mRNA is translated into PD-L1 protein, which is transported to the cell membrane. Growth receptor- and mutated KRAS-induced MAPK signaling increases STAT signaling, potentially adding to transcriptional activity. Also, MAPK signaling increases the stability of CD274 mRNA, resulting in increased mRNA and protein levels, and subsequently increasing PD-L1 membrane expression.
stabilization at the cell membrane [15,43–45]. However, we found no direct effect of EGF or IFNγ on CKLF-like MARVEL transmembrane domain containing protein 6 (CMTM6) protein levels in H292 or H358 cells (data not shown).

Our experiments demonstrated that both EGFR and MEK1/2 inhibitors decrease EGF- and IFNγ-induced PD-L1 expression, potentially increasing immunogenicity of lung adenocarcinoma cells. Nevertheless, because the MAPK pathway is downstream of a plethora of growth factor receptors, downstream inhibition with MEK1/2 inhibitors may be more effective to modulate PD-L1 than inhibition of specific growth factor receptors. This is supported by our finding that MEK1/2 inhibition, but not EGFR inhibition, prevented HGF-induced PD-L1 expression and by earlier findings [46]. This is supported by a fellowship of the Junior Scientific Master Class (JSM) of the University of Groningen.

In conclusion, our results show the importance of growth factor-induced MAPK pathway signaling in lung adenocarcinoma without targetable genetic alterations, because these have a more inflamed tumor microenvironment and respond better to immune checkpoint inhibitors than tumors with targetable genetic alterations, such as EGFR mutations [1,2]. These combination strategies are currently being tested in NSCLC patients (NCT03600701, NCT03299088).

In conclusion, our results show the importance of growth factor-induced MAPK pathway signaling in lung adenocarcinoma without targetable genetic alterations. This provides a rationale to explore the combination of MAPK pathway inhibitors with immunotherapy in this lung cancer subtype.

This work was supported by a POINTING grant of the Dutch Cancer Society to EGE de Vries. TS Stutvoet is supported by a fellowship of the Junior Scientific Master Class (JSM) of the University of Groningen.

Author contributions statement

TS, AK, AT and SJ designed, performed and interpreted the experiments. EV gave valuable input on structuring the experiments. MB and RF, respectively, guided the coculture and in silico experiments. TS and AK wrote the manuscript and put the figures together. EV, MB, RF, AT and SJ made revisions and proofread the manuscript. All authors read and approved the final manuscript.
