We construct five massive deformations of the unique nine–dimensional \( N = 2 \) supergravity, each with two parameters. All of these deformations have a higher–dimensional origin via Scherk–Schwarz reduction and correspond to gauged supergravities. The gauge groups we encounter are \( SO(2) \), \( SO(1,1\!+) \), \( R \), \( R^+ \) and the unique two–dimensional non–Abelian Lie group \( C R_1 \), which consists of scalings and translations in one dimension.

We make a systematic search for two classes of vacuum solutions: maximally symmetric solutions with constant scalars and half-supersymmetric domain wall solutions. In the first category we find explicit solutions in the form of (non-supersymmetric) de Sitter space solutions. In the second category we find precisely the three classes of domain wall solutions that were given in an earlier work.

1. Introduction

The procedure of gauging a global symmetry includes the replacement of the ordinary derivative by a covariant derivative:

\[
\partial_\mu \longrightarrow D_\mu = \partial_\mu + gA_\mu .
\]

Here \( A_\mu \) is the gauge field and \( g \) is the gauge coupling constant which acts as a deformation parameter of the ungauged theory. In the case of Einstein gravity with scalars one can consider as an independent deformation the addition of a scalar potential \( V(\varphi) \):

\[
R + (\partial \varphi)^2 \rightarrow R + (\partial \varphi)^2 + m^2 V(\varphi) .
\]

In the supersymmetric case, i.e. the case of gauged supergravity, the two deformations are not independent. Supersymmetry relates the two deformation parameters:

\[
g = m .
\]

Due to the scalar potential the Minkowski spacetime is no longer a maximally supersymmetric vacuum solution of the gauged supergravity. Instead we will search for other vacuum solutions, like, e.g., non-supersymmetric de Sitter space solutions. A natural class of half-supersymmetric vacuum solutions that makes use of the scalar potential is the set of domain wall solutions. Recently, domain wall solutions of supergravity theories have attracted attention in view of their relevance for a supersymmetric Randall-Sundrum scenario \([1,2]\), the domain wall/QFT correspondence \([3,4]\) and applications to cosmology \([5,6]\). In all these applications the properties of the domain walls play a crucial role and these properties are determined by the details of the scalar potential.

Motivated by this we studied general domain wall solutions in \( D=9 \) dimensions \([7]\). We took \( D=9 \) because on the one hand this case shares some of the complexities of the lower-dimensional cases, on the other hand the scalar potential for this case is simple enough to study the corresponding domain wall solutions in full detail. The supergravity theory we considered in \([7]\) was obtained by a generalized Scherk-Schwarz (SS) reduction of \( D=10 \) IIB supergravity. This is not the most general possibility in \( D=9 \). In this talk we will present a systematic search for massive deformations of the unique \( D=9 \), \( N=2 \) supergravity theory. All deformations we find correspond to gauged supergravities. The hope is that the \( D=9 \) case will teach us something about the more complicated situation in \( D < 9 \) dimensions. The results presented in this talk are taken from \([8]\).
2. Massive deformations of D=9, N = 2 Supergravity

The field content of the unique D = 9, N = 2 massless supergravity theory is given by (i = 1, 2)

\[ e_\mu^a, \phi, \varphi, \chi, A_\mu, A^{(i)}_\mu, B^{(i)}_{\mu\nu}, C_{\mu\nu\rho}, \psi_\mu, \lambda, \tilde{\lambda}. \]

(4)

The massless 9–dimensional theory has four global scaling symmetries, with parameters \( \alpha, \beta, \gamma \) and \( \delta \), respectively. The scaling weights of all these symmetries are given in Table 1.

It turns out that only three out of the four scaling symmetries given in Table 1 are linearly independent. There is a relation

\[ \frac{4}{9} \alpha - \frac{8}{9} \beta = \gamma + \frac{1}{2} \delta. \]

(5)

The massless \( N=2 \), D=9 theory also has an \( SL(2, \mathbb{R}) \) symmetry whose explicit rules can be found in [8].

We now turn to massive deformations of the 9D theory. To obtain these deformations we will apply a SS reduction which can be best illustrated by an example. Consider a single scalar field:

\[ \hat{\mathcal{L}} = \sqrt{-g}(\partial \varphi)^2, \]

(6)

which is invariant under the \( \mathbb{R} \)-symmetry \( \varphi \rightarrow \varphi + c \). In the SS procedure one gives the field a dependence on the compactification coordinate \( z \) which is governed by a global symmetry, in this case the \( \mathbb{R} \)-symmetry:

\[ \hat{\varphi}(x, z) = \varphi(x) + mz. \]

(7)

Using the standard reduction rules the Lagrangian reduces to

\[ \mathcal{L} = \sqrt{-g} \left( (D\phi)^2 + m^2 \right), \]

(8)

where \( D_\mu \phi = \partial_\mu \phi - mA_\mu \) with \( A_\mu \) being the Kaluza-Klein vector.

Applying the above outlined SS dimensional reduction we obtain a number of massive deformations in nine dimensions, as illustrated in Figure 1. By employing the different global symmetries of 11D, IIA and IIB supergravity we obtain

Table 1: The scaling weights of the 9 dimensional supergravity fields.
Figure 1. Overview of all reductions discussed in this talk. These cases can all be interpreted as gauged supergravities, with gauged symmetry and corresponding gauge field as given in the Figure. Mass parameters in the same box, such as $m_{11}, m_{\text{IIA}}$ or $m_1, m_2, m_3$, form a multiplet under $SL(2, \mathbb{R})$. 

(Non-)Abelian gauged supergravities in nine dimensions
seven deformations of the unique $D = 9$ supergravity.

Note that the different massive deformations can be related. Symmetries of the massless theory become field redefinitions in the massive theory that only act on the massive deformations. This means that the mass parameters transform under such transformations: they have a scaling weight under the different scaling symmetries and under such transformations: they have a scaling weight under the different scaling symmetries and fall in multiplets of $SL(2, \mathbb{R})$. In Table 2 the multiplet structure of the massive deformations under $SL(2, \mathbb{R})$ is given. The mass parameter $m_4$ is defined as the S-dual partner of $m_4$ and can not be obtained by a SS reduction of IIA supergravity. All these deformations correspond to a non-Abelian gauge group provided

gauging of a 9D global symmetry. In particular, it is always the symmetry that is employed in the SS reduction Ansatz that becomes gauged upon reduction. The corresponding gauge vector is always provided by the metric, i.e. is the Kaluza–Klein vector of the dimensional reduction. In all but one case this is the complete story and one finds an Abelian gauged supergravity. It turns out that there is one exception, i.e. the case with $m_{1B} \neq 0$, where we find a non-Abelian gauge symmetry. The (non-semi-simple) gauge group is $C\mathbb{R}^1$, the group of scalings and translations of the real line. Further details of the different massive deformations can be found in [8].

3. Combining Massive Deformations

We next try to combine the different massive deformations we found above. Requiring that the fermionic field equations transform under supersymmetry to a complete set of bosonic field equations restricts us to five cases, each containing two nonzero mass parameters:

- **Case 1** with $\{m_{1A}, m_4\}$: this combination can also be obtained by Scherk-Schwarz reduction of IIA employing a linear combination of the symmetries $\hat{\alpha}$ and $\hat{\beta}$, guaranteeing its consistency. It is also a gauging of both this symmetry and (for $m_4 \neq 0$) the parabolic subgroup of $SL(2, \mathbb{R})$ in 9D, giving the non-Abelian gauge group $C\mathbb{R}^1$.

- **Case 2,3,4** with $\{\tilde{m}, m_{1B}\}$: as in the case with $m_{1B} = 0$ and only $m$ this combination contains three different, inequivalent cases depending on $\tilde{m}^2$ (depending crucially on the fact that $m_{1B}$ is a singlet under $SL(2, \mathbb{R})$):
  - **Case 2** with $\{\tilde{m}, m_{1B}\}$ and $\tilde{m}^2 = 0$.
  - **Case 3** with $\{\tilde{m}, m_{1B}\}$ and $\tilde{m}^2 > 0$.
  - **Case 4** with $\{\tilde{m}, m_{1B}\}$ and $\tilde{m}^2 < 0$.

All these combinations can also be obtained by Scherk-Schwarz reduction of IIB employing a linear combination of the symmetries $\hat{\delta}$ and (one of the subgroups of) $SL(2, \mathbb{R})$, guaranteeing its consistency. All cases (assuming that $m_{1B} \neq 0$) correspond to the gauging of an Abelian non-compact symmetry in 9D. Only in the special case $\tilde{m}^2 < 0$, $m_{1B} = 0$ corresponds to a SO(2)–gauging.

- **Case 5** with $\{m_4 = -\frac{12}{\bar{m}} m_{1A}, m_2 = m_3\}$: this case can be understood as the generalized dimensional reduction of Romans’ massive IIA theory, employing the $\mathbb{R}^+$ symmetry that is not broken by the $m_R$ deformations: $\hat{\beta} = \frac{\hat{\alpha}}{12}$. It gauges both this linear combination of $\mathbb{R}^+$’s and the parabolic subgroup of $SL(2, \mathbb{R})$ in 9D, giving a non-Abelian gauge group provided $m_4 \neq 0$.

All five cases are gauged theories and have a higher-dimensional origin. Both case 1 and case 5 have a non-Abelian gauge group provided $m_4 \neq 0$. 

4. Solutions

We have constructed a variety of gauged supergravities with 32 supersymmetries. They all have in common that there is a scalar potential. Our next goal is to make a systematic search for solutions that are based on this scalar potential. In the next Subsections we will search for two types of solutions: (i) $1/2$ BPS domain wall (DW) solutions and (ii) maximally symmetric solutions with constant scalars. We find that, looking for $1/2$ BPS solutions it is convenient to solve the Killing spinor equations, which are obtained by setting the supersymmetry variation to zero. The projector for a DW is given by $\frac{1}{2}(1 \pm \gamma_9)$, where $\gamma$ denotes the transverse direction. We find that, in order to make a projection operator in the Killing spinor equations, we are forced to set all mass parameters to zero except for $\mathbf{m}$, which corresponds to cases 2, 3 and 4 of Section 3 with $m_{\text{IIB}} = 0$. This is a consistent combination of masses and we obtain three classes of domain wall solution which were discussed in detail in [7].

To summarize, we find that there are no new codimension-one $1/2$ BPS solutions to the D=9 supergravity theories we obtained in the previous Sections, as compared to the three classes of domain wall solutions given in [7].

4.2. Maximally Symmetric Solutions with Constant Scalars

The second category of vacuum solutions we consider are the solutions with all three scalars constant. This is a consistent truncation in two cases which both have two mass parameters. In this truncation one is left with the metric only satisfying the Einstein equation with a cosmological term

$$R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R = -\Lambda g_{\mu\nu},$$

with $\Lambda$ quadratic in the two mass parameters. Depending on the sign of this term one thus has anti-de Sitter, Minkowski or de Sitter geometry.

We find that solutions with constant scalars are possible in the following massive supergravities:

- **D=10** with $\{m_{11}\}$ has $\Lambda = +36m_{11}^2 e^{-3\phi/2}$, which gives rise to de Sitter$_{10}$ [12], breaking all supersymmetry. The D=11 origin of this solution is Mink$_{11}$ written in a basis where the $x$-dependence is of the required form [12]:

$$ds^2 = e^{2m_{11}x} (-dt^2 + e^{2m_{11}t} dx_9^2 + dx^2).$$

- **D=9, Case 1** with $\{m_{11A} = -\frac{3}{4} m_4\}$ has $\Lambda = +\frac{63}{4} m_4^2 e^{\phi/\sqrt{7}}$, which gives rise to De Sitter$_9$, breaking all supersymmetry. This case follows from the reduction of Mink$_{10}$ by using a combination of IIA scale symmetries that leave the dilaton invariant so that. This particular scale symmetry allows a SS reduction of a configuration with a zero dilaton so that, after reduction, one is left with a non-trivial metric field only.

- **D=9, Case 4** with $\{m_{\text{IIB}}, m_3\}$ has $\Lambda = +28 m_{\text{IIB}}^2 e^{4\phi/\sqrt{7}}$, which gives rise to de Sitter$_9$ for non-vanishing $m_{\text{IIB}}$. This case follows from the reduction of Mink$_{10}$ by using a combination of IIB scale symmetries.
that leave the dilaton invariant. Note that for vanishing \( m_{\text{IIB}} \) this reduces to Mink_9, despite the presence of \( m_3 \) [13]. For either \( m_{\text{IIB}} \) or \( m_3 \) non-zero this solution breaks all supersymmetry.

5. Conclusions

We have constructed five different D=9 massive deformations with 32 supersymmetries, each containing two mass parameters. All these five theories have a higher–dimensional origin via SS reduction from D=10 dimensions. Furthermore, the massive deformations gauge a global symmetry of the massless theory. The gauge group we have obtained are the Abelian groups \( SO(2), SO(1,1)^+, \mathbb{R}, \mathbb{R}^+ \) and the unique two–dimensional non-Abelian Lie group \( C\mathbb{R}^1 \) of scalings and translations on the real line.

We have analyzed the possibility of combining massive deformations to obtain more general massive supergravities that are not gauged or do not have a higher–dimensional origin. Our analysis shows that the only possible combinations are the five two–parameter deformations, which are all gauged and can be uplifted. We have not made a systematic search for massive D=9 supergravities that are not the combination of gaugings and we cannot exclude that there are more possibilities. This requires a separate calculation.

Finally, not all gauged supergravities we constructed are necessarily the leading terms in a low-energy approximation to (compactified) superstring theory. The deformations with \( m \neq 0 \) or \( m_{\text{IIA}} = \frac{1}{12}m_4 \neq 0 \) definitely correspond to a sector of (compactified) string theory. The other cases are less clear sofar [8].
