Received 3 February 1997/Accepted 26 March 1997

The gene encoding the di- and tripeptide transport protein (DtpT) of *Lactobacillus helveticus* (DtpTLH) was cloned with the aid of the inverse PCR technique and used to complement the dipeptide transport-deficient and proline-auxotrophic *Escherichia coli* E1772. Functional expression of the peptide transporter was shown by the uptake of prolyl-[¹⁴C]alanine in whole cells and membrane vesicles. Peptide transport via DtpT in membrane vesicles is driven by the proton motive force. The system has specificity for di- and tripeptides but not for amino acids or tetrapeptides. The *dtpT* gene consists of 1,491 bp, which translates into a 497-amino-acid polypeptide. DtpTLH shows 34% identity to the di- and tripeptide transport protein of *Lactococcus lactis* and is also homologous to various peptide transporters of eukaryotic origin, but the similarity between these proteins is confined mainly to the N-terminal halves.

*Lactobacillus helveticus* is a gram-positive, facultatively anaerobic thermotolerant lactic acid bacterium that is highly adapted to growth in milk. Although milk contains free amino acids, the amounts are too limited for growth to high cell densities. In order to obtain the amino acids needed for growth, lactic acid bacteria, in general, use a proteolytic system that consists of an extracellular proteinase, peptide transport systems, and intracellular peptidases (11, 17).

The proteolytic system of *L. helveticus* has recently received a lot of attention (reviewed in reference 11), and the available data suggests that this system is very comparable to that of *Lactococcus lactis*. The proteinase and peptidases of *L. helveticus* are similar to those of *Lactococcus lactis*, but the overall proteolytic activity of *L. helveticus* is higher than that of *Lactococcus lactis* (18). *L. helveticus* also possesses several amino acid transport systems with properties similar to those of *Lactococcus lactis* (15). In our studies on peptide metabolism in *L. helveticus*, we found an open reading frame (ORF) downstream of the *pepN* gene whose deduced amino acid sequence is homologous to that of the di- and tripeptide transport protein of *Lactococcus lactis* (6). In this article, we report the cloning of this gene, the functional expression of the protein in *Escherichia coli*, and the characterization of this protein as a di- and tripeptide transporter.

**MATERIALS AND METHODS**

**Bacterial strains, plasmids, and growth conditions.** The bacterial strains and plasmids used are listed in Table 1. *L. helveticus* was grown at 37°C in MRX broth plus 0.5% glucose (19). *E. coli* strains were grown aerobically at 37°C in Luria broth (17a). When needed, ampicillin (100 μg/ml) and kanamycin (40 μg/ml) were added to the indicated concentrations.

**Chromosomal DNA preparation.** Chromosomal DNAs of *L. helveticus* NCD02712 and SBT2171 were prepared essentially as described by Delley et al. (3). Exponentially growing cells (10 ml) were harvested by centrifugation and washed twice with 100 mM potassium phosphate (pH 7.0). The cells were suspended in 1 ml of 10 mM Tris-HCl (pH 7.8) containing 1 mM EDTA and treated with proteinase K (250 μg/ml) and proteinase E (500 μg/ml) for 30 min at 37°C. The cells were washed with TE (10 mM Tris-HCl plus 1 mM EDTA [pH 7.5]) and resuspended in 1 ml of TE. After a digestion of mutanolysin (160 U), the mixture was incubated at 37°C for 30 min. Subsequently, sodium dodecyl sulfate, EDTA, and protease K were added to final concentrations of 0.1%, 75 mM, and 200 μg/ml, respectively, and the incubation continued for 2 h at 65°C. After a wash with phenol-chloroform (50:50 [vol/vol]; three times), chromosomal DNA was precipitated and dissolved in TE with DNase-free RNase (20 μg/ml) overnight at 4°C.

**Southern hybridization.** Chromosomal DNA, digested with the appropriate restriction enzymes, was separated by agarose gel electrophoresis and transferred to a Zeta-blots membrane with the alkaline lysis method (1). Other methods were performed according to standard procedures (17a). In vitro amplification of DNA was performed with Pwo polymerase by using the recommended buffer plus 2 mM MgSO₄ (Boehringer Mannheim GmbH). Amplified DNA was purified with QIAquick PCR purification kit (Qiagen) and analyzed by agarose gel electrophoresis.

**Cloning of dtpT by inverse PCR.** The 5' region of an open reading frame downstream of pepN in *L. helveticus* (2) was found to be homologous to dtpT of *Lactococcus lactis* (dtpTLH). The PCR technique was used to clone a 2.4-kb DNA fragment that encompassed the 3' end of pepN and part of the *L. helveticus* *dtpT* gene (*dtpTLH*). The oligonucleotides PF (5'-GGTCATCGAACAGGTCATG-3') and PR (5'-GTTCACATTAGAACTCAG-3') were used to synthesize this fragment, which was subsequently used to identify a 2.4-kb *Hpa*I fragment by Southern hybridization; the *Hpa*I fragment contained the entire *dtpT* gene. *Hpa*I fragments were extracted from an agarose gel and ligated with T4 DNA ligase (Boehringer Mannheim GmbH). By using oligonucleotides IF (5'-GGCGATGTCTTGGACAGCGCCGAGGC-3') and IR (5'-CCGGAGGATCCACCAGGCAAGG-3') the *dtpT* gene was amplified by inverse PCR, following digestion with EcoRV and BamHI, and ligated into pTAQI (digested with EcoRV plus BamHI; removal of lac promoter region). The recombinant plasmids were used to transform the dipeptide transport-deficient and proline-auxotrophic *E. coli* E1772. The transformed bacteria were spread on M9 agar, supplemented with ampicillin (100 μg/ml) plus 100 μM Pro-Gly as sole source of proline.

**DNA sequence.** DNA was sequenced by the dideoxy method using [³²P]-dATP plus the T7 DNA polymerase kit (Pharmacia) or an automatic sequencing apparatus (Waters) using fluorescent oligonucleotides and cycle sequencing. Prior to the sequencing, fragments were subcloned or shortened by exonuclease III treatment. DNA sequence was determined with the Zeta-plus blotting membrane (Bio-Rad). DNA was labeled with digoxigenin by the Klenow reaction, hybridized at stringent conditions (65°C), and visualized with the CSPD luminescent detection kit (Boehringer Mannheim GmbH).

in 50 mM 2-(N-morpholino)ethanesulfonic acid (MES)-KOH with 2 mM MgSO4 (pH 6.5) and stored in liquid nitrogen until use.

Transport assay using nonradio-labelled peptides. Overnight cultures of L. helveticus NCDO2712 were diluted 20-fold into glucose-MRX medium and incubated for 5 h at 37°C. The cells were washed twice and resuspended in 50 mM potassium phosphate (KP) (pH 6.5). Subsequently, the cells were de-energized with 10 mM 2-deoxyglucose for 20 min at 37°C. The de-energized cells were washed twice and resuspended in MES-KOH supplemented with 2 mM MgSO4 (pH 6.5). The transport assays with alanine, dialanine, trialanine, and tetra-alanine as substrates were carried out as described by Kunji et al. (12), with (pH 6.5). The transport assay using L-prolyl-[14C]alanine.

Cloning and functional expression of dtpTLL in E. coli. Sequence comparisons showed that a gene encoding a putative di- and tripeptide transport protein was present downstream of pepN in L. helveticus (2). The N-terminal 55 amino acids of DtpTLL are 55% identical with DtpTLL. The entire gene encoding the peptide transport protein of L. helveticus was isolated by inverse PCR and ligated into pTAO1, yielding pTDH. Plasmid pTDH was used to transform the peptide transport-deficient and proline-auxotrophic E. coli E1772 (16). The recombinant strain was able to grow on a medium containing Pro-Gly as source of proline, suggesting that the peptide transport gene was expressed functionally.

Subsequent transport experiments confirmed this suggestion. E. coli E1772/pTDH takes up Pro-[14C]Ala at a higher rate than the parent strain (E1772/pTAO1) (Fig. 2). Figure 2 also shows the uptake of Pro-[14C]Ala by E1772/pDT5 (carrying dtpTLL) for comparison. Since the tac promoter region of pTAO1 is missing in pTDH, the cloned gene (dtpTLL) is most likely expressed from its own promoter.

Southern hybridization experiments with the dtpTLL gene as probe confirmed that dtpTLL is present in both L. helveticus NCDO2712 and SBT2171.

The DNA sequence of dtpTLL and the translated amino acid sequence are shown in Fig. 3. An open reading frame of 1,491 nucleotides, encoding a 497-amino-acid polypeptide, was found. The translation initiation site was selected on the basis of the alignment of the protein sequence to DtpTLL (see below). A putative ribosome binding site (5′-GGGAG) is found 19 nucleotides upstream of the start codon. Putative –35 (5′-TGGACA) and −10 (5′-TTATTT) regions, separated by 18 nucleotides, are found in the noncoding region between pepN and dtpTLL. Terminus-like structures are present downstream of pepN and dtpTLL, suggesting that the two genes are

2-deoxyglucose-treated cells. In order to eliminate the possibility that the peptides were degraded outside the cells, i.e., prior to uptake, the extracellular aminopeptidase activity was measured. Aminopeptidase activity (0.178 at A405) was detected in the cell extract (following sonication), but no such activity was found in the extracellular medium, not even after prolonged incubation of the cells in the buffer used for the transport assays. The same observations were made for the industrial strain SBT2171, which possesses very high proteolytic activity (18).

RESULTS

Characterization of peptide transport in L. helveticus. L. helveticus NCDO2712 takes up in the presence of an energy source the l-alanine and the peptides dialanine, trialanine, and tetra-alanine. However, after dansylation and HPLC of the intracellular fraction only free alanine could be detected (Fig. 1). This suggests that the peptides are degraded immediately after uptake. A lag phase in the accumulation of alanine during uptake of alanine or peptides was found to be caused by the ATP synthesis and proton motive force generation during glucose metabolism, i.e., there is a lag in the energy generation of

FIG. 1. Uptake of alanine and alanine-containing peptides by L. helveticus NCDO2712. Cells were de-energized with 2-deoxyglucose as described in Materials and Methods, and the uptake of alanine (V), dialanine (O), trialanine (□), or tetra-alanine (¶) as a substrate was monitored in glucose-metabolizing cells. The final concentration of alanine and peptides was 0.5 mM. Glucose was added 2 min prior to the addition of alanine and alanine-containing peptides.
transcribed separately. The terminator downstream of \(dtpT_{LH}\) consists of a stem of 12 nucleotides and has a \(\Delta G\) of \(-71\) kJ/mol at 25°C.

The overall G+C content of \(dtpT_{LH}\) is 38.6%, which matches well with that of the genome of \(L. helveticus\) (from 38 to 40%). From the \(dtpT_{LH}\) gene a primary amino acid sequence of the DtpT LH protein was deduced; the protein has 68% nonpolar amino acids, a value typical of a membrane protein. Hydrophathy profiling suggested 12 hydrophobic stretches that are long enough to span the membrane in a zigzag fashion; the transmembrane segments are indicated in Fig. 3.

**Properties of DtpT\(_{LH}\).** Membrane vesicles prepared from \(E. coli\) E1772 do not transport Pro-[\(^{14}\)C]Ala in the presence of the electron donor system ascorbate-PMS (data not shown). However, membrane vesicles of strain E1772/pTDH transport this peptide well under those conditions (Fig. 4). This shows that DtpT\(_{LH}\) indeed codes for the di- and tripeptide transporter and that transport of Pro-[\(^{14}\)C]Ala is driven by the proton motive force. The role of the proton motive force was further demonstrated by using ionophores. Valinomycin, which dissipates the membrane potential (K\(^+\) ionophore), and nigericin, which dissipates the pH gradient (K\(^+\)/H\(^+\) ionophore), inhibited transport of Pro-[\(^{14}\)C]Ala significantly (Fig. 4). The presence of both ionophores completely collapsed the proton motive force and reduced the uptake of Pro-[\(^{14}\)C]Ala to equilibration.
levels. These observations indicate that transport of Pro-\(^{14}\)CAla is most likely electrogenetic and occurs in symport with a proton(s).

Information about the substrate specificity of DtpT LH was obtained by following the transport of Pro-\(^{14}\)CAla in the presence of an excess (50-fold) of amino acids or peptides (Table 2). Alanine, tetra-alanine, and Leu-enkephalin (pentapeptide) did not affect the transport of Pro-\(^{14}\)CAla, while di- and trialanine, Pro-Gly, and Phe-Ala strongly inhibited the uptake. Also the branched-chain amino acid-containing peptides di-Leu and tri-Leu inhibited Pro-\(^{14}\)CAla uptake to a great extent, whereas Phe-Val and Leu-Val had much smaller inhibitory effects. These results show that DtpT LH is a di- and tripeptide transporter just as DtpT LL.

**Sequence alignments.** The sequence alignment of DtpT LH and DtpT LL is shown in Fig. 5. Overall, DtpT LH has 34.0% amino acid identity to DtpT LL. Interestingly, the identity is confined largely to the N-terminal halves of the proteins (47.0% identity for the N-terminal 243 amino acids). Not only the sequences but also the hydropathy profiles of DtpT LH and DtpT LL were found to be significantly different at the extreme C-terminal ends of the proteins. Database searches showed that DtpT LH is a member of the peptide transport (PTR) family (19), which includes various peptide transporters of eukaryotic origin. The PTR consensus motif, F-(Y/V/F)-(W/F)-(h)-X-I-N-(h/M)-G-(S/L)-(L/F)-(h/S) (h indicates a hydrophobic residue) (19), is present in the fifth putative membrane-spanning region of DtpT LH as well as in eukaryotic members of the PTR family. Also in this family the similarity is confined mainly to the N-terminal halves of the proteins.

DISCUSSION

In this article, the cloning and characterization of the di- and tripeptide transport gene of \textit{L. helveticus} (\textit{dtpT}144) are described. The \textit{dtpT}144 gene is located downstream of the gene encoding the general aminopeptidase N (\textit{pepN}). The \textit{dtpT}144 gene can be functionally expressed in \textit{E. coli}, presumably from its own promoter.

Studies of peptide transport in \textit{L. helveticus} suggested the presence of a di-, tri-, and also oligopeptide transport system(s). The cloning of the \textit{dtpT}144 gene and the subsequent characterization of \textit{DtpT}144 established that this system is specific for transport of di- and tripeptides. Substrate specificity studies suggest that \textit{DtpT}144 has a preference for more hydrophilic peptides just like \textit{DtpT}1.4. Di- and tripeptides containing hydrophobic amino acids, such as Phe-Val and Leu-Val, inhibit Pro-[14C]Ala uptake only slightly, although the hydrophobic peptides Leu-Leu and Leu-Leu-Leu are quite effective inhibitors of Pro-Ala transport. Foucaud et al. (4) reported that the substrate specificities of \textit{DtpT} and an ATP-dependent di- and tripeptide uptake system (\textit{DtpP}) in \textit{Lactococcus lactis} overlap but that hydrophobic branched-chain amino acid-containing peptides are transported preferentially by \textit{DtpP}. Similar to what is suggested by this study, peptides like Leu-Leu and Leu-Leu-Leu are transported efficiently by \textit{DtpT} of \textit{Lactococcus lactis}, whereas other branched-chain-amino-acid-containing peptides are poor substrates.

Recently, Klein et al. (10) reported the cloning of a gene, \textit{dppE}, encoding a protein involved in dipeptide transport in \textit{Lactobacillus delbrueckii} subsp. \textit{lactis}. Although the primary sequence has not been published, this transporter appears to be different from \textit{DtpT}144 because \textit{DppE} has been reported to be 30% identical to DciAE (14), which encodes the binding protein of the dipeptide transport system of \textit{Bacillus subtilis}. DciAE is a member of the ATP-binding cassette (ABC) transporter superfamily (8). Possibly, \textit{DppE} encodes a \textit{DtpP}-like di- and tripeptide transporter.

The amino acid transport systems of \textit{L. helveticus} were found to have properties similar to those of \textit{Lactococcus lactis} (15). This study shows also that the di- and tripeptide transport system \textit{DtpT}144 is very similar to that of \textit{Lactococcus lactis} (6). On the other hand, the proteinase gene of \textit{L. delbrueckii} subsp. \textit{bulgaricus} (\textit{prtB}) is quite different from the one of \textit{Lactococcus lactis} (5). The proteins of \textit{Lactococcus lactis} and \textit{L. delbrueckii} subsp. \textit{bulgaricus} belong to different serine proteinase subfamilies, i.e., subtilisin and cysteine-subtilisin, respectively. However, the peptides released from \textit{\beta}-casein by the two proteinases appear to be very similar (11). To what extent the proteolytic pathways of \textit{Lactococcus lactis} and \textit{L. helveticus} (or other lactobacilli) are similar or different remains to be determined.
