Abstract

Background: Soft-tissue grafting to thicken the soft tissue around dental implants was proposed to ameliorate the esthetic outcome. Traditionally, connective tissue is used as a grafting material, but a xenogeneic collagen matrix was introduced as an alternative to reduce patient morbidity.

Methods: A total of 60 patients randomly received either no graft (n = 20, NG group), a connective tissue graft (n = 20, CTG group), or a xenogeneic collagen matrix (n = 20, XCM group) when an implant was placed in a preserved alveolar ridge. Changes in mid-buccal mucosal level (MBML) at 1 (T1) and 12 (T12) months after final implant crown placement were compared to the pre-extraction level. Additionally, esthetics, marginal bone level, clinical peri-implant parameters, and patient satisfaction were assessed.

Results: At T12, mean changes in MBML were –0.48 ± 1.5 mm, –0.04 ± 1.1 mm, and –0.17 ± 1.3 mm in the NG, CTG, and XCM groups (P = 0.56), respectively. Regarding the other outcome variables, no significant intergroup differences were observed.

Conclusions: Soft-tissue grafting at single implant placement in preserved alveolar ridges does not result in a better esthetic outcome or in better peri-implant health and should not be considered as a standard procedure.

KEYWORDS
alveolar ridge augmentation, connective tissue, esthetics, gingival recession, single-tooth implants

1 | INTRODUCTION

Single-implant treatment in the maxillofacial esthetic zone to replace a single failing tooth is a valuable treatment modality.1,2 However, long-term data demonstrate stable esthetics in just 37% of the cases.3

It is presumed that, to achieve stable esthetics, the implant should be inserted in an optimal three-dimensional position in the available bone dimensions, with preservation of sufficient buccal bone volume for a proper soft-tissue support.4,5 Because the buccal bone wall in most sites of the maxillary esthetic zone is very thin (≤1 mm)6 and associated with significant buccal bone resorption following tooth removal,7,8 correct three-dimensional implant placement might be impaired. Therefore, to reduce bone dimensional changes, augmentation of the extraction socket prior to implant placement was proposed to preserve both the alveolar ridge5,10 and buccal soft tissue.11 However, bone loss in width and height is still expected, despite alveolar ridge preservation, as are soft-tissue changes.11,12

To compensate for soft-tissue changes, the application of a connective tissue graft (CTG) was proposed to increase soft-tissue volume13,14 and establish a better soft-tissue profile. According to the literature, grafting the buccal peri-implant soft tissue with a CTG effectively increases the soft tissue contour.15–19 Additionally, connective tissue grafting (CT grafting) was demonstrated to be effective in preserving the mid-buccal mucosal level.16,19,20 In contrast to this, a retrospective study21 showed that CT grafting resulted in minimal changes in soft-tissue volume and level without...
significant difference compared to no soft-tissue grafting over 5 years of follow-up.

As an alternative to CTG as the gold standard for soft-tissue augmentation, the use of a xenogeneic collagen matrix (XCM) was introduced to decrease patient morbidity caused by the harvesting procedure of the CTG. In several studies, applying a XCM to increase soft-tissue thickness was found to be as effective as a CTG. XCM was also demonstrated to be effective in the long term, with stable esthetics. In contrast to this, Cairo et al. observed a more effective increase in soft-tissue thickness with the application of CTG than with XCM. In terms of recession reduction using a coronally advanced flap with either a CTG or XCM, both achieved comparable and stable results.

As far as we know, Froum et al. is the only study comparing the effect of applying a XCM with no soft tissue graft during implant placement. They found no differences between the groups, but intragroup comparisons revealed that, compared to baseline levels, patients receiving the XCM showed a significant thickening of the buccal keratinized tissue. There is a paucity of papers evaluating the effect of applying a CTG or XCM on mid-buccal mucosa recession, although CT grafting has been demonstrated to be effective and XCM was judged to be comparable to CTG. Therefore, we assessed whether grafting the buccal peri-implant mucosa using either a CTG or XCM at implant placement in preserved alveolar ridges resulted in less mid-buccal mucosa recession compared to no grafting.

2 | MATERIALS AND METHODS

2.1 | Study design

Between December 2012 and July 2015, all consecutive patients (aged ≥18 years) referred for implant treatment due to a single failing maxillary tooth (incisor, canine, first premolar) were invited to participate in this randomized controlled clinical study. The study was approved by our Medical Ethical Committee (NL43085.042.13) and registered in the Dutch trial register (www.trialregister.nl: NTR3815; 01-23-2013). The following inclusion and exclusion criteria had to be fulfilled: adequate oral hygiene (i.e., modified plaque and sulcus bleeding index ≤1); diastema width ≥6 mm and sufficient interocclusal space for a non-occluding temporary controller with 45 Ncm and provided with a cover screw.

According to a preoperative cone beam computed tomography scan, insufficient bone volume on the palatal side was present to place an implant with primary stability. Additionally, all patients presented with a vertical buccal bone wall defect >5 mm of the extraction socket, assessed after extraction by a bone sounding technique. Therefore, all extraction sockets were augmented prior to implant insertion and closed with a mucosa graft. Four months thereafter, patients were treated with an implant and then randomly distributed, via sealed envelopes opened by an uninvolved research nurse, to receive either:

- No soft tissue graft (no graft [NG] group; n = 20),
- A connective tissue graft harvested from the palate (connective tissue graft [CTG] group, n = 20),
- A xenogeneic collagen matrix† (xenogeneic collagen matrix [XCM] group, n = 20).

2.2 | Intervention procedure

One day prior to implant surgery, patients began taking antibiotics (amoxicillin 500 mg, three times daily for 7 days or clindamycin 300 mg, four times daily for 7 days in case of amoxicillin allergy) and used a 0.2% chlorhexidine mouthwash (twice daily for 7 days) for oral disinfection.

All surgical procedures were performed under local anesthesia by the same oral and maxillofacial surgeon (GMR). In all groups, the extraction socket was augmented with the tuberosity bone graft shaped to match the buccal bone defect and inserted with the cortical side facing the periosteum (Fig. 2A). A mixture of autologous bone and spongious bone substitute (0.25–1.0 mm) was tightly packed into the extraction socket (Fig. 2B). The extraction socket was then closed with a full-thickness mucosa graft (Fig. 2C), which was also harvested from the maxillary tuberosity region.

The implant was inserted 4 months after the augmentation procedure (Fig. 3A). A small palatal crest incision was made to expose the alveolar ridge, followed by extensions through the buccal and palatal sulcus of the adjacent teeth and a divergent relieving incision at the distal tooth to elevate the minimal mucoperiosteal flap. The implant site was prepared according to the manufacturer’s manual and with a surgical template representing the ideal position of the prospective implant crown. All implants were installed with a torque controller with 45 Ncm and provided with a cover screw. The implant shoulder was placed 3 mm apical to the most facial and cervical aspect of the prospective clinical crown to ensure a proper emergence profile, including being at the level as the alveolar bone.

The randomization procedure was done immediately after implant installation. Regarding the CTG group, the CTG was

§ Bio-Oss, Geistlich Pharma AG, Wolhusen, Switzerland
harvested from the palate (Fig. 3B). Both the CTG and the XCM (XCM group) were placed in the prepared mucoperiosteal flap at the facial site and secured with 4-0 acrylic vertical and horizontal mattresses∗ (Fig. 3C-F).

The control group did not have a graft placed in the prepared mucoperiosteal flap. In all groups, the wound at the implant site was closed with 5-0 nylon sutures.† All sutures were removed 2 weeks after surgery. During the healing phase, patients wore a removable partial denture that did not interfere with the wound.

After 3 months, the implants were uncovered and an implant-level impression was made for the fabrication of a screw-retained provisional crown in the dental laboratory. All implants had been installed with a corresponding healing abutment. The provisional crown was fitted that same day onto the implant with 20 Ncm by a manual torque wrench and adjusted to function free from centric and eccentric contact with the antagonist teeth. Patients were instructed to follow a soft diet and to avoid exerting force on the provisional restoration.

Three months later, a final, open-tray implant-level impression was taken using polyether impression material.‡ An individualized zirconia abutment§ was made from the digitally designed final implant crown. Depending on the location of the screw access hole, the final crown was screw retained or cement retained. Abutment screws were torqued with 35 Ncm.

All prosthetic procedures were accomplished by two prosthodontists (HJAM and CS).

2.3 | Photographic assessment

The primary outcome measure was the change in mid-buccal mucosal level (MBML), assessed from standardized intraoral photographs¶ taken before tooth extraction (T_{pre}) and 1 (T_{1}) and 12 months (T_{12}) after final implant crown placement. Changes in interproximal mucosal levels (IML) were measured the same way.

The photographs were calibrated by a periodontal probe* held close to and parallel to the long axis of the tooth next to the implant. Full-screen analysis was done using a digital picture editing program.† MBML changes were measured at T_{pre} and T_{1} by drawing a horizontal line through the incisal edges of the adjacent teeth, and the distance between this line and the mucosal margin was calculated (Supplementary Figure 1A, B). The T_{1} to T_{12} MBML changes were assessed from the length of the implant crown (Supplementary Figure 1C, D). MBML changes between T_{pre} and T_{12} were calculated by adding both measurements.‡

2.4 Radiographic assessment
At T_{1} and T_{12}, the marginal bone level was measured on standardized digital intraoral radiographs taken with an individualized device. The distance between the implant platform and first bone-to-implant contact along the implant was measured using specifically designed software. Bone above the implant platform was scored as no bone loss.

2.5 Clinical assessments
Clinical data of any implant was collected by a single examiner (EGZ), who was blinded regarding group allocation, at T_{1} and T_{12}. The following parameters were assessed: 1) gingival biotype, as measured by means of transparency of a periodontal probe through the gingival margin of the failing tooth (only at T_{pre}); 2) probing pocket depth using a periodontal probe at the mesio-buccal, mid-buccal, and disto-buccal and mid-palatal aspect; 3) amount of plaque (modified plaque index); 4) bleeding after probing (modified sulcus bleeding index); 5) gingival condition (gingival-index); 6) width of the keratinized mucosa: no keratinized mucosa, <1 mm of keratinized mucosa, 1–2 mm of keratinized mucosa, ≥2 mm of keratinized mucosa; 7) volume of the interproximal papilla, using the papilla index; 8) implant

Peri-implant mucosa and implant crown esthetics were assessed from photographs taken at T_{12} using the Pink Esthetic Score-White Esthetic Score (PES/WES).
survival; 9) implant success, defined as \( \leq 1 \) mm marginal bone loss one year after loading and \( \leq 0.2 \) mm thereafter and the absence of pain, infection, mobility, peri-implant radiolucency, and alteration in sensitivity.\(^{41}\)

### 2.6 Patient satisfaction

The Oral Health Impact Profile-14 (OHIP-14) questionnaire,\(^{42}\) including questions about overall satisfaction with the current dentition and compared to the preoperative situation to be answered on a 10-cm Visual Analog Scale (VAS), were completed at T\(_{\text{pre}}\), T\(_1\), and T\(_{12}\). Additionally, questions regarding esthetics and satisfaction with the treatment procedure to be answered on a 10-cm VAS were provided. All questionnaires were handed out and filled in privately before collecting the clinical data.

### 2.7 Statistical analysis

Sample size was calculated using software.\(^7,43\) A recession of the mid-buccal mucosa of 0.5 mm from implant placement to 12 months after placement of the final implant crown was considered to be a clinically relevant difference between the groups. With an expected standard deviation of 0.6 mm, as derived from the literature,\(^{44}\) and a power of 80%, a minimum of 18 patients per group would be needed. We decided to include 20 patients per group in case of any withdrawals from the study.

The Shapiro-Wilk test was used to assess the normal distribution of the continuous variables and Normal Q-Q-plots were depicted. Normal distributed data were analysed using analysis of variance. Non-normal distributed data were evaluated with Kruskal-Wallis tests. Within-group comparisons were done using Wilcoxon tests. Analysis of categorical data was performed with \( \chi^2 \) or Fisher exact tests.

The Pearson correlation coefficient was calculated to explore the influence of gingival biotype on the mid-buccal mucosal level.

All analyses were done using a \( P \) value of 0.05 to indicate statistical significance and were performed using statistical software.\(^6\)

### 3 RESULTS

Baseline characteristics of the 60 included patients are depicted in Table 1. No significant differences between the groups were noticed for sex, age, gingival biotype, implant site location, implant length, or implant diameter. All patients received their assigned treatment (Fig. 1). Figure 3G-I shows

---

\(^6\) G*power 3.1, Heinrich-Heine University, Düsseldorf, Germany

\(^7\) SPSS Statistics 23.0, SPSS Inc., IBM Corporation, Chicago, IL
in Table 2. None of the implant crowns displayed plaque at T12. Upon probing, 55% of the patients in the NG and CTG groups and 45% of the XCM group demonstrated no bleeding (score 0). 30% of the NG and CTG patients and 40% of XCM patients had an isolated bleeding spot (score 1). A score of 2 (confluent red line) was encountered in 15% of the patients across all the groups.

At T12, the peri-implant mucosa was healthy in almost all patients; the exceptions were one patient in the NG group and one in the CTG group who showed signs of mild inflammation. 90%, 75%, and 70% of the patients in the NG, CTG, and XCM groups, respectively, displayed more than 2 mm of keratinized mucosa (score 3). A 1- to 2-mm-wide zone of keratinized mucosa (score 2) was seen in 5%, 15%, and 10% of patients in the NG, CTG, and XCM groups, respectively. In the XCM group, 5% of the patients had a keratinized mucosa of up to 1 mm (score 1). In the NG, CTG, and XCM groups, 5%, 10%, and 15%, respectively, of the patients showed no keratinized mucosa (score 0).

3.5 | Esthetic assessment

No significant intergroup differences were found with respect to PES and WES total scores or the separate scoring items (Table 2). With respect to the peri-implant mucosa, acceptable levels of esthetics (PES/WES-score ≥6) were reached in 75% of the NG group, 80% of the CTG group, and 65% of the XCM group. With respect to the implant crown, acceptable levels were reached in 100% of the NG group, 100% of the CTG group, and 95% of the XCM group.

3.6 | Patient satisfaction

At T12, VAS scores showed no difference in patient satisfaction, except for satisfaction with the implant and implant crown (Table 3). Satisfaction with the current dental situation improved significantly between baseline and T1 (P = 0.00), whereas no further improvement was observed up to 1 year after placement of the final crown (T12; P = 0.94). No intergroup differences were found for the total OHIP questionnaire scores. Within-group comparisons showed a favorable improvement between Tpre and T1 (P = 0.00), which continued between T1 and T12 (P = 0.00).

4 | DISCUSSION

This randomized controlled trial suggests that neither the application of a CTG nor the application of a XCM at implant placement in healed and preserved extraction sites results in better retention of the level of the mid-buccal mucosa or to a better esthetic outcome compared to the application of no soft-tissue graft at implant placement.

The observed recession of the mid-buccal mucosa in all groups in this study was minor and within clinically acceptable levels. Changes in MBML in the NG group and CTG group were in line with recent literature. Comparing the application of a CTG to no soft-tissue graft, we observed no difference for change in MBML, which is in line with a recent study. The interpretation of their results, however, is limited by the retrospective study design and a small sample size. Froum et al. evaluated the effect of a XCM in a randomized controlled clinical trial compared to no soft-tissue graft and reported an outcome comparable to ours regarding the change in height and thickness of the peri-implant soft tissue. However, that study has limitations. Only patients with a thin and deficient keratinized mucosa needing an implant in the posterior region were included and were followed for just 3 months after surgery. This is in contrast to our study, which evaluated single implant placement in the anterior maxilla up to 1 year after loading, without selecting patients according to volume and width of the keratinized mucosa.

The fact that we observed no significant difference between the groups in change in MBML might be explained by the augmentation surgery of fresh extraction sockets with slowly resorbing grafting material and sealing the socket with a mucosa graft, which has been demonstrated to be beneficial in preserving the buccal bone and soft tissue contour. We hypothesize that this augmentation technique already may have contributed to the preservation of sufficient peri-implant soft tissue, which in turn may have led to no further effect when applying a soft-tissue graft at implant placement.

NA, not assessed.
The majority of studies on the effect of soft-tissue grafting assess the change in mid-buccal mucosal volume (MBMV). Measurement of the change in MBMV would have been desirable, but was beyond the scope of this study. CT grafting could have resulted in an increase in the peri-implant soft-tissue volume, which possibly compensated for the bone resorption-inducing effect of flap elevation in all the study groups. Only the last item in the PES, judging root convexity, soft-tissue texture, and color, focuses on changes in soft-tissue volume. However, this is a combined scoring item and only states whether all aspects (score 2), two aspects (score 1), or one/no aspect (score 0) are comparable to the contralateral tooth. The fact that we could not find any differences between the groups for this item can be explained by the limitations of scoring this item, because the PES is not sensitive enough to pick up small changes. The same applies to the other items and the total PES score.

Changes in marginal bone level in this study are in line with the changes in relation to the alveolar ridge preservation procedure observed in previous studies conducted by our group. This is in contrast to Wiesner et al., who observed a higher loss of marginal bone level in the test and control groups. The limited change in bone level in this study may be explained by the reduced bone loss in a vertical direction as a result of the ridge preservation procedure after removal of the failing tooth.

With respect to esthetics, no differences were found in the objective rating according to PES and WES. The rates were in line with recent literature. Overall, patients were highly satisfied with the form and color of the peri-implant mucosa and the implant crown. The exception was the form of the peri-implant mucosa in the CTG group at T1 (Table 3), possibly because the CT grafted sites appeared immature and had not merged with the surrounding peri-implant mucosa, as observed by Nevins et al. This dissatisfaction was not observed 1 year after the final implant crown was placed. Conversely, patients were generally less satisfied with the CT grafted implant sites at T12. This might be explained by the higher patient morbidity when harvesting the CTG from the patients’ palate compared to patients who had not received a graft or a XCM and, thus, did not have a second surgical site. Nevertheless, this could not be seen in question outcomes asking whether patients regretted choosing the treatment they did and whether they would recommend the treatment to others.

5 | CONCLUSION

The application of a soft-tissue graft combined with placement of a single implant in a preserved alveolar ridge in the esthetic zone does not result in a more favorable esthetic outcome than when no soft-tissue graft was applied during implant placement. Thus, soft-tissue grafting should not be considered a standard procedure.

ACKNOWLEDGMENTS

The authors thank Cees Stellingsma (CS; Department of Oral and Maxillofacial Surgery, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands) and Menno van der Veen (MvdV; Gronings Tandtechnisch Laboratorium, Groningen, The Netherlands) for their assistance in the fabrication of the provisional and final implant crowns. The authors report no conflicts of interest related to this study.

AUTHOR CONTRIBUTIONS

EGZ, HJAM, AV, and GMR had substantial contributions to the conception or design of the work and the acquisition, analysis, or interpretation of data for the work. EGZ, HJAM, AV, and GMR were involved in drafting the paper and revising it critically. EGZ, HJAM, AV, and GMR gave final approval of the version to be published. EGZ, HJAM, AV, and GMR agreed to be accountable for all aspects of the work in ensuring that questions related to accuracy or integrity of any parts of the work are appropriately investigated and resolved.
